ABSTRACT

Background Chimeric antigen receptor (CAR) T-cell therapy is an emerging option for cancer treatment, but its efficacy is limited, especially in solid tumors. This is partly because the CAR T cells become dysfunctional and exhausted in the tumor microenvironment. However, the key pathways responsible for impaired function of exhausted cells remain unclear, which is essential to overcome CAR T-cell exhaustion.

Methods Analysis of RNA-sequencing data from CD8+ tumor-infiltrating lymphocytes (TILs) led to identification of Cbl-b as a potential target. The sequencing data were validated using a syngeneic MC38 colon cancer model. To analyze the in vivo role of Cbl-b in T-cell exhaustion, tumor growth, % PD1+Tim3+ cells, and expression of effector cytokines were analyzed in cbl-b+/+ and cbl-b–/– mice. To evaluate the therapeutic potential of Cbl-b depletion, we generated a new CAR construct, hCEAssFv-CD28-CD3ζ-GFP, that recognizes human carcinoembryonic antigen (CEA). cbl-b+/+ and cbl-b–/– CEA-CAR T cells were generated by retroviral transduction. Rag2–/– mice bearing MC38-CEA cells were injected with cbl-b+/+ and cbl-b–/–; CEA-CAR T cells, tumor growth, % PD1+Tim3+ cells and expression of effector cytokines were analyzed.

Results Our results show that the E3 ubiquitin ligase Cbl-b is upregulated in exhausted (PD1+Tim3+) CD8+ TILs. CRISPR-Cas9-mediated inhibition of Cbl-b restores the effector function of exhausted CD8+ TILs. Importantly, the reduced growth of syngenic MC38 tumors in cbl-b–/– mice was associated with a marked reduction of PD1+Tim3+ CD8+ TILs. Depletion of Cbl-b inhibited CAR T-cell exhaustion, resulting in reduced MC38-CEA tumor growth, reduced PD1+Tim3+ cells and increased expression of interferon gamma, tumor necrosis factor alpha, and increased tumor cell killing.

Conclusion Our studies demonstrate that deficiency of Cbl-b overcomes endogenous CD8+ T-cell exhaustion, and deletion of Cbl-b in CAR T cells renders them resistant to exhaustion. Our results could facilitate the development of efficient CAR T-cell therapy for solid tumors by targeting Cbl-b.

INTRODUCTION

Adoptive transfer T-cell therapy is an emerging option for cancer treatment,1 but its efficacy is limited, especially in solid tumors, because the effector CD8+ T-cells that promote antitumor immunity become dysfunctional and exhausted in the tumor microenvironment (TME). Exhausted T cells exhibit progressive loss of effector function (expression of interferon gamma (IFN-γ), tumor necrosis factor alpha (TNF-α) and tumor cell killing) and express inhibitory receptors (PD1, Tim3, and Lag3).2 However, the key pathways responsible for impaired function of exhausted cells remain unclear.

Post-translational modification mediated by ubiquitin conjugation plays an indispensable role in immune cells. Ubiquitination involves a cascade of biochemical reactions through ubiquitin activating (E1) enzymes, ubiquitin-conjugating (E2) enzymes, and ubiquitin ligase (E3) enzymes. The E3 ubiquitin ligases are critical components of this system because they recognize and target specific target proteins for ubiquitination.3

Cbl-b is an E3 ubiquitin ligase that belongs to the Really Interesting New Gene (RING) family. Cbl-b contains an N-terminal tyrosine kinase-binding domain, a RING finger, and a C-terminal proline-rich sequence, and can thus function as both an E3 ligase and a molecular adaptor.3 Here, we demonstrate that Cbl-b is upregulated in exhausted CD8+ tumor-infiltrating lymphocytes (TILs) and plays a crucial role in dysfunction of tumor-reactive TILs.

