ABSTRACT

Background Current immunotherapy for patients with high-risk neuroblastoma involves the therapeutic antibody dinutuximab that targets GD2, a ganglioside expressed on the majority of neuroblastoma tumors. Opsonized tumor cells are killed through antibody-dependent cellular cytotoxicity (ADCC), a process mediated by various immune cells, including neutrophils. The capacity of neutrophils to kill dinutuximab-opsonized tumor cells can be further enhanced by granulocyte-macrophage colony-stimulating factor (GM-CSF), which has been shown in the past to improve responses to anti-GD2 immunotherapy. However, access to GM-CSF (sargramostim) is limited outside of Northern America, creating a high clinical need for an alternative method to stimulate dinutuximab responsiveness in the treatment of neuroblastoma. In this in vitro study, we have investigated whether clinically well-established granulocyte colony-stimulating factor (G-CSF) can be a potentially suitable alternative for GM-CSF in the dinutuximab immunotherapy regimen of patients with neuroblastoma.

Methods We compared the capacity of neutrophils stimulated either in vitro or in vivo with GM-CSF or G-CSF to kill dinutuximab-opsonized GD2-positive neuroblastoma cell lines and primary patient tumor material. Blocking experiments with antibodies inhibiting either respective Fc gamma receptors (Fcy-R) or neutrophil integrin CD11b/CD18 demonstrated the involvement of these receptors in the process of ADCC. Flow cytometry and live cell microscopy were used to quantify and visualize neutrophil-neuroblastoma interactions.

Results We found that G-CSF was as potent as GM-CSF in enhancing the killing capacity of neutrophils towards neuroblastoma cells. This was observed with in vitro stimulated neutrophils, and with in vivo stimulated neutrophils from both patients with neuroblastoma and healthy donors. Enhanced killing due to GM-CSF or G-CSF stimulation was consistent regardless of dinutuximab concentration, tumor-to-neutrophil ratio and concentration of the stimulating cytokine. Both GM-CSF and G-CSF stimulated neutrophils required FcyRIIa and CD11b/CD18 integrin to perform ADCC, and this was accompanied by trogocytosis of tumor material by neutrophils and tumor cell death in both stimulation conditions.

Conclusions Our preclinical data support the use of G-CSF as an alternative stimulating cytokine to GM-CSF in the treatment of high-risk neuroblastoma with dinutuximab, warranting further testing of G-CSF in a clinical setting.

INTRODUCTION

Neuroblastoma, a tumor originating from the early embryonic neural crest, is the most common extracranial solid tumor diagnosed in children. The median age at diagnosis is 19 months and it accounts for almost 15% of all cancer-related mortality in children. The prognosis and treatment options for this neuroendocrine tumor, generally arising in the adrenal glands and sympathetic ganglia, are determined by the stage of the disease. For very low-risk, low-risk and intermediate-risk categories—as classified by the International Neuroblastoma Risk Group, which uses molecular, pathological as well as clinical criteria for patient classification—the risk of recurrence is minimal. However, the prognosis for high-risk neuroblastoma remains poor despite intensive multimodal treatment comprising surgery, chemotherapy, myeloablative therapy with stem cell rescue and radiotherapy. In 2015, the Food and Drug Administration approved the addition of the therapeutic antibody dinutuximab to the maintenance phase of the treatment protocol for patients with high-risk neuroblastoma (online supplemental figure 1). This combination of dinutuximab with the existing multimodal treatment increased the survival rate from high-risk neuroblastoma to 50%. Nonetheless, still
half of the patients relapse and succumb to the tumor. Increasing the efficacy of dinutuximab is therefore of utmost importance.

The chimeric monoclonal antibody dinutuximab binds GD2, a ganglioside present on the surface of neuroblastoma cells. Upon binding, dinutuximab marks the cells for immune-mediated destruction via antibody-dependent cellular cytotoxicity (ADCC) by Fc gamma receptor (FcγR) expressing immune cells.6,7 Natural killer (NK) cells and macrophages play a prominent role in mediating ADCC in diverse cancer types. In neuroblastoma, however, neutrophils have been described as the major cell population involved in dinutuximab-mediated killing of neuroblastoma cells in vitro.8 The cytotoxic activity of dinutuximab can be significantly enhanced when given in combination with cytokines that specifically stimulate the activity of immune cells. Particularly, granulocyte-macrophage colony-stimulating factor (GM-CSF), stimulating neutrophils and macrophages, and interleukin-2 (IL-2), stimulating NK cells, were demonstrated to positively contribute to the efficacy preclinically8–10 and also in clinical trials.11,12 Notably, a partially randomized phase III trial showed a survival benefit for patients with high-risk neuroblastoma treated during alternating cycles of dinutuximab combined with GM-CSF or IL-2, and isotretinoin, as compared with patients treated with isotretinoin alone (COG ANBL0032 study).12 This trial led to the standardization of this combination regimen for the maintenance phase in the treatment protocol for patients with high-risk neuroblastoma in the USA (online supplemental figure 1).13,15 However, the addition of IL-2 has later been shown to bring minimal clinical improvement for dinutuximab-treated patients with neuroblastoma,14,15 and access to GM-CSF for clinical use outside of Northern America is limited.16 Therefore, the immunotherapy regimen for patients with high-risk neuroblastoma in Europe is not fully defined with regard to the cytokine administration, resulting in a potentially increased risk of suboptimal treatment.

