Biomarkers, Immune Monitoring and Novel Technologies

1 CAPTURING THE SPATIAL LANDSCAPE OF TUMOR AND IMMUNE CELL LINEAGES IN THE MICROENVIRONMENT OF HUMAN CANCER TISSUES

[1]Reggie Prioli*, [1]Lisa Arvidson*, [1]Sam Jensen, [2]Michael Smith*, [2]Katie White, [2]Richard Heil-Chapdelaine, [2]Melinda Angus-Hill. [1]*Cell Signaling Technology, Danvers, MA, USA*; [2]*Leica Microsystems Inc, Bellevue, WA, USA*

Background Immune system response to cancer therapies can indicate whether a patient will have positive outcomes following therapy. Understanding how the tumor microenvironment (TME) evolves during tumorigenesis and therapeutic response is crucial to developing personalized treatments with the goal of improving cancer therapy. With robust and comprehensive multiplexed imaging technologies, immune biomarkers can be used to interrogate myeloid and lymphoid cell lineages and structures, and when combined with specific oncology biomarkers, can capture the immune response within the TME in a variety of neoplasms. The availability of cell type specific biomarkers, combined with the ability to interrogate using multiplexed tissue imaging, provides unprecedented and novel insights into immune cell populations and spatial cell interactions with many cell types in the TME.

Cell DIVETM Multiplex Imaging Solution allows probing and imaging of dozens of biomarkers on a whole single tissue section with an iterative staining and dye inactivation workflow. At its core, Cell DIVE is a precise and adaptable open multiplexing solution that enables flexibility in antibody selection of biomarker panels used in a multiplexed imaging study. Cell Signaling Technology (CST) has a broad portfolio of IHC-validated antibodies to detect key proteins in the TME, enabling immune cell detection and phenotyping in tissue. CST offers off the shelf (OTS), ready-to-ship antibody conjugates that have been verified to work on Cell DIVE and offers custom conjugation of IHC-validated antibodies to fluorophores and other detection reagents. CST employs a rigorous approach to IHC validation, followed by verification on the Cell DIVE platform to ensure successful detection of proteins. Here, we demonstrate multiplexed Cell DIVE imaging using a novel panel of dozens of CST biomarkers across multiple tissue types.

Methods Sections were stained using conjugated antibodies (Cell Signaling Technology) to various biomarkers in 4 channels plus DAPI and imaged using Cell DIVE. Multiple rounds of staining and imaging were accomplished using the Cell DIVE workflow (Leica Microsystems).

Results Development of the multiplexed panel required minimal optimization, enabled the identification of complex cell types and revealed their cell-to-cell interactions within the tumor microenvironment.

Conclusions Multiplexed whole slide imaging allows deep analysis of immune cell lineages and provided new insights into immune and tumor cell-to-cell interactions within the tumor microenvironment.

Ethics Approval Stained samples were commercially available.

CHARACTERIZATION OF THE TUMOR MICROENVIRONMENT IN PANCREATIC DUCTAL ADENOCARCINOMA USING MULTIPLEXED IMAGING

Michael J Smith*, Katie O White, Richard A Heil-Chapdelaine, Melinda L Angus-Hill. *Leica Microsystems Inc, Bellevue, WA, USA*

Background The pancreas is surrounded by highly vascularized organs such as the duodenum and the common bile duct. Pancreatic cancer often invades and metastasizes to these organs, and to more distant organs such as the liver, peritonium, lung, brain, kidney and bone. Conventional chemotherapy plus radiation, or in advanced disease chemotherapy plus targeted drug therapy can lengthen patient survival. However, even in patients that only have local disease, the 5-year survival rate is only around 40%, demonstrating that there is need for improved conventional and immune therapies for all pancreatic cancer patients. Tumor cells can evade treatments and continue to grow. Additionally, stromal cells in the tumor microenvironment are a critical support niche for continued tumor growth. Understanding all cells in the tumor microenvironment is essential for understanding tumor metastasis and improving cancer therapies, especially immunotherapies. In this study, dozens of biomarkers have been used to probe tumor heterogeneity in pancreatic ductal adenocarcinoma (PDAC) tissue. With Cell DIVETM multiplexed imaging, dozens of biomarkers can characterize cell heterogeneity, cellular activity and cell-to-cell spatial context within the TME.

Methods Sections were stained using conjugated antibodies (from multiple vendors) to various biomarkers in 4 channels plus DAPI and imaged using Cell DIVE. Multiple rounds of staining and imaging were accomplished using the Cell DIVE workflow (Leica Microsystems).

Results We examined the tumor, stromal compartment and immune cell contributions to the tumor microenvironment (TME). The panel enabled the examination of tumor associated stromal components and tumor infiltrating lymphocytes (TIL), angiogenesis, metastasis, invasion, inflammation, hypoxia, metabolism, and the immune response. We found that these heterogenous activities are often intertwined. For example, subregions within the tumor adapt to hypoxic conditions and can gain dominance by uncontrolled cell growth. Additionally, these hypoxic regions are devoid of immune cells.

Conclusions Taken together, multiplexed whole slide imaging enables spatially resolved tissue analysis of cellular activities in the TME, including new insights into cell-to-cell interactions and immune cell profile.

Ethics Approval Human samples were commercially available.

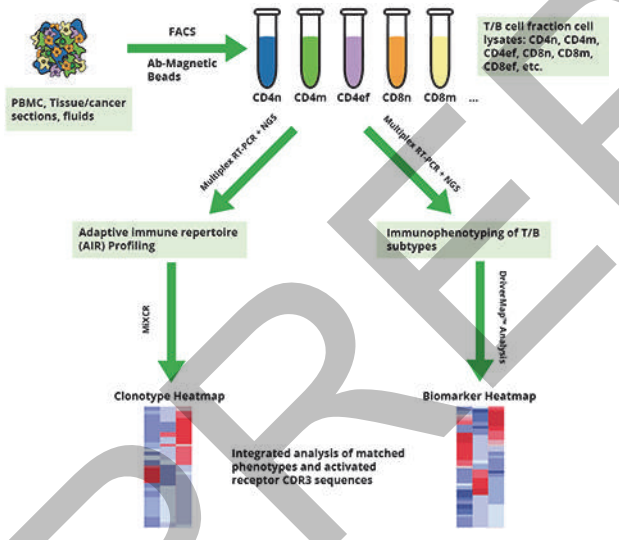
3 ADAPTIVE IMMUNE RECEPTOR REPERTOIRE PROFILING FOR BIOMARKER DISCOVERY

Alex Chenchik*, Mikhail Makhanov, Dongfang Hu, Tianbing Liu, Lester Kobzik. *Cellecta, Inc., Mountain View, CA, USA*

Background Adaptive Immune Receptor (AIR) Repertoire profiling and characterization of antigen-activated immune cells is essential for the discovery of novel prognostic and predictive biomarkers and for studying immune response mechanisms in cancer, auto-immune and other diseases.

Methods To facilitate these studies, we developed a novel technology for combined, unbiased profiling of all human TCR and BCR variable regions; and phenotypic characterization of immune cells in bulk, sorted fraction and single immune cells (figure 1). This method involves multiplex RT-PCR amplification and sequencing of CDR3 regions of TCR and BCR genes along with immunophenotyping with a set 500 highly expressed T- and B-cell subtyping and activation marker genes. Bioinformatic analysis of next-generation sequencing (NGS) data allows comprehensive AIR repertoire profiling, identification of antigen-activated TCR and BCR clonotypes, and detailed phenotypic characterization of T and B cells induced by adaptive immune responses.

Results Preliminary phenotypic AIR profiling studies in metastatic tumor samples and Humira®-treated rheumatoid arthritis cases indicate that AIR immunophenotyping technology has unparalleled throughput and sensitivity for the discovery of immunity biomarkers.



Abstract 3 Figure 1 Integrated AIR repertoire profiling & immunophenotyping

Fig. 1 The workflow illustrates integrated adaptive immune receptor (AIR) repertoire profiling and immunophenotyping directly in sorted cells without RNA purification using multiplex RT-PCR. High-resolution immunophenotyping (matching) of top TCR/BCR clonotypes is based on the expression of 300 key cell typing and activation T and B markers. Candidates were selected from a set of 3000 candidate genes described in >100 public databases, commercial assays, and peer-reviewed publications

4 POTENTIATION OF THE IMMUNE CHECKPOINT BLOCKADE RESPONSE BY TUMOR ACIDOSIS AND HYPOXIA MODULATION IS PREDICTABLE USING MOLECULAR IMAGING

Renee Chin*, Xiaofei Liang, Tianzhe Li, Jorge de la Cerda, F William Schuler, Mark Pagel.
University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background While immune checkpoint blockade (ICB) treatments such as programmed death-1 (αPD-1) and cytotoxic T lymphocyte antigen-4 blockade (αCTLA-4) shifted the paradigm of cancer treatment, this ICB combination produces objective response rates of only 35.9% for patients with non-small cell lung cancer,[1] and 58% for melanoma patients.[2] Tumors are able to suppress the anti-tumor T cells that drive ICB through the reduction extracellular tumor pH,[3–5] and by promoting hypoxia in the tumor microenvironment,[6] both of which are functions inherent to tumor cells due to the Warburg effect. We thus hypothesize that the magnitude of tumor acidosis and hypoxia modulation influences ICB response.

Methods To interrogate modulation of acidity in combination with ICB, we screened a panel of six inhibitors that interfere with tumor cell mechanisms that reduce pH, termed pH sensitizers, using Seahorse, cell viability assay, and T cell suppression assay. We probed the effect of our pH sensitizer candidate in combination with αPD-1 and αCTLA-4 blockade for changes in immunogenicity, tumor control, and correlation between acidity and tumor response or immune cell infiltrate. Tumor pH is measured using a modified Chemical Exchange Saturation Transfer Magnetic Resonance Imaging technique, or acidoCEST MRI, which tracks tumor pH non-invasively. To interrogate the modulation of hypoxia, we measured the correlation between oxygen saturation and immune cell infiltrate and the tumor growth kinetics of myoinositol trispyrophosphate (ITPP) in combination with αPD-1 and αCTLA-4 blockade. Oxygen saturation is monitored non-invasively using Multispectral Optoacoutic Tomography, or MSOT.

Results Out of the pH sensitizers, we found that esomeprazole significantly reduced proton efflux rate without inducing cytotoxicity or T cell suppression. Furthermore, esomeprazole significantly reduced tumor burden when given one day prior to starting αPD-1 and αCTLA-4 treatment (figure 1), an effect mediated by decreasing the frequencies of tumoral Ly6C+ myeloid cells. We also observed that post-esomeprazole pH correlated with tumor mass (figure 2) and the frequencies of TCF-1+ effector CD4 and CD8 T cells in the tumors following αPD-1 and αCTLA-4 treatment. Lastly, we found that ITPP is able to significantly delay tumor growth, and that tumor immunogenicity increases in correlation with oxygen saturation induced by ITPP.

Conclusions AcidoCEST MRI can predict tumor control in the combination treatment of esomeprazole followed by αPD-1 and αCTLA-4 one day afterwards, with TCF-1+ effector CD4 and CD8 T cells being possible biomarkers for treatment success as well. MSOT may also indicate αPD-1 and αCTLA-4 tumor control by determining changes in tumor oxygenation by ITPP.

5 DEVELOPMENT OF A VACCINE TO INTERCEPT ORAL CANCER

[1]Traci Hilton*, [2]Andrew Gunderson, [1]Mark Schmidt, [1]Christopher Paustian, [1]Sam Bookhardt, [1]Glenna McDonnell, [3]Tarsem Moudgil, [1]Hong-Ming Hu, [3]Bryan Bell, [4]Bernard Fox. *[1]UbiVac, Portland, OR, USA; [2]UbiVac, Portland, OR, USA, The Ohio State University Comprehensive Cancer Center, Columbus, Ohio, USA; [3]Providence Cancer Institute, Portland, OR, USA; [4]UbiVac, Portland, OR, USA, Providence Can Institute, Earle A. Chiles Research Institute, Portland, OR, USA*

Background Oral cavity cancer is diagnosed in more than 300,000 people each year worldwide and approximately half of these will die within five years despite standard treatment. These cancers are often preceded by the appearance of a pre-malignant dysplastic lesion, which offers a unique opportunity to identify patients at high risk of developing cancer and offer them a vaccine that may prevent development of this non-viral malignancy. Lesions can be removed but because of a 'field effect' their entire oral mucosa is at risk – thus the vaccine. Recent studies have identified genes that are differentially expressed during progression from normal tissue to oral cancer providing a roadmap to developing a preventative vaccine [PMID: 27027432]

Methods We have manufactured and performed initial characterization of a DC-targeted microvesicle vaccine, DPV-007, made specifically to intercept the progression of oral dysplasia to oral cancer. DPV-007 is manufactured using platform vaccine technology that is in the clinic. This technology captures short-lived and non-canonical proteins that make up the dominant epitopes presented by HLA and packages them in microvesicles containing DAMPs and molecular chaperones. Characterization of DPV-007 included molecular, proteogenomic, biochemical and functional assessments. Preclinical studies were performed evaluating prevention of tumor development in the 4NQO-induced tumor model.

Results The DPV-007 microvesicle vaccine contains more than 200 proteins for genes that are upregulated in oral dysplasia and oral cancer. Preliminary data suggests that the vaccine may contain as many as 30 somatic variants identified as somatic mutations in the COSMIC Database. Additionally, the vaccine contains at least 11 NCI prioritized cancer antigens and has agonist activity for TLR 2, 3, and 9. In the 4NQO preclinical model, vaccination including relevant antigens and agonist activity, provided significant ($p<0.02$) protection from lesion onset and tumor outgrowth.

Conclusions The identification of genes associated with the progression of pre-cancerous lesions to cancer provides targets for active immunotherapy of this disease. In preclinical models we have shown that this vaccine strategy is effective in both protection and therapy studies [PMID: 21810919; PMID: 27874054; PMID: 31747946]. A clinical trial of a similar vaccine, DPV-001, administered as a single agent as adjuvant therapy for NSCLC, documented induction of immunity to a large number of cancer antigens contained in the vaccine and did not identify serious adverse events. Based on data summarized above, we propose to vaccinate patients with dysplastic lesions and investigate whether vaccination reduces lesion recurrence.

USE OF REAL-WORLD (RW) DATA TO ASSESS THE ABILITY OF CIRCULATING CELL-FREE TUMOR DNA (CTDNA) MOLECULAR RESPONSE TO ASSESS THERAPEUTIC OUTCOMES IN PATIENTS WITH NON-SMALL CELL LUNG CANCER (NSCLC)

Caroline Weipert*, Leylah Drusbosky, Leslie Bucheit, Kyle Chang, Shaun Forbes, Sean Gordon. *Guardant Health, Redwood City, CA, USA*

Background Data suggests that changes in ctDNA quantity correlate with response to therapy in patients with advanced solid malignancies. However, there is little consistency on how to calculate and interpret such changes. Here, we apply a clinically-validated molecular response algorithm to a RW cohort of patients with NSCLC to further evaluate its ability to assess treatment outcomes.

Methods We queried the Guardant INFORM database, which comprises aggregated commercial payer health claims and de-identified records from over 173,000 individuals with comprehensive ctDNA testing via Guardant360 (G360) from September 2018-March 2022. Patients with NSCLC treated with either EGFR tyrosine kinase inhibitors (TKI) or immune checkpoint inhibitors (ICI) (monotherapy or in combination) who received a ctDNA test within 15 weeks prior to treatment initiation and a second test 3–15 weeks after treatment initiation were retrospectively evaluated using the G360 Response algorithm. Cox proportional hazards (CPH) were used for RW time to next treatment (TTNT) and time to treatment discontinuation (TTD) analyses. A >50% decrease in mean variant allele fraction ratio from pre-treatment to on-treatment was used to define the molecular response categorical variable. Gender, age, line of therapy (LOT) and comorbidities were included as covariates. Median TTNT and TTD were calculated by Kaplan Meier.

Results 282 patients with NSCLC were identified: 38% of patients received ICI, 26% received an EGFR-TKI, and 36% received other therapies. Of patients receiving either EGFR-TKI or ICI, 34% were classified as molecular responders, 47% were non-responders, and 19% were not evaluable by the algorithm due to no/low ctDNA at one or both timepoints. Molecular responders had significantly longer TTNT on EGFR TKIs and ICI compared to non-responders receiving the same therapy. TTD was significantly longer for molecular responders compared to non-responders in the EGFR-TKI cohort (table 1).

Conclusions Patients with NSCLC classified as molecular responders via the G360 Response algorithm had prolonged TTD and TTNT on both EGFR-TKI and ICI compared to non-responders. This data supports the use of ctDNA molecular response, as calculated by this algorithm, in assessing patient response to therapy; exploration of the utility of this algorithm in adaptive clinical trial design to evaluate the impact of early treatment interventions on patient outcome is ongoing.

Ethics Approval This research was approved by the Quorum Institutional Review Board (IRB) for the generation of de-identified datasets for research purposes.

Abstract 6 Table 1

Treatment Cohort	Clinical Outcome	Median TTNT/TTD, 95% CI (months)	CPH HR, 95% CI	CPH HR, p-value
EGFR-TKI	TTNT	responder (n=30) = 9.8 [5.9-23.6] non-responder (n=33) = 4.7 [2.7-6.3]	0.26 [0.11-0.60]	< 0.005
EGFR-TKI	TTD	responder (n=30) = 6.6 [4-11.8] non-responder (n=33) = 3.4 [2.6-4.8]	0.33 [0.16-0.66]	< 0.005
ICI	TTNT	responder (n=31) = not reached [6.4-inf] non-responder (n=52) = 4.7 [3.1-8.4]	0.43 [0.18-0.99]	0.049
ICI	TTD	responder (n=31) = 5.5 [4.0-6.8] non-responder (n=52) = 2.8 [2.1-4.9]	0.54 [0.28-1.06]	0.073

Abbreviations
CI = confidence interval, CPH = Cox proportional hazards model, ctDNA = circulating cell-free tumor DNA, EGFR-TKI = Epidermal growth factor receptor-tyrosine kinase inhibitors, G360 = Guardant360, HR = hazard ratio, ICI = immune checkpoint inhibitor, inf = infinity, NSCLC = non-small cell lung cancer, TTD = time to discontinuation, TTNT = time to next treatment

TTNT and TTD for molecular responders versus non-responders in NSCLC patients treated with either EGFR-TKI or ICI.

ANTI-PD1 TREATMENT RESPONSE PREDICTION AND MONITORING IN NON-SMALL CELL LUNG CANCER PATIENTS USING PLASMA CELL-FREE DNA HYDROXYMETHYLATION

Gulfem Guler*, Yuhong Ning, David Haan, Michael Kesling, Ceyda Coruh, Giuliana Mognol, Tierney Phillips, Kyle Hazen, Wayne Volkmuth, Samuel Levy. *Bluestar Genomics, San Mateo, CA, USA*

Background Treatment with immune checkpoint inhibitors (ICIs) targeting programmed death-1 (PD-1) can yield remarkable anti-tumor responses in lung cancer patients, however, not all patients respond to ICIs. Biomarkers currently used in clinical practice are insufficient in determining patient populations who may benefit from anti-PD-1 treatment. Non-invasive liquid biopsy approaches for therapy response prediction present key advantages over methods that rely on tumor biopsy, especially in cancer types such as lung cancer, where the location of the tumor may impact both patient compliance and the health risks involved with the procedure. Liquid biopsies offer a simple and convenient alternative and can also help overcome challenges hampering tumor biopsy dependent biomarker discovery and development such as tumor heterogeneity and difficulty in longitudinal sampling over the course of treatment.

Methods 151 whole blood samples were collected from 31 non-small cell lung cancer (NSCLC) patients, prior to therapy start and while on anti-PD1 therapy, namely pembrolizumab or nivolumab (up to 5 timepoints). cfDNA was extracted from plasma, followed by fragment enrichment using 5-hydroxymethyl-cytosine (5hmC)-based epigenomic platform technology. As part of this analysis, both 5hmC and low pass whole genome libraries were generated and sequenced.

Results Here, we investigated the utility of 5-hydroxymethylcytosine (5hmC) signatures obtained from plasma-derived cell free DNA (cfDNA) for non-invasive prediction and monitoring of anti-PD-1 treatment response. Comparison of pre-treatment 5hmC profiles from responders to non-responders revealed differential hydroxymethylation, many of which localized to genes in pathways important for immune response. While anti-PD1 treatment induced changes in hydroxymethylomes of both responding and non-responding patients, these changes were distinct. Upon anti-PD1 treatment, 5hmC further accumulated over genes involved in immune activation such as IFNg and IFNa response, inflammatory response and TNFa signaling, in responding patients but strikingly not in non-responders. On the other hand, non-responder plasma cfDNA had 5hmC increase over genes involved in epithelial to mesenchymal transition, which is associated with metastasis and drug resistance. These pathway-based changes in responders and non-responders are consistent with previous data from tumor tissue analysis. Furthermore, anti-PD1 treatment induced differential 5hmC changes in responders relative to non-responders starting from the first cycle of treatment, suggesting that 5hmC can help monitor treatment response.

Conclusions Our results demonstrate that 5hmC profiling can capture tumor-associated immune response signals in plasma without the need for tissue biopsy. Altogether, these findings show that 5hmC profiling of plasma-derived cfDNA enables non-invasive monitoring of immunotherapy response and can provide putative patient selection biomarkers from blood.

8 UNIVERSAL LCMS-BASED ASSAY PLATFORM, REFMAB-Q NSMOL, FOR MONITORING MONOCLONAL ANTIBODY THERAPEUTICS USING ONE REFERENCE ANTIBODY

[1]Noriko Iwamoto, [2]Yoshinobu Koguchi, [1]Kotoko Yokoyama, [3]Akinobu Hamada, [4]Atsushi Yonezawa, [2]Brian Piening, [2]Eric Tran, [2]Bernard Fox, [2]William Redmond, [1]Takashi Shimada*. *[1]Shimadzu Corporation, Kyotoi, Japan; [2]Providence Cancer Institute, Portland, OR, USA; [3]National Cancer Center Research Institute, Tokyo, Japan; [4]Kyoto University Hospital, Kyoto, Japan*

Background The US FDA has approved more than 100 antibody therapeutics (mAbs) and nearly 900 of them are currently being investigated in clinical trials. Accurate quantitation of antibody is critical for pharmacokinetics studies during the development of mAbs. In clinical settings, mAb monitoring has been applied to the dose adjustment for autoimmune disease. We recently showed that trough levels of mAbs can be a biomarker for cancer immunotherapy.[1] Thus, the deployment of a rapid and universal platform for mAb monitoring may help streamlining processes ranging from drug development to clinical practice for a wide spectrum of diseases. However, mAb monitoring often depends on the development of an individual ligand binding assay, which is impractical to scale.[2] Previously, we developed a method for mAbs quantitation that uses Fab-selective proteolysis of mAb followed by detection of signature peptides by LC-MS called nSMOL (nano-surface and molecular-orientation limited proteolysis) technology.[3] So far, we have established the validated LC-MS conditions for over 35 mAbs.

Methods We confirmed that count per second (CPS) ratio between different signature peptides were constant thanks to negligible matrix effect in nSMOL assay. Therefore, we hypothesized that we could select optimal reference antibody and use that as a universal reference antibody for highly multiplexed mAb quantitation. To select a universal reference mAb (refmAb-Q), we picked 18 mAbs and compared quantitative reproducibility of each mAb from singleplex and 18-plex nSMOL assay with a concentration from LLOQ to HQC.

Results We found that the CPS ratio to trastuzumab was unique to each mAb and consistent when we arbitrarily picked trastuzumab. We identified optimal reference mAb candidates based on the several physicochemical properties of signature peptides. The refmAb-Q nSMOL assay showed perfect concordance with the conventional nSMOL with an authentic reference in clinical sample from ipilimumab-treated patients (NCT00495066), pembrolizumab-treated patients (NCT02575404), and patients with the combination immunotherapy of ipilimumab and nivolumab.

Conclusions This innovative refmAb-Q nSMOL platform may provide a practical solution for quantitating an ever-increasing number of mAbs from developmental to clinical use settings. We envision that wide adaptation of refmAb-Q nSMOL is possible for PK and TDM assays for mAbs in the treatment of cancer and autoimmune diseases. Furthermore, refmAb-Q nSMOL can be applied to the quantitation and structural analysis of individual autoantibodies and neutralizing antibodies.

9 A PAN-CANCER MULTI-OMIC IMMUNE SINGLE-CELL ATLAS FOR CANCER IMMUNOTHERAPY: FOCUS ON CD4 + T CELLS

[1]Roberta Zappasodi, [2]Lydia Mok student*, [1]Andrea Orlando, [2]Julian Lehrer, [2]Joshua Stuart, [3]Nils-Petter Rudqvist, [4]Benjamin Vincent, [5]Anne Monette, [6]Yasin Senbabaoglu, [7]Kellie Smith, [8]Paul Thomas, [9]Nicholas Tschernia, [10]Vesteinn Thorsson, [2]Vanessa Jonsson. *[1]Weill Cornell Medical College, New York, NY, USA; [2]University of California, Santa Cruz, CA, USA; [3]MD Anderson, Houston, TX, USA; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, USA; [5]Jewish General Hospital, Montreal, Canada; [6]Genentech, South San Francisco, CA, USA; [7]Bloomberg~Kimmel Institute for Cancer Immunotherapy, Baltimore, MD, USA; [8]St. Jude Children's Research Hospital, Memphis, TN, USA; [9]Center for Immuno-Oncology, National Cancer Institute, Bethesda, MD, USA; [10]Institute for Systems Biology, Seattle, WA, USA*

Background Despite the success of immunotherapy, clinical responses remain difficult to predict, likely due to diverging tumor immune cell composition and function. Advances in single-cell analysis have revealed heterogeneous immune cell activity within and across individuals with cancer. While CD8 + ?tumor-infiltrating lymphocytes (TILs) have been extensively studied,[1–4] a pan-cancer consensus annotation of CD4+ TIL in immunotherapy is lacking. Robust identification of CD4+ T-cells from admixed single-cell transcriptomes is challenging due to low CD4 transcript expression and CD4+CD8+ T cells. Poor harmonization of CD4+ T-cell annotations across datasets compromises reproducibility and generalization. Here, we present the Cancer Immunotherapy T-cell Atlas (CITA), a harmonized, metadata-rich, pan-cancer, single-cell omics resource, spanning over 1.3M T cells, aimed at discovering CD4+ T-cell related features impacting immunotherapy response.

Methods Publicly available single-cell RNA sequencing (scRNA-seq) data were used to generate the CD4+ T-cell consensus re-annotation and the CITA. Raw count data and metadata were obtained from the Gene Expression Omnibus (GEO) or manuscript supplementary data. Individual datasets were processed using standardized bioinformatics workflow for quality control, integration, normalization, and batch correction.

Results We collected scRNAseq data and clinical metadata from 23 published datasets from 320 donors, across 30 different cancers, 20 immunotherapies, and from diverse tissue types and sequencing platforms[3,5–25] (figure 1). Existing immune cell annotations were harmonized by mapping to our reference cell identity labels, and T cells were subsetted for the CITA. To enable consensus-driven annotation, we resolved precise CD4+ T-cell transcriptional profiles from publicly available, FACS-sorted CD4+ T-cell scRNAseq datasets from liver, lung, and colorectal cancers.[21,22,26] We found CD4+ T cells homogeneously distributed in 12 main clusters across cancer types (figure 2). Foxp3+ regulatory T cells (Tregs) segregated into circulating/naive, tissue-resident, and effector Tregs, consistent with prior studies.[27] Moreover, we resolved naive, central, effector, tissue-resident, activated, and highly proliferating CD4+Foxp3- T cells, as well as Tbet+ Th1, and T follicular helper (Tfh) cells, co-expressing cytotoxic or canonical Tfh genes respectively (figure 2).

Conclusions The CITA provides the foundation for pan-cancer, harmonized, metadata-rich compendium of single-cell omics T-cell data from treatment-naive and immunotherapy-treated patients. Our CD4+ T-cell consensus re-annotation in conjunction with existing and new machine-learning-based classification methods automates annotation of new and existing CD4 +T-cell datasets. CITA will be a publicly available software and data resource at http://cita.cells.ucsc.edu and will include new datasets as they are released.

10 AUTOMATED DETECTION OF RNA, DNA, AND PROTEIN TARGETS IN TISSUES ON THE ONCORE PROX

Julio Masabanda*, Jason Ramos. *Biocare Medical, Pacheco, CA, USA*

Background A detailed assessment of the biological status of tissues can be achieved by performing as many multiple target detections as possible on the same tissue slide of protein, DNA, and RNA. However, the tests methods, can be labor intensive. When applying commercial kits, such as RNAscope from ACD for mRNA detection, the basic manual protocol takes about 8 hours. Here we show the utility of the ONCORE ProX – an open, fully automated slide staining platform – for developing detection protcols of mRNA using different RNAscope kits. Additionally, we developed protocols for the combined detection of Protein/mRNA and Protein/DNA/mRNA on the same slide.

Methods

FFPE tissues used Tonsil, breast MTA. Antibodies used: mouse IG kappa, rabbit ERBB2. FISH probe used: ERBB2/Copy Control 17 red/green in ZipFISH fast hybridization buffer. mRNA probes from ACD: IGK, ERBB2, CD3, CD20. RNA detection and visualization was performed following the main RNAscope protocols[1] for manual applications adapted for performance on the ONCORE ProX. The basic RNAscope protocol for DAB detection was adapted for the combined detection of Protein/mRNA, and for detection of Protein/DNA/mRNA.

Results The RNAscope procedure[1] involves steps present also in IHC and FISH protocols, thus we used this protocol as backbone for the development of protocols for the combined detection of protein and DNA targets. The basic RNAscope protocol for detection of a single mRNA type (e.g., ERBB2) takes 7–8 hours on the ONCORE ProX. We have additionally developed protocols for the sequential detection of protein and mRNA targets (IGK) and this takes about 9 hours. Furthermore, we detected on the same slide protein (ERBB2), DNA (ERBB2/copy control17 FISH probe) and mRNA (ERBB2). This complex procedure takes about 11 hours, and it is possible thanks to ZipFISH buffer for FISH. Additionally, we have performed the RNAscope chromogenic detection of IGK mRNA in DAB and Red, as well as Chromogenic and Immunofluorescent Multiplex detection of CD3 and CD20 mRNAs.

Conclusions In addition to the established function for fully automated IHC, we have demonstrated the suitability of the ONCORE ProX for performing successfully and with relative ease, complex technologies such as RNAscope and furthermore the combined detection on the same slide of multiple targets such as protein (IF), DNA (ZipFISH) and RNA probes (RNAscope).

These features of the ONCORE ProX show its versatility and make it suitable for performing complex protocols to satisfy the needs of a rapidly developing field of molecular histology.

11 TERTIARY LYMPHOID STRUCTURES IN MELANOMAS HARBOR INCREASED PROPORTIONS OF STEM-LIKE EFFECTOR T-CELLS COMPARED TO TUMOR-INFILTRATING LYMPHOCYTES

Ileana Mauldin*, Priya Kaytal, Nicole Edmonds, Craig Slingluff. *University of Virginia, Charlottesville, VA, USA*

Background Tertiary lymphoid structures (TLS) in melanoma are associated with improved survival and response to checkpoint blockade therapy (CBT). However, whether and how TLS contribute to this response is unknown. If TLS contribute to the responses, they may be expected to contain higher proportions of T-cells with therapeutic potential, than tumor infiltrating lymphocytes outside of TLS. TCF1/TCF7 has been identified as a marker for a stem cell-like T-cell that mediates the proliferative response post-CBT in tumor infiltrating cells. We hypothesized that TLS would contain higher fractions of stem-like $TCF7^+$ and $TCF7^+TOX^+$ T-cells poised to respond post-CBT. To address this hypothesis, we evaluated TLS and tumor sites of both desmoplastic and non-desmoplastic melanomas, for markers of stem like T-cells (TCF7, TOX).

Methods Primary desmoplastic melanomas (PDM) and non-desmoplastic metastatic melanomas (NDMM) were evaluated for TLS presence (yes/no) and immune markers, by 7-color multiplex Immunofluorescence histology. Specimens were stained with the following two panels: TLS panel: CD20, CD3, CD8, PNAd, DC-Lamp, Ki67, and DAPI; T cell activity panel: CD3, CD8, CD20, Granzyme-b, TOX, TCF7, and DAPI. Lymphoid aggregates were identified as TLS if possessing organized T-cell and B-cell regions in addition to high endothelial venule-like vasculature ($PNAd^+$). Cells were enumerated from TLS and tumor regions of TLS+ tumor specimens from PDM, and NDMM, with Halo software (Indica Labs). $CD3^+CD8^+$ ($CD8^+$) cells and $CD3^+CD8^-$ ($CD4^+$) cells were evaluated for activation markers, and the proportions of cells expressing activation markers was calculated. Statistical comparisons were done with unpaired Wilcoxon tests in RStudio.

Results TLS were identified in 25 out of 39 evaluated (64%) PDM, and 37 of 111 (33%) NDMM. Comparing TLS to tumor outside the TLS, we found that PDM TLS contain significantly elevated proportions of $CD8^+TCF7^+$ cells and $CD4^+TCF7^+$ cells compared to tumor (table 1). NDMM TLS also contain elevated proportions of $CD8^+TCF7^+$ cells and $CD4^+TCF7^+$ cells relative to tumor (table 1). In addition, TLS in PDM and NDMM contain elevated proportions of $CD8^+TOX^+TCF7^+$ cells and $CD4^+TOX^+TCF7^+$ cells relative to their respective tumor (table 1).

Conclusions The elevated proportion of $TCF7^+$ T-cells, and $TCF7^+TOX^+$ T-cells in TLS from PDM and NDMM relative to their tumor suggests that stem-like T-cells are enriched in TLS, and that T-cell regeneration may be occurring there. Additionally, TLS may be helping in the maintenance or generation of $TCF7^+$ T-cells in the tumor microenvironment.

Abstract 11 Table 1 Proportion of T- or B-cells expressing markers of activation or exhaustion within TLS and tumor (median)

Table 1. Proportion of T- or B-cells expressing markers of activation or exhaustion within TLS and tumor (median)

	PDM Tumor	PDM TLS	P value	NDMM Tumor	NDMM TLS	P value

12 **EVALUATING THE CONTRIBUTION OF EXTRACELLULAR MATRIX INVASION FOR KILLING OF TUMOR CELLS BY NATURAL KILLER CELLS**

Jyothi Mony*, Yama Abassi, Brandon Lamarche. *Agilent Technologies, San Diego, CA, USA*

Background Extracellular matrix (ECM) is a generic term for the diverse types of acellular structural component in tissues that play an important role in homeostasis. The ECM in solid tumors is greatly altered and can contribute to the modulation of immune cell function in the tumor microenvironment. Lymphocytes such as the cytotoxic natural killer and CD8+ T cells that are harnessed in immunotherapy can be regulated by the ECM. We hypothesized that matrigel layer presents a challenge for the NK cells and increasing the distance for invasion would delay the kinetics of tumor cell killing. Furthermore, invasion and killing of tumor targets would depend on their ability to remodel the matrix with matrix-metalloproteinases.

Methods Briefly, increasing volumes (50–110 µL/well) of matrigel (6mg/mL) representing increasing distance for invasion was layered over MCF7-red target tumor cells expressing nuclear-localized mKate2 (red fluorescent protein). NK92 cells were seeded over the solidified matrigel layer at E:T of 3:1. Agilent eLive Green (1 µL/mL) was added to the wells. NK cell invasion and function was evaluated using impedance-based measurements of immune cell killing and live cell imaging data collected on xCELLigence RTCA eSight.

Results Impedance increases with time as MCF7 target cells adhere and proliferate. The addition of NK92 cells results in a drop in impedance due to killing of the target cells. Total time taken for impedance levels to fall to levels at the time of NK92 addition increased progressively from 46h for 50 µL/well to 72 h for 110 µL/well. The eLive green stained NK cells and dead cells, but not healthy MCF7 targets. Consistent with impedance data, the loss of red fluorescence from target cells and increase in green fluorescence was progressively delayed with increasing volume of matrigel. A similar delay in kinetics was achieved with the broad spectrum MMP inhibitor GM6001 (2 µM and 10 µM), suggesting that MMPs played a role in the NK function. Interestingly, the NK-92 cells induce significant morphological changes in MCF7-red target cells prior to invading all the way through the Matrigel, suggesting an early distal effect.

Conclusions The results suggest a role for effector functions of NK cells potentially involving cytokines, that is independent from invasion and/or ability to degrade the matrix, for the killing of susceptible target cells. The assay also demonstrates the potential for adapting the RTCA eSight platform to study various ECM interactions with immune cells.

REAL-WORLD TISSUE-BASED CIRCULATING TUMOR DNA (CTDNA) MINIMAL RESIDUAL DISEASE (MRD) ASSAY PREDICTS OUTCOME IN LUNG CANCER PATIENTS WHO HAD CURATIVE TREATMENTS

[1]Youjin Oh, [1]Liam Il-Young Chung*, [2]Soowon Lee, [3]Timothy Hong, [4]Leesul Kim, [1]Sung Mi Yoon, [1]Joo Hee Park, [1]Trie Arni Djunadi, [1]Young Kwang Chae. *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, USA; [2]Baylor University, WACO, TX, USA; [3]Northwestern University, Evanston, IL, USA; [4]Ascension Saint Francis Hospital Evanston, Evanston, IL, USA*

Background As highly sensitive liquid biopsy assays have been developed, minimal residual disease (MRD) has emerged as a novel tool to predict the prognosis of cancer patients.[1] Monitoring MRD during post-curative-intent treatment can help detect relapse of disease many months earlier compared to radiological imaging evaluation.[1,2,5] Recurrence remains a challenge among early-stage non-small cell lung cancer (NSCLC) patients who are treated with curative intent.[3] Some patients with seemingly successful treatment of early-stage cancer can have occult micrometastases or MRD that persists after the initial therapy which can be a potential source of subsequent metastatic relapse at distant sites.[4] This study compares longitudinal changes in tissue-based ctDNA levels of thirty NSCLC patients.

Methods Thirty patients included in this study were treated with concurrent chemoradiotherapy or surgery and/or neoadjuvant or adjuvant chemotherapy for stage I-IV lung cancer. The patients underwent a multiplex polymerase chain reaction (mPCR) assay for detection of ctDNA in plasma, where 16 individual-specific mutation signatures were identified by upfront tissue sampling. These were matched to normal whole-exome sequencing to identify progression or relapse of disease (SignateraTM, Natera, Austin, Texas). Patients who were MRD-positive at any time point after curative treatment were defined as 'MRD positive (MP)'. Among patients who were monitored for two or more times, patients whose MRD was persistently detected in blood were classified as 'MRD persistently positive (MPP)'.

Results ctDNA was evaluated one time in fifteen patients (42.9%) and two or more times in twenty patients (57.1%). MRD was detectable among nine patients (25.7%) after curative treatment at a median of 4 months (range 0–41 months). Among nine MP patients, six experienced progressions. In twenty-nine patients with NSCLC who did not relapse after surgery, the assay confirmed MRD negativity at 71 of 73-time points. Three patients were MPP, ctDNA was continuously detectable in three out of twenty patients, and all of them showed progression, including one patient who died (figure 1). MRD positive patients had marginally worse overall survival (OS) and progression-free survival (PFS) ($p=0.092$ and $p=0.04$, respectively). However, persistent MRD positivity showed a stronger correlation with poor OS and PFS ($p=0.037$ and $p < 0.001$, respectively) (figure 2).

Conclusions This is the first report of real-world data on tissue-based ctDNA MRD assay among NSCLC patients treated curatively. The results indicate that post-curative-intent treatment ctDNA MRD monitoring can be predictive of clinical prognosis including OS or PFS.