MATERIALS AND METHODS

Mice

C57BL/6, Rag2–/– and cbl-b–/– mice were housed in microisolator cages, and the experiments were performed in accordance with the guidelines of the Institutional Animal Care and Use Committee of UT Southwestern Medical Center.
Cbl-b is upregulated in exhausted CD8⁺PD1⁺Tim3⁺ TILs. (A) Geo dataset (GSE85947) was analyzed and normalized read counts (TPM) for Cbl-b are shown. (B) Volcano plot of differentially expressed genes (−log10 p value vs log2 fold change) in PD1⁺Tim3⁺ versus PD1⁻Tim3⁻ TILs. (C) MC38 tumors were implanted subcutaneously into C57BL6 mice; PD1⁺Tim3⁺ and PD1⁻Tim3⁻ TILs were sorted; and Cbl-b messenger RNA levels were analyzed by real-time PCR. (D) Immunoblot of Cbl-b protein using Fluorescence-activated cell sorted (FACS) PD1⁺Tim3⁺ versus PD1⁻Tim3⁻ TILs. The data are representative of three independent experiments. Statistics are mean±SD, calculated by Student’s t-test (two-tailed). TIL, tumor-infiltrating lymphocyte. TPM, transcript per million; IB, Immunoblotting, FACS, Fluorescence-activated cell sorting.

**Figure 1**

**MC38-carcinoembryonic antigen (CEA) tumor and CD8⁺ TIL isolation**

Cbl-b⁺/+ and cbl-b⁻/⁻ mice were injected subcutaneously with 1×10⁶ MC38-CEA cells and tumor growth was analyzed. Kaplan-Meier estimate was used to analyze the survival of mice. Mice were counted as dead when the tumor diameter reached the length limit of 15 mm. CD8⁺ TILs were isolated using CD8 TIL Microbeads (Miltenyi).

**Construction of retroviral vector (hCEA scFv-GFP) containing chimeric antigen receptor (CAR)**

DNA sequences encoding scFv anti-CEA chimeric receptors were synthesized by Genescript (New Jersey, USA and cloned into the m1928ζ-GFP² retroviral construct by replacing the CD19scFv region between CD8 leader (CD8L) sequence and CD8 hinge region (CD8TM) at the NolI restriction site. The chimeric gene constructs were composed of the mouse CD8 signal peptide (CD8L), scFv-anti-CEA mAb, a membrane proximal hinge region along with the transmembrane domain, and mouse stimulatory domain, which included mouse CD28 and mouse CD3ζ.

**CRISPR-Cas9 targeting**

Three top-ranking guide sequences against Cbl-b exons were designed and cloned into lenti-CRISPR v2 plasmid (Addgene 52961). HEK293FT cells (Thermo Fisher) were transfected with lenti-CRISPR v2 plasmid, along with packaging plasmid pMD2.G (Addgene 12259) and psPAX2 (Addgene 12260). Lentivirus was harvested after 48–72 hours of incubation, passed through 0.45 µm filter and stored at −80°C. The details of the guide RNAs targeting Cbl-b gene are as follows:

- Cbl-b guide RNA1: GATGGGATGTGCGATCTCCCG
- Cbl-b guide RNA2: GCCACTTCGTGCCTTACCCCG
- Cbl-b guide RNA3: GCCGAGTGGTGGAAAGTGA

**Retroviral transduction, CAR T-cell production and adoptive transfer**

CD8⁺ T-cells were stimulated for 24 hours with anti-CD3 clone (1 µg/mL) and anti-CD28 (1 µg/mL) antibodies and were cultured with mIL-2 (100 U/mL) and transduced with the retrovirus by spinoculation method.² On the day of adoptive transfer, GFP⁺ cells were sorted by flow cytometry and (GFP⁺CD8⁺ CAR T cells) adoptively transferred via tail-vein injections.

**Statistical analysis**

Statistical analysis was performed with the Prism V.8.0 software, and all results were summarized as mean±SD. Differences between groups were evaluated by two-tailed Student’s t-test. Log-rank test was used for survival analysis. A p value of <0.05 was considered as statistically significant.