In this study, we aim at providing preclinical evidence for the use of an alternative stimulating cytokine if GM-CSF is unavailable, to ultimately increase dinutuximab responsiveness in the treatment protocol of neuroblastoma. Based on the known ability of granulocyte colony-stimulating factor (G-CSF) to enhance neutrophil-mediated ADCC,13–20 we propose the use of this clinically well-established, and broadly available cytokine. Furthermore, we investigated the potentially negative effect of G-CSF on neuroblastoma cells as an additional safety measure, since several studies suggested G-CSF treatment of chemotherapy-induced neutropenia to cause alterations in tumor cell phenotype, promoting neuroblastoma tumorigenicity.21–25 Our preclinical data on G-CSF efficacy in neutrophil activation against neuroblastoma support the clinical use of G-CSF as it potentiates neutrophil-mediated ADCC of dinutuximab-opsonized neuroblastoma cells to the same extent as GM-CSF.

**MATERIALS AND METHODS**

**Patients, controls and samples**

For in vivo GM-CSF stimulated neutrophils, remnant heparinized blood was collected at Sanquin from granulocyte transfusion donors ~30 hour after subcutaneous injection of 10 µg/kg clinical grade G-CSF (filgrastim, Neupogen). As control, heparinized blood was collected from healthy unrelated volunteers, as well as at least 3 weeks later (when G-CSF is cleared from circulation)24–27 from the same G-CSF injected healthy donor.

**Neutrophil isolation and in vitro stimulation**

Heparinized peripheral blood was diluted 1:2 with phosphate-buffered saline (PBS)+10% trisodium citrate and separated by density gradient centrifugation over isotonic Percoll (1.076 g/mL, GE Healthcare). The pellet fraction, containing both erythrocytes and granulocytes, underwent erythrocyte lysis with ice cold hypotonic ammonium chloride solution (155 mM NH₄Cl, 10 mM KHCO₃, 0.1 mM EDTA in water). After isolation, 5×10⁹/mL neutrophils were resuspended in 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid supplemented with 5 g/L human albumin (Albuman, Sanquin Plasma Products), 1 mM CaCl₂ and 5.5 mM glucose.28

Neutrophils were either used directly after isolation (referred to as unstimulated neutrophils) or were stimulated overnight at 37°C and 5% CO₂ with either 10 ng/mL recombinant human GM-CSF (Peprotech) or 10 ng/mL clinical grade G-CSF (Neupogen), unless otherwise specified. After overnight incubation, the percentage of apoptotic cells was determined using Annexin V staining (BD Biosciences) to correct for the number of viable neutrophils (the percentage of apoptotic neutrophils typically ranged between 10% and 30%) prior to any experiments.

**Cell culture**

The human neuroblastoma cell lines NMB, IMR-32 and LAN-1 were obtained from the Leibniz Institute, Germany. These cell lines were routinely cultured at 37°C and 5% CO₂, and maintained in Iscove’s Modified Dulbecco’s Medium (IMDM, Gibco) supplemented with 20% of...
heat-inactivated fetal calf serum (FCS), 2 mM L-glutamine, 100 units/mL penicillin and 100 µg/mL streptomycin (further referred to as IMDM complete medium) for a maximum of 30 passages. NMB cells were harvested using trypsin; IMR-32 and LAN-1 cells were harvested by tapping the culture flask and resuspending the culture medium. The human neuroblastoma cell lines SHEP-2, SK-N-AS, SH-SY5Y and SK-N-BE (kindly provided by the Department of Oncogenomics, Amsterdam UMC) were routinely cultured at 37°C and 5% CO₂ and maintained in Dulbecco’s Modified Eagle Medium (DMEM, Gibco) completed with 20% of FCS, 0.1 mM non-essential amino acids, 2 mM L-glutamine, 100 units/mL penicillin and 100 µg/mL streptomycin for maximum of 30 passages. These cells grew adherent as well as in suspension and were harvested by collecting supernatant as well as by using trypsin.

