Type-1 immune responses, mediated by IFN γ and TNF α -producing CTLs, Th1, and NK cells, are essential for effective anti-tumor immunity. Despite recent advances in the induction and stabilization of these responses by cancer immunotherapies, the clinical success of these approaches remain limited. Here, we report that the activation of type-1 immunity within the human tumor microenvironment (TME) initiates IFN γ - and TNF α -dependent counter-regulation, driven by amplification of prostaglandin E₂ (PGE₂) and the key regulator of PGE₂ synthesis, cyclooxygenase 2 (COX2). We demonstrate that type-1-activated CTLs and NK cells induce IFN γ /TNF α -mediated over-expression of indoleamine 2,3-dioxygenase (IDO), inducible nitric oxide synthase (iNOS/NOS2), IL-10, and COX2 by tumor-associated myeloid-derived suppressor cells (MDSCs). Importantly, this self-limiting suppressive feedback driven by type-1 immunity could be eliminated not only by neutralization of IFN γ and TNF α , the factors critically required for the anti-tumor activity of immune effector cells, but also by COX2 blockade, which counteracted the IFN γ /TNF α -driven enhancement of all other suppressive factors, amplifying the therapeutic potential of intratumoral type-1 immunity. Our data demonstrate an intrinsic mechanism underlying the self-limiting character of type-1 immunity within the human TME, and provide rationale for targeting the COX2-PGE₂ axis to enhance desirable type-1 responses for cancer immunotherapy.