**RESULTS**

**Cbl-b is upregulated in PD1⁺Tim3⁺ exhausted TILs**

Cbl-b has been shown to be an important negative regulator of T cells,³ and deletion of Cbl-b in T cells results in rejection of established tumors.⁴ Analysis of published RNA-seq sequencing data (GSE85947)⁵ showed that messenger RNA (mRNA) encoding the Cbl-b gene was preferentially upregulated in PD1⁺Tim3⁺ exhausted CD8⁺ TILs in the CT26 colon carcinoma model (figure 1A,B). Further, analysis of the published sequencing results showed that Cbl-b expression was upregulated in exhausted CD8⁺ TILs in multiple tumor models (GSE123738 and GSE85947),⁶ as well as in a lymphocytic choriomeningitis virus infection model (GSE88987).⁷ To confirm these sequencing results, we adopted the syngeneic MC38 colon cancer model. As shown in figure 1C, real-time PCR analysis of RNA isolated from PD1⁺Tim3⁺ TILs showed increased expression of Cbl-b compared with PD1⁻Tim3⁻ cells. Increased Cbl-b expression in PD1⁺Tim3⁺ TILs was further confirmed by immunoblotting (figure 1D). These data collectively suggest that Cbl-b expression is preferentially upregulated in exhausted CD8⁺ TILs in the TME.
Inhibition of Cbl-b restores the effector function of exhausted CD8+ TILs

To test the hypothesis that upregulated Cbl-b supports CD8+ T-cell exhaustion, we knocked down Cbl-b using CRISPR-Cas9. We transduced the PD1+Tim3+ Cbl-b+/+ TILs with guide RNA targeting exons of the Cbl-b gene or non-targeted control guide RNA, along with CRISPR-Cas9 expressing lentiviruses. The efficiency of CRISPR-Cas9-mediated deletion of Cbl-b was confirmed by immunoblotting (online supplemental figure 1A). Deleting Cbl-b restored expression of IFN-γ, TNF-α, granzyme B, and IL-2 in PD1+Tim3+ Cbl-b+/+ TILs (figure 2A–D).

Cbl-b deficiency leads to reduced PD1+Tim3+ TILs

To examine the in vivo role of Cbl-b in regulation of T-cell exhaustion and tumor growth, we inoculated cbl-b+/+ and cbl-b−/− mice with MC38-CEA cells. A markedly reduced growth of MC38 tumors was observed in cbl-b−/− mice compared with cbl-b+/+ mice (figure 3A,B). Our results are consistent with previous reports that cbl-b+/+ mice mount a robust antitumor response against transplanted (TG-1, EL4, EG7, and B16 melanoma), chemically induced and spontaneous tumors.8,11 The increased antitumor activity in cbl-b+/+ mice was attributed primarily to CD8+ T-cells.8,11 Similarly, we found an increased number of CD8+ T-cell infiltration into MC38 tumors in cbl-b−/− mice (online supplemental figure 1B).

To test if Cbl-b deficiency effects CD8+ T-cell exhaustion, we isolated CD8+PD1+Tim3+ TILs from MC38 tumors grown in cbl-b+/+ and cbl-b−/− mice (n=5) were subcutaneously injected with MC38-CEA cells. (A) Tumor volume. (B) Representative images of tumors. (C) Percentage of CD8+PD1+Tim3+ TILs. (D) Representative image showing percentage of CD8+PD1+Tim3+ TILs. (E) CD8+PD1+Tim3+ TILs were sorted and expression of IFN-γ, TNF-α and granzyme B was analyzed by real-time PCR. The data are representative of three independent experiments. Statistics are mean±SD, calculated by Student’s t-test (two-tailed). IFN-γ, interferon gamma; IL, interleukin; TIL, tumor-infiltrating lymphocyte; TNF-α, tumor necrosis factor alpha.
We chose CEA as a model antigen because CEA is overexpressed in many human cancers, most notably in colorectal adenocarcinomas.14

We retrovirally transduced naïve CD8+ T-cells with either control (mock) or hCEAscFv-CD28-CD3ζ.GFP. The transduction efficiency varied between 60% and 65% (online supplemental figure 2A). We cocultured fluorescence-activated cell sorted GFP+ cells (online supplemental figure 2B) with MC38-CEA cells, a mouse colon cancer cell line expressing hCEA.15 Real-time PCR analysis showed that CEA-CAR T cells, but not mock transduced cells, expressed IFN-γ, TNF-α, granzyme B, and IL-2 (online supplemental figure 2C).