**Primary patient-derived neuroblastoma cells**
The primary patient-derived neuroblastoma spheroid line AMC691B (further referred to as 691B) was derived from a bone marrow metastasis (B) of patient 691.²⁹ 691B cells grow in spheroids and were cultured and maintained in DMEM with low glucose and sodium pyruvate (Inovitrogen) supplemented with 25% Ham’s F12 nutrient mixture (Inovitrogen), 1× B-27 supplement minus vitamin A (50×, Gibco), 1× N-2 supplement (100×, Gibco), 20 ng/mL animal-free human epidermal growth factor (Peprotech), 40 ng/mL human basic fibroblast growth factor (Peprotech), 200 ng/mL human insulin-like growth factor (Peprotech), 10 ng/mL human platelet-derived growth factor (PDGF)-AA (Peprotech), 10 ng/mL human PDGF-BB (Peprotech), 100 units/mL penicillin and 100 µg/mL streptomycin for maximum of 24 passages. To obtain a single-cell suspension, cells were treated with Accutase solution for 5 min (Sigma-Aldrich).

**Chromium-based ADCC assay**
Target cells (1×10⁵) were labeled with 100 µCi ⁵¹Cr (PerkinElmer) for 90 min at 37°C and washed with PBS. Chromium-labeled target cells (5×10⁵) were co-incubated with neutrophils in a 96-well U-bottom plate (Corning) in the absence or presence of dinutuximab (Unituxin, Ch14.18, United Therapeutics) in the appropriate culture medium for 4 hours at 37°C and 5% CO₂. A target:effector (T:E) ratio of 1:50 (ie, 5000:250,000 cells) and a final concentration of 0.5 µg/mL of dinutuximab were used, unless specified otherwise. Spontaneous and maximum ⁵¹Cr release were determined by incubating the target cells without effector cells and by treating the target cells with a 0.1% Triton X-100 solution in culture medium, respectively. After incubation, 30 µL of supernatant was subsequently transferred to Lumaplates (PerkinElmer). The plates were dried overnight at room temperature and analyzed in a MicroBeta³⁴ plate reader (PerkinElmer). The percentage of cytotoxicity was calculated as: [(experimental counts per minute (CPM))−(spontaneous CPM)]×100%. All conditions were performed in triplicate.

For Fcγ receptor blocking experiments, F(ab')₂ fragments against FcγRIIA (CD32, clone 7.3, Ancell) or FcγRIIB (CD16, clone 3G8, Ancell) were used and compared with isotype control mlgG1 F(ab')₂ fragments (clone MOPC 31C, Ancell). Using purified human IgG Fc binding fragments (Bethyl, USA), we aimed to saturate the high-affinity FcγRI. Blocking reagents were pre-incubated with neutrophils at 10 µg/mL for 45 min at room temperature. Subsequently, the effector cells were used in the chromium-based ADCC assay.

For integrin blocking experiments, F(ab')₂ fragments against CD18 (clone IB4, Ancell) were pre-incubated with neutrophils at 10 µg/mL for 15 min at room temperature, after which the cells were used in the chromium-based ADCC assay.

**Trogocytosis assay**
The trogocytosis of neuroblastoma cells by neutrophils was quantified using flow cytometry and measured by the uptake of tumor cell membrane by the neutrophils. Tumor cells were stained with 2 µM lipophilic membrane dye 3,3'-dioctadecyloxacarbocyanine perchlorate (DiO, Invitrogen); neutrophils were labeled with 0.625 ng Calcein Violet-AM (Invitrogen) for 30 min at 37°C. After labeling, populations were washed twice with PBS. Cells were co-incubated at a T:E ratio of 1:5 (ie, 50,000:250,000 cells) in the absence or presence of 0.5 µg/mL dinutuximab in a U-bottom 96-well plate (Greiner Bio-One) for 60 min at 37°C and 5% CO₂ in IMDM complete medium. After incubation, cells were fixed with STOPluffer (PBS containing 20 mM sodium fluoride, 0.5% paraformaldehyde (PFA) and 1% bovine serum albumin) and analyzed using flow cytometer Canto II (BD Biosciences). The neutrophil population (all Calcein Violet-AM⁺ events) was assessed for the mean fluorescence intensity of membrane dye DiO. Data were analyzed with FlowJo software (V.10.6.1, Becton Dickinson, Ashland, Oregon, USA).

**Live cell imaging**
NMB target cells labeled with 5 µM lipophilic membrane dye 1,1'-dioctadecyl-3,3',3'-tetramethylindocarbocyanine, 4-chlorobenzenesulfonate salt (DiD, Invitrogen) and 2.5 nM cytoplasmic dye Calcein Red-Orange-AM (ThermoFisher) were co-incubated with unstained neutrophils at a T:E ratio of 1:5 in glass chambered coverslips (Ibidi) of 9.4×10.7×6.8 mm³ well dimensions. Two drops of the DNA-binding Nuc-Green dye were added in the extracellular medium before imaging. Cells were co-incubated for periods up to 4 hours at 37°C and 5% CO₂ in the presence of 0.5 µg/mL dinutuximab in IMDM complete medium. Imaging was performed within 5 min after co-incubation of tumor cells and neutrophils and lasted up to 210 min using a Leica TCM SP8 confocal microscope (Leica).
Flow cytometry staining

For cell characterization, cells were stained with 10 μg/mL fluorescein isothiocyanate (FITC)-labeled antibodies: anti-FcyRI (CD64, clone 10.1, Bio-Rad), anti-FcyRII (CD32, clone AT10, Bio-Rad), anti-FcyRIII (CD16, clone 3G8, BD Biosciences), anti-CD11b (clone CLB-mon-gran/1, B2, Sanquin Reagents) and anti-CD18 (clone MEM48, Diaclone).