14 EXPLORING REAL-WORLD CONCORDANCE OF TUMOR MUTATION BURDEN (TMB) FROM BLOOD AND TISSUE IN PATIENTS WITH SOLID TUMORS

[1]Youjin Oh, [1]Jewel Park, [1]Liam Il-Young Chung*, [2]Soowon Lee, [3]Timothy Hong, [1]Young Kwang Chae. *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, USA; [2]Baylor University, Waco, TX, USA; [3]Northwestern University, Evanston, IL, USA*

Background Tumor mutational burden (TMB) is an approved biomarker for immunotherapy in metastatic cancer patients.[1] While initially measured from tissue (tTMB), TMB derived from circulating tumor DNA (ctDNA) – also known as blood TMB (bTMB) – is increasingly being used in the clinic. Currently, real-world concordance between tTMB and bTMB is not well understood.[2,3]

Methods From October 2020 to July 2022, cancer patients who had both tTMB and bTMB results were selected. Commercial next generation sequencing (NGS) testing for both tissue and blood, i.e. by Tempus xT (Tempus; Chicago, IL) and Guardant360 ?(Guardant Health; Redwood City, CA) were utilized. Patients were classified according to clinical variables and tumor burden, and correlation analyses or tests of independence were performed. To explore the significance of concordant and discordant bTMB:tTMB ratio, patients were divided into tertiles based on their bTMB:tTMB ratio as 'low', 'mid', and 'high'. 'Low' and 'high' subgroups were considered to be discordant while 'mid' was considered to be concordant.

Results From a total of 95 patients included in the study, 69 patients (72.6%) had lung carcinoma and 26 (27.4%) had other cancers, including but not limited to thyroid, brain, and cervical cancer. ??Median bTMB was 9.6 mut/MB and median tTMB was 4.0 mut/Mb. The distributions of bTMB and tTMB differed significantly (Wilcoxon signed-rank V=268.5, n=95, p<0.001). bTMB was moderately correlated with tTMB (Spearman ρ=0.49, p < 0.001) (figure 1). Twelve patients had tTMB > 10 mut/Mb while 45 patients had bTMB > 10 mut/Mb. When patients were divided according to cancer type, moderate correlation between bTMB and tTMB remained statistically significant for both lung adenocarcinoma, lung squamous cell carcinoma, and other lung cancer types. The regression lines for lung cancer subtypes displayed marked differences in slope. Dividing patients by site of tissue biopsy revealed that the degree of correlation was pronounced for tissue samples from primary and metastatic sites, not from the lymph nodes. Correlation appeared equivalent between smoker and never smokers. However, dividing patients by concordant and discordant bTMB:tTMB ratio did not reveal any significant differences in clinical variables or tumor burden (table 1).

Conclusions Cancer type and site of tissue biopsy may influence concordance between tTMB and bTMB. Future studies with more patients may help define the optimal bTMB threshold for receiving immunotherapy, which may be different from the tTMB threshold.

15 **INTEGRATION OF MULTIPLE IMMUNE-ASSOCIATED BIOMARKERS FACILITATES CLASSIFICATION OF SOLID TUMORS BY PRIMARY IMMUNE ESCAPE MODE AND PREDICTION OF PATIENT OUTCOMES**

RJ Seager*, Maria-Fernanda Senosain, Erik Van Roey, Shuang Gao, Mary Nesline, Jeffrey Conroy, Sarabjot Pabla. *OmnSeq, Inc., Buffalo, NY, USA*

Background Many individual biomarkers describe the idiosyncrasies of each tumor and its interactions with the tumor microenvironment (TME). However, tumors often evade immunotherapy through multiple immune escape mechanisms. Here, we present a method of integrating immune and neoplastic biomarkers that classify tumor and immune activity in the TME.

Methods Standard-of-care comprehensive genomic and immune profiling was performed on 5450 FFPE tumors representing 39 histologic types, assessing expression levels of 395 immune genes and >500 tumor-associated genes. From this data, three previously published gene expression signatures were calculated: cell proliferation (CP), tumor immunogenic signature (TIGS), and cancer testis antigen burden (CTAB). PD-L1 status of each tumor was assessed by IHC, and tumor mutational burden (TMB) was calculated. Principle component analysis (PCA) and unsupervised clustering revealed four distinct biological groups. Subsequently, a nearest neighbor method was used to classify an immune checkpoint inhibitor (ICI) treated 242-patient validation cohort (Lung cancer, melanoma and renal cell carcinoma) into these groups, the association between these groups and ICI treatment response was determined by overrepresentation analysis, and overall survival was assessed using Kaplan-Meyer and CoxPH analyses.

Results PCA and clustering generated four groups: 1) Tumor-dominant, exhibiting high CTAB, TMB, and CP, and low PD-L1 and TIGS; 2) Proliferative, exhibiting high CP and low TIGS, PD-L1, CTAB, and TMB; 3) Inflamed, exhibiting high TIGS and low CP, PD-L1, CTAB, and TMB; and 4) Checkpoint, exhibiting high PD-L1, TIGS, and TMB, and low CTAB. Classifying the validation cohort into these groups, significant association with ICI response was found, with the checkpoint group overrepresented by the highest proportion of disease control [p=0.0313]. Kaplan-Meier survival analysis suggested a significant relationship between these groups and overall survival [p=0.035], with the proliferative and checkpoint groups demonstrating increased survival over tumor-dominant and inflamed groups. CoxPH analysis showed the checkpoint group to have a significantly decreased hazard ratio [HR=0.28; p=0.024] for ICI treatment. In all Kaplan-Meier and CoxPH analyses, this approach outperformed any of its constituent biomarkers as a survival predictor.

Conclusions Our study demonstrated that an integrated approach combining comprehensive tumor profiling and emerging biomarkers better predicts ICI response and survival in multiple histologies. Divergent outcomes between the resulting groups are likely the result of distinct tumor-immune interaction modalities. As we further validate this methodology, we hope to produce a treatment decision and clinical trial selection tool leveraging tumor-immune interactions in solid tumors to outperform single marker testing.

16 **MULTI-DIMENSIONAL ANALYSIS OF CD19-CAR T CELLS AT SINGLE CELL RESOLUTION ON THE BERKELEY LIGHTS PLATFORM ENABLE UNIQUE INSIGHTS INTO RELATIONSHIPS BETWEEN CYTOTOXICITY KINETICS AND CYTOKINE SECRETION**

Joseph Valdez*, Guido Stadler, Milton Quintanilla, Pei-Yu Lin, Aribet De Jesus, Deric Griffin, Sapna Tandon, Yiyang Xu. *Berkeley Lights, Emeryville, CA, USA*

Background CD-19 CARs have tremendous efficacy in the clinic and complete clinical responses persisting for >10 years. However, outcome of clinical response cannot be predicted. Traditional analytical methods are complex, labor/cost intensive, with high sample requirements, thus generating deep characterization datasets to define critical quality attributes is an unmet need. In addition, linking parameters at single-cell resolution has not been possible. We show here the ability to rapidly measure and link analytes at single-cell resolution for thousands of cells in parallel.

Methods T cells from a healthy donor were activated with CD3/CD28 beads and transduced with lentivirus encoding CD-19 CAR. Single control or CD-19 CAR T cells were loaded on OptoSelect® chips and placed in co-culture with Raji CD19+ or Raji CD19-KO single cells and a bead conjugated to anti-IFN-y antibody. Co-cultures were under perfusion media culture containing Caspase-3 detection reagent over 22-hour timelapse with 30-minute imaging intervals. Time to detection of Caspase-3 signal and mean fluorescent intensity of anti-IFN-y-PE was recorded.

Results Hundreds to thousands of single cell co-cultures of the populations described above were obtained. Detectable IFN-y signal was observed in 45% of the co-culture events in the CAR-T+CD-19 Raji group while all others were below 1%. Cytotoxicity was observed in 25% of the co-culture events in the CAR-T+CD-19 Raji group, 10% of the co-culture events in the CAR-T+CD-19-KO Raji group and <=1% in the other groups. Rapid cytotoxicity (<= 7 hours) was enriched in the CAR-T+CD-19 Raji group >6 fold compared to the CD-19-KO control. Slow cytotoxicity (>7 hours) showed no significant difference between the CD-19+ and KO groups. Co-cultures double positive for IFN-y and cytotoxicity comprised 13% of the CAR-T + CD-19 Raji population and not present in any others. Significant clustering of rapid killers with low IFN-y secretion was observed.

Conclusions We demonstrate the ability to characterize T cells in co-culture with antigen-presenting cells (APCs) at single-cell resolution. Classic functions of antigen-dependent interactions between CAR-T cells and APCs such as IFN-y secretion and cytotoxicity are enriched when both CAR and antigen are present but largely absent in mismatches as expected. Evaluation of cytotoxicity kinetics and semi-quantitative measurements of cytokines enable identification of potential multimodal mechanisms of action and insights into potency of cell products. This deep characterization dataset can be generated in two days with limited numbers of cells which will enable definition of critical quality attributes to drive next-generation cell therapies.

17 ISOLATION AND EXPANSION OF CIRCULATING TUMOR-REACTIVE LYMPHOCYTES FOR ADOPTIVE CELL THERAPY

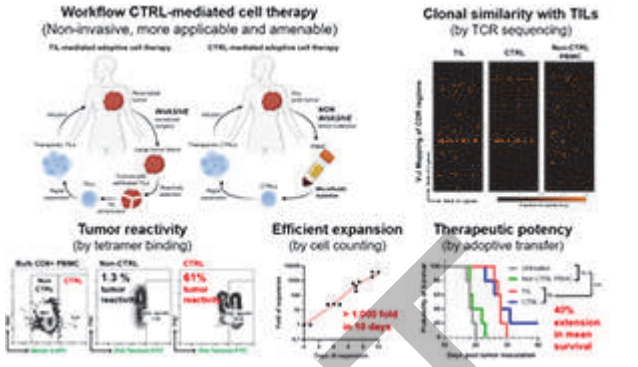
Shana Kelley, Zongjie Wang*. *Northwestern University, Evanston, IL, USA*

Background The autologous transplantation of tumor-infiltrating lymphocytes (TILs) expanded from resected tumors has become a promising therapeutic modality in the clinic. The clinical outcome is extremely encouraging so far – long-term complete responses have been observed in subsets of melanoma patients. Despite positive results in the clinic, the use of tumor-infiltrating lymphocytes (TILs) to treat solid tumors is limited by the use of fresh, large, viable tumor fractions from invasive resectable surgery, which is not often feasible in patients with unresectable tumors or recurrent metastases. Recent studies on peripheral T cell dynamics have revealed a string result – a subset of peripheral lymphocytes shares clonotypes with TILs and their expansion is highly correlated with response to treatment. However, these circulating tumor-reactive lymphocytes (CTRLs) are extremely rare in peripheral T cell populations (as low as 0.002%), and their molecular signature and therapeutic potency are yet to be examined.

Methods Conventional cell sorting is infeasible to enrich CTRLs with high purity as they due to their rarity. We developed a novel approach, named microfluidic immunomagnetic cell sorting (MICS), that efficiently isolates CTRLs from blood circulation for molecular assay, rapid expansion and cellular therapy (figure 1).

Results With the high recovery and purity of MICS, we identified that the expression of $CD8^+MarkerA^+$ almost exclusively defines the CTRL population in circulation. This population has a tissue-resident-like (T_{rm}-like) phenotype and can re-enter blood circulation from primary tumors and accumulate in secondary tumors. We successfully expanded the isolated CTRLs through a feeder-based rapid expansion protocol (REP) and found CTRLs have strong therapeutic potency in multiple adoptive cell transfer models in mice. The cocktail of CTRLs and immune checkpoint blockade successfully achieved an 80% complete response (CR) rate in the mouse colon cancer model. In addition, we also confirmed that the human $CD8^+$ $MarkerA^+$ lymphocytes in blood circulation have higher tumor reactivity, by comparing the level of interferon-gamma (IFN-γ) secretion and clonal similarity.

Conclusions In this work, we adapted our MICS technology for the isolation of CTRLs, a rare tumor-targeting cell population in blood circulation, and deconvolute their molecular signature comprehensively. In addition, we developed the protocols to expand rare CTRLs to a therapeutic scale for the first time. The successful expansion and administration of CTRLs promise to transfer adoptive cell therapy by eliminating invasive surgery and potentially providing a more amenable therapeutic modality that is broadly applicable to all patients.



Abstract 17 Figure 1 Circulating tumor-reactive lymphocytes
Figure 1. Circulating tumor-reactive lymphocytes from blood circulation as a mean for cellar therapy. CTRLs cover major TIL clonotypes, are highly tumor-reactive and expandable, and deliver potent anti-tumor efficacy in vivo. Compared to conventional TIL-mediated therapy, CTRL-mediated are non-invasive, more amenable and broadly applicable to all cancer stages

IDENTIFICATION AND CHARACTERIZATION OF CIRCULAR RNAS AS NOVEL PUTATIVE BIOMARKERS TO PREDICT THE SURVIVAL BENEFIT AMONG METASTATIC MELANOMA PATIENTS TREATED WITH ANTI-PD-1 MONOTHERAPY

[1]Jian-Guo Zhou*, [2]Udo Gaipl, [3]Hu Ma, [4]Haitao Wang. *[1]The Second Affiliated Hospital of Zunyi Medical University, Zunyi, China; [2]Universitätsklinikum Erlangen, Erlangen, Germany; [3]The Second Affiliated Hospital of Zunyi, Zunyi, China; [4]National Institutes of Health, Bethesda, MD, United States*

Background Melanoma is the most aggressive skin malignancy with high morbidity. Anti-programmed cell death protein 1 (PD-1) monotherapy has been applied in metastatic melanoma, however, most patients do not respond to anti-PD-1 and the availability of the present approved biomarkers is limited.

Methods Here we combined the transcriptomic and clinical data in 163 advanced melanoma patients receiving anti-PD-1 from phs000452 (122 patients) as the training and internal validation cohort, and PRJEB23709 (41 patients) as the external validation cohort, respectively.

Results 74,243circular RNAs (circRNA) were identified with NCLscan and CIRCexplorer2, 70 circRNAs significantly associated with progression-free survival and overall survival as novel putative candidates to predict the survival benefit of immunotherapy. The prognostic circRNAs signature (HSA_CIRCpedia_1497, HSA_CIRCpedia_12559, HSA_CIRCpedia_43640, HSA_CIRCpedia_43070, and HSA_CIRCpedia_21660) was determined with LASSO regression. This signature was a prognostic factor of overall survival and progression-free survival among advanced melanoma patients, and the concordance indexes also confirms its credibility and accuracy. Enrichment analysis showed that immune response and currently known pathways were enriched.

Conclusions We constructed and validated a novel prognostic circRNAs signature to serve as a predictor for advanced melanoma patients treated with anti-PD-1 immunotherapy.

PERIPHERAL LYMPHOCYTES AND LACTATE DEHYDROGENASE CORRELATE WITH IMPROVED RESPONSE AND SURVIVAL IN HEAD AND NECK CANCER TREATED WITH IMMUNE CHECKPOINT INHIBITORS

[1]Cassie Pan*, [2]Qian 'Vicky' Wu, [2]Jenna Voutsinas, [1]Jeffrey Houlton, [1]Brittany Barber, [1]Zain Rizvi, [1]Emily Marchiano, [1]Neal Futran, [1]George Laramore, [1]Jay Liao, [1]Upendra Parvathaneni, [3]Renato Martins, [1]Jonathan Fromm, [1]Cristina Rodriguez. *[1]University of Washington, Seattle, WA, USA; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [3]Virginia Commonwealth University, Richmond, VA, USA*

Background Little is known regarding peripheral blood biomarkers (PBBMs) for oncologic outcomes in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) treated with immune checkpoint inhibitors (ICIs). We explored associations of PBBMs with outcomes and toxicities in R/M HNSCC treated with ICIs.

Methods In this single-institution retrospective cohort study, records of 186 adult patients with R/M HNSCC treated with ICIs between 08/2012–03/2021 were reviewed. Pretreatment PBBMs investigated included lactate dehydrogenase (LDH), platelets, neutrophils, lymphocytes, monocytes, eosinophils, neutrophil-to-lymphocyte ratio (NLR), and prognostic nutritional index (PNI). Percent (%) and absolute (abs) values for each cell type were examined. Cox regression was performed to explore associations with time-to-event outcomes, including overall survival (OS) and progression-free survival (PFS). Logistic regression was performed for binary outcomes, including objective response (ORR) by RECIST 1.1 and grade $\geq$3 toxicities (G$\geq$3AE) by CTCAEv5 within 100 days of treatment initiation. Multivariable models for each outcome were created using elastic net variable selection method.

Results Median age was 64 (range 24–90), 145 (78%) were male, 149 (82%) had ECOG $\leq$1, 81 (44%) were never-smokers, and 60 (33%) had p16-positive tumors. Single-agent pembrolizumab or nivolumab was used in 140 (75%) patients. Combined positive score (CPS) was available in 33 patients, with median CPS 31 (range 0–100). Univariate analyses adjusted for ECOG, p16, and smoking revealed that baseline higher LDH (p=0.025), neutrophils (%: p=0.002, abs: p=0.001), monocytes (abs: p=0.043), and NLR (p<0.001), and lower lymphocytes (%: p<0.001, abs: p=0.005), eosinophils (%: p=0.046), and PNI (p=0.005) correlated with worse OS. Elevated platelets (p=0.010), neutrophils (%: p=0.010, abs: p<0.001), and NLR (p<0.001), and decreased lymphocytes (%: p<0.001) and PNI (p=0.007) correlated with worse PFS. No peripheral blood parameter reached significance for G$\geq$3AEs or ORR, although% lymphocytes, absolute neutrophils, and LDH were borderline significant for ORR (p=0.066, p=0.055, p=0.069, respectively). Refitted multivariable models adjusted for ECOG, p16, and smoking confirmed that lower% lymphocytes and higher LDH and absolute neutrophils correlated with worse OS and PFS. Lower% lymphocytes and higher LDH also correlated with worse ORR.

Conclusions In the largest cohort to date of R/M HNSCCs treated with ICIs, our variable selection method showed that baseline lower% lymphocytes and higher LDH and absolute neutrophils correlated with worse OS and PFS, and lower% lymphocytes and higher LDH correlated with worse ORR. PBBMs are promising prognostic tools for immunotherapy in HNSCC and warrant further investigation in a large, prospective study along with validation with CPS biomarker.

DEVELOPMENT OF VISTA-CENTRIC TUMOR IMMUNOPHENOTYPING AS A NOVEL APPROACH FOR IDENTIFICATION OF POTENTIAL BIOMARKERS FOR ANTI-VISTA THERAPY

[1]Andrey Ugolkov*, [1]Hok, [1]Reinhard von Roemeling, [2]Alexander Martin, [1]Robert Martell.
[1]Curis, Lexington, MA, USA; [2]Tufts Medical Center, Boston, MA, USA

Background V-domain immunoglobulin suppressor of T cell activation (VISTA) is a negative checkpoint regulator of immune cells. VISTA has been recognized as a potential mediator of resistance to anti-PD-1 and anti-CTLA-4 immunotherapies in cancer patients. Targeting the VISTA signaling pathway has been suggested as a promising approach for overcoming resistance to current immune checkpoint therapies. Herein, we report the design, development, and analytical algorithm for comprehensive VISTA-centric tumor immunophenotyping to explore potential tumor biomarkers for novel anti-VISTA therapeutic antibody CI-8993, currently under clinical development in Phase 1 trial.

Methods Formalin-fixed paraffin embedded (FFPE) tumor tissue sections from 10 cases of non-small cell lung carcinoma (NSCLC) were purchased from NovoVita Histopath Laboratory. Serial tumor tissue sections were double-immunostained with VISTA combined with CD8 (cytotoxic T cell marker), CD4 (T helper cell marker), CD11b (myeloid cell marker), CD68 (monocyte/macrophage marker), CD56 (NK cell marker), CD19 (B cell marker) or Programmed Death-Ligand 1 (PD-L1).

Results Immunohistochemical analysis revealed the presence of CD8+ cells (9/10 cases), CD4+ cells (3/10 cases), CD11b+ cells (10/10 cases), CD68+ cells (10/10 cases), CD56+ cells (4/10 cases) and CD19+ cells (8/10 cases) in lung tumors. Using double IHC staining, we found that VISTA was expressed in CD8+ cells (5/9 tumors), CD11b+ cells (5/10 tumors) and CD19+ cells (5/8 tumors), whereas VISTA was hardly detectable in CD4+, CD68+ or CD56+ cells. Expression of PD-L1 was detected in cancer cells in 6/10 tumors, whereas VISTA-pos cancer cells were revealed in 1/10 tumors. We developed an algorithm for evaluation of VISTA-centric tumor immunophenotyping and demonstrated that every tumor has a unique cell-type-specific pattern of VISTA expression which could serve as a potential biomarker.

Conclusions Our results demonstrate that comprehensive VISTA-centric immunophenotyping enables spatially resolved and cell-type-specific characterization of VISTA expression in solid tumors and can serve as applicable bioanalytical approach for identification of potential biomarkers to guide anti-VISTA therapeutic treatment decisions.

21 IL-6 AS PROGNOSTIC FACTOR IN ADJUVANT OR METASTATIC SKIN CANCER PATIENTS TREATED WITH IMMUNOTHERAPY – A REAL LIFE STUDY

Domenico Mallardo*, Maria Antonietta Isgrò, Vito Vanella, Marilena Tuffanelli, Lucia Festino, Maria Grazia Vitale, Grazia D'angelo, Francesca Sparano, Mario Mallardo, Eleonora Cioli, Benedetta Alfano, Claudia Trojaniello, Alfredo Budillon, Ester Simeone, Corrado Caracò, Ernesta Cavalcanti, Paolo Ascierto. *Istituto Nazionale Tumori IRCCS Pascale, Napoli, Italy*

Background The immune checkpoint inhibitors revolutioned cancer therapeutic landscape and substantially improved the survival of patients with advanced malignancies, especially in skin cancer patients.[1–5] Several predictive biomarkers are under evaluation, in order to identify patients who can derive benefit from ICI while also limiting exposure and toxicity. IL-6 is a pleiotropic cytokine involved not only in immune responses but it is also a major player in chronic inflammatory diseases.[6–7] Additionally, elevated levels of IL-6 are observed in a large number of patients (pts) with solid tumours.[8] The purpose of this study is to retrospectively investigate the relationships between IL-6 serum concentration and outcome in skin cancer patients treated with immunotherapy.

Methods From June 2020 to October 2021 at INT IRCCS Pascale, Naples, we analyzed interleukin -6 from 265 consecutive serum samples in different skin cancer pts before and during immunotherapy treatment. We included pts with cutaneous squamous cell carcinoma (SCC) treated with cemiplimab (n=32), melanoma in adjuvant setting (n=61), metastatic melanoma treated with: anti-PD1 (n=103), combo ipi+nivo (n=36) and ipilimumab alone (n=32). All patients signed informed consent. Patients baseline characteristics are listed in table 1. IL6 ere measured by Electrochemiluminescence immunoassays (ECLIA) from Roche Cobas. ROC curves were used to determine the best cut off. Survival rates were analyzed using the Kaplan-Meier method and differences among curves were assessed by the log-rank test. Hazard Ratios (HR) and their 95% confidence intervals (CI) were estimated using a Cox regression model.

Results Among 265 pts, lower serum concentration of interleukin-6 was associated with a better PFS (15.07 months (95% CI 9,76 to 18,86) versus 8.01 months (95% CI 2,80 to 4,03), HR = 0.34 (CI 0,23–0,50, p<0.0001), OS (19.83 months (95% CI 18.57 to 21.03) versus 14.53 months (95% CI 12.38 to 16.68), HR = 0.41 (CI 0,26–0,64, p=0.0001) and ORR (95% CI 6.86 to 13.30, p<0.001). Similarly, IL6 (p <0.01) and ORR (p <0.01) are significantly associated with OS and PFS in the multivariate analysis. We also confirmed the association between IL6 with PFS and OS in adjuvant setting. Moreover, pts with an IL-6 ratio (on treatment/baseline) ≤1 have a better PFS and OS.

Conclusions In this retrospective study, we found that lower IL-6 level are associated with better OS, PFS and ORR. In addition, minimum variation of IL-6 during immunotherapy are strongly associated to outcome. Further investigations are needed to get additional information.

ACTIVITY OF THE TUMOR-INTRINSIC NLRP3 INFLAMMASOME PATHWAY PREDICTS FOR RESPONSE TO CHECKPOINT INHIBITOR IMMUNOTHERAPY IN MELANOMA PATIENTS

Tarek Haykal*, Nagendra Yarla, Nicholas DeVito, Georgia Beasley, April Salama, Brent Hanks, Balamayooran Theivanthiran. *Duke University, Durham, NC, USA*

Background We have previously determined that activation of a novel tumor-intrinsic NOD-, LRR- and pyrin domain-containing protein-3 (NLRP3) inflammasome-heat shock protein-70 (HSP70) signaling axis in response to PD-1 blockade triggers the recruitment of granulocytic myeloid-derived suppressor cells (PMN-MDSCs) into the tumor microenvironment, suppresses anti-tumor immunity and, in select settings, promotes tumor hyperprogression. We, therefore, sought to determine whether the activity of the tumor-intrinsic NLRP3-HSP70 pathway may correlate with anti-PD-1 response by interrogating clinical specimens derived from advanced melanoma patients undergoing anti-PD-1 monotherapy.

Methods Three independent approaches were utilized to measure the activity of the tumor-intrinsic NLRP3-HSP70 signaling pathway in 60 advanced melanoma patients undergoing either pembrolizumab or nivolumab monotherapy: 1. baseline week 0 plasma HSP70 levels were measured by ELISA, 2. germline PCR-based genotyping was performed to detect the single-nucleotide polymorphism (SNP), rs12239046, previously associated with enhanced *NLRP3* expression, 3. PCR-based proximity ligation assay (PLA) analysis targeting the NLRP3-ASC proteins in baseline formalin-fixed paraffin-embedded tumor tissue specimens. Detection of the rs12239046 SNP was correlated with progression-free survival (PFS) while plasma HSP70 and NLRP3-ASC PLA levels were correlated with objective response (OR) based on RECIST1.1 assessment of week-12 CT imaging as well as PFS and overall survival (OS).

Results Our studies demonstrate that elevated baseline plasma HSP70 levels ($P = 0.0008$) and elevated baseline tissue NLRP3-ASC PLA levels ($P = 0.0014$) independently correlate with resistance to anti-PD-1 immunotherapy (ICI) based on week-12 OR in melanoma patients. Importantly, melanoma patients developing disease hyperprogression (n=5) in response to ICI exhibited elevations in baseline plasma HSP70 levels ($P = <0.0001$) and baseline tissue NLRP3-ASC PLA levels ($P = <0.0001$) relative to patients with week-12 disease progression (n=10). Above median baseline tissue NLRP3-ASC PLA levels were determined to correlate with both inferior PFS (HR 0.12, $P = 0.0008$) and OS (HR 0.16, $P = 0.0456$) in advanced melanoma patients undergoing ICI. Germline PCR detection of the rs12239046-C SNP was found to be associated with elevated plasma HSP70 levels and trended toward a correlation with inferior PFS (HR 0.50, $P = 0.07$).

Conclusions Baseline markers of the tumor-intrinsic NLRP3-HSP70 signaling pathway correlate with resistance and disease hyperprogression in melanoma patients undergoing anti-PD-1 immunotherapy. These data strongly support the important role of the tumor-intrinsic NLRP3 inflammasome in regulating responses to anti-PD-1 therapy and verify its relevance as a pharmacologic target to enhance immunotherapy efficacy. Expanded studies are warranted to confirm these findings in a larger patient cohort.

23 CLUES FROM THE MATRIX – PERIPHERAL COLLAGEN FRAGMENTS ORIGINATING FROM ACTIVITY OF LYMPHOID CELLS, MYELOID CELLS, AND FIBROBLASTS MAY HAVE BIOMARKER POTENTIAL FOR CANCER IMMUNOTHERAPY

Jeppe Thorlacius-Ussing, Nicholas Willumsen*, Neel Nissen, Christina Jensen, Morten Karsdal. *Nordic Bioscience, Herlev, Denmark*

Background Solid tumors have a high tissue turnover due to increased recruitment and activity of cells related to the fibro-inflammatory axis. The high tissue turnover generates small extracellular matrix (ECM) fragments, primarily from collagens, that are released into circulation. By mapping and quantifying collagen fragments with neo-epitopes that are generated by proteases from specific cell types, it is possible to develop peripheral biomarkers that reflect the activity of lymphoid cells, myeloid cells, and fibroblasts in the tumor microenvironment. Here we investigated the distribution of such biomarkers across 11 different cancer indications.

Methods ECM or collagen fragments related to activity of T-cells (C4G: Collagen-4 degraded by Granzyme B), Neutrophils (CPA9-HNE: Calprotectin degraded by neutrophil elastase), Macrophages (reC1M: Collagen-1 degraded by MMPs) and Cancer Associated Fibroblasts (PRO-C11: pro-peptide from Collagen-11) were measured by ELISA/ECLIA in pre-treatment serum from patients with various solid tumor types (n=220) including stage 1–4 bladder-, breast- colorectal-, head and neck-, kidney-, lung-, ovarian-, pancreatic, stomach-, prostate-cancer, and melanoma and compared to age-matched healthy controls (n=33) by ANOVA and AUROC.

Results As shown in figure 1, biomarkers of neutrophil and fibroblast activity were significantly increased in all solid tumor types ($p<0.001$–0.0001) and with an overall AUROC of 0.99 ($p<0.0001$) and 0.96 ($p<0.0001$), respectively. The macrophage activity marker was significantly elevated in most types of cancer and with an AUROC of 0.88 ($p<0.0001$). The T-cell activity marker was only slightly elevated in a few indications ($p<0.05$–0.01) and with an AUROC of 0.69 ($p=0.0006$). All biomarker levels were independent of age and disease stage (not shown).

Conclusions ECM fragments in serum that are derived from proteolytic activity of myeloid cells and fibroblasts, and to lesser extent lymphoid cells, are altered in serum from patients with cancer. If validated, such tools may increase the understanding of response and resistance mechanism associated to the fibro-inflammatory axis and serve as predictive and pharmacodynamic biomarkers in clinical trials investigating cancer immunotherapy.

Ethics Approval Sample collection was approved by an Institutional Review Board or Independent Ethical Committee and patients gave their informed consent: Russian Oncological Research Centre n.a. Blokhin RAMS (PG-ONC 2003/1) and Western Institutional Review Board, Inc. (WIRB®Protocol #20161665).

24 PROTEOMIC ANALYSIS OF BREAST CANCER BASED ON IMMUNE SUBTYPES

Yeonjin Jeon*, Hee Jin Lee. *Asan Medical Center, Songpa-gu, Korea, Republic of*

Background Immunotherapy was recently conducted on breast cancer to defeat the limitations of survival gain of other treatment modalities like surgery, chemotherapy and targeted therapy. With immunotherapy, a tumour can be classified into immune inflamed, immune excluded and immune desert based on the distribution of immune cells. We assessed the clinicopathological features, each subtype's prognostic value, and differentially expressed proteins between the immune subtypes.

Methods A total of 56 cases of breast cancer with neoadjuvant chemotherapy, including all intrinsic subtypes, between 2014 and 2018 were retrieved from Asan Medical Center. The immune subtype was established based on the tumour-infiltrating lymphocytes' level and Klintrup criteria. Correlation between clinicopathological factors and immune subtypes and each subtype's prognostic value were investigated. Mass spectrometry was used to identify differentially expressed proteins in formalin-fixed paraffin-embedded biopsy tissues.

Results Thirty-one cases (55%) were immune inflamed, 21 cases (38%) were immune excluded, and 2 cases (4%) were immune desert. Only age demonstrated a statistical difference between immune inflamed and excluded/desert, among clinicopathological factors. The old age (age$\geq$50) ratio was higher in immune inflamed than in immune excluded/desert (p=.039). In the Kaplan-Meier survival analysis, there was no difference in the overall survival rate and relapse-free survival (RFS) rates between immune subtypes. Welch's t-test revealed two differentially expressed proteins between immune inflamed and immune excluded/desert. *CORO1A* and *SERPINA1* were up-regulated in immune inflamed (adjusted p=.008) and immune excluded/desert (adjusted p=.008), respectively. *TNN* was up-regulated in pCR than non-pCR among immune inflamed subtypes (adjusted p=.036).

Conclusions Through proteomic analysis using formalin fixed paraffin embedded breast cancer samples, CORO1A showed up-regulation in immune inflamed and SERPINA1 showed up-regulation in immune excluded/desert. TNN was up-regulated in pCR than non-pCR in immune inflamed and probably related to favorable prognosis. Further studies in large representative cohorts needs to be performed to validate these findings.

Ethics Approval Informed consent was obtained from all patients. This study was approved by the Institutional Review Board of Asan Medical Center (2019–1480).

25 POTENTIAL PREDICTIVE BIOMARKERS FOR BXCL701 IN ACUTE MYELOID LEUKEMIA (AML)

Veena Agarwal*, Shubhendu Trivedi, Dimple Bhatia, Zeenia Jagga, Moses Donkor, Vincent O'Neill. *BiXcel Therapeutics, New Haven, CT, USA*

Background BXCL701 (talabostat), an oral innate immune activator is currently in a Phase 2 trial in combination with PD-1 checkpoint inhibitor in metastatic castration-resistant prostate cancer patients. In solid tumors, preclinical data suggest that BXCL701 inhibition of dipeptidyl peptidases (DPPs) enhances antitumor immune responses via two mechanisms: (1) DPP4 inhibition increases tumor content of CXCL9/10, which recruits $CXCR3^+$ NK and T cells, and (2) DPP8/9 inhibition activates the inflammasome resulting in immune cell pyroptosis followed by Th1 proinflammatory cytokine release, and dendritic cells (DCs) activation which further enhances the CXCL9/10-CXCR3 axis[1]. Recent studies show that BXCL701 exhibits single agent cytotoxicity against human AML cells through a similar pyroptotic mechanism[2]. Here, we report the identification of potential predictive biomarkers by using BXCL701-responsive and -nonresponsive human leukemic cell lines.

Methods The cytotoxic activity of BXCL701 was evaluated in a panel of 170 hematological and non-hematological cell lines and confirmed that mostly but not all the leukemic cells were responsive to BXCL701. Four responding cell lines (KG1, MV4–11, THP1 and EOL-1, IC50 = 100 – 700 nM) and 2 non-responding cell lines (K562 and Kasumi1, IC50 >60 μM) were selected based on the cytotoxicity data and their gene expression profiles were compared to identify predictive biomarkers for BXCL701. Nanostring analysis was performed followed by qRT-PCR using cDNA from the cell lines.

Results The analysis identified 20 genes as potential predictive biomarkers. These, include 5?genes (DPP9, DPP8, caspase 1, CARD8 and PYCARD) involved in the inflammasome – pyroptosis pathway that is activated by BXCL701 and correlate with the BXCL701 cytotoxic activity. Most of the genes have 2-to-1,000-fold higher expression in at least 3 responding cell lines in comparison to non-responding cell lines. On the other hand, EPCAM gene has 7,000-fold higher expression in non-responding cell lines vs responding cell lines. Further, copy number was evaluated for BXCL701 target genes (DPP8, DPP9, DPP4 and FAP) by RT-PCR in 11?responding leukemic cell lines and 6 non-responding cell lines. The DPP9 copy number variation (CNV) was found to be directly correlated with BXCL701 cytotoxicity in BXCL701-responding human leukemic cell lines with correlation coefficient (R^2) of 0.813.

Conclusions A gene panel consisting of genes involved in BXCL701 mechanism of action has been identified as a potential predictive biomarker for BXCL701 in leukemia, which can help in selecting patients susceptible to respond to BXCL701 treatment.

26 TUMOR INFILTRATING CD8/CD103/TIM-3 EXPRESSING LYMPHOCYTES IN EPITHELIAL OVARIAN CANCER CO-EXPRESS CXCL13 AND ASSOCIATE WITH IMPROVED SURVIVAL

Vrouyr Bilemjian*, Edwin Bremer. *University of Groningen, Berlin, Germany*

Background Reactivation of tumor infiltrating T lymphocytes (TILs) with immune checkpoint inhibitors or co-stimulators has proven to be an effective anti-cancer strategy for a broad range of malignancies. However, epithelial ovarian cancer (EOC) remains largely refractory to current T cell-targeting immunotherapeutics. Therefore, identification of novel immune checkpoint targets and biomarkers with prognostic value for EOC is warranted. TIL populations in many cancers often express checkpoint receptor TIM-3. However, TIM-3 expression in TILs and the biological consequences thereof are subject of debate, as associations with both poor and favorable prognosis have been reported across multiple malignancies. Here, we identified a small population of CD8/CD103/TIM3 triple-positive T cells in EOC tissue using immunofluorescence microscopy. Upon analysis of an EOC Tissue Micro Array, tumor infiltration of this immune cell subset associated with improved patient survival.

Methods Methods used in my research are the following:

- Analysis of Single Cell mRNA Sequencing Data
- Multicolor immunofluorescent staining
- Perform Flow Cytometry analysis after isolating Tumor Infiltrated Lymphocytes (TILs) from Fresh Tumor Tissues.

Results Combining multicolor immunofluorescent staining's with single cell RNA-sequencing analysis, we here identified a TIM-3/CXCL13-positive tissue-resident memory (CD8/CD103-positive) T cell (Trm) population in EOC. Analysis of a cohort of ~175 patients with high-grade serous EOC revealed TIM-3-positive Trm were significantly associated with improved patient survival. As CXCL13-positive CD8-positive T cells have been strongly linked to patient response to anti-PD1 immune checkpoint blockade, combinatorial TIM-3 and PD-1 blockade therapy may be of interest for the (re)activation of anti-cancer immunity in EOC.

Conclusions We identified a small set of CD8/CD103/TIM-3-expressing tumor infiltrated T cells in EOC patients associated with improved EOC patient survival. Therefore, CD8/CD103/TIM-3 triple-positive TILs may be a prognostic marker for EOC and represents a target population of interest for reactivation by immunotherapeutics. Further, differential gene expression (DEG) analysis revealed upregulated expression of co-stimulatory, cytotoxic, and exhaustive genes, and notably that of CXCL13 within the terminally exhausted CD8-positive T cell fraction. Due to the co-expression pattern of TIM-3 and CXCL13, TIM-3 might also serve as a surrogate marker for prognostically favorable CXCL13-positive CD8-positive TILs.

27 TUMOR AGNOSTIC CD8 IMMUNE-PHENOTYPE RELATED GENE SIGNATURE DEFINES CLINICAL OUTCOME ACROSS EARLY AND LATE PHASE CLINICAL TRIALS

Andreas Roller*, Iakov Davydov, Martha Serrano-Serrano, Astrid Heller, Nicolas Staedler, Claudia Ferreira, Gabriele Dietmann, Irina Klaman, Konstanty Korski, Petra Schwalie, Michael Cannarile. *Roche, Basel, Switzerland*

Background A key question in cancer immunotherapy is the general immune status of the patient's tumor-microenvironment prior to therapy. The patient's underlying tumor immune-contexture may therefore a) guide the therapeutic intervention and b) help to identify potential resistance mechanisms to immune-therapies. The most commonly used classification of the patients' immune status is based on the CD8 tumor infiltrating lymphocytes status referring to either 'cold' or 'hot' tumors.

Methods In this study, we systematically analyzed the CD8 immune-phenotype in 628 patients from 11 Phase 1 clinical trials using immunohistochemistry (IHC) and matched gene expression profiling by RNA-seq. The CD8 immune-phenotype was classified by pathologist assessment into cold (CD8 deserts) and hot (CD8 excluded and inflamed) tumors using CD8+/Ki67+ IHC staining in epithelial and stromal areas of the tumor.