Next, we injected MC38-CEA cells into the right flank of Rag<sup>−/−</sup> mice, and on days 3 and 8, we inoculated with <i>cbl-b<sup>+/+</sup></i> or <i>cbl-b<sup>−/−</sup></i> CEA-CAR T cells. The use of <i>cbl-b<sup>−/−</sup></i> CAR T cells considerably enhanced the survival of <i>Rag<sup>−/−</sup></i> mice as shown in figure 4B. In addition, we observed significantly reduced tumor growth in <i>Rag<sup>−/−</sup></i> mice that received <i>cbl-b<sup>−/−</sup></i> CAR T cells compared with the mice that received <i>cbl-b<sup>+/+</sup></i> CAR T cells (figure 4C).

We retrovirally transduced naïve CD8<sup>+</sup> T-cells with either control (mock) or hCEAscFv-CD28-CD3ζ.GFP. The transduction efficiency varied between 60% and 65% (online supplemental figure 2A). We cocultured fluorescence-activated cell sorted GFP<sup>+</sup> cells (online supplemental figure 2B) with MC38-CEA cells, a mouse colon cancer cell line expressing hCEA.15 Real-time PCR analysis showed that CEA-CAR T cells, but not mock transduced cells, expressed IFN-γ, TNF-α, granzyme B, and IL-2 (online supplemental figure 2C).

Next, we injected MC38-CEA cells into the right flank of <i>Rag<sup>−/−</sup></i> mice, and on days 3 and 8, we inoculated with <i>cbl-b<sup>+/+</sup></i> or <i>cbl-b<sup>−/−</sup></i> CEA-CAR T cells. The use of <i>cbl-b<sup>−/−</sup></i> CAR T cells considerably enhanced the survival of <i>Rag<sup>−/−</sup></i> mice as shown in figure 4B. In addition, we observed significantly reduced tumor growth in <i>Rag<sup>−/−</sup></i> mice that received <i>cbl-b<sup>−/−</sup></i> CAR T cells compared with the mice that received <i>cbl-b<sup>+/+</sup></i> CAR T cells (figure 4C).
To investigate if Cbl-b deficiency affected CAR T-cell exhaustion, these cells were collected and CD8+ TILs were enriched. These cells were stained with anti-PD1 and anti-Tim3 antibodies and were analyzed by flow cytometry. The percentage of PD1+Tim3+ cells were markedly reduced in the tumors in mice that received \( \text{cbl}^{-/-} \) CAR T cells (between 30% and 35% in \( \text{cbb}^{+/+} \) and 4%-6% in \( \text{cbl}^{+/+} \)). Next, we sorted the PD1+Tim3+ and PD1+Tim3- cells that were gated on GFP+ cells and cocultured with MC38-CEA cells to analyze their tumor killing ability using calcein-acetoxymethyl.16 As shown in figure 4D, coculture of MC38-CEA cells with \( \text{cbl}^{-/-} \) PD1+Tim3+ CEA-CAR T cells exhibited markedly reduced tumor killing ability. However, the \( \text{cbb}^{-/-} \) cells retained their tumor killing ability. Further, \( \text{cbb}^{-/-} \) CEA-CAR T cells cocultured with MC38-CEA cells expressed IFN\( \gamma \), TNF\( \alpha \) and granzyme B but not the \( \text{cbb}^{+/+} \) cells (figure 4D). These data collectively suggest that deletion of \( \text{cbl}^{-/-} \) potentiates the antitumor activity of CAR T cells. Since Cbl-b deficiency in T cells is linked to autoimmunity,3 we looked for signs of toxicity in mice that received \( \text{cbb}^{-/-} \) cells. No significant change in spleen size was observed between \( \text{Rag}^{-/-} \) mice that received either \( \text{cbb}^{+/+} \) or \( \text{cbb}^{-/-} \) cells. Similarly, histological analysis of H&E-stained sections of colon, lung and liver tissues of mice that received \( \text{cbb}^{-/-} \) CAR T cells did not show any signs of toxicity (figure 4E).