For target cell characterization, human anti-CD2 antibody dinutuximab (Unituxin, Ch14.18, United Therapeutics) was used to quantify GD2 expression by titrating dinutuximab from 10 μg/mL to 0.001 μg/mL. Secondary antibody Alexa Fluor 647 goat antihuman IgG F(ab')2 fragment (Jackson ImmunoResearch) was used for detection. To determine expression of G-CSF receptor on neuroblastoma cells, 20 μg/mL of anti-CD114 PE-Cyanine7 (BD Biosciences) was used. Cell viability of tumor cells was determined using Hoechst 33342 solution (Invitrogen). All incubations took place for 20 min on ice in the dark. The appropriately labeled IgG isotypes were used to correct for any potential background. After washing, cells were resuspended in PBS supplemented with 6 g/L human albumin (Albuman, Sanquin Plasma Products) and fluorescence was measured on a Canto II flow cytometer (BD Biosciences). Data were analyzed with FlowJo software (V.10.6.1).

Effect of G-CSF on JAK/STAT3 pathway

Tumor cell samples were exposed to 10 ng/mL G-CSF (Neupogen) for 0, 5, 10 and 20 min. Hereafter, cells were fixed with 4% PFA, permeabilized with ice-cold 90% methanol and stained with fluorescently labeled antibodies for total STAT3-PERCP-Cyanine5.5 (BD Biosciences) and phospho-STAT3-PE (pSTAT3, BD Biosciences) as previously described. Neutrophils were used as control in this setting. Fluorescence was measured on a Canto II flow cytometer (BD Biosciences) and data were analyzed with FlowJo software (V.10.6.1).

Effect of G-CSF on neuroblastoma cell proliferation rates

Tumor cells were cultured in the presence or absence of 10 ng/mL clinical grade G-CSF (Neupogen) in the appropriate culture medium for 1–3 weeks. The medium supplemented with cytokine was refreshed twice a week where applicable; 0.5×10⁶ IMR-32 cells or 0.5×10⁶ 691B cells were plated in each well of a 6-well plate (Corning) and the proliferation rate of these cultures were determined by counting the cells using a CASY Cell Counter (Roche Innovatis). The population doubling time of G-CSF-treated cultures was calculated with a doubling time calculator (http://www.doubling-time.com/compute.php).

RNA isolation, cDNA synthesis and RT-quantitative PCR

Total RNA was extracted from neuroblastoma cell lines on days 0, 7, 14 and 21 after G-CSF exposure by using the QIAamp RNA Blood Mini Kit (Qiagen) according to manufacturer’s instructions. Complementary DNA (cDNA) was synthesized from 2 to 3 μg RNA, using the High-Capacity RNA-to-cDNA Kit (Applied Biosystems), as described previously. Quatitative PCR for reference gene beta-glucuronidase (GUSB), adrenergic neuroblastoma marker (32-33) paired-like homeobox 2b (PHOX2B), cholinergic receptor nicotinic alpha 3 (CHRNA3), dopamine beta hydroxylase (DBH) and tyrosine hydroxylase (TH), and mesenchymal neuroblastoma markers (34) paired related homeobox 1 (PRRX1) and peristin (POSTN) was performed using the Via7 (Applied Biosystems) as previously described. Normalization for expression was based on the expression of GUSB with the equation: normalized threshold cycle (dCt) = (Ct_marker −Ct_GUSB). All reactions were performed in triplicate (except GUSB, which was performed in duplicate) and mean values were used. As a positive control, a calibration curve of neuroblastoma cell line IMR-32 was used for the adrenergic markers, plasmin were used for GUSB and the mesenchymal panel to establish the PCR efficiency.