Results In total, we observed 193 inflamed, 144 excluded, and 291 desert CD8 immune-phenotype from 49 different indications. The main source of tumor biopsy tissues was liver metastasis (N=174), lymph node (N=51) and lung tumor tissue (N=69). Further, we developed a RNA-seq based classification as a surrogate to the IHC based CD8 immune-phenotype classification. Using regularized logistic regression (ElasticNet), we identified a 92 gene signature that accurately predicts the CD8 immune-phenotype in primary and metastatic samples (AUC inflamed = 0.846; AUC Excluded = 0.712; AUC Desert = 0.855). Using our new gene signature, we demonstrate prolonged overall survival (ORR) of patients with CD8 inflamed tumors across The Cancer Genome Atlas (TCGA; Hazard-Ratio 0.89; 95%CI [0.80–0.98]) as well as a better ORR to Checkpoint inhibitors (CPI) in the randomized Phase III OAK study in Non-Small-Cell lung cancer patients (Hazard-Ratio 0,75; 95%CI [0.58–0.97]).

Conclusions In summary, we identified a novel prognostic and predictive gene signature accurately predicting the IHC based CD8 immune-phenotype in primary and metastatic tumor samples. Survival analysis indicated that the predicted CD8 inflamed phenotype results in prolonged survival in independent patient cohorts. Our analysis provides important insights and a new precision immune phenotyping tool to characterize the impact of the tissue origin with regards to the tumor microenvironment. The new signature enables multiplex analyses and may be used for retrospective, reverse translation approaches as well as for prospective patient enrichment to identify resistance mechanisms to cancer immunotherapy.

Ethics Approval All patients provided written informed consent. The trials were approved by each center's ethics committee or institutional review board and were performed in compliance with the Declaration of Helsinki and International Conference on Harmonisation Guidelines for Good Clinical Practice.

28 IDENTIFICATION AND FUNCTIONAL VALIDATION OF NEOANTIGENS-SPECIFIC T-CELL RECEPTORS IN LYNCH SYNDROME

Fahriye Duzagac*, Krishna Sinha, Ana Bolivar, Nan Deng, Laura Reyes Uribe, Alexandre Reuben, Eduardo Vilar-Sanchez. *MD Anderson Cancer Center, Houston, TX, USA*

Background Lynch syndrome (LS) is the most common cause of hereditary colorectal cancer (CRC), with >1 million estimated carriers in the US.[1] Normal cells in LS patients become MMR-deficient (MMRd) after acquiring a somatic 'second hit' in the same MMR gene, thus generating thousands of small insertion/deletion (indels) mutations. Indels occurring in coding microsatellite regions give rise to immunogenic frameshift peptides (FSPs) that become mutated neoantigens (neoAg).[2] LS elicits a distinct immune response directed against FSP neoantigens stimulating the adaptive immune cells through recognition by T cell receptors (TCR) of cytotoxic CD8+ T cells.[3–4] Despite the recent advances in silico prediction algorithms for identifying candidate neoAg peptides, large-scale validation of these peptides is still challenging due to low frequency of Neoag-specific T cells and limited availability of patient samples.[5] Our objective was to characterize neoAg-specific T cells response in LS carriers and to validate the functionality of recurrent and shared mutated neoantigens-specific T cells and their TCRs.

Methods We have identified and validated recurrent and shared MHC-I restricted mutated neoAgs in a cohort of LS patients diagnosed with pre-cancer and colorectal cancers using an enzyme-linked immunospot (ELISPOT) assay. NeoAgs validated for eliciting in vitro immunogenicity were used to prime autologous naïve T cells from healthy donors. NeoAg-specific T cells were detected and isolated using Flex-T™ HLA-A*02:01 UVX biotinylated monomers derived peptide-MHC (pMHC) multimers staining. Cytotoxicity and infiltration of isolated NeoAg-specific T cells were measured using innovative NeoAg-specific T cell-mediated co-culture assays in a physiologically relevant microfluidic setup. NeoAgs that showed high cytotoxic activity were used for downstream single-cell TCR sequencing (10x Genomics).

Results We used healthy donor T cell repertoires to eliminate the hurdle in identifying immunogenic and reactive NeoAg. We have validated a set of novel recurrent NeoAg such as RNF43 that showed in vitro immunogenicity with a threshold >30 SFU in ELISPOT assay. Then, we identified and isolated Neoag-specific T cells that recognize endogenously processed and presented epitopes using peptide-MHC (pMHC) multimer staining. Our results showed 5 to 8% CD8+ NeoAg specific T cells enrichment. Robustly enriched and isolated T cells showed cytotoxicity against LS patient-derived organoids that expressed determined NeoAgs. We profiled TCR sequences of validated NeoAg with single-cell TCR sequencing that will serve to perform immune monitoring and early cancer detection.

Conclusions This data suggest that identified neoepitopes and corresponding TCRs provide robust candidate biomarkers to track immunogenicity after vaccination and TCR-based immune monitoring for LS carriers

29 LUNG-MAP COMPOSITE SIGNATURE FOR IMMUNE CHECKPOINT INHIBITOR (ICI) EFFICACY IN ADVANCED SQUAMOUS CELL LUNG CANCER (SCC)

[1]David Gandara*, [2]Xing Hua, [3]Khaled Tolba, [3]David Fabrizio, [3]Lee Albacker, [3]Ryan Brennick, [3]Meagan Montesion, [3]Geoff Oxnard, [4]Stacey Adam, [5]Fred Hirsch, [6]Karen Kelly, [7]Roy Herbst, [8]Michael LeBlanc, [8]Mary Redman, [8]Michael Wu, [9]David Kozono. *[1]University of California Davis Cancer Center, Sacramento, CA, USA; [2]Fred Hutchinson Org, Seattle, WA, USA; [3]Foundation Medicine, Cambridge, MA, USA; [4]Foundation for the NIH, North Bethesda, MD, USA; [5]Mount Sinai Health System, New York, NY, USA; [6]International Association for the Study, Denver, CO, USA; [7]Yale School of Medicine, New Haven, CT, USA; [8]Fred Hutchinson Cancer Center, Seattle, WA, USA; [9]Brigham and Women's Hospital Harvard Med, Boston, MA, USA*

Background Predictive biomarkers for ICI regimens in NSCLC, namely PD-L1 and tumor mutational burden (TMB), remain suboptimal, leaving oncologists with limited decision-making tools. We sought to develop a more comprehensive solution, integrating genomic alterations detected by comprehensive genomic profiling (CGP), to enrich for association with progression-free survival (PFS) and overall survival (OS).

Methods Lung Master Protocol (Lung-MAP) is an NCI-sponsored public-private partnership evaluating new therapies for previously-treated advanced stage NSCLC. In this analysis, 320 SCC patients from sub-studies S1400A (n=68; durvalumab) and S1400I (n=252; nivolumab ± ipilimumab) had tissue CGP data by Foundation Medicine. 204 patients from S1400A (n=43; SP263) and S1400I (n=161; 28–8 pharmDX) had PD-L1 IHC. We evaluated TMB (0–9, 10–20, >20 mut/Mb), PD-L1 IHC, HLA loss of heterozygosity (LOH) of $\geq$ 1 gene (evaluable for n=206), mutations in KEAP1/NFE2L2, DNA damage response genes,ARID1A, and loss of CDKN2A as potential ICI biomarkers. Wilcoxon and Fisher's exact tests assessed association between continuous TMB/PDL1 IHC (<1%, 1–49%, $\geq$50%) and each binary biomarker, and between pairs of binary markers. Cox proportional hazards model evaluated the association between each biomarker and OS/PFS, adjusting for age, sex, smoking status, and stage. Based on significance (at the nominal 0.1 level without correction for multiplicity) from univariate analysis, multiple combination signatures were analyzed using a predetermined scoring system. Biomarkers in the most significant combination signature was further examined by adjusting for TMB and PD-L1, to demonstrate if they provided additional value.

Results Despite associations between TMB and ARID1A mutations (P = 0.009), PD-L1and KEAP1/NFE2L2 mutations (P = 0.007) and ARID1A mutations and KEAP1/NFE2L2 mutations (OR = 2.89; 95% CI, 1.43 – 5.91, P = 0.0016), the magnitude of correlation was modest, thus representing complementary predictors. Higher TMB (>20 vs. 10–20 vs. 0–9) was the most significant positive predictor of OS (HR=0.79; 95% CI, 0.65–0.95, p=0.01). A composite combinatorial signature (ICIsig) inclusive of TMB, PD-L1, HLA LOH, ARID1A, and KEAP1/NFE2L2 mutations was associated with better OS (HR=0.76; 95% CI, 0.63–0.92, p=0.005) and PFS (HR=0.84; 95% CI, 0.70–0.99, p=0.048). Landmark 3-year OS rates were 29% vs. 6% in ICIsig high vs. low. ICIsig high represented 39% of the evaluable population.

Conclusions We show that a composite ICIsig extending beyond TMB and PD-L1 captures NSCLC patients benefiting from ICI therapy more effectively than single biomarkers. ICIsig could inform treatment selection in today's rapidly expanding therapeutic landscape. Validation from a large randomized Phase III trial is ongoing.

SINGLE CELL MULTIOMIC PROFILING OF THE ANTIGEN-SPECIFIC IMMUNE RESPONSE USING ANTIGEN SPECIFIC DCODE DEXTRAMER® (RIO) REAGENTS AND BD® ABSEQ REAGENTS ON THE BD RHAPSODY™ SINGLE-CELL ANALYSIS SYSTEM

Kivin Jacobsen*, Dilek Inekci, Liselotte Brix. *Immudex aps, Virum, Denmark*

Background Understanding the specific T- and B- cellular immunity during an induced cellular immune response is important for development of anti-tumor immunity in personalized immunotherapy. Advanced single-cell genomics technologies have enabled researchers to do single cells immune profiling, by assessing cell surface proteins, the transcriptome and TCR and/or BCR gene clonotypes. However, understanding antigen-specific recognition at the immune synapse is key to understand the specific immune response in cancer. The dCODE MHC Dextramer® technology combine single-cell genomic profiling with antigen-recognition allowing deep analysis of antigen-specific T-, and B-cells at the single cell level pairing TCR recognition adding to unveil the antigen specific immune response, in cancer and infectious diseases.

Methods We have combined two powerful technologies, Immudex® dCODE Dextramer® (RiO) Reagents and the BD Rhapsody™ Single-Cell Analysis System, to detect and characterize low-frequency antigen-specific T- and B cells, including the full sequences of the V(D)J gene segments of the antigen-specific T- and B cell receptors, as well as profile transcriptome and cell phenotyping by surface protein expression. We used a panel of dCODE Dextramer® (RiO) reagents directed against 10 virus-specific antigens + 6 negative control reagents, spanning MHCI and MHCII, to profile two HPBMC samples, together with 15 BD® AbSeq immune related antibodies, and over 350 immune related genes.

Results We identified 10 different virus-specific T-cell responses over the two samples and revealed major clonotypes of all responses in the two samples, alongside with phenotypic activation profile using the BD® AbSeq reagents and immune target gene expression of the antigen-specific T cells identified by the dCODE® (RiO) Dextramer reagents. Data on antigen-specific B-cell responses is pending.

Conclusions Here we show an assay with the ability to analyze antigen-specific immune cells, by applying combined antigen-specific detection, with surface phenotyping, and gene expression, resulting in a deep phenotypic characterization of the immune cells in the donor. The ability to do high-resolution B and T cell profiling has broader implications and utility in immuno-oncology, infectious diseases, and autoimmunity.

31 CELLULAR COMPOSITION OF MALIGNANT PLEURAL EFFUSIONS SHOW A SIMILAR LANDSCAPE TO THAT OF THEIR PRIMARY TUMOR SITES: A PILOT STUDY

Caddie Laberiano- Fernández, Qiong Gan, Auriole Tamegnon, Sinchita Roy Chowdhuri, Edwin Parra*. *MD Anderson Cancer Center, Houston, TX, USA*

Background Malignant pleural effusion (MPE) is a frequent complication of advanced malignancy with significant associated morbidity and mortality. Metastases from lung cancer are the most common cause of MPE, followed by breast cancer. This pilot study aims to characterize the immune landscape of stage IV primary tumors (PT) and their MPE counterparts, to compare the cellular and immune landscape of these tumors.

Methods We studied the immune contexture of six breast carcinoma and five lung adenocarcinoma PT samples and their respective MPEs using three immune-oncology multiplex immunofluorescence panels (figure 1). The slides were scanned using Vectra Polaris and analyzed by InForm image analysis software. We characterized the cellular composition to compare PT and MPE samples (figure 1). In addition, we use the densities of cell phenotypes from PTs and the percentages from MPE to correlate with clinicopathologic characteristics (table 1).

Results Overall, the immune cell phenotypes were similar between PT and their respective MPE samples, as shown in figure 2. The predominant cell densities for CD3+ T-cells (45.5%) and CD3+CD8+ cytotoxic T-cells (4.7%) were observed in lung MPEs, while in the PTs the same phenotypes showed a median, 262 cells/mm2 and 42 cells/mm2, respectively. CD68+ macrophages were found mainly in breast MPE (61%) and in their PTs (median 82.5 cells/mm2). However, two breast carcinoma cases showed suppressive components related to regulatory T-cells CD3+Foxp3+CD8^{neg} expression in their MPEs but not in their PTs; whereas in one case T cell antigen-experienced CD3+PD1+ was present in the breast PT but not in the corresponding MPE. One lung MPE showed T cell antigen-experienced CD3+PD1+ while this expression was absent in the PT. In contrast, one lung MPE case had no expression of CD3+PD-L1+, CD3+CD8+PD-L1 + or T regulatory CD3+Foxp3+CD8^{neg} cells, but these cells were present in their respective lung PTs. No correlation was observed with clinicopathologic characteristics.

Conclusions While our results showed some differences in cellular compositions between MPE and their corresponding PT, the overall cellular compositions showed a similar landscape. Therefore, our results suggest that MPE may be used as a surrogate for PT to explore new target options or predict treatment responses. A more extensive study with a larger dataset would be necessary to confirm our results.

32 REAL-WORLD PREVALENCE OF DEFICIENT MISMATCH REPAIR ACROSS 5 SOLID TUMOR TYPES IN CHINA

[1]Xiaohua Shi*, [2]Xiang-Hong Yang, [3]Jing-Ping Yun, [4]Xiang-Shan Fan, [5]Ying-Yong Hou, [2]Zhe Wang, [3]Peng Li, [4]Jie-Yu Chen, [5]Juan Yu, [1]Longyun Chen, [6]Yan Wang, [7]Rubentiran Ramar, [7]Michael Wong, [1]Zhiyong Liang. *[1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, and Peking Union Medical College, Beijing, China, Beijing, China; [2]Shengjing Hospital of China Medical University, Shenyang, China, Shenyang, China; [3]Sun Yat-sen University Cancer Center, Guangzhou, China, Guangzhou, China; [4]The Affiliated Drum Tower Hospital of Nanjing University Medical University, Nanjing, China, Nanjing, China; [5]Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai, China; [6]MSD China, Shanghai, China, Shanghai, China; [7]MSD International GmbH, Singapore, Singapore*

Background The anti–PD-1 monoclonal antibody pembrolizumab has a tumor-agnostic approval by the US FDA for previously treated advanced tumors characterized as microsatellite instability-high (MSI-H)/deficient mismatch repair (dMMR). Although several studies have reported on the global prevalence of MSI-H/dMMR, data on the prevalence of dMMR across advanced solid tumor types in Chinese patients are limited. Here, we report real-world data on dMMR across 5 tumor types in Chinese patients.

Methods Adult patients with treatment-naive or previously treated advanced (stage III/IV) biliary tract, cervical, endometrial, gastric, or ovarian cancer from 5 study centers in China were included in this analysis. MMR testing was performed on archival formalin-fixed, paraffin-embedded tissue samples using the Ventana MMR RxDx panel. The primary objective of this study was to determine the prevalence of dMMR. Secondary objectives were to assess clinicopathologic characteristics and treatment patterns.

Results Of 748 patients who had tissue samples evaluable for MMR status, 314 (42.0%) had gastrointestinal (GI) tumors and 434 (58.0%) had gynecologic (GYN) tumors. The prevalence of dMMR was 9.4% (70/748) overall, 4.1% (13/314) in GI tumors (4.3% [8/186] biliary tract, 3.9% [5/128] gastric) and 13.1% (57/434) in GYN tumors (2.7% [6/221] cervical, 29.9% [49/164] endometrial, 4.1% [2/49] ovarian). In the dMMR population (n = 70), most patients were aged 18–65 years (88.6%), had stage III disease at diagnosis (78.6%), and had undergone surgery (91.4%). At the protein level, the frequency of a co-occurring loss of MLH1 and PMS2 in patients with dMMR tumors was 68.6% (table 1), which is consistent with global reports in colorectal cancer. Evaluation of the treatment history of dMMR versus the proficient mismatch repair populations showed that a higher proportion of patients with dMMR tumors received radiation (40.0% vs 23.0%), chemotherapy (70.0% vs 48.5%), and/or treatment with immune checkpoint inhibitors (11.4% vs 4.6%) at some point since their initial diagnosis.

Conclusions Prevalence of dMMR and co-occurring loss of MLH1 and PMS2 at the protein level across the 5 different tumor types in Chinese patients are consistent with reports in the literature.

33 ROLE OF PLASMA T-CELL-DERIVED CIRCULATING DNA LEVEL IN ANTI-PD(L)1 IMMUNOTHERAPY IN ADVANCED STAGE NON-SMALL CELL LUNG CANCER

Nuthchaya Mejun, Nophol Leelayuwatanakul, Pongsakorn Ouwongprayoon, Chanida Vinayanuwattikun, Nattiya Hirankarn. *Chulalongkorn University, Bangkok, Thailand*

Background We previously published prognostic impact of T-cell-derived circulating DNA (T-cirDNA) and its correlation with intra-tumoral CD8 tumor-infiltrating lymphocyte (TIL) in advanced stage non-small cell lung cancer (NSCLC). Currently, PD-L1 staining is solely the standard biomarker of anti-PD-(L)1 immunotherapy treatment response. However, not perfect correlation in individual patient.

Methods We prospectively explored plasma T-cirDNA and cirDNA (total circulating DNA), using real-time PCR with Taqman assay-specific rearranged TCR-beta CDR3 region in 47 advanced NSCLC patients treated with anti-PD-(L)1 immunotherapy. We defined patients into undetectable, low (≤1% ratio) and high (>1% ratio) T-cirDNA/cirDNA based on previous study. Demographic characteristics such as sex, age, ECOG performance status, smoking, histology, PD-L1 staining, treatment regimen were integrated with T-cirDNA/cirDNA into the cox-regression analysis model.

Results Out of 47 patients, 60% of participants had detectable plasma T-cirDNA/cirDNA with a median of 0.03 [range 0–4.7] $ngml^{-1}$(table 1). Undetectable group was significantly correlated with the longest overall survival (OS) with a median of 25.5 [range 8–73.7] months (p-value 0.05) (figure 1). Multivariate analysis of progression-free survival (PFS) revealed 0–1 ECOG performance status and undetectable T-cirDNA correlated with favorable outcome, hazard ratio (HR) of 0.05 [95% CI 0.007–0.4, p-value 0.005] and 0.1 [95% CI 0.01–0.7, p-value 0.02] respectively. High amount of circulating DNA which represented high tumor burden and mono-anti-PD-(L)1 immunotherapy were correlated with unfavorable disease control with the HR of 6.6 [95% CI 1.1–37.9, p-value 0.03] and 6.3 [95% CI 1.3–29.1, p-value 0.01] respectively. For detectable T-cirDNA group, high level correlated with better disease control than low level (HR 0.1 [95% CI 0.02–0.8, p-value 0.03]) (table 2). We did observe paradoxical effect in predictive implication in undetectable and high level of T-cirDNA/cirDNA%ratio.

Conclusions Incorporate with demographic characteristic, T-cell-derived circulating DNA could be adopted for predictive implication of anti-PD(L)1 immunotherapy usage.

34 NEUTROPHIL-TO-EOSINOPHIL RATIO AS A BIOMARKER FOR CLINICAL OUTCOMES IN ADVANCED STAGE MELANOMA PATIENTS TREATED WITH ANTI-PD-1 THERAPY

Vincent Pozorski*, Yeonhee Park, Dahlia Tesfamichael, Yusuf Mohamoud, Vincent Ma. *University of Wisconsin, Madison, WI, USA*

Background An association between lower neutrophil-to-eosinophil ratios (NER) and improved clinical outcomes in patients with metastatic renal cell carcinoma treated with combination ipilimumab/nivolumab (I/N) was recently reported.[1] While neutrophil-to-lymphocyte ratios (NLR) and eosinophil counts have been associated with improved survival in melanoma patients treated with immunotherapy[2, 3], no studies have investigated NER as a predictor of outcomes in advanced melanoma patients receiving anti-PD-1 therapy.

Methods We conducted a single-center, retrospective review of unresectable stage III and IV melanoma patients treated with anti-PD-1 monotherapy (nivolumab or pembrolizumab) or I/N between 2011 and 2022. Overall survival (OS) and progression-free survival (PFS) were measured from the first dose of treatment to date of death and clinical or radiographic progression, respectively. Treatment-related adverse events (trAEs) of grade ≥3 were also assessed. Baseline NLR and NER were measured relative to anti-PD-1 treatment start date. Change in NLR and NER from baseline were measured at 3-months follow up. Patients were divided into groups by median NLR and NER at baseline (<mNER vs ≥mNER) and analyzed for OS and PFS using univariate and multivariate analyses with Cox proportional hazard (CPH) models. Logistic regression models were used to evaluate risk differences for trAEs. The multivariate analyses accounted for the following covariates: Age, gender, anti-PD-1 therapy type, primary melanoma type, pre-treatment LDH, BRAF status, presence of brain or liver metastasis, and prior adjuvant or non-anti-PD-1 treatment for advanced-stage melanoma.

Results 190 patients were identified. Lower NER at baseline, relative to the mNER of 30.7, was associated with improved OS [HR: 0.330, 95% CI: 0.175–0.623, p=0.0006] but not PFS (table 1). Both PFS and OS differed between groups relative to the mNER and an explicit NER cut-off of 35 on univariate analysis (figure 1). Neither PFS nor OS differed between groups based on baseline NLR. A trend towards decreased grade ≥3 trAEs was associated with lower NER at baseline [OR: 0.411, 95% CI: 0.157–1.022, p=0.061]. Baseline NLR was not associated with trAEs. Change in the NLR and NER at three months relative to baseline was not associated with clinical outcomes.

Conclusions Lower pre-treatment NER is associated with improved OS in patients with advanced-stage melanoma treated with anti-PD-1 based regimens. Survival outcomes may differ with an explicit NER cut-off of 35. Higher baseline NER may be associated with high-grade trAEs. Further validation is warranted to evaluate NER as a predictive marker for clinical outcomes in melanoma patients treated with immune checkpoint inhibitors.

35 EARLY PHARMACODYNAMIC CHANGES MEASURED BY RNA SEQUENCING IN PERIPHERAL BLOOD FROM PATIENTS IN A PHASE 1 STUDY WITH MITAZALIMAB, A POTENT CD40 AGONISTIC IGG1 MONOCLONAL ANTIBODY

[1]Malin Lindstedt*, [2]Peter Ellmark, [1]Aastha Sobti, [2]Karin Enell Smith, [2]Yago Pico de Coaña, [2]Sumeet Ambarkhane. *[1]Lund University, Lund, Sweden; [2]Alligator Bioscience, Lund, Sweden*

Background Mitazalimab is a human FcgR crosslinking-dependent human IgG1 CD40 agonistic antibody developed for cancer immunotherapy.[1–3] Mitazalimab has demonstrated a manageable safety profile when administered once every 2 weeks both with or without corticosteroid pre-treatment.[3] Treatment with mitazalimab induces transient increases in levels of selected chemokines and activation of peripheral B cells.[3] An ongoing phase 2 study (OPTIMIZE-1) is currently evaluating the efficacy of mitazalimab in patients with metastatic pancreatic cancer (NCT04888312).

Methods Cell-free RNA from whole blood was collected from subjects both pre- and post-treatment in a dose escalation study of mitazalimab in patients with solid tumors (NCT02829099). The whole transcriptome sequencing was conducted according to Illumina TruSeq Stranded protocol. Samples obtained pretreatment and one day after treatment from cohorts receiving 75, 200, 600 and 900 µg/kg mitazalimab without corticosteroid pretreatment (pre/post treatment;75 µg: n=3/3, 200 µg: n=5/5, 600 µg: n=10/11 and 900 µg: n= 13/14) and 600 µg/kg mitazalimab with corticosteroid pretreatment were analyzed (pre/post treatment; n=10/5). The normalized data was analyzed utilizing the edgeR limma workflow on R software. Differentially expressed genes were analyzed according to dose level and corticosteroid (yes vs no) administration. Cell phenotyping was conducted according to CIBERSORTX and Xcell cell signatures. Gene expression results were further correlated with peripheral blood concentrations of 15 cytokines 24 hours after treatment.

Results Significant mitazalimab treatment-induced transcriptional activity was identified using pre-selected gene signatures related to event associated to CD40 biology at the 600 and 900 µg/kg dose levels without corticoid pre-treatment. In contrast, the number of significantly expressed genes in the lower dose groups were limited. Gene signatures related to activation of B cell- and myeloid/dendritic activation were upregulated post treatment, confirming the CD40 agonistic activity of mitazalimab. Additionally, corticosteroid pre-treatment significantly reduced the magnitude of the mitazalimab treatment induced changes in gene expression in circulating immune cells in patients. This was confirmed at the protein level for circulating cytokines.

Conclusions The analysis of RNAseq data obtained from whole blood clearly demonstrated that mitazalimab induce strong CD40-mediated responses, such as activation of myeloid cells and B cells in patients. Furthermore, corticosteroid pretreatment reduced the immune stimulatory activity of mitazalimab. The presented gene expression data confirms the biological activity of mitazalimab, further strengthening the proof of mechanism.

36 ANALYSIS OF T-CELL RECEPTOR SEQUENCES IDENTIFIES SIGNATURES ASSOCIATED WITH NEOANTIGEN EXPOSURE IN PERIPHERAL BLOOD OF LYNCH SYNDROME PATIENTS

Ana Bolivar*, Eduardo Vilar-Sanchez, Krishna Sinha, Laura Reyes Uribe, Nan Deng, Fahriye Duzagac, Alexandre Reuben. *MD Anderson Cancer Center, Houston, TX, USA*

Background Lynch Syndrome (LS) is the most common inherited colorectal cancer (CRC) syndrome. It constitutes the perfect model to understand DNA mismatch repair deficient (dMMR) carcinogenesis, which underlies 15% of early-stage CRC.[1] LS patients develop dMMR tumors with high loads of shared neoantigens, which are recognized by the immune system[2]. Elucidating the role and molecular landscape of public T-cell receptors (TCRs), provides potential as a diagnostic strategy for exposure to viruses and other immune-related phenotypes[3–5]. This study aims to characterize the TCR beta chain (TCRB) landscape of LS patients and to identify the presence of cancer-specific TCRB clones in the peripheral blood of LS carriers.

Methods A total of 122 PBMCs and 29 colorectal tissue samples have been collected from patients enrolled during their routine screening colonoscopy to an ongoing IRB-approved biospecimen protocol (MDACC IRB# PA12–0327). All TCRB repertoires were sequenced using the Immunoseq TCRB assay (Adaptive Biotechnologies). Bioinformatics analyses were performed using the immunarch R package[6,7] and the immuneML software[8] by comparing the TCRB repertoires among LS cancer survivors, LS healthy carriers (with no cancer history), and controls with no cancer and no family history of LS. To validate some of the identified TCRBs, a viral peptide and a cancer neoantigen predicted to be recognized by these public TCRBs were used to isolate peripheral T-cells from healthy human donors using pMHC-tetramer assays and single-cell TCR sequencing.

Results Our data show that LS cancer survivors have less diverse TCRB repertoires compared to LS healthy carriers due to the presence of hyper-expanded TCRBs in the group of survivors. Our results also show that a set of highly expanded cancer-specific public TCRBs is detectable in the peripheral blood of LS cancer survivors after annotation to the McPas-TCR database[9]. We observe an overlap of TCRBs between the tissue (precancers and cancers) and PBMCs in patients for which both types of samples were collected at the same time-point. Finally, with our pMHC-tetramer assays, we are capable of isolating TCRBs that were initially identified with bulk-TCR sequencing.

Conclusions Overall, our data suggest that the T-cell response of LS patients against developing cancers is not entirely restricted to their tumor microenvironment, with expanded cancer-specific public TCRBs being detectable in the peripheral blood of LS cancer survivors. This is the first step toward identifying a TCR signature that serves as a biomarker of early cancer detection in LS patients.

37 SIGNAL AMPLIFICATION STRATEGIES FOR IN SITU DETECTION OF LOW-EXPRESSED MARKERS IN MULTIPLEX IMMUNOFLUORESCENCE

Pino Bordignon*, Paula Juričić, Alexandre Kehren, Victor de Gautard, Saska Brajkovic, Diego Dupouy. *Lunaphore Technologies, Tolochenaz, Switzerland*

Background The characterization of the tumor microenvironment is essential for a deep understanding of tumor biology and the identification of personalized targeted therapies. By means of new spatial proteomic approaches, a detailed mapping of the different immune cells has been made possible[1]. Among them, multiplex immunofluorescence has emerged as a key technology, maximizing the amount of extractable information from a cancer tissue section[2]. While lineage markers can usually be easily detected via canonical indirect immunofluorescence, functional markers often show much lower levels of expression and would benefit from a signal amplification strategy[3]. Combining the possibility to amplify low-expressed markers with a system capable of performing multiplex staining could provide significantly improved tumor immunoprofiling with detailed information on immune cell activation and exhaustion.

Here, we aim to implement amplification technologies on the COMET™ system, capable of performing automated multiplex immunofluorescence, to improve the detection of low-expressed markers.

Methods The COMET™ platform is a microfluidic-based system that enables fully automated sequential immunofluorescent (seqIF™) assays based on iterative series of fast tissue staining, imaging, and antibody elution cycles on the same tissue section. Two amplification technologies were automated: Fluorescent Signal Amplification via Cyclic Staining of Target Molecules (FRACTAL)[4], and enzymatic Tyramide-based Signal Amplification (TSA)[5], also testing different commercially available TSA kits. The effects of amplification on low-expressed markers were evaluated with respect to standard assays on multiple human FFPE tissues. Normalized Mean Intensity and Signal to Background ratio have been used as parameters for the evaluation.

Results The two amplification technologies, FRACTAL and TSA, were successfully automated and optimized on COMET™. The signal intensity of multiple challenging markers, including FoxP3, PD1, PD-L1, and IDO-1 – though being detectable by standard seqIF™ – was significantly amplified by the two techniques. Overall, FRACTAL appeared to be the most suitable technology as shown by the better performance in terms of signal amplification (by NMI or SBR quantification) over the TSA amplification tested on COMET™. Importantly, optimization of the elution step resulted in efficient removal of all antibody layers employed in the FRACTAL method from the stained tissues, therefore allowing its use in sequential staining cycles on the same section.

Conclusions The implementation of amplification technologies in the COMET™ workflow for hyper-plex panel development will allow the detection of difficult-to-target biomarkers, such as functional markers with low-expression levels. This strategy can provide a significant improvement in immune cell profiling of tumor samples.

FULLY AUTOMATED SPATIAL MULTI-OMICS ANALYSIS TO MAP THE TUMOR MICROENVIRONMENT WITH SINGLE-CELL RESOLUTION

Pino Bordignon*, Alice Comberlato, Saska Brajkovic, Diego Dupouy. *Lunaphore Technologies, Tolochenaz, Switzerland*

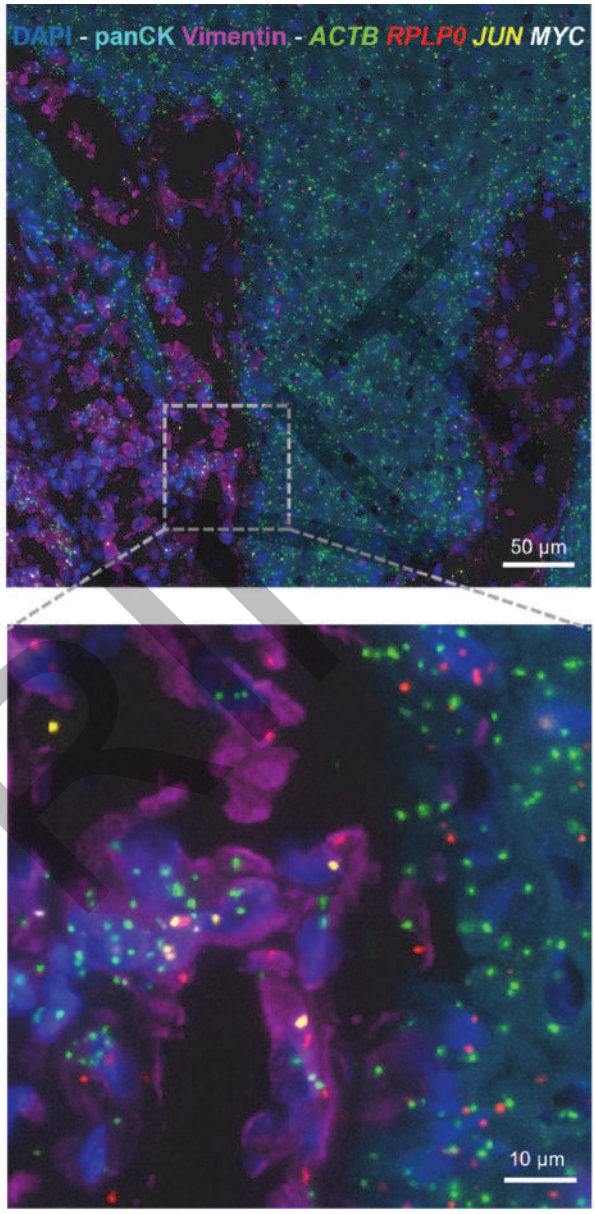
Background The tumor and its microenvironment are distinguished by highly heterogeneous cell types in dynamic evolution[1]. In the past decades, the adoption of single-cell RNA sequencing technologies improved our understanding of intra- and inter-patient variations, refining cancer diagnosis and targeted therapy, while still lacking spatial context information[2]. The spatial analysis of single-cell gene expression provides previously missing information on cell interactions, crucial for innovative treatment opportunities. However, the large-scale implementation of these assays is hampered by the lack of automated and user-friendly workflow solutions[3].

Here, we aim at automating an in situ transcriptomic assay and integrating it with a proteomic workflow on the COMET™ platform for easy and comprehensive mapping of the tumor microenvironment.

Methods COMET™ is a microfluidic-based instrument capable of automated sequential immunofluorescence (seqIF™) assays. The *in situ* RNA detection was based on DNA padlock probe hybridization and ligation, followed by rolling circle amplification and gene detection with fluorophore-tagged probes. A panel of probes targeting various immune-oncology genes was designed and the gene expression was evaluated in combination with a high-plex seqIF™ analysis.

Results The protocol for *in situ* RNA detection was automated and optimized on COMET™, resulting in specific detection of multiple transcripts (cell-type specific markers, transcription factors, secreted cytokines) on various tumor samples, with a signal quality that allows downstream computational analysis of gene expression signals. The transcriptomic assay was then integrated with a seqIF™ workflow for the co-detection of several target proteins for tumor microenvironment characterization on the same tissue section (figure 1). Double RNA and protein analysis allowed to examine the expression of biomarkers for which no good antibody clones are available, validation of new antibodies by detecting RNA and protein co-localization, in addition to the identification of the cellular source of secreted molecules. Compared to the manual protocol, the combined automated workflow resulted in a drastic time reduction being based on iterative fast cycles of detection and imaging of two transcripts or proteins each, lasting approximately 30 and 40 minutes, respectively.

Conclusions We showed here that in situ spatial transcriptomics assays can be fully automated and combined with spatial proteomics on the COMET™ platform for a multi-omics approach with advantages in terms of time and complexity reduction with respect to manual protocols. This combinatorial automated detection of RNAs and proteins of pivotal biomarkers provides a powerful new tool for a simpler and better mapping of the tissue spatial context.



Abstract 38 Figure 1 Automated and simultaneous in situ detection of RNA and prot
RNA (ACTB, RPLP0, JUN, MYC) and protein (panCK and Vimentin) targets are co-detected on a human melanoma frozen section with a fully automated workflow on the COMET™ platform. Background autofluorescence was subtracted and brightness adjusted for visualization purposes

39 INTERROGATING ELITE RESPONDER HUMORAL RESPONSES TO IDENTIFY NOVEL TARGETS AND THERAPEUTIC ANTIBODIES FOR THE TREATMENT OF CANCER

Ramya Chandrasekaran*, Darbie Whitman, Ray Fox, Tom Graddis, Kamal Puri. *OncResponse, Seattle, WA, USA*

Background The development of checkpoint inhibitors (CPIs) has transformed the treatment landscape for certain cancers. However, the response rates are modest for most cancers and some cancers are not amenable to CPIs and represent a significant unmet medical need.[1,2] CPIs promote anti-tumor adaptive responses by lifting the brakes off immune activation, which is known to break tolerance to self-antigens and induce autoantibody formation.[3–5] A subset of these autoantibodies may mediate anti-tumor responses and enhance CPI efficacy. B cells and tertiary lymphoid structures have been shown to contribute to CPI efficacy.[6–8] We have evaluated serum autoantibody profiles of cancer patients who responded well to CPI therapy and interrogated their memory B cell repertoires to identify novel targets, epitopes, biomarkers, and immunomodulatory anti-cancer antibodies.

Methods Solid tumor patients who remain on CPI therapy for at least 6 months with stable disease, or at least 3 months with a partial or complete response were designated as Elite Responders for this study. Serum samples from healthy donors and matched serum and peripheral blood mononuclear cells from Elite Responders were collected. For novel targets, epitopes, and biomarker discovery, serum samples were tested on proteome microarrays containing >21,000 unique full length human proteins. Serum samples were also probed for binding, by flow cytometry, to a panel of myeloid cells. Elite Responders with seroreactivity specific to suppressive myeloid cells were selected for B cell activations and antibody discovery using the OncoResponse platform. Myeloid-targeting antibodies were subsequently cloned, expressed and evaluated for anti-tumor activity in functional assays.

Results Autoantibody profiling using the microarrays corroborated some targets known to have immunomodulatory activities in the TME across several cancer types, e.g., LILRB2, VSIG1, CD47, Siglec, and identified additional immune-oncology targets of interest. Some autoantigens exhibited broad serological responses across several solid tumor types, while others were specific to a cancer type. The functional importance of the Elite Responder's humoral response was demonstrated by the discovery of a myeloid-targeting antibody, OR2805, which specifically binds immunosuppressive M2 macrophages and converts them into an immunostimulatory phenotype. In M2 macrophage/T cell coculture assays, OR2805 rescues T cell activation and proliferation and amplifies anti-PD-1 activity. A phase 1–2 dose escalation-expansion study of OR2805 alone or in combination in subjects with advanced solid tumors is ongoing (NCT05094804).

Conclusions Interrogation of humoral responses in cancer Elite Responders is an attractive strategy for discovery of novel targets and therapeutic antibodies for the treatment of cancer.

40 NGS-BASED IMMUNOLOGY PANEL: APPLICATIONS IN PRECLINICAL IMMUNO-ONCOLOGY RESEARCH

[1]Jia Xue*, [1]Xiaobo Chen, [1]Xiaoyu An, [1]Jingjing Wang, [2]Henry Li, [1]Sheng Guo. *[1]Crown Bioscience Inc., Suzhou, China; [2]Hanx Biopharmaceuticals, Inc., Wuhan, China*

Background Cancer immunogenomics encompassing tumor cells and tumor microenvironment (TME) is critical for unravelling the complexity of tumor immunity, understanding the mechanism of action (MOA) for immunotherapies, and revealing potential predictive/pharmacodynamic biomarkers. We previously described a new and comprehensive 1080 mouse immuno-oncology (I/O) gene RNA-Seq panel (mouse I/O RNA-Seq panel) that has an improved dynamic range for rare IO transcripts and is more cost effective over conventional microarray assays (e.g., NanoString nCounter Mouse Pan-Cancer IO 360™ Panel) when analyzing bulk tumor samples. In this study, we set out to explore its applications in preclinical IO studies evaluating immune checkpoint inhibitor (ICI) response.