DISCUSSION

Immunotherapy for cancer via checkpoint blockade and adoptive transfer of tumor antigen-specific CAR T cells have shown promising results.1 However, only a subset of patients achieves complete remission with checkpoint blockade. Similarly, CAR T cells have been effective against hematopoietic malignancies but not against solid tumors. Several lines of evidence implicate exhaustion in limiting the potency of CAR T cells.9 Here, we demonstrate that deletion of Cbl-b inhibits CAR T-cell exhaustion, which can be exploited therapeutically.

The mechanism by which Cbl-b deficiency leads to such a remarkable effect on CD8+ T-cell exhaustion currently remains unclear. However, recent studies suggest that exhaustion results due to activation of nuclear factor of activated T-cells (NFAT) in the absence of AP-117 and several studies have implicated the NFAT-driven transcription factors NrfA7 and TOX in T-cell exhaustion.18-20 Interestingly, Cbl-b expression was induced by constitutively active NFAT,17 suggesting the potential role of Cbl-b in NFAT-driven mechanisms.

Previous studies have shown that Cbl-b deficiency leads to tumor rejection, which is predominantly mediated by CD8+ T-cells.8,11 Further, the antitumor activity of \( \text{cbb}^{-/-} \) CD8+ T-cells was shown to be independent of CD4+ T-cell help.8,11 In line with these studies, we found reduced MC38 tumor growth, which was associated with increased infiltration of CD8+ T-cells in \( \text{cbb}^{-/-} \) mice. However, Cbl-b has also been shown to regulate natural killer cells and dendritic cells.21,22 Therefore, we do not completely exclude the function of these immune cells in Cbl-b-mediated antitumor response.

It was demonstrated that Cbl-b deficiency uncouples the requirement for costimulation for T cells and hence heightened antitumor activity.3 Our results show that Cbl-b is upregulated in PD1+Tim3- exhausted CD8+ T-cells, and depletion of Cbl-b restores their effector function, suggesting a novel role for Cbl-b in CD8+ T-cells. Further, adoptive transfer of CEA-specific CD8+ CAR T cells resulted in reduced tumor growth and substantial survival benefit in \( \text{Rag}^{-/-} \) mice, suggesting the potential of targeting Cbl-b in CAR T cells. However, a significant difference exists between spontaneous tumors that arise in humans and the transplanted tumors. Therefore, further investigation in spontaneous tumor models and humanized mice is essential before the translation into clinical trials.

CAR T cells specific to CEA have shown clinical efficacy in gastrointestinal adenocarcinomas.25 However, another trial failed due to preconditioning-dependent respiratory toxicity.24 While we did not observe any significant toxicity in mice that received \( \text{cbb}^{-/-} \) CAR T cells, further studies using mice transgenically expressing human CEA in gastrointestinal or lung epithelia cells are essential to fully assess the potential toxicity. Nevertheless, our studies clearly suggest that Cbl-b could be potentially targeted to overcome CAR T-cell exhaustion.

CONCLUSION

Our studies demonstrate that deficiency of Cbl-b overcomes endogenous CD8+ T-cell exhaustion, and deletion of Cbl-b in CAR T cells render them resistant to exhaustion. Our results could facilitate the development of efficient CAR T-cell therapy for solid tumors by targeting Cbl-b.