RESULTS

GM-CSF and G-CSF equally enhance neutrophil-mediated ADCC of neuroblastoma cells

To compare the effect of GM-CSF with G-CSF on the tumor cell killing capacity of neutrophils, we performed ADCC experiments with various GD2-positive and GD2-negative neuroblastoma cells (all cell line characteristics are summarized in online supplemental table 1, titration of dinutuximab depicted in online supplemental figure 2A–C) using neutrophils that were unstimulated or stimulated overnight with the respective cytokines in vitro. Unstimulated neutrophils were not able to kill dinutuximab-opsonized GD2-positive neuroblastoma cell lines NMB, IMR-32 and LAN-1, whereas stimulation of neutrophils either with GM-CSF or G-CSF enhanced the cytotoxicity levels significantly, with neither cytokine being superior to the other (figure 1A). The effect of either GM-CSF or G-CSF stimulation on the killing efficacy remained equal, irrespective of the concentration of dinutuximab tested (figure 1B and online supplemental figure 3A), different T:E ratios (figure 1C and online supplemental figure 3B) or the various concentrations of GM-CSF and G-CSF used to stimulate neutrophils (figure 1D and online supplemental figure 3C). The high concentrations of dinutuximab (figure 1B, exceeding 5 μg/mL) led to decreased cytotoxicity, probably due to the formation of immune complexes. We observed no killing of GD2-negative neuroblastoma cell lines SH-SY5Y and SK-N-BE in the presence of dinutuximab, regardless of the stimulating cytokine used (online supplemental...
Neuroblastoma cell lines SHEP-2 and SK-N-AS, expressing lower levels of GD2 (online supplemental figure 2B), were also killed by stimulated neutrophils irrespective of the cytokine used (figure 1E), although at lower levels than the GD2-positive cell lines NMB, IMR-32 and LAN-1 (figure 1A). To test the ability of both cytokines to promote neutrophil-mediated killing of primary patient material, we used GM-CSF and G-CSF stimulated neutrophils in an ADCC assay with GD2 expressing 691B cells derived from bone marrow metastasis of a patient with high-risk neuroblastoma (characteristics in online supplemental figure 2C and online supplemental table 1). Both stimuli induced effective killing of primary tumor cells and no differences were seen between the two cytokines (figure 1F). Together, these observations show that the in vitro stimulating effect of G-CSF is as effective as GM-CSF in boosting neutrophil-mediated ADCC of neuroblastoma cells.

**GM-CSF and G-CSF both mediate neutrophil ADCC through FcγRIIa and CD11b/CD18 integrins**

In order to perform ADCC, neutrophils need expression of Fcγ receptors (neutrophils can express FcγRI, FcγRIIa/c and FcγRIIb) and CD11b/CD18 integrin.35 36 As stimulation with GM-CSF or G-CSF enhances tumor cell killing (figure 1), we explored whether the killing of...
tumor cells by differently stimulated neutrophils required presence of these molecules in a similar fashion. Freshly isolated, unstimulated, neutrophils constitutively express low-affinity and intermediate-affinity FcγRIIa or FcγRIIc (CD32a/c) and FcγRIIIb (CD16b), respectively. It has been shown that on stimulation with G-CSF neutrophils upregulate the expression of FcγRI (CD64) and shed FcγRIIIb.\(^{18, 37, 38}\) We showed that overnight stimulation of neutrophils with either GM-CSF or G-CSF in vitro significantly lowered FcγRIIIb expression compared with unstimulated neutrophils, whereas FcγRIIa expression remained unaltered on stimulation. FcγRI expression increased slightly but this was not statistically significant. No differences in neutrophil Fcγ receptor levels were observed between GM-CSF and G-CSF stimulation (figure 2A,B). Next to this, we investigated which Fcγ receptor(s) neutrophils need to facilitate killing of neuroblastoma cells. Previous studies showed that FcγRIIa is the major Fcγ receptor that mediates the killing of antibody-opsonized solid cancer cells.\(^{35, 36, 39}\) Indeed, blocking FcγRIIa using F(ab')\(^2\) fragments reduced ADCC of dinutuximab-opsonized NMB cells for both GM-CSF and G-CSF overnight stimulated neutrophils, while blocking FcγRI or FcγRIIIb had no effect on the killing capacity of neutrophils, regardless of the stimulating cytokine used (figure 2C).

In addition to Fcγ receptors, neutrophils need functional expression of the heterodimer integrin CD11b/CD18 to perform ADCC.\(^{35, 38, 40}\) After overnight in vitro stimulation with GM-CSF or G-CSF, neutrophils upregulated CD11b/CD18 integrins as shown by flow cytometry (figure 2A,B). Blocking of CD18 integrin with F(ab')\(^2\) fragments had no effect on the ADCC capacity of neutrophils, but CD11b blockade substantially reduced ADCC of dinutuximab-opsonized NMB cells for both GM-CSF and G-CSF overnight stimulated neutrophils (figure 2D).
stimulation with either GM-CSF or G-CSF, the expression of CD11b and CD18 remained similar to unstimulated neutrophils (figure 2A,B). When blocking CD18 using F(ab')2 fragments, known to inhibit CD11b/CD18 integrin function,26 tumor cell killing was abolished similarly for both GM-CSF and G-CSF stimulated neutrophils (figure 2D), suggesting that both cytokines stimulate neutrophils to kill neuroblastoma cells through functional CD11b/CD18 integrins.