Methods A panel of 14 mouse syngeneic tumors was profiled using the mouse I/O RNA-Seq panel to benchmark the baseline expression of IO transcripts and compared to the tumor-infiltrate leukocyte (TIL) analysis of the same tumors by flow cytometry. The pharmacodynamic profiles of selected syngeneic models upon ICI and CD4+ cell depletion treatment was also examined to reveal potential MOAs.

Results The panel of syngeneic models had a differential profile of response to ICI, TIL infiltration and IO gene expression. The mouse I/O RNA-Seq panel gene expression highly correlated with that from whole transcriptome sequencing (RNA-Seq) across the panel of syngeneic models, but mouse I/O RNA-Seq panel showed generally > 12x higher sensitivity for comparable sequencing data sizes. Using a collection of comprehensive gene signatures for TIL lineage identification, the mouse I/O RNA-Seq panel revealed rich TIL components in syngeneic mouse tumors that were confirmed by flow cytometry demonstrating the value and depth of coverage in studying TME at the gene expression level without the need for a wide array of antibodies and complex gating operations in flow cytometry and also the potential scalability of mouse I/O RNA-Seq assay. The mouse I/O RNA-Seq panel was then used for pharmacodynamic profiling upon anti-PD-1 antibody and CD4+ cell depletion treatment, and revealed different IO related pathway activity changes, with higher accuracy than the NanoString 360™ Panel.

Conclusions With NGS-based technology becoming ubiquitous, our mouse I/O RNA-Seq panel can be a powerful, fast and cost-effective solution in the preclinical IO research, improving our understanding of the tumor and immune cell interactions in unprecedented detail and in response to immunotherapeutics.

41 **EXTERNAL REPRODUCIBILITY OF PD-L1 IHC 22C3 PHARMDX FOR CERVICAL CANCER AT CPS ≥ 1 AND CPS ≥ 10**

[1]Greg Cherryholmes*, [1]Alexander Posch, [1]Siena Tabuena-Frolli, [1]Jesse Vasquez, [1]Tiffany Evans, [1]Chris La Placa, [1]Kristopher Kersch, [1]Angeliki Apostolaki, [2]Jonathan Juco, [1]Karina Kulangara. *[1]Agilent Technologies, Inc., Carpinteria, CA, USA; [2]Merck and Co., Inc., Kenilworth, NJ, USA*

Background Despite advancements in cervical cancer care, women with persistent, recurrent, or metastatic cervical cancer face difficult prognoses with limited treatment options. Recent results from clinical trials KEYNOTE-158 (NCT02628067) and KEYNOTE-826 (NCT03635567) have demonstrated clinically meaningful results in patients with recurrent or metastatic cervical cancer whose tumors express PD-L1 with a Combined Positive Score (CPS) ≥ 1. Here we give evidence of the reproducibility of PD-L1 expression determination in cervical cancer utilizing PD-L1 IHC 22C3 pharmDx at the CPS ≥ 1 and CPS ≥ 10 cutoffs.

Methods External reproducibility studies tested the inter-site, intra-site, inter-observer, and intra-observer assay reproducibility for cervical cancer at CPS ≥ 1 and CPS ≥ 10. To test inter- and intra-site reproducibility, five replicate sets of a blinded and randomized cervical cancer specimen set were tested at each of the three external sites. For inter- and intra-observer reproducibility, three external sites evaluated one pre-stained set of cervical cancer specimens. Percent agreement was calculated using Negative Percent Agreement (NPA), Positive Percent Agreement (PPA), and Overall Percent Agreement (OA). Pre-specified acceptance criteria (AC) for all components of the analyses were ≥ 85.0% for the lower bound value of a 95% two-tailed percentile bootstrap confidence interval (CI) of each percent agreement point.

Results At the CPS ≥ 1 cutoff: (i) inter-and intra-site NPA/PPA/OA met AC with point estimates (PE) ≥97.5% and CI lower bounds ≥94.7%, and (ii) inter- and intra-observer NPA/PPA/OA met AC with PE ≥ 98.1% and CI lower bounds ≥ 94.9%. At the CPS ≥ 10 cutoff: (i) inter-and intra-site NPA/PPA/OA met AC, with PE ≥92.8% and CI lower bounds ≥86.7%, and (ii) inter- and intra-observer NPA/PPA/OA met AC, with PE ≥98.4% and CI lower bounds ≥95.9%.

Conclusions This study demonstrates high external lab reproducibility of PD-L1 IHC 22C3 pharmDx with respect to expression determination in cervical cancer at CPS ≥ 1 and CPS ≥ 10 cutoffs.

Ethics Approval The external reproducibility study was approved by WCG IRB, study numbers 1284639, 1284652, and 1284653.

42 MODULATION OF FIBROSIS AND ANGIOGENESIS IN POST-ISCHAEMIC EXTRACELLULAR MATRIX

[1]Paolo Contessotto*, [2]Doriana Orbanic, [3]Mark Da Costa, [4]Chunsheng Jin, [3]Peter Owens, [4]Niclas Karlsson, [2]José Carlos Rodríguez-Cabello, [3]Peter Dockery, [3]Michelle Kilcoyne, [3]Abhay Pandit. [1]*University of Padova, Padova, Italy*; [2]*University of Valladolid, Valladolid, Spain*; [3]*NUI, Galway, Galway, Ireland*; [4]*University of Gothenburg, Gothenburg, Sweden*

Background Modulation of post-ischaemic remodelling is a significant clinical need.[1] Ischaemia results in the loss of millions of living cells as a result of the hypoxic condition.[1] However, our tissue is programmed to compensate for this loss by activating a remodelling program which leads to the formation of a fibrotic scar.[1] Inspired by the natural extracellular matrix, we have developed an injectable elastin-based hydrogel which showed marked functional and biological improvements in the ischaemic hearts by using a large animal model.[2]

Methods Focal infarcts were induced in male sheep by multiple suture ligations of side branches of the left anterior descending coronary artery. Functional data of ejection fraction and fractional shortening were obtained using transthoracic echocardiography prior to the induction of infarcts, prior to intervention, and at three weeks after intervention. Samples were analysed by bulk RNA-seq, LC-ESI-MS/MS proteomics and N-glycomics. Histology included Masson's Trichrome, anti-CD31 and lectin histochemistry.

Results ELRs-treated sheep showed less fibrosis and more angiogenesis compared to the untreated ones, as validated by expression, proteomic, glycomic, and histological analyses [3]. Remarkably, the effects of the hydrogel injection were already significant 21 days post-treatment, thus in the acute phase of the disease. Since our ELRs-hydrogel also contained matrix metalloproteinase-responsive motifs (MMP-2 and -9), this study showed that the combination of ELRs sequences together with MMP-2 and -9 responsive motifs in the cross-linked hydrogel network enabled the recruitment of endothelial cells to promote an angiogenic effect (figure 1). The enhancement of a stable angiogenic response resulted in a protective effect towards the cardiomyocytes located in the border zone of the infarct that play a crucial role in the functional recovery of the infarcted heart. Here, an unbiased approach based on RNA-sequencing and proteomic analyses enabled us to identify GATA4 as the most relevant regulator of the improved response in the hydrogel-treated sample. We have validated our molecular analysis by evaluating the preserved mitochondrial integrity in the GATA4+ cardiomyocytes in the border zone of the hydrogel-treated animals.

Conclusions In this up-to-date scenario, our ELRs-hydrogel has a distinct advantage for its translational potential due to its marked benefit despite the absence of any stem cell or growth factor. Our study highlighted the elastin-derived molecular signalling advantages, thus acting as a timely reminder not to underestimate the potential of ECM proteins which were only partially studied when compared with paracrine effect-dependent cellular systems.

43 TUMOR MUTATIONAL BURDEN CORRECTED FOR HUMAN LEUKOCYTE ANTIGEN SOMATIC DEFECTS PREDICTS RESPONSE TO CHECKPOINT BLOCKADE IN ADVANCED NON-SMALL CELL LUNG CANCER

Yinjie Gao*, Ramit Bharanikumar, Aly Khan, Michelle Stein. *Tempus Labs, Los Angeles, CA, USA*

Background Tumor mutational burden (TMB) has been proposed as a biomarker for predicting response to immune checkpoint blockade (ICB) therapies in patients with non-small cell lung cancer (NSCLC). However, a subset of patients with high TMB tumors do not have a long-term response to ICB. Several studies have hypothesized that somatic events in the antigen processing machinery may contribute to ICB resistance. In this study, we determined that TMB adjusted for the number of neoantigens lost due to human leukocyte antigen (HLA) somatic defects better predicted response to ICB.

Methods Using the real-world Tempus Database, we selected a cohort of 378 de-identified NSCLC patient records with DNA data and recorded outcomes following ICB. Loss of heterozygosity in HLA-I genes (HLA-LOH) were identified in this cohort. TMB was adjusted to match the proportion of neoantigens estimated to escape HLA presentation due to loss of specific HLA alleles. Cox proportional hazards models were fitted to determine the relationship between HLA-adjusted TMB and time to progression (TTP), with hazard ratios (HRs) and confidence intervals (CIs) reported. In addition, immune inflammation signatures were calculated for 249 patients for whom paired RNA data were available.

Results HLA-LOH was observed in 27% of late-stage NSCLC tumors. Notably, the presence of HLA-LOH was significantly associated with shorter TTP in TMB-high (>10mut/Mb) tumors versus TMB-high, HLA-stable tumors (HR [CI]=2.99 [1.39–6.40]). This association was not observed in tumors with low levels of TMB (HR [CI]=0.75 [0.46–1.20]). In addition, HLA-adjusted TMB improved the estimated risk ratio in comparison to unadjusted TMB. Binarization of HLA-adjusted TMB further stratified TMB-low and TMB-high groups (TMB-low HR[CI]=1.67[1.09–2.56]; HLA-adjusted TMB-low HR[CI]=2.08[1.19–3.08]). Immune-inflamed environment was also associated with longer TTP in the HLA-adjusted TMB-low group (HR[CI]=0.58 [0.36–0.92]), indicating that HLA-adjusted TMB can be used in conjunction with immune phenotypes to predict outcomes to ICB.

Conclusions In this study, we observed that high TMB, HLA-stable patients had a longer TTP in NSCLC. Furthermore, we discovered that HLA-adjusted TMB outperformed unadjusted TMB in predicting ICB response, and that an inflamed immune phenotype was associated with longer TTP within HLA-adjusted TMB subgroups. Our findings suggest that HLA-adjusted TMB can be used alone as a DNA-based biomarker or in combination with immune signatures to better predict ICB response in NSCLC patients.

IMMUNE SIGNATURES OF SEVERE IMMUNE-RELATED ADVERSE EVENTS DETECTED BY MASS CYTOMETRY IMMUNE PROFILING IN BLOOD IN PATIENTS WITH ADVANCED MELANOMA TREATED WITH IMMUNOTHERAPY

[1]Connor Healy*, [2,3]Magdalena Kovacsovics*, [1]Natalia Sigal, [1]Li-Chun Cheng, [1]Shane Evans, [3]John Marsiglio, [2]Berit Gibson, [2]Yoko DeRose, [3]Annaleah Larson, [1]Carlos Medina, [1]Jolien Sweere, [1]Ramji Srinivasan, [4]Matthew Spitzer, [2]John Hyngstrom, [2]Siwen Hu-Lieskovan. *[1]Teiko Bio, Salt Lake City, UT, USA; [2]Huntsman Cancer Institute, Salt Lake City, UT, USA; [3]University of Utah, Salt Lake City, UT, USA; [4]University of California San Francisco, Chan Zuckerberg Biohub, Parker Institute for Cancer Immunotherapy, San Francisco, CA, USA*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0044

Background Immune-related adverse events (irAE) are major barriers of clinical management and further development of cancer immunotherapy. In this study, we used mass cytometry to characterize the immune system before and during presentation of severe (grade 3+ that required clinical intervention) irAE to identify cell signatures correlated with irAE development.

Methods We performed analysis on banked peripheral blood mononuclear cells (PBMCs) from 29 patients with melanoma undergoing checkpoint inhibitor (CPI) therapy, of which 18 developed severe irAEs (3 gastrointestinal, 5 endocrine, 4 cutaneous, 9 hepatobiliary, 4 musculoskeletal, 1 pulmonary irAEs and 1 acquired lipodystrophy) while 11 did not. Samples were taken at initiation of CPI (pre-treatment), before onset of irAE (pre-irAE) and at presentation of irAE (irAE max). The median number of CPI cycles per patient was 5 for patients with severe irAEs and 11 for patients without severe irAEs. We used a 44-marker mass cytometry panel designed to capture cell subsets and activation states across the innate and adaptive immune system, with both supervised analysis of manually gated immune cell subpopulations and unsupervised analysis by **C**lustering **LAR**ge **A**pplications (CLARA) clustering.

Results At the peak of irAE presentation, patients with severe irAE demonstrated significantly more CD38+ (marker of immune activation) CD4+ central memory T cells (TCM), CD39+ (marker of tumor antigen-specificity) and HLA-DR+ (marker of activation) CD8 TCM cells, and CCR7+ (marker of migration) CD4+ T cells compared to patients with no or non-severe irEAs. Conversely, patients with severe irAEs had significantly fewer CD16+ NK cells and CD161+ (marker of inhibition) CD4+ T cells. Interestingly, patients with severe irAEs already had fewer CD16+ NK cells and CD161+ CD4 + T cells pre-treatment, and more CCR7+ CD4+ T cells pre-irAE. Presentation of severe irAEs was also correlated with significantly lower levels of TIGIT+ regulatory T (Treg) cells pre-treatment, and more CD4+ T naïve cells at all three timepoints.

Conclusions Development of severe irAE in melanoma could be the result of reduced inhibitory immune capacity pre-treatment, marked by fewer regulatory TIGIT+ Treg cells and CD161+ CD4+ T cells, leading to dysregulated increase in migratory CCR7+ CD4+ T, activated CD38+ and tumor-reactive CD39+ TCM cells, and activated CD16+ NK cells. This study demonstrates that high-dimensional immune profiling can detect novel blood-based immune signatures associated with presentation of severe irAEs.

Ethics Approval The study was approved by Huntsman Cancer Institute's Ethics board, approval number IRB_00010924. Participants gave informed consent before taking part in the study.

45 PREVALENT BINDING MOTIF IN C57BL6 MICE CURED OF B78 MELANOMA VIA IMMUNOTHERAPY

[1]Anna Hoefges*, [1]Nicholas Mathers, [1]Sean Mcilwain, [2]Richard Pinapati, [2]Bradley Garcia, [2]Jigar Patel, [1]Amy Erbe, [1]Irene Ong, [1]Paul Sondel. *[1]University of Wisconsin Madison, Madison, WI, USA; [2]Nimble Therapeutics, Inc, Madison, WI, USA*

Background Using a high-density peptide array, we assessed potential protein-targets for antibodies detected in mice cured of melanoma through a combined immunotherapy regimen. Our goal was to determine the linear peptide sequences recognized by anti-tumor antibodies produced in mice cured of melanoma following immunotherapy.

Methods Mice bearing B78 melanoma tumors were treated with a combination immunotherapy (local radiation therapy + intratumoral anti-GD2 mAb linked to IL2) capable of inducing an '*in situ* vaccine' effect (ISV), enabling mice to be cured of their tumors with long-term immune memory.[1] Naïve (prior to tumor injection) and immune (post-rechallenge/after cure) sera were collected from these mice. Using flow cytometry, immune sera showed strong antibody-binding against B16 (parental cell line of B78) and B78. These sera were then used on a Nimble Therapeutics' whole-proteome peptide-array to determine specific antibody-binding sites, and data were analyzed using a dynamic programming method that scans adjacent peptides to determine whether a peptide is bound by antibodies. Epitopes were selected if peptides were bound using immune sera but not bound, or significantly less, with the sera from naïve mice.

Results We identified many binding epitopes only present in immune mice. Among the epitopes found, we noticed a repeating motif consisting of 4 amino acids that made up over 60% of epitopes that are present in at least 50% of mice in our most restrictive binding category. However, the 4 amino acid long motif is not the only reason for binding as some peptides including this motif do not show binding. The amino acid (aa) sequence before and the 2aa sequences following the motif seem to be important for binding. Using an unrelated cohort of mice we were able to show binding of some additional immune mouse samples to selected peptides containing the identified motif

Conclusions We think that this motif might be an important piece in anti-tumor immunity to B78 melanoma. We are further investigating what causes binding vs no binding to the motif, and if the antibodies against it originated at one specific site vs multiple sites. The presence of antibodies against this motif might be a useful biomarker to predict response to our ISV regimen and might have the potential to be used for other immunotherapy treatments.

46 GENETIC ANALYSIS OF TUMOR CELLS DERIVED FROM THE STRESS OF IMMUNE RESPONSE FOR UNDERSTANDING OF IMMUNOTHERAPY

[1]Tomoyuki Ishiguro*, [1]Daisuke Takayanagi, [1]Toshiaki Tsurui, [1]Risako Suzuki, [1]Nana Iriguchi, [1]Yuya Hirasawa, [1]Ryotaro Ohkuma, [1]Hirotsugu Ariizumi, [1]Yutaro Kubota, [1]Kazuyuki Hamada, [1]Atsushi Horiike, [1]Satoshi Wada, [1]Kiyoshi Yoshimura, [2]Kazuyoshi Takeda, [1]Takuya Tsunoda. *[1]Showa University, Tokyo, Japan; [2]Juntendo University, Tokyo, Japan*

Background Cancer immunotherapy with immune checkpoint inhibitors (ICIs), unlike conventional anticancer agents and molecular targeted drugs, shows Kaplan-Meier curves characteristic of long-term survival in patients with advanced stage IV cancer, which is so-called the 'kangaroo tail phenomenon'. However, the response rate of ICI is limited at only 20–30%, and improvement of therapeutic efficacy needs to be developed. We believed that a thorough elucidation of the mechanism of the kangaroo tail phenomenon would be one of the most important aspects to improve the therapeutic efficacy of ICIs.

Methods Using a mouse model of breast cancer 4T1 cells subcutaneously transplanted into wild type (natural immunological response) and immunocompromised mice with CTL transferred (tumor specific immunological response) (RAG-/- + ACT), we isolated tumor cells that had shrunk once and then re-expanded in two systems and performed whole exon RNA sequencing using tumor cells immediately after transplantation as controls. We analyzed the genetic changes induced by anti-tumor immune stress that tumors undergo from natural immune response.

Results In all samples, Tumor Mutational Burden and MSI scores increased compared to the control which is under no immunological stress, and many new genetic mutations were observed. In addition, the immunogenicity was maintained, with high affinity between neoantigens and MHC, which was inferred from the mutation information with amino acid changes. This suggests that the kangaroo tail phenomenon is caused by the repeated recognition and cytotoxic activity of neoantigens by CTLs with 10^{18} repertoire T cell receptors.

On the other hand, the genetic mutations common to each sample appeared the genes related to immune response, and mutations were also found in genes related to repair mechanisms such as DNA repair. For elective splicing, intron retention was found to have more genes related to DNA repair, while exon skipping had more genes related to DNA repair and the cell cycle. Copy number analysis also showed loss of heterozygosity in chromosome 17, which is located at MHC. These results were suggested that immune evasion by immunological pressure may be derived from the mutations such as abnormal immune response and loss of antigen-presenting ability.

Conclusions This study provides the first molecular biological insights into the mechanisms by which ICI produces long-term survivors. Furthermore, this study also provides clues to further improve the response rate of ICI through the understanding of the mechanism of action of ICIs in effective cases, at the same time understanding the immune evasive mechanism that occurs in ineffective cases.

MULTISPECTRAL IMAGING TO DETECT IMMUNE PHENOTYPES ASSOCIATED WITH THE TUMOR MICROENVIRONMENT IN A MULTI-TISSUE STUDY: A FULL AUTOMATED 7-COLOR MIF IMMUNO-ONCOLOGY WORKFLOW

[1]Navi Mehra*, [1]Bhavika Patel, [1]Stephanie Allen, [1]Noah Ramirez, [2]Najiba Mammadova, [2]Agnes Haggerty. *[1]Lanterne Dx, Boulder, CO, USA; [2]Akoya Biosciences, Menlo Park, CA, USA*

Background Immunotherapy and precision medicine are rapidly developing approaches to cancer therapy. Biomarkers that detect the tumor and tumor microenvironment allow for the development of strategies that accelerate the advancement of treatments to enhance a patient's immune system. Akoya's MOTiF™ PD-1/PD-L1 Panel is a validated, multiplex immunoassay enabling detection of the 6 most clinically relevant immuno-oncology and spatial biomarkers: PD-1, PD-L1, FoxP3, CD8, CD68, and PanCK.

Methods The MOTiF™ PD-1/PD-L1 Panel was used to analyze the tumor microenvironment and specifically assess immune phenotypes of different types of cancers: non-small cell lung cancer (NSCLC), colon adenocarcinoma, head and neck squamous cell carcinoma (HNSCC), and breast cancer.

Results We demonstrate the utility of Akoya's MOTiF™ PD-1/PD-L1 panel kit in studying the cellular diversity of various cancers while retaining spatial context. Stained slides were analyzed using the InForm® and PhenoptrReports image analysis platforms to identify and better understand spatial relationships between a variety of simple and complex cell phenotypes. The MOTiF™ PD-1/PD-L1 panel kit provides reproducibility across different tissue types.

Conclusions These data provide insight into the innate and adaptive immune environment for targeted design of new immunotherapies and have implications for improving the treatment paradigm across many tumor types.

48 **WHOLE-SLIDE MULTISPECTRAL IMAGING REVEALS THE IMMUNE SUBTYPES OF MELANOMA ASSOCIATED WITH THE TUMOR MICROENVIRONMENT: AN AUTOMATED 7-COLOR MIF ASSAY**

[1]Navi Mehra*, [1]Bhavika Patel, [1]Stephanie Allen, [1]Noah Ramirez, [2]Najiba Mammadova, [2]Agnes Haggerty. *[1]Lanterne Dx, Boulder, CO, USA; [2]Akoya Biosciences, Menlo Park, CA, USA*

Background Immunotherapy and precision medicine are rapidly developing approaches to cancer therapy. Biomarkers that detect the tumor and tumor microenvironment allow for the development of strategies that accelerate the advancement of treatments to enhance a patient's immune system. Akoya's MOTiF™ PD-1/PD-L1 Auto Melanoma Kit is a validated, multiplex immunoassay enabling detection of the 6 most clinically relevant immuno-oncology and spatial biomarkers: FoxP3, PD-L1, Sox10/S100, PD-1, CD8 and CD68.

Methods In this study, the MOTiF™ PD-1/PD-L1 panel was used to analyze the tumor microenvironment and specifically assess immune phenotypes within melanoma samples from 3 patients. This study demonstrates a fully optimized and end-to-end workflow solution for biomarker discovery in melanoma.

Results We demonstrate the utility of Akoya's MOTiF™ PD-1/PD-L1 Melanoma panel kit in studying the cellular diversity while retaining spatial context. Stained slides were analyzed using the InForm® and Phenoptr Reports image analysis platforms to identify phenotypes and better understand spatial relationships between cell phenotypes. The MOTiF™ PD-1/PD-L1 panel kit provides reproducibility across different patient samples.

Conclusions This data provides insight into the innate and adaptive immune landscape for targeted design of new immunotherapies as well as improved efficacy and reduced toxicity in the treatment of melanoma.

49 IMMUNO-ONCOLOGY IMAGING MASS CYTOMETRY STUDY OF THE STRUCTURAL AND CELLULAR COMPOSITION OF THE TUMOR MICROENVIRONMENT IN HUMAN CANCERS

Thomas Pfister*, Christina Loh, Sam Lim, Qanber Raza, Shaida Ouladan, Nick Zabinyakov.
Standard BiTools, Toronto, Canada

Background Multiplex imaging is becoming an increasingly valuable tool to study the tumor microenvironment (TME) in immuno-oncology. Imaging Mass Cytometry™ (IMC™) provides a means for visualization and analysis of the complex spatial biology of the TME. IMC permits detailed assessment of cell phenotype and function using 40-plus markers simultaneously at subcellular resolution on a single slide without spectral overlap or background autofluorescence. The ability to analyze multiple markers can facilitate accurate prediction of disease progression and clinical outcome measures from precious tissue samples and microarrays. Here, we demonstrate how our reagents support these applications.

Methods Antibodies targeting T cells, natural killer cells, myeloid cells, immune checkpoint markers, epithelial-to-mesenchymal transition (EMT) and extracellular matrix (ECM) proteins were used to study the immune microenvironment in multiple cancer histologies. Antibodies were selected from the Maxpar® and Maxpar OnDemand™ catalog. Data acquisition was performed using a Hyperion™ Imaging System (Standard BioTools™). To facilitate cell segmentation, an IMC Cell Segmentation Kit (Standard BioTools) was applied to enhance nucleus and cell membrane boundaries. Single-cell analysis was completed using custom MATLAB® script for pixel classification, CellProfiler™ for cell segmentation and histoCAT™ for phenograph clustering.

Results IMC analysis of human cancer tumor microarrays (TMAs) stained with panels of Maxpar and Maxpar OnDemand antibodies is presented here. We identified major cell populations and phenotypes via clustering (PhenoGraph). Immune cell phenotype and ECM staining data are overlaid on IMC images and complemented with t-SNE embeddings and signal intensity heat map. Additionally, we classified the activation state of immune cell populations, EMT progression and molecular composition of the TME ECM.

Conclusions Highly multiplexed IMC has enabled us to compare the TME across cancer histologies. Spatial analysis of the tumor architecture revealed details of tumor immune cell interaction at single-cell resolution. This work demonstrates the capability of IMC for quantitative and spatial identification of multiple immune parameters and detailed analysis of the TME from a single slide from cancer patients.

50 MERKEL CELL POLYOMAVIRUS-SPECIFIC CD8 T CELLS IN BLOOD, BUT NOT IN TUMORS, CORRELATE WITH IMMUNOTHERAPY RESPONSE IN MERKEL CELL CARCINOMA

[1]Thomas Pulliam*, [1]Saumya Jani, [1]Lichen Jing, [2]Jiajia Zhang, [1]Rima Kulikauskas, [1]Candice Church, [3]Charlie Garnett-Benson, [4]Kelly Paulson, [2]Kellie Smith, [2]Andrew Pardoll, [1]David Koelle, [2]Suzanne Topalian, [1]Paul Nghiem. *[1]University of Washington, Seattle, WA, USA; [2]Johns Hopkins University, Baltimore, MD, USA; [3]Bristol Myers Squib, Princeton, NJ, USA; [4]Swedish Health Services, Edmonds, WA, USA*

Background PD-1 pathway blockade has revolutionized oncology, though most patients do not derive durable benefit. Accurate prediction of response is not currently possible. Cancer-specific CD8 T cells can mediate tumor regression, however, identifying these cells is difficult because many tumor antigens are patient-specific. Merkel cell carcinoma (MCC), driven by Merkel cell polyomavirus (MCPyV) oncoproteins in ~80% of cases, is an attractive cancer for studying tumor-specific T cells due to shared, viral antigens and a low tumor mutational burden. Using samples from a recent trial of neoadjuvant nivolumab in MCC (NCT02488759), we studied anti-PD-1 resistance by interrogating MCPyV-specific CD8 T cells before and during therapy.

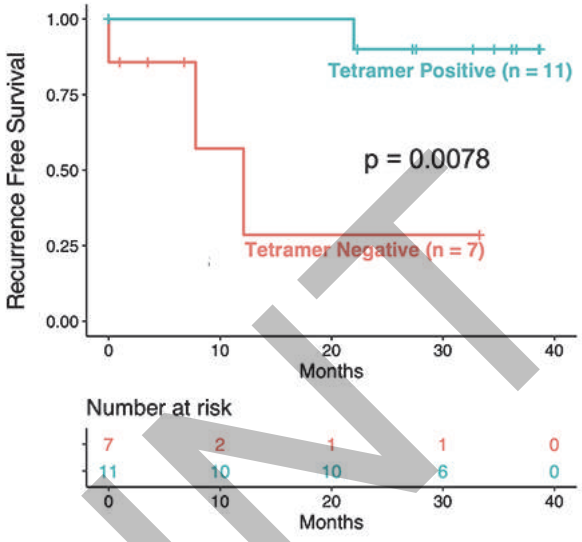
Methods MCPyV-specific CD8 T cells were identified using an expanded panel of 16 MCPyV-specific HLA class I multimers. PBMC from 21 patients with suitable multimers (among 35 patients assessed) collected before, 2 and 4 weeks after initiating anti-PD-1 were stained with MCPyV-multimers in 26-plex flow cytometry. Intratumoral MCPyV-specific T cell frequency was calculated using a combination of 1) HLA-I multimers and paired T cell receptor (TCR)-seq of phytohemagglutinin-expanded tumor infiltrating lymphocytes to identify virus-specific TCRs and 2) beta-TCRseq of formalin-fixed tumors to determine T cell clone frequency. To study phenotypic differences between cancer-specific CD8 T cells found in tumors versus blood, single cell RNAseq and paired TCRseq were performed on a separate cohort of 7 MCC patients.

Results Patients without detectable circulating MCPyV-specific CD8 T cells before treatment had shorter recurrence-free survival (RFS; figure 1; median RFS=12 months; n=7) than patients with detectable MCPyV-specific cells (median RFS not reached; n=11; p=0.0078). In contrast, response was not associated with intratumoral, MCPyV-specific CD8 T cells (13% [mean] of intratumoral T cells in patients with pathological complete response versus 23% in those without response; p=NS). T cells were considered 'dysfunctional/exhausted' if they fell within single cell RNAseq clusters characterized by TOX, PD-1, and LAG-3 transcripts. MCPyV-specific T cells were significantly more likely to be dysfunctional/exhausted if they were intratumoral (>90% dysfunctional) versus in blood (0–50%; p=0.002).

Conclusions MCC-specific CD8 T cells in blood were less dysfunctional than their intratumoral counterparts. The frequency of pre-existing MCC-specific CD8 T cells in blood strongly correlated with anti-PD-1 response, while their frequency within tumors was unrelated to response. These results suggest that approaches to increase the number of circulating, less exhausted, cancer-specific T cells may benefit patients with anti-PD-(L)1-refractory MCC, and the frequency of these cells may be a predictive marker of anti-PD-(L)1 response.

Trial Registration NCT02488759

Ethics Approval This study was approved by the Fred Hutchinson Cancer Center's Institutional Review Board, approval number 6585. All patients represented here participated with written informed consent.



Abstract 50 Figure 1 T cell frequency and response
Frequency of Merkel cell polyomavirus-specific CD8 T cells in blood predicts response to neoadjuvant PD-1 pathway blockade. Kaplan Meier curve showing survival of patients who had MCPyV-specific CD8 T cells in blood above (tetramer positive; blue) or below (tetramer negative; red) the limit of detection (0.01% of CD8 T cells; p=0.0078 via log-rank test)

51 A COMBINATION OF ANTIGEN PRESENTATION AND T-CELL RECOGNITION FEATURES IMPROVES NEOANTIGEN IMMUNOGENICITY PREDICTIONS

Neeraja Ravi*, Rachel Pyke, Steven Dea, Prateek Tandon, Richard Chen, Sean Boyle. *Personalis, San Francisco, CA, USA*

Background The assessment of tumor neoantigen burden has been shown to outperform tumor mutational burden in predicting patient response to checkpoint inhibitor immunotherapy by better capturing the biological mechanism underlying response.[1]. However, immune recognition of neoantigens by T-cells requires more than antigen presentation, which has been the focus of tumor neoantigen burden assessment to date. Here, we extend the existing SHERPA® MHC-presentation framework.[2] To include a model for the prediction of neoantigen immunogenicity.

Methods For feature engineering, training and validation, we utilized two datasets containing peptides experimentally validated for immunogenicity. The first dataset, curated by Schmidt et al.,[3] aggregates experiments from 17 different sources, identifying 1282 immunogenic peptides across 67 MHC alleles. While the diversity of this dataset enables generalizability, a lack of associated sequencing data limits the features that can be investigated. The second dataset, curated by the TESLA consortium, contains 37 immunogenic peptides across 13 MHC alleles and patient-specific exome and transcriptome sequencing data, broadening the potential feature landscape.[4] Using both datasets, we developed and validated features associated with antigen availability, processing, presentation and recognition. To inform the assessment of antigen availability, we measured gene expression level and variant allele fraction. We built a cleavage probability predictor from immunopeptidomics data for antigen processing, while SHERPA MHC binding probability was used to quantify antigen presentation. Finally, we included measures to predict T-cell recognition based on antigen hydrophobicity, agreotopicity, dissimilarity to self antigens and similarity to known foreign antigens. We utilized a two-tiered machine learning model that selectively learns the weights of features from the dataset that is most informative and least biased.

Results The Schmidt et al. dataset was used in the first tier of the model to develop an immunogenicity score using peptide-derived features. The first tier score distinguished immunogenic peptides with an area under the precision recall curve (AUPRC) of 0.74, far greater than SHERPA or NetMHCpan-4.1 alone (0.48 and 0.39 respectively). The second tier of the model was trained on the TESLA dataset and used the first tier score as a feature along with other patient-specific features. Cross validation yielded a 37% fold increase in AUPRC over the method developed by the TESLA consortium.

Conclusions By combining antigen presentation and T-cell recognition features in a two-tiered model, we can better predict immunogenic neoantigens and make progress towards using neoantigens as biomarkers to assess checkpoint inhibitor efficacy.

52 DIGITAL PATHOLOGY TRAINING EFFECTIVENESS FOR THE EVALUATION OF PD-L1 EXPRESSION IN MULTIPLE TUMOR INDICATIONS

Jennifer Robinson*, Edward Manna, Charlotte Roach, Ryan Marczak, Arkendra De, Joshua Littrell, Micki Adams. *Agilent Technologies, Inc., Oxnard, CA, USA*

Background In-person pathologist trainings during the COVID-19 pandemic became impossible, necessitating a shift to remote-digital whole slide image (WSI) training. High concordance between WSI and glass slide scores from the same specimens stained with PD-L1 IHC 22C3 pharmDx (SK006) across multiple tumor indications supported the validity of digital training.[1] However, in-person microscope (glass-slide) training versus remote-digital (WSI) training effectiveness must be assessed. Collated testing data on specimens (SK006 stained) spanning multiple indications scored by external pathologists during Agilent led training and testing (T&T) sessions via glass slides were compared to sessions utilizing WSIs.

Methods Stained slides (30 unique specimens per tumor indication) were scanned on an Aperio AT2 scanner to generate WSIs for digital T&T. Remote T&T sessions used WebEx and PathcoreScholar's online platform to discuss scoring guidelines and WSI training cases. Subsequently, external pathologists evaluated WSIs in PathcoreScholar for PD-L1 expression using either Tumor Proportion Score (TPS) or Combined Positive Score (CPS) scoring algorithms and interpreted these scores at predefined cutoffs (figure 1). In both glass and WSI scoring test modalities, passing is defined as inter and intra-observer overall agreement (OA) ≥85%. Training effectiveness pass rates from glass slide data (2018–2020) and WSI data (2021–2022) spanning multiple indications and scoring algorithms were calculated and then compared using the Fisher-Freeman-Halton test, with a significance threshold of 0.05. Only data from initial pathologist tests were included in the pass rate calculation; data from re-tests executed after initial test failure were excluded.

Results The differences between pass rates for microscope (glass slide) and digital (WSI) testing were not statistically significant (p-value > 0.05) (tables 1 and 2). Testing pass rates for indications scored with TPS or CPS using microscope glass slide vs digital WSI T&T was not statistically significant (p-value > 0.05) (table 3).

Conclusions No statistically significant differences in pathologist training effectiveness for PD-L1 were observed between remote and in-person trainings across multiple tumor indications, scoring algorithms, and cutoffs. These results demonstrate the effectiveness and equivalency of remote-digital pathologist trainings for evaluation of PD-L1 expression as detected by PD-L1 IHC 22C3 pharmDx in multiple tumor indications when compared to in-person-microscope glass slide T&T. Use of digital training and scoring proficiency testing can provide pathologists around the world with access to high-quality, interactive training from leading experts in PD-L1 expression evaluation.

Abstract 52 Table 1 Pass rates of microscope (glass slide) vs digital (WSI) testing

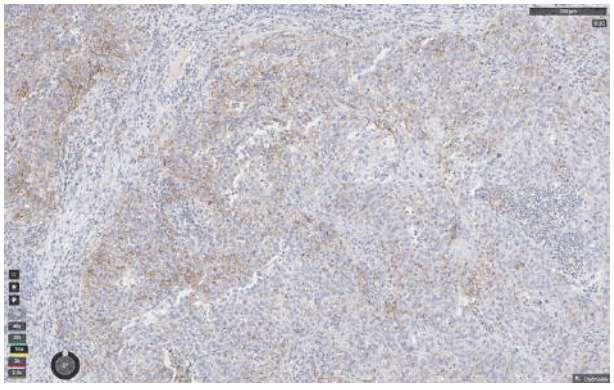
Training and Testing Modality	Pass Rate (Participants: Passing/Total)
Glass (in-person)	100*(97/102) = 95.1%
Digital (remote)	100*(110/111) = 99.1%

Abstract 52 Table 2 Glass and digital pass rates by indication

Indication	Scoring Algorithm	2018-2020 Glass Pass Rate (Participants: Passing/Total)	2021-2022 Digital Pass Rate (Participants: Passing/Total)
Colorectal carcinoma (CRC)	CPS	No data	100*(20/20) = 100%
Cervical cancer	CPS	100*(6/6) = 100%	100*(3/4) = 75%
Biliary tract adeno cancer (BTAC)	CPS	100*(7/8) = 88%	100*(16/16) = 100%
Urothelial carcinoma (UC)	CPS	100*(3/3) = 100%	100*(2/2) = 100%
Non-small cell lung cancer (NSCLC)	TPS	100*(6/6) = 100%	100*(22/22) = 100%
Esophageal cancer	CPS	100*(6/6) = 100%	100*(21/21) = 100%
Head and neck squamous cell carcinoma (HNSCC)	TPS	100*(16/19) = 84%	100*(16/16) = 100%
Pan-breast carcinoma (including triple-negative breast cancer, TNBC)	CPS	100*(44/44) = 100%	100*(10/10) = 100%
NSCLC cytology	TPS	100*(8/8) = 100%	No data
Small cell lung cancer (SCLC)	CPS	100*(4/4) = 100%	No data
Gastric adenocarcinoma	CPS	100*(7/8) = 88%	No data

Abstract 52 Table 3 Pass rates of microscope (glass slide) vs digital (WSI) testing for indications scored with CPS or TPS

Scoring Algorithm	Microscope (Glass) Pass Rate (Participants: Passing/Total)	Digital (WSI) Pass Rate (Participants: Passing/Total)
CPS	(80/85)*100 = 94.4%	(88/89)*100 = 98.8%
TPS	(17/17)*100 = 100%	(22/22)*100 = 100%



Abstract 52 Figure 1 Digital (WSI) of a triple-negative breast cancer (TNBC) specimen stained with PD-L1 IHC 22C3 pharmDx primary antibody and scored on PathcoreScholar online platform with

corresponding H&E and negative control reagent (NCR) WSIs for use as aids in the interpretation of PD-L1 staining

53 EVALUATION OF TUMOR ANTIGEN-SPECIFIC ANTIBODY RESPONSES IN PATIENTS WITH METASTATIC TRIPLE NEGATIVE BREAST CANCER TREATED WITH CYCLOPHOSPHAMIDE AND PEMBROLIZUMAB

Eric Routh*, Benjamin Vincent, Jonathan Serody, Mark Woodcock. *UNC-Chapel Hill, Chapel Hill, NC, USA*

Background Although T cells have been a central focus of cancer immunotherapy studies, there is a growing appreciation for the role of B cells in anti-tumor immunity. We recently reported that increased B cell gene signature expression and B cell receptor diversity in pretreatment samples were associated with clinical response to immune checkpoint blockade (ICB) in triple negative breast cancer (TNBC).[1] In murine models of TNBC, ICB response has been found to be dependent upon B cell responses.[2] Beyond TNBC, intratumoral presence of tertiary lymphoid structures (TLS; enriched with B cells, T cells and dendritic cells (DCs)) have been associated with ICB response in various cancer types.[3–7] Deeper understanding of B cell responses in the context of ICB is needed.

