Background The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) Omicron variant has demonstrated high transmissibility and possesses several spike protein mutations that allow for evasion of previously established immunity.1 mRNA vaccines against the spike protein of the ancestral strain of the virus have been reported to induce robust T cell immunity against the omicron variant when examined in healthy individuals.2 However, the effectiveness of the booster vaccine doses in late-stage lung cancer patients undergoing active anti-PD-1/ PD-L1 agent immunotherapy has yet to be investigated.3

Methods To address this question, we assessed both CD8+ and CD4+ T cell responses using a modified activation-induced marker (AIM) assay that was performed on peripheral blood mononuclear cells (PBMCs), which was coupled with high dimension spectral flow cytometry analyses. The PBMCs were obtained using cryopreserved blood samples collected from The COVID-19 Vaccine Study of Infections and Immune Response (SIREN) trial, and a total of 51 patient samples (20 non-cancer patients and 31 lung cancer patients) were assessed.

Results Our observations included that booster vaccines induced CD8+ T cell response in both non-cancer subjects and lung cancer patients against ancestral strain and omicron variant, while only marginal induction or trend was detected for CD4+ T cells in normal subjects. Pertinent results also consisted of identification of distinct subpopulation dynamics involving varying degrees of differentiation of antigen-specific CD8+ and CD4+ T cells in lung cancer patients compared to non-cancer subjects, thus demonstrating evidence of dysfunc-
tion. Another noteworthy finding included the observation of sex biased T cell responses with female lung cancer patients demonstrating more efficient antigen-specific T cell responses compared to males.

Conclusions We conclude that lung cancer patients in our study cohort have substantial qualitative deviation in their T cell response to mRNA vaccine from the normal individuals. This altered response may be a consequence of altered T cell differentiation states, resulting in the high degree of heterogeneity of AIM+ T cells identified in booster vaccinated individuals. Moreover, the dampened T cell response to omicron in cancer patients could implicate that less protection was estab-
lished by vaccination for lung cancer patients, especially given that humoral response is also reduced in cancer patients.4 This further highlights the need for heightened protective measures for cancer patients to minimize the risk of breakthrough infection with the omicron and other future variants of SARS-CoV-2.5

Acknowledgements We thank individuals who participated in sample collection, preparation, and preservation/storage, including Jamie Hamon, Donna Bucci, Mohamed Yusuf, Robert Davenport, and Taylor Charlton from Pelotonia Institute for Immuno-Oncology and Immune Monitoring and Discovery Platform of the Pelotonia Institute for Immuno-Oncology. Additional gratitude is extended toward the Wherry lab, including Mathew Divij for providing detailed protocol for AIM assay and discussion.