GM-CSF and G-CSF stimulation induce trogocytosis of neuroblastoma cells by neutrophils and is accompanied by tumor cell death

The ability of immune cells to perform trogocytosis, an active mechanism involving the uptake of plasma membrane from a donor cell, is well-known.36 In the recent years, it has become clear that trogocytosis can also be a cytotoxic mechanism, at least in the context of antibody-dependent tumor cell killing by myeloid cells.37 More specifically, neutrophil-mediated trogocytosis in which the neutrophil takes 'bites' from the plasma membrane of antibody-opsonized cancer cells can result in cancer cell lysis, also known as trogoptosis. This has been described for trastuzumab-opsonized breast cancer cells and it has been shown to be dependent on functional FcγRIIa and CD11b/CD18 integrins.36 To investigate whether GM-CSF and G-CSF stimulated neutrophils could trogocytose neuroblastoma cells, we performed a FACS-based trogocytosis assay where we labeled overnight stimulated neutrophils with Calcein Violet-AM and freshly harvested NMB cells with the membrane dye DiO (figure 3A). In conditions with dinutuximab, neutrophils stimulated with either GM-CSF or G-CSF became positive for the membrane dye DiO, indicative of trogocytosis (figure 3A,B), although this was significantly higher in G-CSF stimulated neutrophils. In an attempt to demonstrate whether trogocytic events by neutrophils coincided with tumor cell death, we performed live cell confocal imaging on dinutuximab-opsonized cells. We labeled NMB cells with membrane dye DiD and cytoplasmic dye Calcein Red-Orange-AM, which were co-incubated with stimulated neutrophils. As a live/dead indicator, a membrane-impermeable DNA-binding dye was added to the extracellular medium during imaging. During co-incubation of tumor cells with neutrophils stimulated overnight with either GM-CSF or G-CSF, we observed that neutrophils became positive for the neuroblastoma membrane dye, but not the cytoplasmic dye (which would indicate phagocytosis; figure 3C). In addition, we found that neutrophil trogocytic interactions were followed with tumor cell death as appreciated by the staining of nuclear material exposed to the extracellular medium on membrane disruption induced by the attacking neutrophils (figure 3C). Collectively, these data support a link between trogocytic events and subsequent tumor cell death.

G-CSF treatment does not alter neuroblastoma cell phenotype in vitro

Currently, G-CSF is used to treat chemotherapy-induced neutropenia, often occurring in patients with high-risk neuroblastoma,43 which was shown to be an advantageous addition to the treatment protocol.44 However, although not generally supported by clinical or in vitro data, previously published studies have suggested a potential role of G-CSF with regard to neuroblastoma proliferation and invasive properties of neuroblastoma cell lines.21 Also, the tumorigenicity and metastasis formation in human xenograft and murine neuroblastoma tumor models were suggested to be enhanced in some studies.22 23 Neuroblastoma cells express the G-CSF receptor (figure 4A) and therefore we investigated whether exposure of neuroblastoma cells to G-CSF could alter their phenotype and possibly make them more resistant towards neutrophil-mediated killing. First, we investigated the effect of G-CSF on its cognate receptor signaling. Activation of STAT3 is known to take place downstream of the G-CSF receptor after ligand binding35 and therefore we measured the level of STAT3 phosphorylation (pSTAT3) by intracellular flow cytometry staining of IMR-32 cells that were exposed to the cytokine for 0, 5, 10 or 20 min. Compared with neutrophils used as positive control, IMR-32 cells did not show any phosphorylation of STAT3, suggesting no STAT3-mediated signaling through the G-CSF receptor (online supplemental figure 4A,B). To verify that no other (ie, long-term) effects due to G-CSF binding to its receptor occurred, we cultured IMR-32 and patient-derived 691B neuroblastoma cells in the absence or presence of G-CSF for up to 3 weeks, as this is the period during which clinical grade pegylated G-CSF stays in circulation.24 27 No changes on GD2 or G-CSF receptor expression were detected over time and expression remained high at all time points tested (7, 14 and 21 days; online supplemental figure 4C–F). During incubation with G-CSF, the proliferation rates of tumor cell cultures were similar to control, with no proliferative advantage of the G-CSF exposed cells (figure 4B and online supplemental figure 4G–J). Since IMR-32 and 691B cells have an adrenergic (epithelial) phenotype34 (online supplemental table 1), we studied whether exposure to G-CSF initiated epithelial-to-mesenchymal transition (EMT) in these cells. The transition from an adrenergic to a mesenchymal phenotype is known to increase invasive properties of tumor cells facilitating metastasis.46 48 We performed quantitative RT-PCR on RNA samples isolated from IMR-32 and 691B cells cultured with or without G-CSF. We investigated mRNA expression of several adrenergic (PHOX2B, CHRNA3, DBH and TH) and mesenchymal (PRRX1 and POSTN) markers that have been described to be specific for neuroblastoma.32–34 Overall, no differences in mRNA expression were seen for any of the mesenchymal markers PRRX1 and
POSTN during G-CSF culture at any of the time points (7, 14 and 21 days) when compared with the control (untreated) condition. Also, no changes of adrenergic markers were detected, implying no signs of EMT (figure 4C,D). Last, the susceptibility of G-CSF exposed neuroblastoma cells towards neutrophil ADCC was studied by co-incubating IMR-32 cells cultured for 0, 7, 14 and 21 days with G-CSF with overnight in vitro G-CSF stimulated neutrophils (figure 4E). No differences were found in the extent of neutrophil-mediated cytotoxicity between G-CSF cultured tumor cells and control tumor cells. Altogether, these results
show that in vitro G-CSF has no detectable effect on neuroblastoma phenotype, nor on the susceptibility of tumor cells towards neutrophil-mediated ADCC.