Methods We evaluated tumor antigen-specific antibody responses in patients with metastatic triple negative breast cancer treated with pembrolizumab following low dose cyclophosphamide therapy using custom peptide arrays (figure 1).

Results We found that a minority of predicted linear epitopes were associated with antibody signal, and antibody signal was associated with both mutated epitopes and self epitopes. No associations were observed between antibody signal and subcellular localization or RNA expression of parent proteins (figure 2). Patient-specific patterns of antibody signal boostability (e.g., antibody signal increase on-therapy) were observed and were independent of clinical response (figure 3). Intriguingly, measures of cumulative antibody signal intensity relative to immunotherapy treatment showed that the one complete responder in the trial had the greatest increase in total antibody signal (figure 3), which supports a putative association between ICB-dependent antibody boosting and clinical response. The antibody boost in the complete responder was largely driven by increased levels of IgG specific to a sequence of N-terminal residues in native Epidermal Growth Factor Receptor Pathway Substrate 8 (EPS8) protein (figure 4), a known oncogene in several cancer types including breast cancer. Structural protein prediction analysis showed that the antibody-targeted region of EPS8 was in a region of the protein with mixed linear/helical structure, and that this region was solvent-exposed and not predicted to bind to interacting macromolecules (figure 4).

Conclusions High-throughput peptide arrays can be used to map tumor antigen-specific antibody responses. This study highlights the potential importance of humoral immune responses recognizing neoantigen epitopes and unmutated self protein epitopes in anti-tumor immunity. Future studies will be needed to better elucidate the role of tumor antigen-specific antibodies in tumor growth inhibition and immunotherapy response.

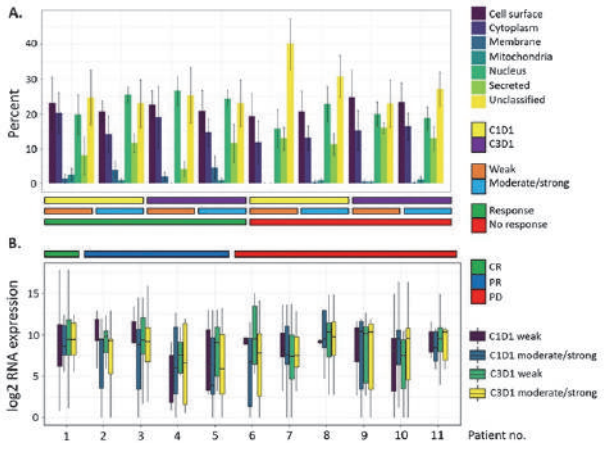
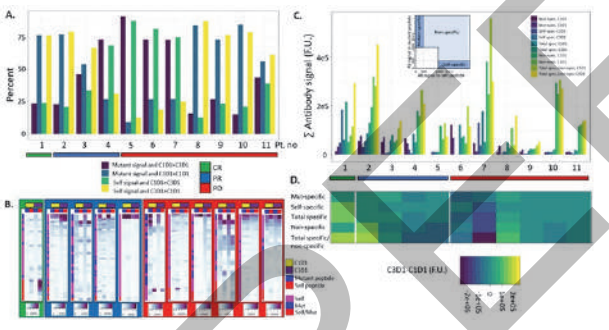
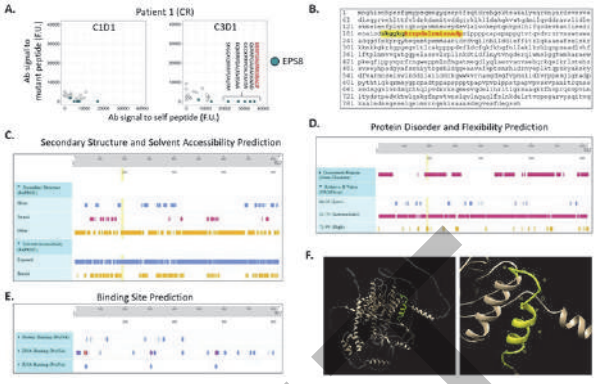
Abstract 53 Figure 1 Experimental approach to examine neoantigen-specific antibody responses. Patients with metastatic triple negative breast cancer underwent a clinical trial to examine the efficacy of regulatory T cell depletion with cyclophosphamide plus PD-1 inhibition with pembrolizumab. Eleven patients from this cohort were selected based on clinical response for analysis of tumor antigen-specific antibody responses via multiplex ELISA (peptide arrays). Downstream analyses included examination of protein subcellular localization and RNA expression, as well as antibody boostability relative to immunotherapy treatment. Antibody responses were seen at baseline, and in some patients, increased after therapy



Abstract 53 Figure 2 Subcellular protein localization and RNA expression do not associate with antibody signal or response group. (A) Subcellular localization of parent proteins of self/mutant peptide pairs subset based on associated antibody signal level (weak vs. moderate/strong), and further categorized by treatment time point and response. Peptide pairs were considered to have moderate/strong signal if either peptide of the pair (self or mutant) had >2,000 F.U. signal intensity. Peptide pairs were considered to have weak signal if both peptides of the pair (self and mutant) had signal intensity >500 F.U. and <2000 F.U. Error bars represent standard error (n=5 for responders; n=6 for non-responders). (B) Distribution of RNA expression of parent proteins categorized according to antibody signal level, treatment time point and response



Abstract 53 Figure 3 Boostability of antibody response relative to ICB treatment. (A) Percentage of mutant or self-peptides that had associated antibody signal (>500 F.U. at either C1D1 or C3D1) and greater signal relative to the other time point. (B) Heatmap depiction of antibody signal relative to treatment time point. Signal was ranked according to intensity of signal to C3D1 mutant peptide. A peptide pair was included if there was any signal >2,000 F.U. for either self or mutant peptide at either C1D1 or C3D1 time point. Colored sidebar denotes whether antibody signal was associated with mutant peptide, self peptide or both. (C) Absolute antibody signal (summed) categorized by signal specificity, treatment time point and response. Inlay depicts signal thresholds that were used to denote specificity classes. (D) ICB-associated boostability difference in antibody signal, which is derived by subtracting C1D1 antibody signal from C3D1 signal for respective specificity classes



Abstract 53 Figure 4 Complete responder displayed ICB-dependent boostability of both mutant and self-peptides, with particularly strong boost of IgG specific to native EPS8 peptides. (A) Relative antibody signal to self- versus mutant peptides at C1D1 and C3D1. Annotation shows ICB-dependent boost of antibody signal to self-EPS8 peptides. Peptides with greatest boost corresponding to S187-P107 residues are shown. (B) Primary protein structure of EPS8, with S187-P107 highlighted. The primary structure for EPS8 protein was input into PredictProtein (https://predictprotein.org) to query secondary structure and solvent accessibility (C), protein disorder and flexibility (D), and macromolecular binding site predictions (E). (F) Tertiary structure of EPS8 as predicted by Alphafold Protein Structure Database (https://alphafold.com), with S187-P107 highlighted in yellow. 3D structure was visualized and annotated using Chimera v1.16 software (https://www.cgl.ucsf.edu/chimera/)

Background Evidence supports the association between tumor-infiltrating lymphocytes with disease prognosis and response to immunotherapy. Here, we evaluated the prognostic value of an immunoscore reflecting CD3+ and CD8+ T cell density in patients with advanced malignancies treated with immune checkpoint inhibitors (ICIs).

Methods We utilized real-world clinical and transcriptomic data collected under the Total Cancer Care Protocol (NCT03977402) and Avatar® project within the Oncology Research Information Exchange Network (ORIEN) of 18 cancer centers to which all included subjects provided a written informed consent at their participating institutions. The immunoscore for each patient was calculated based on the estimated densities of tumor CD3+ and CD8+ T cells (Galon, 2020) utilizing CIBERSORTx and the LM22 gene signature matrix. Overall survival (OS) predictions were assessed using Harrell's concordance index (C-index). Kaplan-Meier (KM) curves and the log-rank test were used to assess the immunoscore ability to stratify risk groups.

Results Patients (n=522) with 4 cancer types including melanoma (n=125), renal cell carcinoma (n=149), non-small cell lung cancer (n=128) and head and neck cancer (n=120) treated with 6 immune checkpoint inhibitor (ICI) regimens were included in this analysis. ICI regimens were nivolumab (n=219), pembrolizumab (n=202), ipilimumab+nivolumab (n=69), ipilimumab (n=30), avelumab (n=1) and cemiplimab (n=1). Table 1 summarizes the overall C-index and associated 95% CIs and log-rank *p* values for the entire cohort resulting from estimated immunocore categorizations. KM analyses of the entire cohort are displayed in figure 1. We compared the performance of the immunoscore as a prognostic biomarker in the 4 cancer types, with significant results seen only in the melanoma and head and neck cancer cohorts (table 2, figure 2).

Conclusions The CD3+, CD8+ T Cell immunocore estimated from transcriptomic data represents a prognostic biomarker for estimating overall survival in patients with metastatic melanoma and head and neck cancer treated with ICIs in a real-world setting and can be used as a reference in prognostic biomarker development. Integration with other biomarker candidates that may guide the choice of ICI regimen (anti-PD1 monotherapy versus combinations) is underway.

Acknowledgements We are grateful to the participating patients and their family members as well as all research staff supporting the conduct of the Total Cancer Care protocol.

55 IDENTIFICATION OF THE O-GLYCAN EPITOPE TARGETED BY AN ANTI-HUMAN CARCINOMA MONOCLONAL ANTIBODY (MAB) NEO-201

[1]Massimo Fantini*, [1]Anjum Zaki, [1]Sharon Mavroukakis, [2]Christina Annunziata, [1]Philip Arlen, [1]Kwong Tsang, [1]Kwong Tsang. *[1]Precision Biologics, Inc., Bethesda, MD, USA*; *[2]National Cancer Institute, Bethesda, MD, USA*

Background NEO-201 is a humanized IgG1 mAb reactive against multiple human carcinomas, but not normal epithelial tissues. NEO-201 can mediate antitumor activity through multiple mechanisms such as antibody-dependent cellular cytotoxicity, complement dependent cytotoxicity, and blockade of the CEACAM5/CEACAM1 immune checkpoint inhibitory pathway. In addition to solid tumors, flow cytometry analysis has demonstrated that NEO-201 binds to 98.9% of $CD15^+$ granulocytes, human regulatory T cells as well as various human hematological neoplastic cell lines. However, NEO-201 does not bind to other immune subsets and to the majority of $CD4^+$ T cells. Furthermore, we have demonstrated that NEO-201 binds to mammalian expressed rhCEACAM6 but not bacterial expressed rhCEACAM6. These findings suggest that NEO-201 binds to glycans linked to specific proteins. Glycosylation is an important post-translation modification of protein and is affected by oncogenesis. Aberrant O-glycans may serve as potential targets to improve the monitoring and treatment of cancers. Based on this information, this study was designed to focus on the identification of the O-glycan binding epitope of NEO-201.

Methods An O-glycan array consisting of 94 O-glycans was used to identify the O-glycans targeted by NEO-201. O-glycan profiles were elucidated from human pancreatic cancer cell line (CFPAC-1), human hematological neoplastic cell lines (HL60, U937, K562) and human neutrophils. Different truncated C-terminus of CEACAM6 and CEACAM5 gene constructs were designed and the truncated CEACAM6 and CEACAM5 proteins were expressed in mammalian expression system to identify the NEO-201 binding region in CEACAM6 and CEACEAM5.

Results The O-glycan array analysis shows that NEO-201 interacts with O-glycans 01, 02 (Tn antigens), 06 (Core 1), 023 (Core 2), 026 (Core 3) and 039 (Core 4). The Core-1 binding interaction was the strongest of any observed. The O-glycan profiling studies demonstrated that CFPAC-1 and human neutrophils express mostly the Core 1 profile. HL-60 expresses mainly the extended Core 1 profile, U937 expresses mainly the extended Core 1 and Core 2 profiles and K562 expresses only the Core 2 profile. Flow cytometry analysis demonstrated that NEO-201 binds to CFPAC-1, human neutrophils, HL60 and U937 cells but not to K562. We also proved that in both CEACAM5 and CEACAM6 NEO-201 binds to regions containing threonine. GalNAc residue can be added onto threonine to form O-glycans.

Conclusions This study demonstrated that NEO-201 binds strongly to Core 1 and/or extended Core 1 O-glycans and confirms our finding that NEO-201 binds only mammalian expressed rhCEACAM6 express O-glycans.

56 HIGH PRETREATMENT DHEA LEVEL IS ASSOCIATED WITH SHORTER OVERALL SURVIVAL IN NEWLY DIAGNOSED METASTATIC NON-SMALL CELL LUNG CANCER PATIENTS RECEIVING IMMUNE CHECKPOINT INHIBITORS

Yumeng Zhang*, Lancia Darville, Stephanie Hogue, Julie Hallanger Johnson, Youngchul Kim, Jhanelle Gray, Lary Robinson. *Moffitt Cancer Center, Tampa, FL, USA*

Background Sex is an important factor in determining response to immune checkpoint inhibitors (ICI) in cancer patients.[1] Sex hormones can modulate the immune response in preclinical studies.[2] Our study aimed to determine if the pretreatment sex hormone level can predict outcomes in metastatic non-small cell lung cancer (mNSCLC) patients undergoing ICI therapies.

Methods This study included 61 patients with newly diagnosed mNSCLC who received ICI as part of the upfront therapy. Pretreatment plasma and fecal samples were collected before the first ICI infusion, and we measured sex hormone levels using ultra-high-performance liquid chromatography high-resolution mass spectrometry. Sex hormone levels were compared between the clinical benefit and no clinical benefit group. Patients were then divided into high DHEA and low DHEA groups based on the sex-specific median of the cohort. Overall survival (OS) and progression-free survival (PFS) were compared between high DHEA and low DHEA using Kaplan Meier's methods. A similar analysis was based on the 5-androstenediol level. We used the univariate and multivariate Cox proportional hazards (PH) model to measure hazard ratios (HRs) for PFS and OS.

Results Pretreatment plasma samples were collected from 61 patients, and 31 patients were female (table 1). Among them, 30 plasma samples had measurable DHEA levels, and 46 patients had measurable 5-androstenediol levels (table 2). Patients in the clinical benefit group had significantly higher plasma DHEA levels and 5-androstenediol levels than those in the no clinical benefit group (figure 1)

The high DHEA group had fewer patients with clinical benefits from ICI therapy (27% vs. 87% in the high DHEA and low DHEA groups, respectively) (figure 2). Patients with high DHEA also had shorter OS (mOS: 11.4mo vs. not reached for high DHEA and low DHEA group respectively, p=0.0001) and shorter PFS (mPFS: 4.1mo vs. 22mo for the high DHEA and low DHEA groups, respectively, p<0.0001). High 5-androstenediol also had fewer patients with clinical benefit (46% vs 72% for the high 5-androstenediol and low 5-androstenediol groups, respectively).

Univariate Cox PH analysis confirmed our observation. High DHEA level was associated with poor OS (HR-8.29, 95% CI:2.31–29.79) and PFS (HR=10.23, 95% CI:3.4–30.74). High 5-androstenediol level was associated with shorter PFS (HR=2.26, 95% CI: 1.07–4.75) (table 3).

Conclusions Pretreatment DHEA level and 5-androstenediol level were significantly lower in patients with clinical benefit from ICI. Our study supports the use of pretreatment DHEA as a promising predictive biomarker in patients with metastatic NSCLC receiving ICI therapies.

57 CD8+FOXP3+ CELLS REPRESENT EARLY, EFFECTOR T-CELLS AND PREDICT OUTCOMES IN PATIENTS WITH RESECTABLE NON-SMALL CELL LUNG CARCINOMA (NSCLC) RECEIVING NEOADJUVANT ANTI-PD-1-BASED THERAPY

[1]Emily Cohen, [2]Daphne Wang, [2]Elizabeth Engle, [2]Benjamin Green, [2]Justina Caushi, [2]Jiajia Zhang, [2]Joel Sunshine, [1]Sonali Uttam, [1]Michael Fotheringham, [3]Alexa Fiorante, [1]Nicole Espinosa, [3]Bhakti Pandey, [1]Teodora Popa, [2]Aleksandra Ogurtsova, [2]Sigfredo Soto-Diaz, [2]Jose Loyola, [2]Jeffrey Roskes, [2]Margaret Eminizer, [2]Dmitry Medvedev, [4]Jamie Chaft, [2]Julie Brahmer, [2]Joshua Reuss, [2]Patrick Forde, [2]Alexander Szalay, [2]Andrew Pardoll, [2]Kellie Smith, [2]Janis Taube, [1]Tricia Cottrell*. *[1]Queen's University, Kingston, Canada; [2]Johns Hopkins University, Baltimore, MD, USA; [3]University of Toronto, Toronto, Canada; [4]Memorial Sloan-Kettering Cancer Center, New York City, USA*

Background PD-1/PD-L1 pathway blockade has improved survival in patients with advanced NSCLC. Neoadjuvant (pre-operative) anti-PD-1 plus chemotherapy was also recently approved for patients with resectable stage II/III NSCLC. However, among patients receiving neoadjuvant anti-PD-1-based therapy, only 33–45% achieved a major pathologic response (MPR, ≤10% of residual viable tumor), highlighting the need for biomarkers predicting response.[1,3] Based upon recent results in advanced melanoma showing that CD8+FoxP3+ cells were strongly associated with therapeutic response,[4] we hypothesized that these cells would also be predictive of response in resectable NSCLC. Additionally, we performed single-cell RNA sequencing (ssRNAseq) to define the phenotype of CD8+FoxP3+ cells, given reports suggesting an immunosuppressive role.

Methods Pre-treatment formalin-fixed paraffin-embedded tumor specimens from the first-in-human clinical trial of neoadjuvant anti-PD-1 (nivolumab) +/- anti-CTLA-4 (ipilimumab) in NSCLC (NCT02259621) [1,3] were stained with a 6-marker multiplex immunofluorescence mIF panel (PD-1, PD-L1, CD8, CD163, FoxP3, and cytokeratin). Eight specimens were from patients demonstrating MPRs and 17 were from patients with non-MPRs. The densities of immune cell populations within the tumor microenvironment (TME) were analyzed using the AstroPath platform and the area under the receiver operating characteristic curve (AUC) for each possible cell phenotype was calculated for predicting MPR.[4] The association for cell phenotypes with event-free survival (EFS) and overall survival (OS) was determined using the log-rank test. scRNAseq analyses were performed on freshly collected CD3+ TIL from 15 of the same NSCLC patients. T-cells were clustered by UMAP and were queried for co-expression of CD8 and FoxP3.

Results The density of CD8+FoxP3+ T-cells was significantly elevated in patients achieving MPR (AUC=0.78, p=0.014, N=25). This association was strongest in the PD-1(+) (AUC=0.83, p=0.004) and PD-L1(-) (AUC=0.81, p=0.007) subsets. The AUCs for CD8+FoxP3+ cells were stronger than any other cell phenotype labeled by this 6-plex mIF assay. Patients whose TMEs contained CD8+FoxP3+ cells (n=18) when compared to those lacking this phenotype (n=7) had improved EFS and OS (41 vs. 8 months, p=0.041; and 26 vs. 8 months, p=0.074, respectively). scRNAseq studies of the CD8+FoxP3+ T-cell subset revealed a transcriptome compatible with a highly-activated, cytotoxic phenotype (*CCL5, CD8A, GZMB, NKG7, CTSW, CD8B*, *LINC02446*, *GZMK* all highly expressed).

Conclusions CD8+FoxP3+ T-cells in the NSCLC TME do not represent immunosuppressive cells, as has been previously reported, but instead represent highly-potent early, effector T-cells. When detected by mIF in pre-treatment NSCLC tumor specimens, these cells associate with major pathologic response and improved survival outcomes following neoadjuvant anti-PD-1.

58 EXAMINING ELEVATED TMB AND CLINICAL BENEFIT OF 1L IMMUNE CHECKPOINT INHIBITOR IN ADVANCED NSCLC

[1]David Carbone*, [2]Jacob Sands, [3]Gerald Li, [3]Alexa Schrock, [3]Ryon Graf, [3]Liangliang Zhang, [3]Karthikeyan Murugesan, [3]Jeffrey Ross, [3]Khaled Tolba, [3]Geoffrey Oxnard, [3]Richard Huang, [4]David Spigel. *[1]The Ohio State University, Columbus, OH, USA; [2]Dana-Farber Cancer Institute, Boston, MA, USA; [3]Foundation Medicine, Cambridge, MA, USA; [4]Sarah Cannon Research Institute, Nashville, TN, USA*

Background For patients with advanced non-small cell lung carcinoma (NSCLC), immune check point inhibitor (ICPI) and chemotherapy (chemo)-ICPI represent 2 distinct first-line standard-of-care regimens without clear and established biomarkers to inform the optimal choice for individual patients. Here, we examined the complementary roles of tumor mutational burden (TMB) and PD-L1 immunohistochemistry (IHC) to inform first-line therapy using a large real-world (rw) data set.

Methods The study included patients with NSCLC from the Flatiron Health (FH)-Foundation Medicine (FMI) de-identified clinico-genomic database (CGDB). All patients underwent genomic testing using FMI's tissue comprehensive genomic profiling (CGP) assay and PD-L1 IHC assay scored for tumor cell staining (TS).

Results Of 2,165 patients included in the analysis, 150 exhibited durable benefit from first line ICPI regimens (these patients were enriched for PD-L1 TS ≥50, non-squamous histology, and TMB ≥20 mutations/Megabase [muts/Mb]). Comparing low TMB (<10 muts/Mb), high TMB (10–19 muts/Mb), and very high TMB (≥20 muts/Mb) receiving ICPI alone, we observed a stepwise increase in median rwPFS (real world-progression free survival) (6.5, 7.5, 17.2 months) and rwOS (real world-overall survival) (10.1, 11.8, 26.9 months) as TMB increased. In the low PD-L1 (TS <50%) cohort, TMB <10 muts/Mb (HR:0.70 [0.54–0.92]) and 10–19 muts/Mb (HR:0.48 [0.32–0.72]) showed a more favorable rwPFS on chemoICPI when compared to ICPI alone while no significant additional increases in rwPFS is observed when adding chemo onto ICPI in the TMB ≥20 muts/Mb (HR:1.18 [0.56–2.48]) cohort.

Conclusions This study provides evidence that higher TMB cut-offs, such as 20 muts/Mb, can identify patients with prolonged benefit. TMB ≥20 muts/Mb may identify patients in whom an ICPI without chemo could be considered, even in the setting of lower PD-L1 levels. Prospective validation of these findings could increase access to chemo-sparing regimens for the first-line treatment of advanced NSCLC.

Ethics Approval Institutional Review Board approval of the study protocol was obtained prior to study conduct and included a waiver of informed consent.

59 DETERMAIO (IO SCORE) IS ASSOCIATED WITH EFFICACY OF ICI MONOTHERAPY IN ADVANCED NSCLC PATIENTS: A RETROSPECTIVE BC CANCER STUDY

[1]David Saltman*, [2]Nicole Croteau, [1]Heather Lockyer, [3]Rob Seitz, [3]Frank McMahon, [3]Jeremy Spille, [3]Andrea Dickey, [3]Jordan Jennings, [3]Matthew Varga, [3]Kimberly McGregor, [3]Tyler Nielsen, [3]David Hout, [3]Brock Schweitzer, [3]Douglas Ross, [4]David Gandara. *[1]BC Cancer, Victoria, Canada; [2]The University of British Columbia, Vancouver, Canada; [3]Oncocyte Corporation, Nashville, TN, USA; [4]University of California, Davis, Sacramento, CA, USA*

Background Immune checkpoint inhibitors (ICI), either as monotherapy or in combination with platinum-based chemotherapy, is standard of care in aNSCLC. However, most patients do not respond to ICI therapy, even when PD-L1≥50% (PD-L1 high). At BC Cancer, only those patients with PD-L1 high are eligible for first line (1L) ICI monotherapy, offering an opportunity to study potential new biomarkers in a relatively unbiased cohort of patients treated by ICI without chemotherapy. DetermaIO (IO score) is a 27-gene RT-qPCR immuno-oncology assay that classifies the tumor immune microenvironment (TIME) as IO+ or IO- and has been previously shown to associate with clinical benefit to ICI therapy in multiple tumor types.

Methods All available FFPE blocks were assembled for ECOG≤2 patients treated with at least one cycle of ICI monotherapy in the 1L (required to be PD-L1≥50%) or later line (2L+). DetermaIO was performed using a CAP/CLIA validated RT-qPCR assay for cases where sufficient tissue was available. IO score classification was analyzed for association with PFS and OS in patients treated in the 1L.

Results Considering the entire cohort of 147 patients, DetermaIO was significantly associated with OS (HR=0.68, 95%CI 0.47–0.89, p=0.042) and PFS (HR=0.62, 95%CI 0.43–0.88, p=0.0069). When examining the cohort by line of therapy, 78 (53%) were treated in 1L with ICI monotherapy and were all PD-L1 high. DetermaIO in this subgroup was significantly associated with PFS (HR=0.55, 95%CI 0.32–0.94, p=0.028) and demonstrated meaningful clinical benefit when measuring OS (HR=0.60, 95%CI 0.34–1.06, p=0.078). The objective response rate in the 1L subgroup was 53% for IO+ (2CR, 28PR out of 56 patients) and 23% for IO- (5PR out of 22 patients). The net reclassification rate of IO- amongst the PD-L1 high 1L group was 54.5% (12/22, p<0.01) for response.

Conclusions Retrospective analysis of outcomes of aNSCLC patients treated 1L with ICI monotherapy found that DetermaIO was significantly associated with PFS and trended towards significance for OS. First-line PD-L1 high patients who were IO- had significantly worse outcomes for PFS than PD-L1 high IO+ patients potentially informing the selection of combination therapy in PD-L1 high patients. These data confirm and expand previous studies of DetermaIO in advanced NSCLC and suggest IO score classification may offer significant incremental information for helping to make complex treatment decisions in aNSCLC.

Ethics Approval This study was approved by the Research Ethics Board (REB) of University of British Columbia (H20–02635). Individual consent for this retrospective analysis and the use of tumor samples for the IO score assay was required for live patients. Consent was waived by the REB for deceased patients.

60 ENABLEMENT OF SINGLE-CELL SPATIAL INSIGHT ADDRESSING T-CELL AND CAF INVOLVEMENT IN PANCREATIC INVASIVE DUCTAL ADENOCARCINOMA USING AI-BASED DEEP LEARNING IMAGE ANALYSIS

[1]Andrew Quong*, [1]Smriti Kala, [1]Nina Lane, [1]Michelle Macpherson, [2]Gourab Chatterjee, [2]Devan Fleury, [2]Kirsteen Maclean, [3]Dan Winkowski, [3]Fabian Schneider, [3]Jeppe Thagaard, [3]James Mansfield. [1]*Standard BioTools, South San Francisco, CA, USA*; [2]*Ultivue, Cambridge, MA, USA*; [3]*Visiopharm, Roanoke, VA, USA*

Background As the fourth most common cause of death in developed countries, pancreatic cancer remains a deadly disease due to difficulties hindering its early diagnosis, giving way to metastasis of the tumor, resulting in poor prognosis. Pancreatic invasive ductal adenocarcinoma (PDAC) is the most common of pancreatic neoplasms and treatment options are few, with poor overall survival. While it is clear that immunotherapy has revolutionized the treatment of solid tumors by leading to cures where none existed a decade ago, optimally selecting patients as candidates for immunotherapy-chemotherapy combinations remains a critical challenge.

The complexities of the tumor microenvironment (TME) have been implicated in the failure of treatments options. The TME of PDAC is especially rich with multiple interactions between pancreatic epithelial/cancer cells, stromal cells, immune cells, and the extracellular matrix (ECM). PDACs are characterized by a complex ECM of desmoplastic reaction consisting of an extensive and dense fibrotic stroma that surrounds and infiltrates clusters of malignant epithelial cells, together with the loss of basement membrane integrity and an abnormal vasculature. As critical players in the development of PDACs, cancer-associated fibroblasts (CAFs) are the predominant cell type within the tumor stroma; they exhibit considerable heterogeneity that can have both tumor-promoting and tumor-repressing functions. Given that these effects are potentially affected by the tumor-stromal crosstalk and the spatial context of other cell types, a deeper understanding with respect to the different cell types present and their relationship to each other will help uncover the much-needed therapeutic approaches for this disease.

Methods Herein, we demonstrate a spatial phenotyping workflow combining complementary methods that can unravel the complexity of the PDAC TME, in particular the important spatial relationships of different T cells subsets and CAFs. We highlight the utility, robustness, and ability to derive meaningful biological and actionable insights in PDAC samples using the InSituPlex® (ISP), Imaging Mass Cytometry® (IMC) spatial technologies coupled to Oncotopix Discovery® A.I.-based multiplex image analysis.

Results This workflow utilizes a 4-plex whole-slide ISP assay with image analysis to define regions of interest for a comprehensive 40-plex IMC imaging and analysis. Both assays were analyzed using a workflow that includes tissue region and cellular segmentations followed by cellular phenotyping and spatial analyses.

Conclusions Our novel tissue imaging workflow affords the comprehensive and multiparametric *in situ* exploration of the TME at the single cell level, but importantly alludes to a better understanding of PDAC tumor immunology and potential optimization of immunotherapy protocols for this disease.

61 COMBINATION OF NOVEL BIOMARKERS OF COLLAGEN FIBER AND IMMUNE ARCHITECTURE ARE ASSOCIATED WITH CLINICALLY RELEVANT OUTCOMES IN GYNECOLOGICAL CANCERS TREATED WITH IMMUNOTHERAPY

[1]Arpit Aggarwal*, [2]Sepideh Azarianpour-Esfahani, [2]Haojia Li, [2]Pingfu Fu, [2]Mojgan Mokhtari, [2]Stefanie Avril, [3]Haider Mahdi, [4]Anant Madabhushi. [1]*Georgia Tech and Emory University, Atlanta, GA, USA*; [2]*Case Western Reserve University, Cleveland, OH, USA*; [3]*University of Pittsburgh, Pittsburgh, PA, USA*; [4]*Emory University, Atlanta, GA, USA*

Background Qualitative studies suggest collagen fiber organization (CFO) is associated with gynecological cancer (GC) prognosis.[1, 2] Previous studies have shown the prognostic role of quantitative characterization of architecture of tumor-infiltrating-lymphocytes and their interplay with cancer cells in GC prognosis, known as ArcTIL.[3] However, combination of CFO and immune architecture in GC prognosis is not yet studied. In this work, we use computational and machine learning tools to develop quantitative biomarkers combining collagen fiber orientation disorder (CFOD) and ArcTIL features from H&E slides and evaluate its association with progression-free-survival (PFS) in women undergoing surgical resection followed by immunotherapy.

Methods Whole-Slide-Images (WSIs) of H&E slides from surgically-resected ovarian cancer treated with adjuvant chemotherapy were obtained from TCGA used for training (St, n=95) and surgically-resected GC treated with adjuvant immunotherapy were obtained from Cleveland Clinic Foundation used for validation (Sv, n=48). ArcTIL features were derived from cell cluster graphs of nuclei within epithelial nests, surrounding stroma, and invasive tumor front compartments of WSI. The ArcTIL model previously developed by our group,[3] was used for this study and prognostic subset having 7 features was selected. For calculating CFOD, WSI was partitioned into array of tumor neighborhoods and then entropy of fiber orientations in stromal regions was quantified within each neighborhood using derivative-of-Gaussian model. The first-order-statistics of CFOD feature maps were extracted for 9 different neighborhood sizes, yielding 27 features. Using these features, three Cox Regression models (CRM+LASSO) were trained that assigned risk of recurrence to each patient in St. The CRM+LASSO model trained using CFOD features selected 9 features, model trained using ArcTIL features selected 4 features and model trained using CFOD+ArcTIL features selected 6 features (4 ArcTIL and 2 CFOD features) for predicting risk scores in St and Sv. For each model, the mean risk score obtained in St was used to stratify patients as low, high-risk in Sv.

Results In Sv (figure 1, table 1), univariate analysis yielded Hazard-Ratio= 2.74, p-value= 0.03 for high-risk CFOD+ArcTIL. Multivariable analysis controlling for prognostic clinical variables, FIGO Stage (I, II, III, IV) and Tumor Grade (1, 2, 3), showed CFOD+ArcTIL (Hazard-Ratio= 2.84, p-value= 0.02) was independently associated with PFS.

Conclusions Our results found that CFO is more ordered in high-risk patients (figure 2) and evenly distributed, smaller clusters in ArcTIL-defined low-risk patients. Independent multi-site validation should allow for deployment of CFOD +ArcTIL as a prognostic decision support tool for management of GC patients treated with immunotherapy.

62 RESISTANCE TO FRAMESHIFT NEOANTIGEN-SPECIFIC T CELL SURVEILLANCE IN MICROSATELLITE UNSTABLE CANCERS

Matthew Brown*, Leandra Velazquez, Mona Saleh, Alexandros Polydorides, Aimee Lucas, Cansu Cimen Bozkus, Robert Samstein, Nina Bhardwaj. *Icahn School of Medicine at Mount Sinai, New York, NY, USA*

Background Patients with Lynch syndrome (LS), characterized by germline inactivation of one allele of the mismatch repair (MMR) genes, have an increased risk (up to 80%) of developing cancers with high microsatellite instability (MSI-H).[1] MSI-H tumors account for 15–30% of all colon, endometrial, and gastric cancers.[2] Due to unrepaired frameshift (fs) mutations, these cancers possess a high tumor mutational burden which has enabled microsatellite instability to emerge as a biomarker of immune checkpoint blockade (ICB) response. However, there is still a significant population of MSI-H patients unresponsive to ICB treatment.[3,4] Therefore, novel strategies to prevent LS-associated tumor development and predict ICB resistance are urgently needed. T cell surveillance in LS is evidenced by (i) elevated fs-loads in MMR-deficient (MMRd) nonneoplastic tissue[5] and (ii) a correlation between increased T cell infiltration into normal mucosa of LS patients and delayed onset of colorectal cancer.[6] We previously characterized unique immunogenic fs-peptides shared in MSI-H cancers[7] and identified T cell receptors (TCRs) specific to MSI-H-associated fs-peptides. Utilizing TCR sequencing, we demonstrated that fs-specific T cells were present in the primary tumor, draining lymph nodes, and metastases of an LS patient. However, tumor growth in the presence of these fs-specific T cell clones suggests suboptimal T cell surveillance.

Methods Our hypothesis is that MMRd precancerous and malignant lesions expressing fs-neoantigens escape immune surveillance due to suppression of T cell infiltration and activity. We investigated whether this is the result of immunosuppressive activity from innate immune cell populations and/or T cell dysfunction. Using normal, precancerous, and tumor tissue collected from our cohort of LS and sporadic MSI-H cancer patients we are leveraging whole-exome sequencing, spatial transcriptomics, and multiplexed immunohistochemistry.

Results This has allowed us to begin to define the spatiotemporal landscape of fs-neoantigen expression, innate immune cell localization, and T cell dysfunction in the course of MSI-H tumor development to explain how MMRd lesions escape T cell surveillance. Additionally, our analysis of MSI-H tumors from The Cancer Genome Atlas (TCGA) with high fs-neoantigen loads but low cytotoxic T lymphocyte (CTL) signatures (assessing granzyme and perforin expression) have revealed lower immune-stimulatory macrophage and higher activated mast cell-related gene signatures. We have also observed high frequencies of exhausted (PD-1+TIM-3+) tumor infiltrating lymphocytes in advanced MSI-H tumors assessed by flow cytometry.

Conclusions This work supports the development of fs-neoantigen-based vaccination/immunomodulation strategies to prevent LS-associated tumor development and identifies potential ICB resistance biomarkers for advanced MSI-H tumors.

63 EPISCAN: A SYNTHETIC BIOLOGY PLATFORM FOR TARGETED IMMUNOPEPTIDOMICS

[1]Peter Bruno*, [2]Richard Timms, [3]Nouran Abdelfattah, [4]Yumei Leng, [4]Felipe Lelis, [4]Duane Wesemann, [5]Xu Yu, [1]Stephen Elledge. *[1]Department of Genetics, Harvard Medical School and Division of Genetics, Brigham and Women's Hospital, Boston, MA, USA, and Howard Hughes Medical Institute, Chevy Chase, MD, USA; [2]University of Cambridge, Cambridge, UK; [3]Harvard Medical School, Boston, MA, USA; [4]Brigham and Women's Hospital, Boston, MA, USA; [5]Ragon Institute of MGH, MIT and Harvard, Boston, MA, USA*

Background Identification of $CD8^+$ T-cell epitopes is critical for the development of immunotherapeutics. Existing methods for empirical determination of peptide binding are time-intensive, expensive and highly specialized. Mass spectrometry, the predominant high-throughput approach for MHC-I ligand discovery, is unable to easily interrogate defined subsets of proteins. Thus, we sought a high-throughput, accessible method for the identification of MHC-I ligands derived from user chosen, synthetically encoded sources of peptides. Here we present EpiScan, a programmable genetic strategy to identify MHC-I ligands amongst predetermined starting pools comprising >100,000 peptides.

Methods To accomplish this, we used CRISPR-Cas9 to create 'EpiScan cells' that lack both endogenous MHC-I and short peptides in ER. Then, separate lentiviral introduction of an MHC-I allele and a single exogenous short peptide into the ER restores cell surface MHC-I levels according to the affinity of the peptide to the chosen MHC-I allele. We exploited the programmability of EpiScan to screen 12 different MHC-I alleles with large peptide libraries including the entire SARS-CoV-2 proteome.

Results These screens uncovered an unappreciated role for cysteine that increases the number of predicted ligands by 12–21%, revealed affinity hierarchies by analysis of biased-anchor peptide libraries, and identified conserved, high-affinity, T-cell reactive SARS-CoV-2 epitopes. Using these data, we generated and iteratively refined peptide binding predictions to create EpiScan Predictor, or ESP. ESP performed comparably to other state-of-the-art MHC-I peptide binding prediction algorithms while not suffering from underrepresentation of cysteine-containing peptides. Overall, the new specificities identified by EpiScan and ESP increase the number of peptides predicted to bind MHCs by over 15% on average. This significantly expands the potential human epitope landscape, facilitating epitope discovery efforts and the design of immunotherapeutics.

Conclusions Our work significantly expands the potential human epitope landscape, facilitating epitope discovery efforts and the design of immunotherapeutics.

64 SPATIAL WHOLE TRANSCRIPTOME PROFILING OF THE TUMOR MICROENVIRONMENT IN ARCHIVED AND FRESHLY-MOUNTED FFPE TISSUES

Jun Chiang*, Augusto Tentori, Hardeep Singh, Anuj Patel, Han Lu, Alex Hermes. *xgenomics, Pleasanton, CA, USA*

Background The tumor microenvironment (TME) is composed of highly heterogeneous cell types that dynamically interact with each other. The constant interaction between a tumor and its microenvironment plays a critical role in how the cancer develops, progresses, and responds to therapies. Traditional tissue-based studies of the TME can be limited to a small number of target analytes, which can limit biological insights. In this work, we used the Visium CytAssist instrument and Visium Spatial Solutions from 10x Genomics which enable whole transcriptome gene expression and immunofluorescence-based protein expression profiling from archival and freshly preserved FFPE cancer tissues. Our data provided a more comprehensive understanding of cellular behavior in and around tumors yielding new insights into disease progression and therapeutic response.

Methods Tumor FFPE tissues (breast, liver, lung, and ovarian cancer) were spatially profiled using the Visium CytAssist instrument and Visium Spatial Solutions. Tissues were mounted on glass slides, H&E or IF stained, and imaged to select the target region for whole transcriptome analysis. Following decrosslinking and probe hybridization, the samples were prepared for probe transfer to spatially barcoded Visium slides with 6.5 x 6.5 or 11 x 11 (mm x mm) capture areas. The captured probes were used in a downstream genomics workflow to generate sequencing-ready libraries.

