Background FLX475 (tivumecirnon) is a selective CCR4 antagonist designed to block the recruitment of immunosuppressive regulatory T cells (T_{reg}) into the tumor microenvironment. The FLX475-02 trial (NCT03674567) is a phase 1/2 study of FLX475 as monotherapy and in combination with pembrolizumab in subjects with advanced cancer. Early encouraging data on the biologic effects, safety and antitumor activity of FLX475 have previously been presented.\(^1\)\(^-\)\(^4\) We now present the results from the completed Phase 2 cohort of combination therapy in subjects with non-small cell lung cancer (NSCLC) not previously treated with checkpoint inhibitor (CPI-naive).

Methods Subjects with CPI-naive, locally advanced or metastatic NSCLC received FLX475 100 mg orally once daily with pembrolizumab (200 mg IV Q3 weeks). The primary study objectives were safety and tolerability, and antitumor activity. The primary efficacy endpoint was objective response rate (ORR), based on RECIST 1.1 criteria. Additional efficacy endpoints included progression-free survival (PFS). Data cutoff was 31Aug2023.

Results Of the 35 subjects with relevant NSCLC histologies evaluable for response, median follow-up was 192 days (9 – 660 days) and median lines of prior therapy was 1 (0 – 5). As previously described,\(^5\) the only adverse event determined to be specifically related to FLX475 treatment was asymptomatic and reversible QT prolongation (managed by dose reduction). Across all the subjects evaluable for response regardless of PD-L1 status (n=35), confirmed partial response (cPR) was observed in 9 (ORR: 26%). Amongst the subgroup of subjects whose tumors expressed PD-L1 (tumor proportion score [TPS] \(\geq\) 1%) (n=20), cPR was observed in 7 (ORR: 35%), with an ORR of 31% (5/16) and 50% (2/4) in subjects with tumors expressing low and high levels of PD-L1 (TPS 1-49% or \(\geq\) 50%), respectively. As of the data cutoff, the PD-L1 TPS \(\geq\) 50% subgroup had a median PFS of 6.3 months with 8 subjects still on treatment.

Conclusions FLX475, an oral CCR4 antagonist, has previously demonstrated clear monotherapy and encouraging combination activity with pembrolizumab.\(^2\)\(^-\)\(^3\) In this completed Phase 2 cohort of subjects with CPI-naive NSCLC, FLX475 in combination with pembrolizumab was shown to be well tolerated and has demonstrated encouraging clinical activity compared to pembrolizumab monotherapy in PD-L1+ NSCLC (based on historical results) – in both subjects with low (TPS 1-49%) and those with high (TPS \(\geq\) 50%) PD-L1 expression – supporting the continued development of this combination therapy for NSCLC.

Acknowledgements Thank you to the patients who have participated in the study, and to their families and caregivers. Over 30 sites in the United States, Australia, South Korea, Taiwan, Thailand, and Hong Kong have participated in this study. Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA has provided pembrolizumab for the study.

Trial Registration ClinicalTrials.gov Identifier: NCT03674567