**Comparable ex vivo killing of neuroblastoma cells by in vivo GM-CSF or G-CSF stimulated neutrophils**

Although in vitro GM-CSF and G-CSF stimulated neutrophils show enhanced killing capacity towards neuroblastoma cells (figure 1), whether this also occurs in vivo and in patients with neuroblastoma is still unclear. To take this a step closer to the anticipated situation in patients, we investigated the respective abilities of GM-CSF and G-CSF at potentiating neutrophils to kill neuroblastoma cells after in vivo stimulation. We obtained blood from patients with high-risk neuroblastoma that were administered GM-CSF subcutaneously for three consecutive days prior to blood sampling (patient characteristics are summarized in online supplemental table 2). In addition, we collected blood from granulocyte transfusion donors ~30 hours after subcutaneous G-CSF injection. We found similar Fcγ receptor expression profiles for both GM-CSF and G-CSF in vivo stimulated neutrophils. Compared with unstimulated neutrophils, in vivo G-CSF stimulated neutrophils, as well as in vivo GM-CSF stimulated neutrophils showed a significant increase of FcγRI expression and a decrease of FcγRIIIb expression, whereas the expression of FcγRIIa remained unaltered (figure 5A–D), similar as observed

*Figure 4*  G-CSF treatment does not alter neuroblastoma cell phenotype. (A) Representative histograms depicting G-CSF receptor expression (gray) on IMR-32 (left panel) and 691B cells (right panel). (B) Proliferation curves of IMR-32 (left panel) and 691B (right panel) when cultured in the absence (control, white circles) or presence (gray circles) of G-CSF for 7 days. IMR-32 n=4, 691B n=3 of four and four individual experiments, respectively. Statistical significance was assessed with a paired T-test on AUC (online supplemental figure 3C,D). (C, D) Normalized expression (dCt, delta cycle threshold = Ctmarker–CtGUSB) levels of adrenergic neuroblastoma markers PHOX2B, CHRNA3, DBH and TH, as well as mesenchymal neuroblastoma markers PRRX1 and POSTN on IMR-32 cells (C) and patient-derived 691B cells (D) cultured in the absence (control, white symbols) or presence of G-CSF for 7 (gray circles), 14 (gray triangles) or 21 (gray squares) days. IMR-32 n=2–8, 691B n=4–5 of two individual experiments. Statistical differences were tested with ordinary one-way ANOVA with post hoc Sidak test. (E) ADCC of IMR-32 cells cultured in the absence (control, white symbols) or presence of G-CSF (gray bars) for 7 (circles), 14 (triangles) or 21 (squares) days opsonized with (+) or without (−) dinutuximab (dimab) by in vitro G-CSF stimulated neutrophils. N=4–13 of five individual experiments. Statistical significance was tested with ordinary one-way ANOVA with post hoc Sidak test. ADCC, antibody-dependent cellular cytotoxicity; ANOVA, analysis of variance; G-CSF, granulocyte colony-stimulating factor; AUC, areas under curve; ns, not significant.
for the in vitro stimulated neutrophils (figure 2A,B). The capacity of in vivo stimulated neutrophils to kill dinutuximab-opsonized neuroblastoma cells was investigated ex vivo. Neutrophils from GM-CSF injected patients with neuroblastoma induced significantly greater cytotoxicity levels of the GD2-positive neuroblastoma cell lines NMB and IMR-32 as compared with unstimulated neutrophils (figure 5E and online supplemental figure 5). Likewise, the cytotoxic ability of in vivo G-CSF stimulated neutrophils was similarly enhanced (figure 5F). Overall, this indicates that both cytokines can stimulate neutrophils in vivo to kill neuroblastoma cells ex vivo.