Results We applied this method to measure gene expression within the TME of archived human lung and ovarian cancer FFPE samples. Normalized gene expression levels superimposed on the H&E images demonstrated similar clustering patterns delineating the tumor and stromal region. In the lung cancer sample, canonical gene makers, *TP63 and KRT5*, confirmed the general phenotype of non-small cell carcinoma. In addition, other keratin and mucin genes revealed intra-tumor heterogeneity. In the same lung cancer sample, immune response genes were expressed in the stromal region, adjacent to the tumor bed, identifying the presence of immune cell subsets such as activated T, B, and regulatory dendritic cells. Freshly prepared breast and liver cancer samples were screened with fluorescently labeled antibodies in addition to transcriptomic profiling. In particular, PCNA and Vimentin showed the precision and accuracy of probe transfer using the Visium for FFPE spatial solution.

Conclusions The data highlights that Visium CytAssist can retrieve transcriptome information from archived and freshly prepared FFPE sections in a spatial context. Visium CytAssist provides a more comprehensive understanding of clinical tissue samples and provides novel insights into architectural and cellular heterogeneity across multiple diseases.

66 SURFACE NANOTOPOGRAPHY AND CELL SHAPE MODULATE TUMOR CELL SUSCEPTIBILITY TO NK CELL CYTOTOXICITY

[1]Jeehun Park*, [1]Junsang Doh, [2]Yongbum Cho. *[1]Seoul National University, Seoul, Korea, Republic of; [2]Pohang University of Science and Egineer, Pohang, Kosovo, Republic of*

Background Natural killer (NK) cells are innate cytotoxic lymphocytes exerting cytotoxicity against virally infected cells and tumor cells.[1] NK cell cytotoxicity is primarily determined by biochemical signals received by ligands expressed on target cell surfaces. In addition to the biochemical signals, NK cell cytotoxicity could be regulated by biophysical environments of tumor cells such as nanoscale surface topography typically existing on extracellular matrixes (ECMs) or cell morphology determined by ECM or cell density. Matrixes.[2, 3] Engineered surfaces, including soft substrates with various rigidities, nanostructured surfaces, and micropatterned surfaces, may serve as alternative tools to further dissecting the roles of biophysical cues in tumor microenvironment in NK cell cytotoxicity.

Methods To test this possibility, we used engineered surfaces that allowed control of cell shape and surface nanotopography to investigate how NK cell cytotoxicity is regulated by tumor cell shape and surface nanotopography.[4, 5] Tumor cells were plated on flat vs. nanogrooved surfaces, or micropatterned into circular vs. elliptical geometries, and the effects of surface topography and tumor cell morphology on NK cell cytotoxicity were investigated. Cell morphology and cytotoxicity of NK cells were analyzed by live fluorescence imaging. For the filamentous actin intensity measurement, patterned cells were fixed and permeabilized and stained with fluorescence labeled phalloidin.

Results NK cells exhibited significantly higher cytotoxicity against tumor cells on nanogrooved surfaces than those on flat surfaces. However, it was not clear whether nanotopography underlying tumor cells itself was a major factor for enhanced NK cell cytotoxicity or not, as cells cultured on nanogrooved surfaces typically exhibit elongated morphologies. To directly test whether elongated morphology of tumor cells is sufficient for enhanced NK cell cytotoxicity, we manipulated tumor cell shape to circular and elliptical. NK cell exhibited significantly higher cytotoxicity against tumor cells on tumor cells in elliptical patterns than tumor cells in circular patterns. Both nanogrooved surfaces and elongated morphology of tumor cells induced stress fiber formation, which in turn increase cytoskeletal tension. Thus, we checked correlation between stress fiber formation and cytotoxicity, and found positive correlation between them.

Conclusions These results indicate that tumor cells in elliptical micropatterns or on nanogrooved surfaces are more susceptible for NK cell-mediated cytotoxicity due to increased cellular tension by stress fiber formation. These results suggest that biophysical microenvironments surround tumor cells influence NK cell cytotoxicity against tumor cells by cytoskeletal tension regulation.

GERMLINE MUTATIONS IN DNA DAMAGE RESPONSE AND REPAIR GENES ARE ASSOCIATED WITH INCREASED CLINICAL BENEFIT FROM IMMUNE CHECKPOINT INHIBITORS

Michael Dennis*, Sophia Bylsma, Lisa Madlensky, Sandip Patel. *University of California San Diego, La Jolla, CA, USA*

Background Impaired DNA damage response (DDR) can impact the efficacy of immune checkpoint inhibitors (ICIs). Defects in the DDR pathway can also lead to heightened immune activation. The purpose of this study was to determine if pathogenic germline mutations in DDR pathways would increase the efficacy or toxicity of ICIs.

Methods We performed a single-institution retrospective analysis of all patients for whom germline DNA testing was available and who were treated with ICIs between January 1st, 2014 and September 1st, 2022. Patients without measurable disease were excluded. The best response to therapy and the incidence of immune-related adverse events (irAEs) were compared between patients that had pathogenic germline mutations in DDR genes (DDR+) and those who did not (DDR-). Clinical benefit (CB) was defined as stable disease, partial response, or complete response as determined by the treating physician. IrAEs were graded according to the Common Terminology Criteria for Adverse Events v5.0.

Results We identified 152 patients that met the inclusion criteria. Forty-two patients were DDR+, of which 25 had mutations in homologous recombination genes (HRD), and 11 had mutations in mismatch repair genes (dMMR). DDR+ patients were more likely to derive CB than DDR- patients in univariate and multivariate analysis (table 1) (81% vs 53%, unadjusted odds ratio [OR] = 3.81; 95% CI, 1.59 to 9.11; adjusted OR 3.58; 95% CI, 1.29 to 9.93). Adjustments were made for the line of therapy, tumor mutational burden, and history of tyrosine kinase inhibitor (all associated with CB in univariate analysis, $p \leq 0.05$). Similar results were observed in HRD patients (76% HRD vs 53% DDR-, adjusted OR = 3.16; 95% CI, 1.00 to 9.94). dMMR patients were more likely to receive CB from ICIs in the univariate analysis (91% dMMR vs 53% DDR-, OR = 8.96; 95% CI, 1.10 to 72.89), but this did not reach statistical significance in multivariate analysis (OR = 4.99; 95% CI, 0.49 to 51.17). When dMMR patients were removed from the DDR+ group (DDR+MMR-), there remained a significant difference in CB from ICIs (77% DDR+MMR- vs 53% DDR-, adjusted OR 3.35, 95% CI 1.13 to 9.95). There were no significant differences in the rate of irAEs for DDR+ patients regardless of the subgroup.

Conclusions Patients with germline pathogenic DDR mutations are more likely to derive CB from ICIs without added immune toxicity. The fact that MMR intact germline DDR mutations are associated with significant CB is a novel finding.

Abstract 67 Table 1 Association of germline pathogenic mutations and clinical benefit

			Unadjusted		Adjusted[a]	
	No CB	CB[b]	OR (95% CI)	p-value	OR (95% CI)	p-value
DDR- (n=91)	43 (47)	48 (53)	-	-	-	-
DDR+ (n=42)	8 (19)	34 (81)	3.81 (1.59-9.11)	<0.01	3.58 (1.29-9.93)	0.01
HRD (n=25)	6 (24)	19 (76)	2.84 (1.04-7.76)	0.04	3.16 (1.00-9.94)	0.049
dMMR (n=11)	1 (9)	10 (91)	8.96 (1.10-72.89)	0.04	4.99 (0.49-51.17)	0.18
DDR+MMR- (n=31)	7 (23)	24 (77)	3.07 (1.20-7.84)	0.02	3.35 (1.13-9.95)	0.03

[a]adjusted for metastatic disease, line of therapy, TMB status, and history of tyrosine kinase inhibitor
[b]Clinical benefit data was not available for 19 patients
CB, clinical benefit; OR, odds ratio; CI, confidence interval; DDR, DNA damage response; HRD, homologous recombination deficient; dMMR, mismatch repair deficient; (+) indicates the presence of a pathogenic mutation

69 A HIGH CONTENT SCREENING PLATFORM FOR TESTING IMMUNOTHERAPIES IN PATIENT-DERIVED ORGANOIDS

Gera Goverse*, Saskia de Man, Tomas Veenendaal, Nataliia Beztsinna, Daniel Okkes, Ashgard Weterings, Kuan Yan, Leo Price. *Crown Bioscience, Leiden, Netherlands*

Background Patient-derived organoids (PDOs) are advanced 3D cell culture models, which have high predictive value of patient drug responses in the clinic. In this study a high throughput screening platform is presented, which allows testing of cancer immunotherapies in co-cultures of human organoids with immune cells. Incorporating diverse cellular players from the immune system and stromal compartment, such as cancer associated fibroblasts (CAFs), allows the reconstitution of complex cellular interactions that occur in the tumor micro-environment (TME). Our proprietary, automated high content imaging (HCI)-based analysis provides visualization and quantification of immune cell-mediated effects in this complex physiological relevant 3D screening platform. Functional readouts such as migration of immune cells towards organoids, infiltration into the organoids and their killing are obtained, allowing for a better understanding of the immune-modulatory profile of immuno-oncology drugs.

Methods PDOs, obtained from HUB Organoid Technology, generated from different cancer indications among colon and ovarian were cultured in protein hydrogel. Partially HLA-matched immune cells isolated from different healthy PBMC donors were labelled and added (naïve or activated) to the 3D culture after incorporation of different suppressive populations, including pre-labelled CAFs and myeloid cells. High content microscopy combined with morphometric image analysis software was used to quantify the capacity of immune cells to infiltrate and subsequently kill the organoids.

Results Differences in the sensitivity and kinetics of organoid models from the same indication and from different indications towards the killing by immune cells was profiled. Pre-activation or reactivation of immune cells within the 3D co-cultures increased the sensitivity towards killing of the organoids, while incorporation of suppressive cellular players within the TME could reduce immune cell mediated killing effects. Moreover, testing of different immune cell donors, although showing slight donor-to-donor variability, indicated an overall consistency of organoid sensitivity towards immune cell-mediated killing effects. Additionally, quantitative readouts strictly dependent on a 3D environment such as immune cell migration and infiltration could be measured and analyzed upon treatment with different immune modulators such as T cell engagers.

Conclusions HCI of complex *in vitro* 3D co-cultured organoids enables rapid, reproducible, physiologically relevant and spatial readouts for testing various cancer immunotherapies within different cancer indications. Visualization and quantification of these complex cellular interactions within the TME via our high content screening platform is a powerful tool for immunotherapeutic drug development in patient-relevant models to select the most promising candidates, better understand their mechanism of action, and ultimately stratify patient cohorts for clinical success.

70 **WHOLE GENOME CRISPR-CAS9 SCREENS IN A CANCER CELL LINE PANEL CO-CULTURED WITH ANTIGEN-SPECIFIC CYTOTOXIC CD8 T CELLS ARE A POWERFUL ENGINE FOR IMMUNO-ONCOLOGY DRUG TARGET DISCOVERY**

Serge Gueroussov*, Chengyin Min, Alan Huang, Samuel Meier, Jessica Finkler, Lei Ji, Ashley Choi, Tenzing Khendu, Disha Subramanya, Shangtao Liu, Binzhang Shen, Teng Teng, Xuewen Pan, Yi Yu. *Tango Therapeutics, Cambridge, MA, USA*

Background Cytotoxic T lymphocytes (CTLs) are a key driver of the anti-tumor immune response. Understanding the molecular mechanisms mediating this process can reveal therapeutic targets whose pharmacological inhibition can increase responses to immunotherapy. In recent years, forward genetic screens with CRISPR-Cas9 have been successfully applied to study the interaction between tumor cells and CTLs in vitro. Here, we extend this approach to a broad panel of human cancer cell lines and define methods for prioritization and validation of immuno-oncology therapeutic targets.

Methods A panel of seven HLA-A*02 cancer cell lines were prioritized to span multiple cancer lineages. Tumor cells were infected with a whole-genome CRISPR-Cas9 library and co-cultured with primary human CD8+ T cells expressing the NYESO1 HLA-A*02-restricted T cell receptor. Next-generation sequencing and statistical analysis were used to define the top genes that affected tumor cell killing by CTLs. We validated the top hits from the screen *in vitro* and developed an adoptive cell transfer model to validate the sensitizing effects *in vivo*.

Results Comparison of screen hits uncovered both known and novel pathways that sensitize tumor cell lines to CTL killing, including surface checkpoint molecules, epigenetic regulators, genes that control cytokine response, autophagy, post-transcriptional regulation, and cell surface glycosylation. We prioritized genes for validation based on effect size, druggability, and TCGA correlation between target expression and an immune-deficient tumor microenvironment. We showcase our approach using the known immune regulator, PTPN2. PTPN2 knockout in tumor cells sensitized them to CTL-mediated killing in co-culture assay *in vitro* and adoptive cell transfer model *in vivo*.

Conclusions Our cancer cell and T cell co-culture CRISPR screening platform revealed multiple known as well as novel genes to comprehensively characterize the mechanisms regulating tumor cell killing by CTLs, providing a rich resource of therapeutic targets to advance into drug discovery.

HIGH SCORING PRECISION DEMONSTRATED IN MULTIPLE TUMOR INDICATIONS STAINED WITH PD-L1 IHC 22C3 PHARMDX USED IN CONJUNCTION WITH COMBINED POSITIVE SCORE

Julia Hand*, Francisco Ponce, Stephanie Hund, Lindsay Peltz, Micki Adams, Deanna Moquin, Megan Kalpakoff, Siena Tabuena-Frolli, Jay Milo, Angeliki Apostolaki, Karina Kulangara. *Agilent Technologies, Carpinteria, CA, USA*

Background PD-L1 22C3 IHC pharmDx (SK006) is a qualitative immunohistochemical (IHC) assay using anti-PD-L1, Clone 22C3 to detect PD-L1 in formalin-fixed, paraffin-embedded (FFPE) tumor tissues using the Autostainer Link 48. PD-L1 expression is determined by Combined Positive Score (CPS), which is the number of PD-L1 staining cells (tumor cells, lymphocytes, macrophages) divided by the total number of viable tumor cells, multiplied by 100.[1] SK006 has been analytically validated using CPS across multiple tumor indications and diagnostic cutoffs and is used as an aid in identifying patients for treatment with KEYTRUDA®. A previous publication presents the analytical performance of the following indications: gastric or gastroesophageal junction (GC/GEJ) adenocarcinoma (CPS $\geq$ 1), cervical cancer (CPS $\geq$ 1), head and neck squamous cell carcinoma (HNSCC) (CPS $\geq$ 1), esophageal cancer (EC/ESCC) (CPS $\geq$ 10), and triple-negative breast cancer (TNBC) (CPS $\geq$ 10).[2] This study evaluated the analytical performance of the SK006 assay for an additional five individual tumor indications (ovarian carcinoma (OC), prostate cancer (PC), colorectal carcinoma (CRC), renal cell carcinoma (RCC), biliary tract adeno cancer (BTAC)) and a group of 11 rare tumor indications in a basket trial (BT).[3] Two CPS cutoffs were evaluated: CPS $\geq$ 1 (OC, PC, CRC, RCC, BTAC and BT [3]) and CPS $\geq$ 10 (OC, CRC and BTAC).

Methods Combined precision measured inter-instrument, -operator, -day and -lot variation. Intra-run measured repeatability and Inter/Intra-Observer measured scoring reproducibility. Negative percent agreement (NPA), positive percent agreement (PPA), and overall agreement (OA) with two-sided 95% bootstrap confidence intervals (CIs) were used for data analysis, based on the PD-L1 binary status at the evaluated cutoffs. Each tumor indication and cutoff pair was analyzed individually for Combined Precision, and Intra-Run and Inter/Intra Observer reproducibility. Meta-analysis was also performed on pooled data from all indications per study and cutoff.

Results Analyses for each indication/cutoff pair showed NPA, PPA, OA point estimates (PE) of $\geq$89.6% and CI lower bounds (CILB) of $\geq$81.8%. Meta-analyses for all indications and cutoffs showed NPA, PPA, OA PE of $\geq$92.5% and CILB of $\geq$89.3%. Table 1 summarizes the PD-L1 binary status results for all indications and the pooled meta-analysis.

Conclusions PD-L1 IHC 22C3 pharmDx used in conjunction with CPS provides high precision for evaluating PD-L1 expression across multiple tumor indications and cutoffs under standard, day-to-day laboratory testing conditions.

Abstract 71 Table 1 PD-L1 binary status results for all indications and results of meta-analysis pooled data

Table 1: PD-L1 binary status results for all indications and results of meta-analysis pooled data.

Cutoff	Study	Indication	NPA[1]	PPA[1]	OA[1]

INTRAVITAL MULTIPHOTON AUTOFLUORESCENCE IMAGING IS SENSITIVE TO CHANGES IN CD8 T CELL AND TUMOR CELL METABOLISM DURING IMMUNOTHERAPY IN A MURINE MELANOMA MODEL

[1,2]Alexa Heaton*, [2]Anna Hoefges, [1]Peter Rehani, [2]Nathaniel Burkard, [2]Arika Feils, [2]Dan Spiegelman, [2]Noah Tsarovsky, [2]Alina Hampton, [2]Amy Erbe, [2]Alexander Rakhmilevich, [2]Paul Sondel, [1]Melissa Skala. [1]*Morgridge Institute for Research and University of Wisconsin, Madison, WI, USA*; [2]*University of Wisconsin, Madison, WI, USA*

Background Intravital multiphoton autofluorescence microscopy provides *in vivo*, label free, single cell imaging of metabolic changes. These metabolic changes are quantified via the metabolic coenzymes NAD(P)H and FAD which are autofluorescent molecules endogenous to all cells. Metabolic reprogramming of tumor and immune cells is closely associated with cancer progression and cell phenotype.[1–3] We aim to study metabolic changes during administration of an effective, triple-combination immunotherapy within murine melanoma tumors.[4] This therapy includes external beam radiation, intratumoral hu14.18-IL2 immunocytokine (anti-GD2 mAb fused to IL2), and intraperitoneal anti-CTLA-4 leading to *in situ* vaccination and cure of GD2 + murine tumors.[5] Previous work has shown that a T cell response is critical to the efficacy of this therapy[4–5], so we created an mCherry-labeled T cell mouse model to study this response. Here, intravital multiphoton metabolic imaging was used to image concurrent tumor and CD8+ T cell metabolic trends during administration of immunotherapy.

Methods We implanted syngeneic B78 (GD2+) melanoma cells into the flanks of mCherry-labeled CD8+ T cell reporter mice (C57Bl/6 background) to induce tumors. Under anesthesia, skin flap surgery was performed and tumors were imaged at several time points during therapy. Multiphoton imaging was performed to collect NAD(P)H, FAD, mCherry, and collagen signal through a 40X objective (figure 1A). Fluorescence lifetime data was collected using time correlated single photon counting electronics. Tissues were harvested and analyzed via flow cytometry and multiplex immunofluorescence to corroborate intravital imaging findings and characterize the immune infiltrate.

Results Here we demonstrate that our intravital imaging is sensitive to metabolic changes in both B78 melanoma and CD8 T cells from immunotherapy treated tumors versus control tumors. These metabolic differences include changes in protein binding and redox balance (figure 1B) within treated tumors. We also show remodeling of collagen (figure 1C), a major component of the extracellular matrix, during immunotherapy that may be explained by an observed decrease in macrophages. Flow cytometry and multiplex immunofluorescence illustrate changes in the immune infiltrate composition, activation, and cytotoxicity during therapy (figure 1D).

Conclusions These results show that intravital metabolic imaging enables single cell quantification of metabolic changes in tumor and immune cells during therapy. Combined with other traditional assays, we can elucidate key immune cell populations and the crucial timepoints during therapy where changes are occurring. With continued efforts, this imaging platform may be leveraged to develop new combinations of immunotherapies.

Abstract 72 Figure 1 *In vivo* multiphoton imaging and flow cytometry of tumor and CD8 T cell populations during immunotherapy. A) Experimental workflow showing B78 flank tumor implantation and growth, administration of triple therapy, and representative *in vivo*

fluorescence intensity image of B78 melanoma tumor growing in a mCherry reporter mouse. Image shows mCherry-expressing CD8 T cells (red) infiltrating tumor tissue as well as autofluorescent metabolic coenzymes NAD(P)H (blue) and FAD (green) expressed by the tumor and T cells. Scale bar 25 μm. B) *In vivo* single cell B78 tumor fluorescence lifetime data shows increased NAD(P)H protein binding in treated CD8 T cells with decreased protein binding in treated tumor cells (left panel). Corresponding *in vivo* optical redox ratio fluorescence intensity data shows redox balance within the tumor microenvironment (right panel). Both CD8 T cells and tumor cells from treated tumors exhibited a decreased optical redox ratio, compared to control tumors, indicating they are more oxidized (n = 2 mice, B78 tumor cells = 1039, CD8 T cells = 132, mean ± SD, Mann-Whitney U Test). C) *In vivo* second harmonic generation images of B78 tumors show collagen morphology and alignment without labels. Collagen fibers from control tumors show little change from Day 0 pretreatment to Day 12 of PBS treatment while collagen fibers from treated tumors show remodeling of collagen towards a healthier tissue phenotype by Day 12 of immunotherapy treatment (healthy tissue collagen is typically very tortuous while tumor tissue collagen is typically very aligned). D) Flow cytometry data of B78 tumors shows differences in immune infiltrate populations in immunotherapy treated mice at Day 12 versus PBS control mice at Day 12 (n = 4 mice per condition, average%CD45+ cells). Immunotherapy treated mice show an increase in CD8 T cells and NKTs while macrophage numbers decrease.

73 DELTA-RADIOMICS PREDICTS RESPONSE AND OVERALL SURVIVAL IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH DURVALUMAB

[1]Mohammadhadi Khorrami, [1]Vidya Sankar Viswanathan*, [2]Amit Gupta, [3]Qin Li, [3]Ashok Gupta, [3]Ikbel Achour, [3]Brian Fitzgerald, [4]Vamsidhar Velcheti, [1]Anant Madabhushi. *[1]Emory University, Atlanta, GA, USA; [2]University Hospitals Cleveland, Cleveland, OH, USA; [3]AstraZeneca, Cambridge, MA, USA; [4]New York University, Pepper Pike, OH, USA*

Background Immune checkpoint inhibitors (ICI) are the standard of care for advanced non-small cell lung cancer (NSCLC). However, the response rates to these immuno-oncology agents remain modest (~45% in the frontline setting and ~20% in the second line setting). The ability to determine early response during treatment is important to allow early adjustment of treatment regimens. Currently, there is a lack of objective methods for early evaluation of clinical benefits from ICI treatments. In this study, we evaluated the performance of a CT-based delta-radiomics model for predicting early response in advanced NSCLC patients enrolled in CP1108 durvalumab nonrandomized phase 1/2 trial (NCT01693562) as an independent validation set.[1] Change of feature statistics between baseline and post-treatment scans was defined as the delta radiomic features.

Methods Baseline and first post-treatment chest CT scans from 225 NSCLC patients were acquired from 3 sites. A maximum of 2 lung lesions were annotated on both scans as per RECIST v1.1 and patients with objective response were defined as 'responders', and those with progressive disease or stable disease were defined as 'non-responders'. Patients lacking follow-up scans or measurable lung lesions were excluded. A previously trained classifier on D1=111 patients from two institutions (Cleveland Clinic Foundation and University of Pennsylvania Health System)[2] was validated on D2=114 cases from CP1108 durvalumab study[1] to assess the probability of treatment response using ROC curve as AUC. 454 intratumoral and 7426 peritumoral texture features were extracted from the scans and relative radiomic differences were computed to yield a set of 'delta-radiomic' features. A Cox regression model that was previously trained was used to evaluate the overall survival on CP1108 durvalumab study and relative HR with 95% confidence intervals (CI) was reported. A blinded validation was performed by AstraZeneca.

Results A combination of peritumoral and intratumoral delta radiomic features yielded an AUC of 0.77 ± 0.07 in D1 and a corresponding AUC of 0.7 in D2, respectively. Univariate Cox regression analysis indicated that delta-radiomic signature was significantly associated with OS in D1 set [HR: 1.95; 95% CI, 1.5–2.5; P<0.001; C-index=0.70) and D2 set [HR: 1.34; 95% CI, 1.05–1.7; P=0.018; C-index=0.55).

Conclusions We validated that a delta-radiomics based prediction model enables the identification of advanced NSCLC patients who respond to durvalumab treatment. Our study demonstrates the potential of radiomics and delta-radiomics as non-invasive imaging biomarkers to assess response and overall survival to immune checkpoint inhibitors including durvalumab.

74 DEEPTCRMATCH: AN EFFECTIVE WAY OF COMPUTING T CELLS ANTIGEN SPECIFICITY

[1]Seungtae Park*, [2]Sungsik Kim, [3]Hee Joon Jeon, [3]Na Ri Yoon, [2]Bo Ryeong Lee, [2]Sungmin Kim, [2]Woong-Yang Park, [4]Hyung Ju Hwang. *[1]Pohang University of Science and Technology, Pohang, Korea, Republic of; [2]Geninus Inc., Seoul, Korea, Republic of; [3]AMSquare Inc., Pohang, Korea, Republic of; [4]Pohang University of Science and Technology and AMSquare Inc., Pohang, Korea, Republic of*

Background To determine the specificity of T cells based on their receptor sequence is a demanding task due to cross-reactivity, complicated patterns and limited size of public dataset. An effective computational model, which finds CDR3 patterns of shared antigen specificity in the existing dataset, can predict specificity of T cells accurately. In this work, we developed a deep learning methodology that computes the similarity among T cells in terms of antigen specificity using *k*-mer features.

Methods Our model consists of two parts. First, it encodes every overlapping *k*-mers of CDR3 into numerical vectors. We parallelize such *k*-mer encodings into several allowable ways, so that the independent semantics of each *k*-mers are effectively learned. Second, among the encoded *k*-mer features, we select only meaningful *k*-mers using a self-attention structure. By doing this, we remove unwanted correlations among overlapping *k*-mers.

We train our model with preprocessed public datasets: IEDB, VDJdb and McPAS. We optimize the overall process to find an optimal contrastive predictive coding, which is an unsupervised objective function. After optimization, we define a kernel function of *k*-mer features to define similarity between two CDR3s.

Results We designed an one-of-many unsupervised task: for a given arbitrary CDR3 sequence, whether our model can correctly select CDR3 with a similar specificity among N randomly sampled candidates. With N=10, our model achieves accuracy 0.3 for an independent dataset. We also test supervised task: whether our model can induce probable cognate antigens for a given CDR3. Our model achieves precision 0.7.

Conclusions Our deep learning model can extract *k*-mer information that only represents antigen specificity. This information is an invaluable numerical vector for computing similarity of antigen specificity. By doing this, our model can solve the one-of-many problem and predict the antigen specificity. In the future, our model will improve its performance as a size of training dataset grows.

75 METHODS TO IMPROVE CO-EXPRESSION EFFICACY OF GENES MODULATING PROMOTER AND LINKER

Suji Kim, [1]Grad Student*, [1]Jong Moo Hong, [2]Kwanghee Kim, [3]Hee Jin Lee, [2]Hee Jin Lee, [3]Gyungyub Gong. *[1]University of Ulsan College of Medicine, Seoul, Korea, Republic of; [2]NeogenTC cop., Seoul, Korea, Republic of; [3]Asan Medical Center, Seoul, Korea, Republic of*

Background Adoptive T cell therapy is an important modality of cancer immunotherapy. Engineering of various genes associated with improved T cell function, such as viability, sustainability, migration potential, and target specificity is important. Therefore, we need to identify effective methods for multigene transfer to T cells. The selection of appropriate promoters or linkers in the production of virus vectors is critical for efficacy of multigene expression.

Methods In order to optimize vectors that can increase the expression efficiency of multigenes, we intended to compare the expression amount of each gene with different promoters and linkers. The expression of each gene was compared when 1G4 TCR (alpha and beta chains are linked by furin-SGSG-P2A) and CCR10 were linked using IRES, T2A, or furin-SGSG-T2A. Three cloning vectors were produced using one EF1a, one EFS, or two EFS to express 1G4 and CCR10 genes simultaneously with T2A. Transfection was performed on Lenti-x 293T and transduction was performed in Jurkat cells to measure the difference in expression of the 1G4 with mouse TCR constant antibody and CCR10 protein by flow cytometry. Finally, 1G4 and CCR10 dual expressing cells were sorted and cultured to see the persistence of expression on the day of culture, day 6, and day 12.

Results Since CCR10 was not expressed with the vector using IRES, T2A was selected. In addition, differences in protein expression between T2A and furin-SGSG-T2A were not observed. Using two EFS promotors, 1G4 and CCR10 were expressed at 4.3% and 33.4%, respectively, so they were not studied further. When using one EFS promotor, 1G4 was expressed at 97.6%, but CCR10 (downstream of T2A) was expressed significantly lower at 26.1% on the transduction day. When using the EF1a, the expression of 1G4 was decreased to 74.2%, but CCR10 expression was increased to 37.4%. After sorting of dual expressing cells, the expression of 1G4 and CCR10 with the EFS decreased from 100% and 86.1% (day 0) to 89.5% and 2.66%, respectively (day 12). However, with the EF1a, the expression of 1G4 was almost the same from 99.2% (day 0) to 99.7% (day 12), and CCR10 expression decreased slightly from 94.6% (day 0) to 73.5% (day 12).

Conclusions T2A showed better gene expression efficiency for downstream gene than IRES. EF1a was better than EFS and it was associated durable transduction efficacy. Comparison of linkers and promoters are necessary to improve multigene transfer to T cells for adoptive T cell therapy.

76 DISCOVERY OF BLOOD PHARMACODYNAMIC BIOMARKERS FOR ATR INHIBITORS

[1]Ya Kong, [1]Lulu Jiang, [2]Bin Jiang*, [1]Hui Yuwen, [3]Jay Mei, [3]Bo Shan, [3]Bing Hou. *[1]Shanghai Antengene Corporation Limited, Shanghai, China; [2]Antengene Biotech LLC, Doylestown, PA, USA; [3]Antengene Corporation Co., Ltd, Shaoxing, China*

Background The ataxia telangiectasia and rad3-related kinase (ATR) is a critical mediator of DNA damage response (DDR), which induce cell cycle arrest and facilitate DNA repair via downstream targets. Targeting ATR has become an attractive therapeutic strategy in cancer treatment and ATR inhibitors are currently being tested as anti-cancer agents in clinical trials, where pharmacodynamic (PD) biomarkers are crucial to help guide dose and scheduling and support mechanism of action studies. Tumor is the obvious tissue in which to measure PD effect but collecting tumor biopsies is often challenging for the patients.[1] Phosphorylation of Chk1 or γH2AX has been reported to be PD markers of ATR inhibitors. However, these markers are difficult to measure directly using blood samples. ATG-018 is an oral, potent and selective small-molecule inhibitor of ATR. In this study, to identify clinically easy-to-use blood PD biomarkers of ATR inhibitor, we screened the gene expression changes *in vitro* using peripheral blood mononuclear cells (PBMCs) treated by different concentrations of ATG-018 and validated the marker in *in vivo* mouse models.

Methods We first assessed gene expression changes induced by ATG-018 on human PBMCs *in vitro*. Human PBMCs from three different donors were treated with different concentrations of ATG-018 (10, 100, 300, 1000 ng/ml), and NanoString technology was used for high-throughput gene expression profiling at transcriptional level. To further validate the identified potential biomarkers, wild type mice were treated with ATG-018 and Meso Scale Discovery was used to detect the protein expression of potential PD markers in plasma.

Results In *in vitro* test, a series of genes were found to change in a dose-dependent manner in response to ATG-018 in PBMCs (figure 1A). ATG-018 significantly inhibited the expression of chemokine genes, especially CCL2, CCL3/L1 and CCL4. Under the condition of 1000 ng/mL ATG-018 treatment, the log2 fold change of these three genes was more than -1.5 compared with the control group (figure 1B). In *in vivo* assay, the inhibition of CCL2, CCL3 and CCL4 protein expression could still be observed in plasma from Balb/c mice orally treated with ATG-018. Expression of CCL4 was significantly downregulated after administration of ATG-018 compared with the control group.

Conclusions In this study, we found the expression of chemokines, especially CCL2, CCL3/L1, and CCL4 are potential novel PD biomarkers of ATG-018, which could be detected in unmanipulated blood samples, and may guide dose and scheduling and support mechanism of action studies of both ATG-018 and other ATR inhibitors in clinic.

77 AN NGS ASSAY TO IDENTIFY HLA LOSS OF HETEROZYGOSITY FOR FUTURE CEA AND MSLN LOGIC-GATED CAR-T SOLID TUMOR PROTOCOLS DESIGNED FOR REDUCED ON-TARGET, OFF-TUMOR TOXICITY

[1]Scott Kopetz*, [1]Maria Pia Morelli, [2]Julian Molina, [3]Diane Simeone, [4]J Randolph Hecht, [5]Kedar Kirtane, [6]Mitesh Borad, [3]Theodore Welling, [4]Edward Garon, [7]Armen Mardiros, [7]Xueyin Wang, [7]Eric Ng, [8]Tyler Danek, [8]Shannon Gallagher, [8]Ariane Lozac'hmeur, [8]Karl Beutner, [7]John Welch, [9]David Maloney, [7]William Go, [10]Sandip Patel. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Mayo Clinic, Rochestser, MN, USA; [3]New York University Langone Health, New York, NY, USA; [4]University of California at Los Angeles, Los Angeles, CA, USA; [5]H. Lee Moffitt Cancer Center, Tampa, FL, USA; [6]Mayo Clinic Cancer Center, Scottsdale, AZ, USA; [7]A2 Biotherapeutics, Inc., Agoura Hills, CA, USA; [8]Tempus, Chicago, IL, USA; [9]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [10]University of California San Diego, La Jolla, CA, USA*

Background Chimeric antigen receptor (CAR) T-cell therapy has shown clinical efficacy in hematologic cancers, but success is limited in solid tumors due to a lack of tumor-specific targets that distinguish cancer from normal cells and an immunosuppressive tumor microenvironment.[1] Integrating synthetic biology and comprehensive molecular profiling of tumors may provide active and tolerable approaches to CAR T-cell therapy in patients with solid tumors.

Human leukocyte antigen (HLA) loss of heterozygosity (LOH) in tumors offers a definitive tumor vs normal discriminator target for CAR T-cell therapy.[2] The Tmod platform[3,4] is a modular logic-gated CAR T system comprising different versions including a carcinoembryonic antigen (CEA)- or mesothelin (MSLN)-targeting CAR activator and a separate blocker receptor targeting HLA-A*02 or other HLA alleles to protect normal cells. Compared with existing immunohistochemistry (IHC) tests, Tempus xT-Onco is a standard-of-care next-generation sequencing (NGS) assay[5] that detects somatic alterations including HLA LOH and generates whole transcriptome RNA data (eg, CEA or MSLN expression) and a tumor immune infiltration profile, which can effectively identify patients appropriate for Tmod CAR T-cell therapy.

Methods HLA LOH in solid tumors was assessed with paired germline and somatic DNA sequencing. Common driver mutations, microsatellite instability status, and tumor mutational burden were examined in HLA-A LOH or HLA-A intact cohorts. Tumor expression of CEA and MSLN was evaluated via RNA sequencing and compared with immunohistochemistry (IHC) results.

Results A total of 21,053 tumor samples in the Tempus database were compared with their matched-normal samples. HLA-A LOH was detected in 16% of 10,867 advanced solid tumors (table 1) and similar LOH frequencies were observed among common HLA-A alleles. Clinical factors and molecular biomarkers were similar between HLA-A LOH and HLA-A intact cohorts. High CEA expression was seen in IHC-positive patients.

Conclusions The frequency of HLA-A LOH in solid tumors in the Tempus database is similar to that reported in the Cancer Genome Atlas.[6] Tempus xT-Onco reliably detects HLA LOH and quantifies CEA and MSLN expression. Based on these data, patients with solid tumors are now being prospectively screened for HLA LOH using xT-Onco in an ongoing tissue banking study (BASECAMP-1, NCT04981119), preparing for future interventional protocols.

78 MAPPING THE TISSUE COMPOSITION WITH HYPERPLEX IMMUNOFLUORESCENCE ON DELICATE SAMPLES

Joanna Kowal*, Diego Dupouy, Jonathan Mignot, Benjamin Pelz. *Lunaphore Technologies, Tolochenaz, Switzerland*

Background In health and disease, cells are interacting with their microenvironment, which shapes their homeostasis and response to any stimuli.[1] Deciphering the tissue architecture emerged as a crucial step to better understand tissue biology and harness it in a future therapeutic intervention.[2]

Recently, advancements were made to interrogate the tissue spatial composition with the development of immunofluorescence-based hyperplex assays,[3,4] allowing the investigation of dozens of biomarkers on a single tissue slide. There is a growing interest to apply hyperplex assay on fresh frozen sections (FS), yet harsh procedures used in manual protocols are detrimental to tissue morphology and limit the use of this application.[5] Furthermore, manual protocols are laborious and time-consuming, allowing to process a limited number of samples.

Here, we describe the capability to perform automated hyperplex assays for up to 32 biomarkers on fragile FS tissues as a cogent case combining staining quality with tissue preservation.

Methods COMET™ platform allows performing sequential immunofluorescence (seqIF™) assays based on an iterative series of fast tissue staining, imaging, and antibody elution cycles. Fresh frozen tissue sections of human and murine origins were fixed and permeabilized prior to loading on the device for automated staining protocols. Multiplex assay was performed for up to 32 biomarkers on a single tissue slide. To assess the tissue morphology preservation, standard hematoxylin and eosin (H&E) staining was performed on FS freshly processed or post-staining protocol.

Results In this study, a sequential immunofluorescence protocol was automated and optimized on COMET™ for both human and mouse frozen tissue sections. Murine spleen, brain and lung tissues were stained with multiplex panels of up to 6 proteins and showed an accurate detection of both common immune and organ-specific biomarkers. For a deep characterization of human lung cancer, 32 biomarkers were simultaneously detected on a single FS with optimal staining and a total procedure time of 23 hours. An H&E staining performed on the slide retrieved from the platform after the multiplex protocol showed excellent preservation of the tissue architecture in comparison with an unprocessed FS slide.

Conclusions This work proves the feasibility of performing automated hyper-plex assays on a variety of delicate frozen samples with high-quality results. With this new toolbox, we aim to support and hasten discovery studies across multiple research fields overcoming current limitations in tissue spatial biology.

79 **HIGH-DIMENSIONAL SPATIAL PHENOTYPING OF CUTANEOUS SQUAMOUS CELL CARCINOMA FROM IMMUNE-COMPETENT AND IMMUNOCOMPROMISED PATIENTS**

[1]Arutha Kulasinghe, [2]Niyati Jhaveri*, [2]Dmytro Klymyshyn, [2]Bassem Ben Cheikh, [3]Rahul Ladwa, [3]Howard Liu, [3]Caroline Cooper, [1]Gabrielle Belz, [3]Sandro Porceddu, [2]Oliver Braubach. *[1]The University of Queensland, Brisbane, Australia; [2]Akoya Biosciences, Menlo Park, CA, USA; [3]Princess Alexandra Hospital, Brisbane, Australia*

Background Cutaneous squamous cell carcinoma (cSCC) is the second most common non-melanoma skin cancer and represents a major global health burden. Approximately 50% of cSCC patients develop primary resistance and 20% will develop secondary resistance to immune checkpoint inhibitors (ICI). There are few biomarkers that reflect the tumor dynamics predictive of response to ICI therapy and we thus need to better understand the cSCC tumor microenvironment (TME).