**DISCUSSION**

High-risk neuroblastoma is an aggressive cancer affecting children mostly before the first year of age. Therapy consists of intense multimodal treatment,
including immunotherapy with anti-GD2 antibody dinutuximab. The treatment regimen in the USA encompasses dinutuximab administered in combination with GM-CSF and IL-2 in alternating cycles, as these have been shown to improve therapeutic efficacy. However, this is not the case for other countries, where GM-CSF (sargramostim) is not approved for clinical use. The limited availability of GM-CSF poses a risk of suboptimal treatment of these patients. For this reason, finding a widely available alternative stimulating cytokine that potentiates the killing of neuroblastoma cells is of high clinical relevance in areas where GM-CSF is not available. Enhancing the cytotoxic capacities of effector cells may improve dinutuximab responsiveness, which could further increase the overall survival of patients with high-risk neuroblastoma. As neutrophils are considered the main players in dinutuximab-mediated killing of neuroblastoma cells, we tested the capacity of neutrophils stimulated with G-CSF as opposed to GM-CSF in killing dinutuximab-opsonized GD2-positive neuroblastoma cells. For this we used both in vivo and in vitro GM-CSF or G-CSF stimulated neutrophils from either patients with neuroblastoma or healthy adult donors, and various neuroblastoma cell lines, including primary patient-derived material.

In the present study, we critically compared GM-CSF with G-CSF in the context of neutrophil ADCC of neuroblastoma cells. Previous studies showed that in vitro stimulation with GM-CSF increased the magnitude of cytotoxicity of dinutuximab-opsonized neuroblastoma cells specifically for granulocytes, while this effect was not obtained when stimulating peripheral blood mononuclear cells, emphasizing the specificity of GM-CSF on granulocytes. Similarly, G-CSF stimulation of neutrophils has been found to greatly enhance their capacity for ADCC in solid cancers. In this report, we found G-CSF to be as effective as GM-CSF in enhancing neutrophil ADCC of neuroblastoma cells, both after in vitro stimulation, as well as after in vivo stimulation. For the latter, we were able to use neutrophils from healthy granulocyte transfusion donors injected with G-CSF and neutrophils from patients with neuroblastoma treated with GM-CSF. Both in vivo stimulations enhanced neutrophil-mediated ADCC as opposed to unstimulated conditions, demonstrating that in vivo stimulated neutrophils can perform ADCC. We did not have access to unstimulated neutrophils of patients with neuroblastoma, but a previous report demonstrated that neutrophils of neuroblastoma patients displayed the same abilities as healthy adult neutrophils in mediating killing of neuroblastoma cells ex vivo, supporting comparison between these different cohorts.

We found that both GM-CSF and G-CSF stimulated neutrophils induced the same effect on Fcγ receptor and integrin expression on stimulation: shedding of FcγRIIib, and no apparent changes in expression of FcγRIIa or CD11b/CD18 integrins. We did see an increase in FcγRI expression after in vivo stimulation, in line with existing literature, and to a lesser extent also after in vitro stimulation. A previous study demonstrated that both FcγRIIa and CD11b/CD18 integrins are indispensable for neutrophil-mediated killing of antibody-opsonized solid tumor cells, and this is consistent with our findings in the context of dinutuximab-opsonized neuroblastoma cells; blocking CD11b/CD18 integrin function completely abolished ADCC, with FcγRIIa being a dominant Fcγ receptor contributing to the process. The reason ADCC could not be fully inhibited on FcγRIIa blockade is not completely understood, especially as we found that killing itself seemed to be fully antibody-dependent. It might be that the concentration of FcγRIIa blockade using the F(ab′)_2 fragments was suboptimal or not complete during the 4 hours ADCC. In addition, the same might hold true for the purified IgG1 Fc tails for the saturation of FcγRI.

Furthermore, neutrophils stimulated overnight with either GM-CSF or G-CSF in vitro were able to trogocytose dinutuximab-opsonized neuroblastoma cells and this was followed by tumor cell death. This is in line with previous findings where neutrophils trogocytosed trastuzumab-opsonized breast cancer cells, which led to cell rupture and death.

Finally, we investigated the effect of G-CSF on the neuroblastoma cells. Our results showed no unfavorable effects of G-CSF during the 3-week cultures on neuroblastoma cell growth and on the susceptibility towards neutrophil-mediated ADCC in vitro, and no signs of EMT were observed. Of interest, a recent phase I/IIa clinical trial in a cohort of patients with neuroblastoma in Japan—where GM-CSF is also unavailable—assessed the tolerability, safety and feasibility of either G-CSF or macrophage colony-stimulating factor (M-CSF) during dinutuximab immunotherapy with IL-2. This study showed that G-CSF was well-tolerated, which complements our preclinical data on the safety of G-CSF.

Although biologically very relevant, validating our findings in an in vivo mouse model would technically and methodologically be challenging. Considering syngeneic tumor mouse models, fundamental differences are observed between human and mouse neutrophil biology, reflected in the number of circulating neutrophils, function and their antitumor effects, which hamper the translatability of preclinical findings in such models. As for a xenogeneic mouse tumor model, the major obstacle is the availability of patient-derived xenograft models in mice with fully functional human immune system, including neutrophils, suitable for studying dinutuximab-based immunotherapies in neuroblastoma. In vitro preclinical data on the efficacy and safety of G-CSF, together with extensive clinical experience with G-CSF in other (pediatric) indications, support direct evaluation of...
G-CSF in a clinical setting to improve immunotherapy of patients with neuroblastoma.