Methods Our retrospective study profiled tissues from 50 patients at the Princess Alexandra Hospital (Brisbane, AU). Study groups included patients with de novo local cSCC (n=10) and regional nodal metastasis (n=10) who have remained disease free for >2 years. Additional groups included patients with locoregional recurrent disease (n=10), recurrent and/or metastatic disease (n=10) treated with immunotherapy, and immunocompromised de novo or recurrent disease (n=10). In this exploratory study, we designed a high-dimensional >40-plex antibody panel identifying cell lineages, activation states, and checkpoints, as well as markers for cell metabolism, vasculature, and tissue structure. Whole-slide spatial phenotyping was conducted on the PhenoCycler®-Fusion spatial biology system and spatial features, including spatial phenotypic composition, cell-to-cell localization, and cellular neighborhoods were analyzed and compared against clinicopathological findings and response to ICI therapy

Results We have profiled the TME of cSCC via ultrahigh-plex, single-cell spatial analyses of whole tissues. Our data have revealed unique cell phenotype compositions within the TME of different patient cohorts. Additionally, spatial phenotyping analysis revealed distinct cellular neighborhoods within the tissue cohorts. Taken together, this high-dimensional imaging approach of the cSCC TME has revealed new tissue insights

Conclusions There is a need to understand the immune contexture of the cSCC immune microenvironment. Here we identify distinct cellular phenotypic compositions and cellular neighbourhoods in tissues from immune-competent and immunocompromised cSCC. We thereby confirm biological differences in tissue composition and cellular interactions between these tissues and provide putative new biomarkers for cSCC patient stratification.

Ethics Approval This study has Metro South Human Research Ethics Committee (HREC) Approval (LNR/2020/QMS/66612) and The University of Queensland ethics ratification.

80 TUMOR-SPECIFIC ALTERNATIVE SPLICING GENERATES IMMUNOGENIC SPATIALLY-CONSERVED HLA-BINDING NEOANTIGENS DETECTED THROUGH INTEGRATIVE TRANSCRIPTOMIC AND PROTEOMIC ANALYSES

Darwin Kwok*, Takahide Nejo, Chibo Hong, Aidan Du, Maggie Colton, James Woo, Joseph Costello, Hideho Okada. *University of California San Francisco, San Francisco, CA, USA*

Background While immunotherapy is profoundly efficacious in certain cancers, its success is limited in cancers with lower mutational burdens, such as gliomas.[1] Therefore, investigating neoantigens beyond those from somatic mutations can expand the repertoire of immunotherapy targets. Recent studies detected alternative-splicing (AS) events in various cancer types that could potentially translate into tumor-specific proteins.[2, 3] Our study investigates AS within glioma to identify novel MHC-I-presented neoantigens through an integrative transcriptomic and proteomic computational pipeline, complemented by an extensive spatiotemporal analysis of the AS candidates.

Methods Bulk RNA-seq of high tumor purity TCGA-GBM/LGG (n=429) were analyzed through a novel systematic pipeline, and tumor-specific splicing junctions (neojunctions) were identified in silico by cross-referencing with bulk RNA-seq of GTEx normal tissue (n=9,166). Two HLA-binding prediction algorithms were subsequently incorporated to predict peptide sequences with a high likelihood for HLA presentation. Investigation of the tumor-wide clonality and temporal stability of the candidates was performed on extensive RNA-seq data from our spatially mapped intratumoral samples and longitudinally collected tumor tissue RNA-seq. Proteomic validation was conducted through mass-spec analysis of the Clinical Proteomic Tumor Analysis Consortium (CPTAC)-GBM repository (n=99).

Results Our analysis of TCGA-GBM/LGG bulk RNA-seq identified 249 putative neojunctions that translate into 222 cancer-specific peptide sequences encoding 21,489 tumor-specific n-mers (8–11 amino acids in length, figure 1). Both prediction algorithms concurrently identified 271 n-mers likely to bind and be presented by HLA*A0101, HLA*A0201, HLA*A0301, HLA*A1101, or HLA*A2402. We confirmed the expression of 17 out of 74 HLA*A0201-binding candidates in RNA-seq of two HLA*A0201+ patient-derived glioma cell lines with a subset of candidates found tumor-wide (figure 2). Analysis of CPTAC-GBM mass-spec data detected 42 tumor-specific peptides generated specifically from 23 GBM-specific splicing events (figure 3). 4 candidates were selected for downstream immunogenicity analysis and were selected based on high *in silico* HLA-presentation scores and detection in RNA sequencing and mass spectrometry. *In vitro* sensitization of healthy donor-derived CD8+ T-cells was performed with the 4 candidates along with an influenza positive control condition and a no peptide negative control condition. 1 of the 4 neoantigen candidates, mutant-RPL22, was shown to elicit a CD8+ T-cell-specific immune response based on IFNγ ELISA assay analysis (figure 4).

Conclusions Tumor-specific neojunctions identified in our unique integrative pipeline present novel candidate immunotherapy targets for gliomas and offer a new avenue in neoantigen discovery across cancer types.

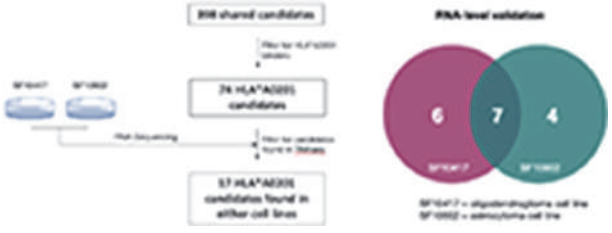
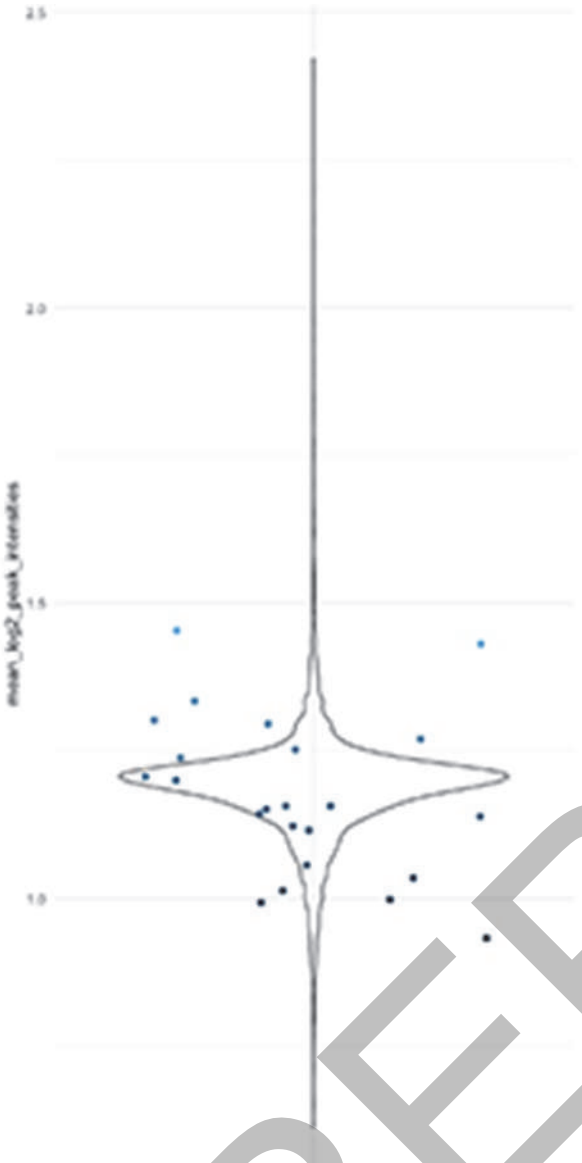
Abstract 80 Figure 1 Identification of top HLA-presented neoantigens
Neoantigen sequences were predicted from glioma-specific neojunctions identified from our novel in silico pipeline. 398 top-candidates were selected based on high HLA-presentation scores identified in two independent HLA-prediction algorithms.

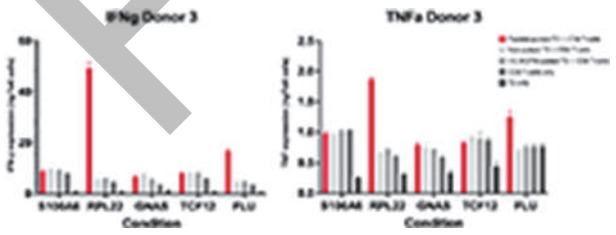


Abstract 80 Figure 2 RNA-level validation of neojunctions
RNA-expression of neojunctions was validated by analyzing RNA-sequencing data from two patient-derived HLA-A*0201 glioma cell lines. 74 of the 398 top candidates were shown to bind strongly to HLA-A*0201. Neojunctions expressing 14 of the candidates were detected in either cell lines

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0080



Abstract 80 Figure 3 Peptide-level validation of NJ-derived neoantigens
Protein-level expression of the neojunctions was detected by analyzing mass-spectrometry data from CPTAC. Mass spectrometry data of GBM patients (n=99) detected 42 peptides that are uniquely derived from 23 unique neojunctions



Abstract 80 Figure 4 NJ-derived neoantigens elicit CD8+ T-cell response
Four neojunction-derived neoantigen candidates demonstrated high HLA-presentation scores and were detected on both an RNA- and peptide-level. Neoantigen sensitization was performed on donor derived PBMCs, and neojunction-derived mutant-RPL22 elicited a CD8+ T-cell-specific immune response

81 T CELL STIMULATION ASSAY AND IMMUNOASSAYS COMPARISON FOR SOLUBLE CYTOKINES PROFILING IN DRUG DISCOVERY

Celine Lefranc, Nicole Meritet, Karine Berthelot, Odile Flamand, Jeremy Baudhuin, Jack Pollard, Luc Canard, Angelique Biancotto*. *Sanofi, Paris, France*

Background T cell stimulation assays are commonly used in invitro pharmacological assays to understand immunomodulatory functions of drugs in development.[1–3] Assays read outs are common activation markers measured by flow cytometry and cytokines secretion detected in culture supernatants. In addition to monitoring activation markers, cytokines and their expression are critical for biomarker discovery and essential in understanding immune biology in addition to being commonly used as a read out in T cell stimulation.

Methods In this work, we report CD25 CD69 expression after stimulation at 24,48,72h and IL-4, IL-2, TNFa, IFNg production from 33 healthy donors. We used a subset of samples to compare 4 technologies used in drug discovery; Meso Scale Discovery [MSD], Cytometric Bead Array [CBA] and Sartorius Q Beads Plexscreen. Through experimental data analysis, several assay features were compared, including sensitivity, dynamic range, and robustness.

Results Out of all parameters monitored, we identified that measurement of IL-2 at 48h was the best read out using these assay features to quantify T cell stimulation level. Our studies revealed normal range of cytokines production after CD3 CD28 stimulation of isolated T cells. Comparing cytokines measurement technologies, we showed that MSD has the best sensitivity in the low detection limit and the broadest dynamic range, while CBA and Luminex also demonstrate superior performance in the sensitivity and dynamic range. Additional aspects of these technologies, including assay principles, formats, throughputs, robustness, costs, and multiplexing capabilities, were also reviewed, and compared. MSD was the most sensitive technology for IL-4, while CBA was the most suitable one for cytokine high-throughput screening with multiplexing capability.

Conclusions This report aims to help readers understand analyte variance in healthy donors at baseline and upon stimulation, to select the proper cytokines secretion method for their specific applications.

82 DIFFERENTIAL EXPRESSION AND FUNCTION OF TOLL-LIKE RECEPTOR 3 WITHIN TUMOR IMMUNE MICROENVIRONMENT OF CLEAR CELL RENAL CELL CARCINOMA

Mingjia Li*, Patrick Stevens, Maciej Pietrzak, Jinesh Gheeya, Amir Mortazavi, Ming Yin, Steven Clinton, Daniel Spakowicz, Anil Parwani, Zihai Li, Yuanquan Yang. *Ohio State University, Columbus, OH, USA*

Background High intratumoral toll-like receptor 3 (TLR3) expression is associated with improved survival in patients with clear cell renal cell carcinoma (ccRCC). However, the function of TLR3 in the tumor immune microenvironment is poorly understood. Here, we assessed the expression of TLR3 in tumor-infiltrating immune cell subsets, and the differential gene expressions comparing TLR3+ VS TLR3- cells within each subset.

Methods Single-cell RNA-Seq dataset was obtained from the publication by Braun et al (PMI 33711273). Seurat version 4.0.4 was used for analysis. Uniform Manifold appreciation (UMAP) and projection reduction were performed with principal component analysis independent from previous work. Clusters were identified at a resolution of 0.8 with the Louvain algorithm using 1:20 dimensions in function. Clusters were labeled based on a combination of previous cell barcode annotation and our input. Differential gene expression was performed on normalized gene expression using FindMarkers function (only.pos = FALSE, min.pct = 0.15, logfc.threshold= 0.15) from each cluster/condition tested against all other cells. Genes were significantly elevated when Log2 fold change ≥0.20 with corrected p-value ≤0.05. Cells were segregated based on TLR3 expression if a cell has at least 1 expression unit of TLR3. Quiagen IPA was used to perform pathway analysis. IPA Z-scores of ≥2 and ≤-2 were used to determine the significance of activation and inhibition, respectfully.

Results A total of 164,722 cells from 13 patients with early (n=8) and advanced stage (n=5) ccRCC were included. TLR3 expression was enriched in myeloid compartment (figure 1). The top three TLR3 expressing immune cell types were: inflammatory macrophages (IM) with 636 out of 3309 cells (19.2%), CD141+ dendritic cells (DC) with 541 out of 3010 cells (18.0%), and tumor-associated macrophages (TAM) with 1209 out of 9749 cells (12.4%) (table 1). In IPA analysis, TLR3 positivity was associated with increased function of cell adhesion in DC141+DC (Z-score=2.0), response of antigen presentation in TAM (z score=2.2), and cell migration of IM (Z-score=2.2). Whereas TLR3 negativity was associated with inhibited cell movement of DC (Z-score= -2.1). The top differentially expressed genes between TLR3+ vs TLR3- cells of each subset was shown in figure 2–4.

Conclusions TLR3 expression is enriched in macrophages and dendritic cells within ccRCC tumor microenvironment. TLR3 signaling may promote cell adhesion, migration, and antigen presentation function of these cells.

Ethics Approval This research was exempt from IRB review per institutional policy. This study utilized previously published and publicly available data. Data contained in this study is not individually identifiable or potentially identifiable.

83 IMMUNOTHERAPY ELUTING INTRATUMORAL NANOSEED ACHIEVES LOCAL AND SYSTEMIC TUMOR CONTROL OF PANCREATIC CANCER

Hsuan-Chen Liu, Daniel Davila Gonzalez, Robin Vander Pol, Dixita Viswanath, Shani Saunders, Corrine Ying Xuan Chua*, Alessandro Grattoni. *Houston Methodist Research Institute, Houston, TX, USA*

Background Intratumoral immunotherapy is a clinically investigated approach based on the premise that local priming of the antitumor immune response can yield durable systemic immunity and avoid toxicities associated with systemic administration. However, direct intratumoral injection rapidly disseminates from the tumor, resulting in diminished efficacy and undesirable systemic exposure.[1] Variations in intratumoral injection methods as well as lesion type and location could further affect local bioavailability and consequently, clinical outcome.[2] Moreover, clinical protocols typically require repeated administration, which could be challenging for hard to reach tumors. To address these challenges, we present an immunotherapy eluting intratumoral 'nanoseed' for in situ treatment.[3–5] Sustained intratumoral immunotherapy release occurs autonomously through diffusion across a nanofluidic membrane mounted on the nanoseed without requiring pumps, ports or manipulation after implantation. We posit that nanoseed-mediated sustained intratumoral release of agonist CD40 antibody could promote local and systemic antitumor responses for effective tumor control.

Methods We investigated our approach using the syngeneic KPC pancreatic cancer murine model. When tumor volumes approximated ~140 mm^3, nanoseed containing agonist CD40 antibody was intratumorally implanted in a one-time minimally invasive trocar procedure for sustained in situ delivery (8 ug/day), in comparison to systemic administration (100 ug every other day for a total of 4 doses) and vehicle controls. Treatment response and adverse effects were evaluated using tumor volume, flow cytometry and imaging mass cytometry assessment of immune activity, serum ELISA, liver histology and Kaplan Meier survival analysis.

Results Sustained release of agonist CD40 antibody directly into the tumor microenvironment through the nanoseed resulted in significant tumor burden reduction and prolonged survival of KPC mice without toxicities. With nanoseed-CD40 treatment, local tumor immune microenvironment modulation was observed with increased intratumoral CD8+ effector T cells and M1 macrophages, as well as decreased M2 macrophages and Foxp3+ Treg. Moreover, local treatment with nanoseed-CD40 yielded systemic reduction of M2 macrophages. As opposed to systemically treated mice, which showed inflammatory liver histology and elevated serum IL-6, IFN-γ, TNFa, and M-CSF levels indicative of cytokine storm, nanoseed-CD40 cohort were comparable to vehicle controls. Further, in a bilateral KPC model, nanoseed-CD40 treatment significantly inhibited growth of the contralateral untreated tumor, suggestive of a systemic antitumor response.

Conclusions Overall, our results support further development of the nanoseed as a clinically viable approach for intratumoral immunotherapy delivery in a safe and effective manner to locally modulate tumor immune microenvironment for systemic antitumor effects.

84 SYSTEMIC LEVELS OF THE SOLUBLE CO-INHIBITORY AND CO-STIMULATORY IMMUNE CHECKPOINT MOLECULES IN BASAL CELL CARCINOMA

[1]Nonkululeko Z Malinga, [1]Bernardo Rapoport*, [1]Siwele Shalete, [1]Helen Steel, [1]Luyanda Kwofie, [1]Pieter Meyer, [1]Ronald Anderson, [1]Mahlatse Kgokolo, [2]Teresa Smit. *[1]University of Pretoria, Pretoria, South Africa; [2]The Medical Oncology Centre of Rosebank, Johannesburg, South Africa*

Background Although co-inhibitory immune checkpoint proteins are primarily involved in promoting inhibitory cell-cell interactions in adaptive immunity, especially tumor immunity, the soluble cell-free variants of these molecules are also detectable in the circulation of cancer patients where they retain immunosuppressive activity. Nevertheless, little is known about the systemic levels of these soluble co-inhibitory immune checkpoints in patients with various subtypes of basal cell carcinoma (BCC), which is the most invasive and treatment-resistant type of this most commonly occurring malignancy.

Methods We have measured the systemic concentrations of five prominent co-inhibitory immune checkpoints, namely CTLA-4, LAG-3, PD-1/PD-L1, and TIM-3, as well as those of C-reactive protein (CRP) and vitamin D (VD), in a cohort of patients (n = 40) with BCC, relative to those of a group of control participants (n = 20), using the combination of multiplex bead array, laser nephelometry, and ELISA technologies, respectively. Additionally, in the subsequent study, we measured co-stimulatory checkpoints (CD27, CD28, CD40, ICOS, GITR, GITRL, CD8,6, and CD80), co-inhibitory checkpoints (PD-1, PD-L1, CTLA-4, TIM-3, LAG-3, BTLA-4) and dual checkpoints (TRL-2 and HVEM).

Results The median systemic concentrations of CRP and VD were comparable between the two groups; however, those of all five immune checkpoints were significantly elevated (P= 0.0184 – P < 0.00001), with those of CTLA-4 and PD-1 being highly correlated (r = 0.87; P< 0.00001) (table 1). The levels of CD27, CD28, CD40, and other immune checkpoint levels will be presented at the time of the meeting as this study is ongoing.

Conclusions This novel finding identifies the existence of systemic dysregulation in BCC and underscores the therapeutic promise of immune checkpoint targeted therapy, as well as the potential of these immune checkpoint molecules to serve as prognostic/predictive biomarkers in BCC.

Ethics Approval Ethics approval was granted by The Research Ethics Committee, Faculty of Health Sciences, University of Pretoria (Ethics Committee Approval Numbers 326/2016, 251/2019 and 510/2020).

85 MAPPING THE TUMOR MICROENVIRONMENT WITH SEQUENTIAL IMMUNOFLUORESCENCE, AN AUTOMATED IMAGE ANALYSIS PIPELINE, AND SPATIAL METRICS

[1]Joanna Kowal*, [1]Diego Dupouy, [1]Pedro Machado Almeida, [2]James Mansfield, [1]Benjamin Pelz, [2]Fabian Schneider, [2]David Mason. *[1]Lunaphore Technologies, Tolochenaz, Switzerland; [2]Visiopharm A/S, Horsholm, Denmark*

Background Spatial biology enables the interrogation of tissue composition at a single cell level with preservation of spatial context, which opens new avenues for tumor microenvironment (TME) studies.[1] Biomarkers' composition of the tissue can be interrogated with hyperplexed immunofluorescence, wherein an imaging detection is performed for each marker on the same slide. The COMET™ platform performs sequential immunofluorescence (seqIF ™) and enables full automation of such workflow, where: up to 40 biomarkers can be detected with full automation from staining to data acquisition. The resulting hyperplex images are rich sources of data about the specimens. To extract information from such a dataset, Oncotopix® Discovery (Visiopharm) has a dedicated pipeline for image analysis that delivers single cell phenotypic information and biodistribution, providing access to the spatial composition of the TME.

Methods An FFPE Lung Tissue Microarray underwent sequential cycles of staining and imaging with COMET™ platform seqIF™ assay. Iterative cycles of staining, imaging and antibody elution allowed the detection of 20 antigens spanning across epithelial tumor and immune markers (panCK, E-Cad, aSMA, CD31, CD3, CD4, CD8, FoxP3, CD20, HLA-DR, Ki67, Vimentin, CD16, CD68, CD11b, CD163, CD14, CD11c, PD-1, PD-L1). The resulting image contains 23 channels: nuclear detection with DAPI, 2 channels of tissue autofluorescence (AF), and 20 marker channels. All layers were aligned and stitched into a single ome.tiff automatically by the COMET™ control software. Subsequent AF subtraction was performed in the Viewer by Lunaphore. The AF-subtracted image was analyzed using Oncotopix Discovery. The analysis pipeline consisted of a deep-learning (DL)-based tissue segmentation (tumor, stroma, necrosis, etc.), a pre-trained DL DAPI nuclear segmentation step, cellular phenotyping, and spatial metrics among the various cell types.

Results We interrogated tumor composition with the use of COMET™ platform and Oncotopix Discovery Software from Visiopharm. Specific cellular phenotypes of interest are proliferating tumor cells, proliferating T cells, immunosuppressive macrophages and antigen-presenting cells and their interactions with a focus on the PD-(L)1 pathway.

Conclusions The combination of hyperplex staining and advanced image analysis and in situ cellular phenotyping allows the identification of tissue composition. It is a crucial step for understanding and harnessing tissue biology. Being able to analyze the spatial distribution of specifically phenotyped cells in the TME enables to identify reliable biomarkers as predictive factors of response to therapies.

86 HPV16 E1 AND E2 ELICIT A ROBUST CYTOTOXIC IMMUNE RESPONSE IN VIRALLY DRIVEN OROPHARYNGEAL SQUAMOUS CELL CARCINOMA

[1]Christine McInnis*, [1]Shilpa Bhatia, [1]Brinda Vijaykumar, [1]Qiaomu Tian, [1]Yanbo Sun, [1]Del Leistritz-Edwards, [2]Charles Quinn, [2]Sean Donnelly, [2]Ravindra Uppaluri, [2]Ann Marie Egloff, [1]Daniel Pregibon, [1]Lakshmi Srinivasan, [1]Anthony Coyle, [2]Glenn Hanna. *[1]Repertoire Immune Medicines, Cambridge, MA, USA; [2]Dana Farber Cancer Institute, Boston, MA, USA*

Background Human papillomavirus (HPV) infection is a risk factor for oropharyngeal squamous cell carcinoma (OPSCC). HPV+ OPSCC is characterized by distinct biology, a heterogenous immune landscape, and accounts for approximately 14,400 new diagnoses per year in the U.S. For patients with locoregional recurrence or distant metastasis, systemic treatment options beyond immune checkpoint inhibitors are limited. Though a decline in HPV+ HNSCC is expected due to HPV vaccination campaigns, incidence is currently increasing, prompting a wave of therapeutic development. While most therapeutic efforts have been focused on eliciting a cellular response to HPV early antigens E6 and E7, we sought to identify additional highly prevalent, immunogenic targets in both early stage as well as in relapsed/refractory HPV+ HNSCC.

Methods Treatment-naïve HPV+ OPSCC patients (n=19) were prospectively enrolled under an institutional review board (IRB)-approved tissue collection protocol (DF/HCC#09–472) for collection of surgical specimens. Tumor tissue from a biopsy or definitive oncologic transoral robotic-assisted resection specimen was collected prospectively for analysis. Multiplexed, barcoded peptide-MHC-I tetramer libraries containing epitopes derived from the HPV16 genome were used to probe dissociated tumors followed by single cell RNA sequencing using the 10x Genomics platform. SingleR and published gene marker sets were used to phenotype and perform broad lineage assignment.

Results We found broad T-cell reactivity to several HPV proteins across multiple HLA alleles and epitopes. E1 and E2-reactive T-cells were cytotoxic and highly expanded, whereas E5, E6 and E7-reactive T-cells were rare and displayed exhausted or naïve phenotypes. Cytotoxic E2 T-cell responses were associated with loss of E2 expression in at least one tumor suggesting functional capacity of these T-cells. We also identified evidence of pseudo-public TCR sequences, as TCR alpha, beta or paired CDR3 sequences associated with E2 reactivity were shared across multiple patients with common HLAs. TCR specificity was confirmed for several TCR-epitope interactions using recombinant TCRs and cognate peptide.

Conclusions We employed high-throughput, single-cell immune synapse profiling to characterize the cellular response to HPV + HNSCC across common HLA haplotypes and identified new candidates for immunotherapeutic intervention. We found that HPV16 proteins E1 and E2 induce robust, effective cytotoxic responses in HPV16-driven OPSCC. These findings indicate HPV16 E1 and E2-directed immunotherapy may be effective among patients with OPSCC expressing these antigens.

Ethics Approval Patients were consented and enrolled under an institutional review board (IRB)-approved tissue collection protocol (DF/HCC#09–472).

87 DEEP PHENOTYPING AND SPATIAL IMMUNE CONTEXTURE THROUGH A COMBINED MULTIPLEX IMMUNOFLUORESCENCE APPROACH

Harry Nunns, Arezoo Hanifi, Erinn Parnell, Nam Tran, Sara Pollan, Qingyan Au*. *NeGenomics Laboratories Inc., Aliso Viejo, CA, USA*

Background Tertiary lymphoid structures (TLS) have been observed in a variety of solid tumors and growing evidence has shown that TLS can be promising prognostic indicators of positive outcomes for patients with solid tumors including colorectal cancer (CRC).[1] Large-scale retrospective analysis shows patients with mature TLS in particular respond to PD-1/PD-L1 antibody treatment with improved objective response, progression-free and overall survival.[2] Since not all patients respond to immune checkpoint blockade (ICB) therapy, identifying patients with TLS can be clinically relevant as it enables selection of patients likely to respond. In this study, we demonstrate a tissue-based phenotyping workflow combining two complementary multiplex immunofluorescence (mIF) platforms to enable identification of TLS, characterization of TLS maturation stage and spatial phenotyping of tumor infiltrating lymphocytes (TIL) on whole slide scan.

Methods In this study, 40 CRC patients were first stained with an in-house developed PhenoImager™ mIF panel detecting CD20, CD21, CD23, CD3 and Cytokeratin. Whole slide scan was acquired using PhenoImager HT, followed by biomarker classification and TLS identification using custom analytics algorithm generated with Indica HALO® platform.

An adjacent section of tumor sample was then stained and analyzed with a 17-plex MultiOmyx™ mIF panel. Using the MultiOmyx assay in combination with proprietary deep-learning-based image analysis (NeoLYTX), we further characterized the TLS maturation stage and interrogated the correlation of the TLS presence with subtypes of TIL expression in the CRC samples.

Results PhenoImager 5-plex TLS panel combined with Halo custom analysis successfully identified TLS in the tumor microenvironment (TME) of CRC samples and led to the strategic selection of regions of interest (ROI) for further characterization by high-plex assay. The TLS detection was found to be concordant between both mIF platforms in the CRC samples. MultiOmyx 17-plex analysis was able to provide a detailed picture of TLS and enabled further classification of TLS into different maturation stages based on biomarker expression and spatial organization of immune cells in the CRC samples.

Conclusions Combination of PhenoImager and MultiOmyx IF provides a complementary and powerful solution to study cellular composition within the TME. PhenoImager assay characterizes the immunophenotypes and visualizes the spatial distribution of TIL at single-cell resolution on whole slides. High dimensional analysis by MultiOmyx can provide greater understanding of the immune contexture within the TME and deeper insights into the correlations between biomarkers. This combined approach may have broad application and provides novel insights into the complex TME.

GENETIC ASSOCIATION BETWEEN VITILIGO GENETIC SUSCEPTIBILITY AND RESPONSE TO IMMUNE-CHECKPOINT INHIBITORTHERAPY IN ADVANCED MELANOMA PATIENTS

[1]Wouter Ouwerkerk*, [1]Saskia Chielie, [1]Marcel Bekkenk, [2]Remco van Doorn, [3]Christian Blank, [3]John Haanen, [4]Karlijn de Joode, [4]Ron Mathijssen, [4]Astrid van der Veldt, [2]Ellen Kapiteijn, [5]Karijn Suijkerbuijk, [6]Kalijn Bol, [7]Geke Hospers, [8]Tomas Kirchhoff, [1]Rosalie Luiten. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]LUMC, Leiden, Netherlands; [3]NKI, Amsterdam, Netherlands; [4]Erasmus MC, Rotterdam, Netherlands; [5]University Medical Centre Utrecht, Utrecht, Netherlands; [6]Radboudumc, Nijmegen, Netherlands; [7]UMCG, Groningen, Netherlands; [8]Perlmutter Cancer Center, New York, NY, USA*

Background Only ~50% of advanced melanoma patients show objective responses to immune checkpoint inhibitor (ICI) therapy. Currently, there are still no reliable predictive biomarkers explaining ICI response heterogeneity. Vitiligo development during ICI therapy is associated with a better prognosis in melanoma patients. Genetic susceptibility to vitiligo has been well-characterized using multiple large GWAS studies, and includes genes that are also associated to other autoimmune diseases.

Objective To test if the germline genetic association to vitiligo is able to predict response to ICI in patients with advanced melanoma.

Methods Data from >1,000 patients from 6 melanoma centers in the Netherlands participating in the international IO-GEM melanoma consortium were analyzed in this study. DNA was extracted from blood or saliva and genotyped by Illumina GSA MD v3.0. Clinical data was obtained from the Dutch Melanoma Treatment Registry. We developed a polygenetic vitiligo-susceptibility score using a pre-defined set of 54 vitiligo-associated single nucleotide polymorphisms (SNPs) predicting overall survival.

Results We found a significant protective relation of the unweighted vitiligo-susceptibility score to all-cause mortality. Weighted for the association to vitiligo, the vitiligo-susceptibility score outperformed the unweighted score in predicting all-cause mortality.

Conclusions These results suggest that genetic susceptibility to vitiligo may be associated with more favorable survival outcome in melanoma patients upon ICI treatment. The risk scores will be validated in the remaining part of IO-GEM.

MULTIPLEXED ION BEAM IMAGING (MIBI) UNCOVERS ADAPTIVE IMMUNE RESPONSES ASSOCIATED WITH CLINICAL OUTCOMES IN ORAL CAVITY SQUAMOUS CELL CARCINOMA TREATED WITH NEOADJUVANT PD-1 INHIBITOR

[1]Raghav Padmanabhan, [2]Hannah Knochelmann*, [1]Monirath Hav, [1]Mate Nagy, [1]Peng Si, [1]Sweta Bajaj, [3]Gregory Lesinski, [4]David Neskey, [3]Chrystal Paulos. *[1]Ionpath, Inc., Menlo Park, CA, USA; [2]Emory University, Charleston, SC, USA; [3]Emory University School of Medicine, Atlanta, GA, USA; [4]Sarah Cannon Research Institute, Charleston, SC, USA*

Background Oral cavity squamous cell carcinoma (OCSCC) is a subset of head and neck cancer with high recurrence rates. Recent evidence suggests that effective anti-tumor immunity can be induced by neoadjuvant immunotherapy in subsets of head and neck cancer patients, though immune mechanisms of response remain unclear. CD26, a novel costimulatory molecule, marks T cells with potent antitumor activity; therefore, we hypothesized that tumor infiltration by CD26+ T cells and other immune subsets may be related to treatment responsiveness. Here, using Multiplexed Ion Beam Imaging (MIBI), we report a first-in-class analysis of CD26 expression in relation to the immune and spatial architecture of the OCSCC microenvironment in patients treated with neoadjuvant nivolumab.

Methods Surgical pathology specimens from 8 OCSCC patients treated with pre-surgical nivolumab were stained with a panel of 31 metal-labeled antibodies. Tissues were imaged using MIBITM, and single cell segmentation was performed using a machine learning based tool that enabled downstream enumeration of 35 cell populations and quantitative analyses of both the costimulatory protein CD26 and immune checkpoint proteins as well as their spatial distribution. Cell population, protein expression, and spatial architectural differences were compared between patients with progressive disease and those with partial response.

Results A higher density of proliferating tumor cells was found in tumors from patients with progressive disease ($p=0.01$). Conversely, tumors from patients with partial response contained higher densities of cytotoxic T cells ($p=0.004$), particularly the activated and CD26+ cytotoxic T cell subsets. Evaluation of checkpoint expression across all populations showed that CD26 was predominantly expressed on T cells although a few of the myeloid subsets also expressed high CD26, particularly in patients with partial response. Finally, spatial analysis revealed pronounced interaction between tumor cells and cytotoxic T cells, notably of the activated cytotoxic T cell phenotype, in the samples from patients with partial response.

Conclusions MIBITM offers high-parameter tissue imaging, with a sensitivity and resolution suited to understanding the differences in the tumor immune landscape between patients with varied responsiveness to immunotherapies. In this study, OCSCC tumors from patients with partial response to neoadjuvant PD-1 inhibition showed evidence of adaptive immune responses with significant increases in infiltration of activated cytotoxic T cells and CD26+ cytotoxic T cells as well as greater interaction between activated cytotoxic T cells and tumor cells.

90 CIRCULATING ALTRUISTIC STEM CELLS AS A MARKER OF IMMUNOSUPPRESSION IN ORAL CANCER

[1]Lekhika Pathak*, [1]Seema Bhuyan, [2]Bidisha Pal, [1]Partha Saikia, [1]Sukanya Gayan, [1]Shirsajit Mitra, [1]Tutumoni Baishya, [2]Ramana Chilakamarti, [1]Bikul Das. *[1]KaviKrishna Laboratory, Guwahati, India; [2]Thoreau Laboratory for Global Health, Boston, MA, USA*

Background Head & neck cancer is the 4th cancer, and most of them are diagnosed late, and treated with cisplatin monotherapy. In these subsets of patients, immunotherapy has been tried, but without major success.[1] We speculate that circulating altruistic stem cells may serve as biomarker for immunotherapy. Previously, we showed that oral cancer CSCs reprogram MSCs to altruistic phenotype,[2, 3] an embryonic stem cell like phenotype having niche defending ability.[5] Here, we propose to test the immunosuppressive ability of ASCs, and their detection in the circulation of head & neck cancer subjects undergoing platinum based chemotherapy.

Methods We obtained ASCs by culturing CD271+ BM-MSCs with the conditioned media of EPCAM+/ABCG2+ CSCs of SCC-25 cancer cell line or primary tumors as previously described.[2] The immunosuppression test: immunosuppressive secretory factors, mixed lymphocyte reaction (MLR) assay, and a Boyden chamber based co-culture assay with NK cells.[4] Next, we obtained circulating CD271+/CD45- cells of stage IV head and neck cancer subjects (n=20) (5). Kaplan-Meier survival analysis and log-rank test to find association between the presence of circulatory ASCs and overall survival (OS).

Results CSCs including primary tumor obtained CSCs reprogram CD271+ MSCs to ASC phenotype; these cells secrete high level of Nitric oxide, IDO, TGF-beta, IL-10 and PGE-2. ASCs exhibited marked immunosuppression in the MLR test. In Boyden chamber assay, ASCs markedly decreased the number of NKG2D+ NK cells, and CD8+ T cells by 4–5 fold ($p<0.02$; n=3), whereas increased the CD4+/FoxP3/CD25- T-reg cells by 3-fold ($p<0.05$, n= 4). Moreover, ASCs, upon co-culture, increases the clonogenic capacity of non-CSCs (EPCAM+/ABCG2-/ALDH-) cells by 5-fold ($p<0.02$; n=4), while significantly decreasing the secretion of NKG2DL of these cancer cells. Next, we isolated circulating CD271+/CD45- cells from the 12/20 subjects with oral cancer and confirmed their ASC phenotype (figure 1A-E). These cells were in vitro cultured (figure 1D), and the conditioned media obtained showed marked immunosuppressive activities including significant reduction of NKG2D+ NK cells in the in vitro Boyden chamber assay. Importantly, these 12 out of 20 patients showed poor treatment response to platinum therapy. The OS at 6 months was 24.6% for circulating ASC-positive patients and 47.4% for circulating ASC-negative patients (log-rank test, $p<0.001$).

Conclusions The circulatory ASCs could be a promising biomarkers for immunotherapy.

Abstract 90 Figure 1 Subjects with advanced oral squamous cell cancer e

A. Representative flow cytometry profile depicting the presence of CD271+ cells in a population of EpCam-/CD45- cells sorted from peripheral blood mononuclear cells (PB-MNCs) of subjects with Oral cancer (supplementary table 4). The PB-MNCs were subjected to immunomagnetic sorting for EpCam-/CD45- cells. The sorted population was then mixed with CD271-/CD45+ cells recovered from the same subject for 1-day in serum free medium, fixed in 4% formaldehyde, and subjected to CD271 staining. The mixing with CD271-/CD45+ cell was done to minimize cell loss during flow cytometry procedure. B. The quantitative data of viable circulating CD271+/CD45- cells was estimated by trypan blue exclusion assay. Healthy subjects did not exhibit circulating CD271+/CD45- cells. C. Relative CFU-F was estimated in the isolated circulating CD271+/CD45- cells to confirm the mesenchymal phenotype. High Grade Oral Cancer (HG cancer) CFUs: 4.2 ±1.5/103cells (n=4). D. Relative protein level of p53 as measured by In-cell ELISA of CD271+/CD45- cells cultured in vitro in serum free medium. E. Gene expression profiles of circulating CD271+/CD45- cells. Note that circulating CD271+ cells exhibited enhanced expression of HIF-2a, Nanog, Sox-2 and Oct-4. The CD271+/CD45- cells were cultured in the serum free StemSpan medium for one week to obtain mRNA. The values were compared with Day-8 CM treated MSCs. F. CM of circulating CD271+/CD45- cells obtained from HG- cancer exhibited higher capacity to enhance the tumorigenicity of non-SP cells compared to CM of R-MSCs (Day-8, reprogrammed by SCC-25 ABCG2+CSC-CM).

91 CIRCULATING LIPID PROFILE AS A PROGNOSTIC FACTOR IN PATIENTS WITH ADVANCED SOLID TUMORS TREATED WITH IMMUNE CHECKPOINT INHIBITORS

[1]Federica Pecci*, [1]Luca Cantini, [1]Valeria Cognigni, [2]Fabiana Perrone, [1]Veronica Agostinelli, [2]Giulia Mazzaschi, [2]Elda Favari, [2]Michele Maffezzoli, [3]Alessio Cortellini, [1]Francesca Rossi, [1]Rebecca Chiariotti, [1]Francesco Venanzi, [1]Giulia Mentrasti, [4]Giuseppe Lo Russo, [4]Giulia Galli, [4]Claudia Proto, [4]Monica Ganzinelli, [1]Francesca Tronconi, [1]Francesca Morgese, [5]Carla Campolucci, [5]Marco Moretti, [1]Arianna Vignini, [6]Melissa Bersanelli, [2]Sebastiano Buti, [1]Rossana Berardi. *[1]Università Politecnica delle Marche, Ancona, MA, USA; [2]University of Parma, Parma, Italy; [3]Imperial College London, London, UK; [4]IRCCS Istituto Nazionale dei Tumori, Milano, Italy; [5]A.O.U. Ospedali Riuniti, Ancona, Italy; [6]University Hospital of Parma, Parma, Italy*

Background Components of lipid profile seem to impact differently on phenotype and activity of immune cells in cancer.[1,2] Their prognostic role in solid cancer patients treated with immune checkpoint inhibitors (ICIs) is still matter of debate.

Methods We retrospectively collected baseline clinicopathological characteristics including circulating lipid profile [total cholesterol (TC), triglycerides (TGs), low-density lipoproteins (LDL), high-density lipoproteins (HDL)] of consecutive solid cancer patients treated with ICIs and we investigated their impact on clinical outcomes. Cut-off values showing alteration of plasma lipid profile were ≥200 mg/dl for TC, ≥170 mg/dl for TGs, ≥130 mg/dl for LDL, <40 mg/dl for HDL in males, <45 mg/dl for HDL in females.

Results Among 432 patients enrolled, 67% (N=289) were men, 61% (N=266) were diagnosed with advanced non-small cell lung cancer and 86.6% (N=374) of patients were treated with ICIs as monotherapy. Patients' circulating lipid assessments were described in tables (tables 1–3). At a median follow-up of 46 months, patients with TC≥200 mg/dl showed an improved, although not significant, progression free survival (PFS) (6.61 versus 4.67 months, p=0.4) and longer overall survival (OS) (19.4 versus 10.8 months, p=0.02) compared to those with TC<200 mg/dl. Conversely, patients with TGs≥170 mg/dl showed a shorter PFS (2.8 versus 5.07 months, p=0.006) and OS (5.92 versus 12.99 months, p<0.001) compared to those with TGs<170 mg/dl. Then, we combined TC and TGs in a LIPID-score that identified three subgroups: good risk (GR) (TC≥200 mg/dl and TGs<170 mg/dl), intermediate risk (IR) (TC<200 mg/dl and TGs<170 mg/dl or TC≥200 mg/dl and TGs≥170 mg/dl) and poor risk (PR) (TC<200 mg/dl and TGs≥170 mg/dl). The median PFS of GR, IR and PR groups was 7.76, 4.18 and 2.40 months, respectively (p<0.001). Moreover, median OS of GR, IR and PR was 20.36, 11.18 and 4.14 months, respectively (p<0.001) (figure 1). At multivariate analyses, after adjusting for baseline performance status, histology, treatment line, sex, statin use, number of metastatic sites and body mass index, the impact of LIPID score remained significant for both PFS and OS (table 4). Looking at TC components, HDL and LDL, a significant association was detected only for HDL and OS, with patients characterized by higher HDL levels showing longer OS (15.3 vs 10.1 months, p=0.02).

Conclusions LIPID score seems to strongly define subgroups of patients treated with ICIs with different prognosis. Further mechanistic insights are needed to clarify the prognostic and predictive role of lipid profile components in patients treated with ICIs.

92 NOVEL RNA-SEQ PLATFORM ENABLES REPURPOSING OF APPROVED DRUGS IN RARE CANCERS, IMPROVING OUTCOMES

Gitte Pedersen*. *Genomic Expression Inc, Beverly, MA, USA*

Background Rare cancers are those that affect fewer than 40,000 people per year in the U.S. As a group, they make up just over 25% of all cancers and are responsible for 25% of all cancer deaths each year. There are few effective drug treatment options for rare cancers, whereas over 300 drugs have been approved by the FDA for treating non-rare cancers. Repurposing already approved cancer drugs to treat rare cancers is much faster and cost-effective than developing new drugs, but success depends on matching these drugs to rare cancers with the corresponding drug targets.

RNA sequencing has the potential to identify many clinically actionable molecular changes, whereas DNA sequencing is limited to some targeted drugs and typically misses the identification of aberrantly expressed checkpoint inhibitors, tumor antigens, and fusion events.

To enable RNA-sequencing in clinical samples, we had to overcome two issues: 1) tissue samples are typically embedded in FFPE, which results in highly fragmented RNA, making sequencing of samples difficult; 2) how best to interpret aberrant gene expression events and translate these results into clinical action.

Methods We address this issue through the implementation of our CLIA-validated *quantitative* OneRNA®-sequencing platform for treatment navigation. The OneRNA platform is an end-to-end integration of 1) CLIA-validated quantitative mRNA sequencing chemistry optimized for FFPE tumor specimens and low input liquid biopsy samples, such as blood, saliva, or urine, and 2) a validated bioinformatics pipeline, normalization methods, and an interpretative database that matches aberrant gene expression events to already approved drugs. Actionable genes are defined as genes that code proteins or nucleic acids that (1) are direct targets of drugs, (2) are ligands for the drug targets, or (3) are treatment selection biomarkers listed on the FDA label.

Results This study demonstrates the potential clinical utility of OneRNA® in detecting aberrant gene expression events and connecting them through a drug target and biomarker database to already approved drugs. Examples of improved outcomes in rare cancers are presented. The potential impact includes truly individualized treatment options in rare cancers. OneRNA® typically identifies 5 or more already approved drugs in all patients, whereas DNA sequencing only identifies 1 drug in 80% of the patients.

Conclusions The OneRNA® Platform can be used to expand treatment options for patients with rare cancers and with refractory cancers by matching tumors to existing drug targets, and by identifying high penetrance gene expression variants that may serve as targets for future drugs.

PCR ASSAY TO IDENTIFY WOODCHUCK HEPATITIS VIRUS POSTTRANSCRIPTIONAL REGULATORY ELEMENT IN CAR-T AND TCR-T CELLS FOR FRESH AND FORMALIN-FIXED SAMPLES

[1]Shalini Pullarkat*, [1]Jocelyn Wright, [1]David Woolston, [1]Erik Kimble, [1]Bo Lee, [1]Alexandre Hirayama, [1]Aude Chapuis, [1]Denise Buenrostro, [1]Graeme Black, [1]Marie Bleakley, [1]Brandon Seaton, [2]Jennifer Specht, [1]Cameron Turtle, [1]Cecilia Yeung. *[1]Fred Hutchinson Cancer Center, Seattle, WA, USA*; *[2]University of Washington, Seattle, WA, USA*

Background Chimeric antigen receptor T-cell (CART) and engineered T-cell receptor cytotoxic T cell (TCRT) therapy are adoptive cellular therapies developed by modifying T-cells to target surface antigens of cancer cells in CART, and both cell surface and intracellular antigens in the case of TCRT.[1] Producing CART and TCRT cells involves transduction with viral vectors that usually contain the Woodchuck Hepatitis Virus Posttranscriptional Regulatory Element (WPRE) to enhance transcription.[2] As adoptive cellular therapies become more widely used in cancer care, adverse events (AE) and safety monitoring questions have been raised requiring methods to quantify the amount of CART and TCRTs in patient tissues. We developed a PCR assay to target WPRE for use on archival formalin-fixed, paraffin embedded (FFPE) tissues with the goal of providing valuable information regarding CART/TCRT localization and AEs as most engineered cell products used at our institution are transduced with a viral vector containing WPRE.

Methods DNA from 4 pre-infusion CART (JCAR14 and Kymriah anti-CD19 CARTs) and TCRT (HA-1 TCRT, and MAGEA1 TCRT) products along with unmodified peripheral blood mononuclear cells (PBMC) were extracted.[3,4,5] WPRE primers were designed to generate short amplicon of 159 base pairs for use on FFPE tissues. Using Phusion High-Fidelity PCR Kit (ThermoFisher Scientific) per manufacture protocol, we verified the assay with fresh DNA as well as FFPE samples. FFPE DNA was extracted from curls cut from paraffin blocks containing cell pellet admixtures of CART or TCRT products and human PBMCs resuspended in Histogel and embedded to mimic cells in fixed tissues.

Results Our PCR protocol detects CART/TCRT constructs in fresh and FFPE samples for JCAR14 CART, Novartis (Kymriah) CART, HA-1 TCRT, MAGEA1 TCRT products. Through limit-of-detection experiments, we detected fresh CART DNA in dilution up to 0.1% (figure 1a) in JCAR14 products. Using fresh TCR-T samples, we detected TCR DNA up to 0.1% (figure 1b) in HA-1 TCRT products. For FFPE-derived DNA, we detected WPRE sequences (figure 1c, d) in four samples with an input amount of 25ng CART/TCRT DNA and various CART/TCRT admixtures confirmed by WPRE-ISH on RNAscope (table 1).

Conclusions Detecting CART/TCRT using a WPRE PCR assay optimized for use on FFPE is a novel yet simple technique suitable for clinical application in understanding AEs and tumor localization of the adoptive cellular therapy. In detecting CART and TCRT in FFPE, we are now able to study trafficking of these immune effector cells when AE occurs or when post-treatment biopsies are available.

94 CYTOF AND SERUM PROTEOMICS SHOW DISTINCT DIFFERENCES IN IMMUNE RESPONSES BETWEEN MYCOSIS FUNGOIDES AND SEZARY SYNDROME TO MONO- AND COMBINATION ANTI-PD-1 IMMUNOTHERAPY

[1]Nirasha Ramchurren*, [1]Rachael Parks, [1]Laura Islas, [1]Steven Fling, [2]Michael Khodadoust, [1]Evan Newell, [1]David Glass. *[1]Fred Hutch Cancer Center, Seattle, WA, USA; [2]Stanford University, Palo Alto, CA, USA*

Background Cutaneous T cell Lymphoma (CTCL) is a rare malignancy of CD4+ T cells that has few treatment options. Mycosis Fungoides (MF) and Sezary Syndrome (SS) are the most common subtypes of CTCL, with MF confined to the skin and SS a leukemic variant. The PD-1 checkpoint inhibitor, Pembrolizumab, used as a single agent or in combination with Interferon Gamma (IFNg) to treat CTCL in two Cancer Immunotherapy Trials Network (CITN) studies produced positive clinical outcomes of ~38% in each trial. Additional therapeutic approaches are needed to treat patients refractory to therapy, and informative biomarkers are essential to predict patient response. Here we describe findings from multi-omic studies conducted in the two CITN trials that were designed to elucidate such biomarkers.

Methods A mass cytometry (CyTOF) antibody panel targeting phenotypic, metabolic, and functional proteins expressed by reactive and neoplastic human T cells was developed. This panel was used to interrogate PBMC at several longitudinal timepoints. The serum proteome was also evaluated at these time-points using the Olink platform.

Results CyTOF revealed that the neoplastic T cells, while having patient-specific phenotypic profiles, tended to overexpress checkpoint and exhaustion molecules as compared to reactive T cells. IFNg therapy induced robust activation of innate immune cells, while anti-PD-1 preferentially activated CD8+ T cells. Neither therapy had significant effect on the activation state of neoplastic T cells. PD-1 expression dropped dramatically across most T cell subsets, including neoplastic T cells, following anti-PD-1 therapy. Serum proteomic evaluation revealed that high levels of the chemokines CXCL9, CXCL10 and CXCL11 at baseline were associated with negative and positive clinical outcomes in MF and SS subjects respectively following anti-PD-1 therapy as a single agent. Though not statistically significant, treatment with exogenous IFNg may have reversed this trend.

Conclusions We describe features of the immune response as seen in MF and SS subjects following anti-PD-1 monotherapy and in combination with IFNg and emphasize that these subtypes behave as two distinct diseases in response to therapy. It is therefore important to analyze biomarkers in SS separately from MF as combining the diseases may cloud putative signatures.

Ethics Approval These studies were approved Fred Hutch IRB; CITN-10 (anti-PD-1 monotherapy) approval number 8268 and CITN-13 (anti-PD-1 plus IFNg combination therapy) approval number 8588.

95 CHARACTERIZATION OF HUMAN BREAST CANCER TISSUE WITH THE XENIUM IN SITU PLATFORM REVEALS A NOVEL MARKER FOR INVASIVENESS

Robert Henley*, Nicole Rapicavoli, Amanda Janesick, Robert Shelansky, Albert Kim, Janine Hensel, Francesca Meschi, Navid Farahani, Vijay Kumar, Xiaoyan Qian, Sarah Taylor.
x Genomics, Pleasanton, CA, USA

Background Breast cancer became the most diagnosed cancer globally for the first time in 2020. Of these breast cancers, approximately 20% are ductal carcinoma in situ (DCIS). Within the mammary gland ducts, myoepithelial cells and their surrounding basement membrane form a layer separating the breast epithelium from the surrounding stroma.[1] Using Xenium, an in situ analysis platform capable of detecting gene expression patterns of hundreds of RNA targets with subcellular spatial resolution, we investigated the myoepithelial layer of human DCIS breast cancer tissue and observed gene expression alterations that may serve as markers of a transition to tumor invasiveness.

Methods Ten micron thick FFPE tissue sections were prepared from breast tissue blocks containing DCIS and invasive tumor areas. Tissue sections were screened using a Xenium In Situ gene panel of 205 markers and subsequently stained with H&E and imaged at 20X magnification using a light microscope. RNA expression was analyzed with Xenium Explorer software.

Results We analyzed FFPE sections of human DCIS tissues with invasive and non-invasive tumor regions with both H&E staining and with Xenium In Situ for spatial RNA expression profiles. Our data-driven and curated Xenium In Situ gene panel design allowed for the annotation of multiple cell types, including lymphocytes and macrophages, with specific immune subpopulations surrounding the cancerous lesions. In DCIS non-invasive tumor areas, we observed high KRT14 expression and intact myoepithelial tissue. Conversely, in invasive tumor areas, we observed low KRT14 expression and a disrupted myoepithelial layer. The same areas of low KRT14 expression were also positive for progesterone receptor (PGR).

Conclusions Progesterone receptor has previously been identified as playing a role in driving luminal B cell proliferation and invasion.[2] In our study, Xenium In Situ analysis reveals that PGR is associated with regions where the myoepithelial layer appears to have broken down and may represent a novel marker for the transition between DCIS and invasive cancer in human breast tissue.

METASTATIC BREAST CANCER IS ASSOCIATED WITH INCREASED LEVELS OF SOLUBLE INHIBITORY IMMUNE CHECKPOINT PROTEINS AND DECREASED LEVELS OF SOLUBLE STIMULATORY IMMUNE CHECKPOINT PROTEINS

[1]Bernardo Rapoport*, [1]Helen Steel, [2]Carol Benn, [3]Liezl Heyman, [3]Teresa Smit, [1]Ronald Anderson. [1]*University of Pretoria, Pretoria, South Africa*; [2]*Netcare Breast Care Centre, Johannesburg, South Africa*; [3]*The Medical Oncology Centre of Rosebank, Johannesburg, South Africa*

Background Checkpoint proteins regulate the immune system. Breast cancer (BC) cells exploit the up-regulation or down-regulation of these proteins to evade anti-tumor immune responses. Soluble forms of immune checkpoint molecules (ICM) can be measured in human plasma; however, their biological and clinical significance remain essentially unknown. The present analysis aimed to measure plasma ICMs in metastatic BC patients (pts) and compare them to healthy controls.

Methods Soluble forms of ICM and RANTES, arginase and TGF-b1 were measured using Multiplex® bead array and ELISA technologies, respectively. Plasma samples from 20 metastatic breast cancer (MBC) pts and 45 healthy controls were analyzed for each protein. Data was prospectively obtained. Measured levels were compared between MBC pts and healthy controls using a non-parametric test (Mann-Whitney), p-values below 0.05 were considered statistically significant.

Results The median age of the cohort was 53 years (range 34–79 years). The main metastatic sites included liver (10 pts), bone (8 pts), and lung (6pts), with brain-, nodal-, rectum- and skin metastasis presenting in one patient each. The performance status was as follows; PS=0 (11 patients), PS=1 (7 patients,) and PS=2 (2 patients). The median neutrophil-lymphocyte ratio (NLR) was 3.18 (range 0.35 – 10.97). The soluble co-stimulatory molecules, GITR (p<0.0011), GITRL (p< 0.0000), CD27 (p< 0.0039), CD28 (p<0.0069), CD40 (p< 0.0022), CD86 (p< 0.0000) and ICOS (p< 0.0157), as well as the co-inhibitory molecules, PD-L1 (p< 0.0002), CTLA-4 (p< 0.0002) and BTLA (p<0.0145) levels were significantly lower in MBC pts compared to healthy controls. Inhibitory molecules TIM-3 (p< 0.0001) and LAG-3 (p<0.0000 were significantly higher than those of healthy controls. Other biomarkers with raised serum concentrations included TLR (p<0.0039). Serum CD80 (p<0.0992), PD-1 (p<0.2325), HVEM (p<0.062,6) and RANTES (p<0.4861) levels were not significantly different between the MBC pts and the healthy controls (table 1).

Conclusions We identified lower levels of CD27, CD28, CD40, ICOS, GITR, GITRL, CD86, PD-L1, CTLA-4, BTLA, arginase, and TGF-β1, and higher levels of TIM-3 and LAG-3 immune checkpoint molecules in MBC pts compared to healthy controls. These results indicate that a down-regulation of soluble ICM pathways and an up-regulation of some inhibitory ICM pathways are associated with MBC patients. To our knowledge, this is the first study to describe soluble immune checkpoint molecules in MBC pts.

Ethics Approval Ethics approval was granted by The Research Ethics Committee, Faculty of Health Sciences, University of Pretoria (Ethics Committee Approval Numbers 517/2017.

EFFECT OF ADMINISTRATION OF NEOADJUVANT CHEMOTHERAPY TO NEWLY DIAGNOSED EARLY BREAST CANCER PATIENTS ON THE DEPRESSED PLASMA LEVELS OF SOLUBLE CO-STIMULATORY AND CO-INHIBITORY IMMUNE CHECKPOINT MOLECULES

[1]Bernardo Rapoport*, [1]Helen Steel, [2]Carol Benn, [3]Simon Nayler, [4]Teresa Smit, [4]Liezl Heyman, [1]Annette Theron, [1]Nomsa Hlatshwayo, [1]Luyanda Kwofie, [1]Pieter Meyer, [1]Ronald Anderson. [1]*University of Pretoria, Pretoria, South Africa*; [2]*Netcare Breast Care Centre, Johannesburg, South Africa*; [3]*Drs Gritzman and Thatcher Inc, Johannesburg, South Africa*; [4]*The Medical Oncology Centre of Rosebank, Johannesburg, South Africa*

Background Neoadjuvant chemotherapy (NAC) may alter the immune landscape of patients with early breast cancer (BC), potentially setting the scene for more effective implementation of checkpoint-targeted immunotherapy, albeit by largely unexplored mechanisms.

Methods This study investigated which alterations in the plasma concentrations of 16 soluble co-stimulatory and co-inhibitory, immune checkpoints were measured in a cohort of newly diagnosed, early BC patients (n=72) pre-treatment, post-NAC, and post-surgery using a Multiplex® bead array platform.

Results Relative to a group of healthy control subjects (n=45), the median pre-treatment levels (table 1) of 5 co-stimulatory (CD27, CD40, GITRL, ICOS, GITR) and 3 co-inhibitory (TIM-3, CTLA-4, PD-L1) soluble checkpoints were significantly lower in the BC patients vs. controls ($p<0.021$—$p<0.0001$; and $p<0.008$—$p<0.00001$, respectively). Following NAC (table 2), the plasma levels of 6 soluble co-stimulatory checkpoints (CD28, CD40, ICOS, CD27, CD80, GITR), all involved in activation of $CD8^+$ cytotoxic T cells, were significantly increased relative to pre-treatment levels ($p<0.04$—$p<0.00001$), being comparable with control values and remaining at these levels post-surgery (table 3). Of the soluble co-inhibitory checkpoints, 3 (LAG-3, PD-L1, TIM-3) increased significantly post-NAC, while PD-1 was unchanged and BTLA and CTLA-4 were significantly decreased ($p<0.03$ and $p<0.00001$, respectively). A pathological complete response was documented in 65% of patients (mostly TNBC).

Conclusions Normalization of soluble co-stimulatory immune checkpoints is seemingly indicative of reversal of systemic immune dysregulation following administration of NAC in early BC, independent of response to treatment, while recovery of immune homeostasis may explain the increased levels of several negative checkpoint proteins, albeit with the exceptions of CTLA-4 and PD-1.

Ethics Approval Ethics approval was granted by The Research Ethics Committee, Faculty of Health Sciences, University of Pretoria (Ethics Committee Approval Numbers 517/2017.

98 IMAGING MASS CYTOMETRY IDENTIFIES IMMUNO-ONCOLOGY-BASED PATHOPHYSIOLOGICAL FEATURES OF THE MOUSE TUMOR TISSUE MICROENVIRONMENT

Thomas Pfister*, Christina Loh, Michael Cohen, Sam Lim, Qanber Raza. *Standard BiTools, Toronto, Canada*

Background Mouse tumor models are widely utilized as the preferred model organism for cancer studies and pre-clinical drug development. An obstacle in predicting therapeutic drug efficacy is the ability to quantitatively evaluate the multi-parametric post-treatment response in the tumor microenvironment (TME). Particularly, identification of immunological and oncological processes that dictate tumor growth, metastasis and immune response are essential for selecting promising drug candidates for further clinical evaluation. Imaging Mass Cytometry™ (IMC™) enables analysis of 40-plus distinct tissue and cellular markers simultaneously on tumor samples, providing a thorough assessment of the spatial landscape of the TME on a single slide without spectral overlap or background autofluorescence. Here, we showcase application of the Mouse Immuno-Oncology (IO) IMC Panel Kit for identification of pathophysiological features of the mouse TME.

Methods We compiled the Maxpar® OnDemand™ Mouse Immuno-Oncology IMC Panel Kit to quantitatively assess IO-related processes and applied it to a tissue microarray containing multiple mouse tumors. Antibodies in panel kits were selected from the Maxpar and Maxpar OnDemand catalog. Data acquisition was performed using a Hyperion™ Imaging System (Standard BioTools™). To facilitate cell segmentation, the IMC Cell Segmentation Kit (Standard BioTools) was applied to enhance nuclear and cell membrane demarcation. Single-cell analysis was completed using a custom MATLAB® script for pixel classification, CellProfiler™ for cell segmentation and histoCAT™ for PhenoGraph clustering.

Results The Maxpar OnDemand Mouse Immuno-Oncology IMC Panel Kit successfully identified pathophysiological processes such as immune cell infiltration and activation, signaling pathway activation, biomarkers of epithelial to mesenchymal transition, metabolic activity, growth and the tissue architecture of the TME. Single-cell analysis of non-small-cell lung carcinoma and B cell lymphoma separated distinct cellular clusters representing tumor, immune, stromal and vascular cells. Based on expression of activation markers in the panel kits, cellular processes associated with signaling, growth and metastasis were identified in tumor cells. In addition, cytotoxic and inflammatory activation in lymphoid and myeloid immune cell subtypes was detected.

Conclusions Application of IMC based multiparametric analysis successfully identified the spatial landscape of the TME at single-cell resolution. Quantitative analysis of tumor composition revealed critical insights regarding prognostic parameters such as metastatic and growth potential of tumors, and identification and activation of immune cell infiltrates. Overall, this work demonstrates the power of IMC technology and provides evidence of its successful application in mouse tumor models.

99 SPATIAL INSIGHTS INTO TUMOR IMMUNE EVASION ILLUMINATED WITH THE COSMX™ SPATIAL MOLECULAR IMAGER PLATFORM

Jason Reeves*, Patrick Danaher, Shanshan He, Sean Kim, Michael Patrick, Julian Preciado, Justin Jenkins, Rachel Liu, Sarah Murphy, Christine Kang, Byron Hartman, Vik Devgan, Youngmi Kim, Michael Rhodes, Joseph Beechem. *NanString Technologies, Seattle, WA, USA*

Background Patient response to immunotherapy has been revolutionary but remains limited due to the inability to convert excluded or cold tumors into ones which would be permissive to therapeutic intervention. To treat patients that evade immune therapy, comprehensive understanding of their tumor microenvironment (TME) is needed. To date, most profiling efforts have lacked the ability to capture high-plex 'omics data while retaining the spatial architecture of the TME. We developed the CosMx™ Spatial Molecular Imager for analyzing formalin-fixed paraffin-embedded (FFPE) or fresh-frozen (FF) tissue and capturing the expression of over 1000 RNA targets simultaneously with subcellular resolution from a single histopathology slide.

Methods We profiled a cohort of 10 patient samples with CosMx using the Human Universal Cell Characterization Panel across a range of solid tumors. This cohort represents a diverse array of patients which include both infiltrated and excluded tumors. We included technical replicates for 5 of the samples to better understand reproducibility of the assay. We were able to characterize over 1.8 million cells, and detected on average over 80% of the panel per patient and assigning more than 95% of the transcripts profiled to unique cells across these samples.

Results We were able to robustly identify more than 20 cell types by integrating our data with previous single-cell sequencing projects from the human cell atlas. We demonstrate robust delineation of critical immune cell populations from across lymphoid and myeloid lineages, as well as stromal cell populations, including cell types frequently missed using dissociated cell sequencing, such as vascular endothelium associated with immune cell migration into the tumor bed. We leveraged 450 + genes from our panel dedicated to cell lineage, cell-cell interaction, and ligand-receptor signaling to identify unique interactions happening at different scales between the tumor and the TME. These include evidence of direct inhibition of T-cell function through the PDL1 axis between tumor, and tumor intrinsic and extrinsic interactions that mediate tissue architecture and T-cell exclusion.

Conclusions The CosMx platform for profiling tissue allows for robust resolution of critical immunogenic signaling cascades and cellular interactions that are necessary to truly understand the tumor architecture. By maintaining the tissue structure, we can directly measure cellular interactions and capture cells commonly missed during dissociative studies. With this new platform, we are better poised than ever to truly understand the molecular mechanisms which drive tumor response to intervention.

FOR RESEARCH USE ONLY Not for use in diagnostic procedures.

100 TUMOR HOMOLOGY WITH SELF AS A BIOMARKER FOR RESPONSE TO CHECKPOINT INHIBITOR THERAPY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0100

[1]Guilhem Richard*, [2]Gary Steinberg, [1]Nicole Ruggiero, [1]William Martin, [1]Anne de Groot.
[1]EpiVax Therapeutics, Inc., Providence, RI, USA; [2]NYU Langone Health, NYC, NY, USA

Background As tumor genomes are shaped by their interaction with the immune system, a phenomenon known as immunoediting, it is critical to understand how immunotherapies impact this process. Checkpoint inhibitors directly influence T cells responding to neoantigens, as such, these therapies drastically affect the genomes of surviving tumor clones. Similar to the concept of immune camouflage, where genomes of pathogens evolve in a way to avoid immune detection, we hypothesized that tumor clones surviving checkpoint inhibition therapy harbor mutations more prone to immune avoidance.

Methods We analyzed a published cohort of Nivolumab-treated melanoma patients (n=41) for which tumor samples were collected from the same site prior ('Pre' samples) and during ('On' samples) Nivolumab therapy.[1] The immunogenic and tolerance potential of mutations from the Pre and On samples were evaluated with the Ancer neoantigen screening platform,[2] which includes the EpiMatrix algorithm to identify HLA class I and HLA class II neoepitopes and the JanusMatrix algorithm to evaluate neoepitopes for homology with the self genome. Prior work with JanusMatrix showed that neoantigens highly homologous to self might be inhibitory.[3]

Results Tumor samples collected during Nivolumab therapy demonstrated increased homology (self-like) scores from their matched pre-therapy samples (paired t test, p=0.0475). While this increase in homology with self was significant across the cohort, the effect was more pronounced in patients exhibiting complete (CR) or partial responses (PR), compared to patients with stable (SD) or progressive disease (PD). An ANOVA analysis confirmed that increase in homology after Nivolumab therapy was significantly greater in CR/PR patients, as opposed to SD or PD patients (p=0.0005). This observation was supported by Receiver Operating Characteristic (ROC) analysis discriminating CR/PR patients from SD/PD patients based on differences in homology with self between Pre and On treatment samples (AUC=0.7484, p=0.0313). A comparative ROC analysis employing baseline patient tumor mutation burden (TMB) yielded non-conclusive results (AUC= 0.5054, p=0.9613).

Conclusions Our Ancer analysis highlights that Nivolumab therapy affects the tolerance profile of tumors in a manner that is consistent with the concepts of immunoediting and immune camouflaging. Interestingly, tumors in patients with favorable outcomes demonstrated the greatest increase in self-like neoepitopes. This observation suggests that collecting tumor biopsies shortly after the initiation of checkpoint inhibitor therapy and evaluating their tolerance profile may be employed as a prognostic biomarker. Furthermore, this approach highlights in silico tools may distinguish effector from tolerance inducing neoepitopes, a critical feature for designing novel neoantigen-based precision immunotherapies.

101 DETERMAIO (IO SCORE) IS ASSOCIATED WITH EFFICACY OF ICI MONOTHERAPY IN ADVANCED NSCLC PATIENTS WITH ECOG 2

[1]David Saltman*, [2]Rob Seitz, [2]Tyler Nielsen, [2]Matthew Varga, [3]Nicole Croteau, [1]Heather Lockyer, [2]David Hout, [2]Brock Schweitzer, [2]Douglas Ross, [4]Amit Jain, [4]Gregory Vidal, [5]David Gandara. *[1]BC Cancer, Victoria, Canada; [2]Oncocyte Corporation, Nashville, TN, USA; [3]University of British Columbia, Vancouver, Canada; [4]West Cancer Center, Memphis, USA; [5]University of California, Davis, Sacramento, CA, USA*

Background Immune checkpoint inhibitor (ICI) therapy is an attractive option for aNSCLC patients with poor performance status (ECOG 2) but several studies have failed to demonstrate benefit. DetermaIO (IO score) is a 27-gene RT-qPCR immuno-oncology tumor immune microenvironment (TIME) RNA expression classifier that has been previously shown to be associated with clinical response to ICI therapy in multiple tumor types. This study was performed to explore the possibility that the IO score (IO+/IO-) could identify responders in patients with ECOG 2 whose overall poor outcome might otherwise obscure detecting a significant clinical benefit.

Methods Available FFPE specimens with ECOG 2 from two studies of advanced NSCLC patients treated with ICI monotherapy were analyzed independently. The first, composed of 46 patients from BC Cancer (BCCA), was split into two cohorts due to the differences in treatment and PD-L1 status: Cohort 1 was composed of patients with PD-L1 $\geq$ 50% who received 1st line ICI monotherapy (n=26). Cohort 2 was composed of mostly PD-L1 negative or 1–49% patients who received ICI monotherapy in the 2nd+ line (n=20). Cohort 3 was comprised of thirteen patients of mixed PD-L1 phenotype and mixed line of therapy from an independent center, West Cancer Center (WCC). In total, 59 patients treated with ICI monotherapy from the three cohorts were analyzed separately for association with PFS using Cox proportional hazards.

Results Overall, 35 of 59 patients were IO+ (cohort 1 = 18/26, cohort 2 = 10/20 cohort 3 = 7/13). Median PFS improved for IO+ versus IO- in each of the three cohorts (cohort 1 IO- = 67, IO+ = 357; cohort 2 IO- = 100, IO+ =189; cohort 3 IO- = 127, IO+ = 404). The Cox proportional hazard for cohort 1 was 0.27 (95%CI 0.10 to 0.72, p=0.0095), cohort 2 was 0.51 (95%CI 0.20 to 1.32, p=0.17), and cohort 3 was 0.14 (95%CI 0.027 to 0.76, p=0.023).

Conclusions DetermaIO has identified significant benefit for PFS from two cohorts of ECOG 2 patients and trended towards significance in a 3rd cohort treated in the 2nd+ line. While each cohort alone is modestly powered, the consistent results in three independent cohorts, separated for analysis to control for other confounding prognostic variables, suggests that DetermaIO is worthy of further study as a biomarker to better identify ECOG 2 patients likely to benefit from ICI therapy.

Ethics Approval This study was approved by the Research Ethics Board (REB) of University of British Columbia (H20–02635). Individual consent for this retrospective analysis and the use of tumor samples for the IO score assay was required for live patients. Consent was waived by the REB for deceased patients.

102 EXPLORING THE SPATIAL HETEROGENEITY OF IMMUNE CELLS IN NASOPHARYNGEAL TUMOURS

Aastha Sobti*, Christina Sakellariou, Johan Nilsson, David Askmyr, Lennart Greiff, Malin Lindstedt. *Lund university, Lund, Sweden*

Background Nasopharyngeal cancer (NPC) is a squamous cell carcinoma of the upper pharynx, strongly associated with Epstein-Barr virus (EBV), and with varying incidences in the world. We have previously investigated the presence and distribution of $CD8^+$ T cells in NPC and found that an 'inflamed profile', with $CD8^+$ T cells in and around cancer cell areas, was associated with better disease-free survival (*cf.* non-inflamed 'desert' tumours). In this study, we explore immune-related biomarkers in a spatial context to assess distribution of cell types and quantify selected biomarkers within the NPC.

Methods Using the GeoMx Digital Spatial Profiler (DSP), 49 target proteins were digitally quantified on an NPC tissue microarray consisting of 30 unique biopsies. DSP combines spatial and molecular profiling technologies and enable assessment of different features of intratumoral structures in a cell type-specific manner while simultaneously performing protein expression analysis on selected regions-of-interest (ROIs). A total of 96 ROIs were obtained based on morphological staining using CD45, CD8, and PanCK antibodies, and a quantitative analysis was performed between ROIs within the tumour area and outside/stroma.

Results To evaluate unbiased grouping of segments, principal component analysis and k-means clustering were conducted. Protein targets CD56, CD20, CD68, PD-1, FOXP3, and Ki-67 were the most differentially expressed in the $CD45^+$ segments within the tumour area, suggesting a presence of B cells, NK cells, macrophages, and regulatory T cells in the tumour area. In contrast, B7-H3, fibronectin, CD163, CD4, VISTA, LAG3, and TIM3 were higher in the $CD45^+$ segments outside the tumour barrier, indicating a presence of suppressive populations of myeloid cells and T cells. Additionally, the expression of B7-H3 correlated best with a presence of CD14, fibronectin, and CD163. Interestingly, the presence of PD-1 was limited to within tumour-rich regions, in contrast to other 'immune regulatory' proteins like LAG3, VISTA, and TIM3, which were found on the tumour border and in the stroma. The detected proteins were validated with multiplexed staining.

Conclusions This study considers the spatial heterogeneity of the NPC immune microenvironment and demonstrates a variable expression of immune checkpoint markers in NPC. The identified immune profiles and highlighted biomarkers may be of relevance as a prognostic tool and for therapeutic targeting.

Ethics Approval The collection of biobank samples from Lund University was approved by ethics committee Dnr 2014/117.

Consent In accordance with the ethics approval, informed consent was not required, but the study was advertised in print media with the option to opt-out

103 SPATIAL PROTEIN ANALYSIS OF THE TUMOR MICROENVIRONMENT AND BIOMARKERS IN HODGKIN'S LYMPHOMA

[1]Alexander Xu*, [2]Tomohiro Aoki, [2]Aixiang Jiang, [1]Alicia Gamboa, [1]Anthony Colombo, [2]Christian Stiedl, [1]Akil Merchant. [1]*Cedars Sinai Medical Center, Los Angeles, CA, USA*; [2]*BC Cancer, Vancouver, Canada*

Background The tumor microenvironment (TME) is the milieu of cells and molecules surrounding the tumor. Single cell methods have been used to identify subpopulations of cells that have pro- or anti-tumor properties, and modulating these is critical to immunotherapy. However, there is limited information on the spatial organization of these subpopulations, which determines how they signal and their therapeutic potential. **Single cell spatial computational analysis is needed to describe the interactions of the TME and their effect on patient outcomes.** Hodgkin's Lymphoma presents a unique TME due to the sparse distribution of Hodgkin's Reed-Sternberg tumor cells. Though it is difficult to disentangle signaling in Hodgkin's tumor cells from the immune TME, Hodgkin's is receptive to checkpoint inihibitors among lymphomas and insights gleaned from the Hodgkin's TME could inform immunotherapies across lymphomas.

Methods Here we apply Imaging Mass Cytometry (IMC), a technology to perform ~40-plex protein analysis with 1 micron resolution in tissue, to study a cohort of 260 matched samples at diagnosis and after relapse from 90 patients with relapsed/refractory Hodgkin's Lymphoma. We developed a computational pipeline to perform cell phenotyping, spatial analysis, and biostatistics, to describe tumor architecture and propose putative biomarkers of Hodgkin's clinical response and relapse. A novel feature of the pipeline is to quantify proteins and spatial analysis on the same numerical scale for each cell, to generate hybrid biomarkers.

Results We analyzed over 7 million cells for their phenotype and spatial organization. We use IMC to describe spatial features of the tumor that correlate to clinical outcomes. We identify proteins such as CXCR5 that correlate to survival in spatial contexts, and we describe spatial reorganization from diagnosis to the relapsed tumor as it relates to survival and relevant clinical factors such as MHC expression and EBV infection. A significant conceptual advance was to use spatial metrics to perform 'digital biopsies', a selection of tumor regions comparable across patients. We validated multiple existing biomarkers in the literature using our data set and proposed novel biomarkers using IMC data.

Conclusions Spatial analysis of the HL microenvironment revealed composite features of the TME that predict clinical outcomes. These features cannot be described using single cell tools or low-plexed imaging, and represent a truer picture of HL biology. The pipeline developed here can be applied to other spatial protein data for biomarker discovery and analysis.

104 COMPREHENSIVE SINGLE-CELL IMMUNE PROFILING OF LYMPHOID AND PERIPHERAL TISSUES OF AGED MICE USING HIGH-PARAMETER FLOW CYTOMETRY BY CYTOF TECHNOLOGY

Wenxi Xu, Stephen Li, Alexandre Bouzekri, Thomas Pfister*, Christina Loh. *Standard BiTools Inc., Markham, Canada*

Background High-parameter flow cytometry is a major tool used in human and mouse studies to discover novel immunological mechanisms of infectious diseases, cancer and immunosenescence. Fluorescence-based cytometry can be especially challenging in mouse model studies due to the large amount of cell samples needed for single-stained controls. CyTOF® technology has transformed high-parameter flow cytometry by enabling 50-plus-marker analysis per tube of sample, with easy panel design and no need for single-stained or autofluorescence controls. Flow cytometry by CyTOF thus provides an efficient and unbiased approach to discovering novel cell populations and unique functional states of immune cells with minimal cell number requirements. Here we present how Standard BioTools™ commercially available mouse antibody products can be incorporated into a high-parameter panel, enabling comprehensive single-cell immune profiling of both lymphoid and peripheral tissues of individual aged mice.

Methods Antibodies from the Maxpar® and Maxpar OnDemand™ catalogs were used to create a panel identifying lymphocytes, myeloid cells, functional markers and immune checkpoint markers (for example, PD-1 and PD-L1). Lymphoid and peripheral tissues (for example, lung and spleen) from young adult and aged mice were harvested and processed for cell staining with a 42-parameter cytometry panel. Sample acquisition was performed using the Helios™ mass cytometer. High-dimensional single-cell data analysis was carried out with Maxpar Pathsetter™ and R package PhenoGraph and UMAP.

Results In young adult and aged mice, we identified more than 10 major immune cell populations, including lymphocytes and myeloid cells in multiple lymphoid and peripheral tissues, by unsupervised high-dimensional data clustering. We further defined and quantified more than 30 immune cell clusters with distinct phenotypes (for example, naive, effector, effector memory and central memory T cells). The frequency, activation and checkpoint marker status of these cell clusters were analyzed and compared between young adult and aged mice to identify the age-related changes in the immune system of multiple organs.

Conclusions This work demonstrates that by using CyTOF technology together with Maxpar and Maxpar OnDemand mouse antibodies, comprehensive single-cell phenotyping of the immune system in multiple distinct tissues of individual aged mice is easily accomplished. Moreover, the high-parameter panel can be further customized for deep functional characterization of specific lymphocytes and myeloid cell subsets. Thus, by utilizing the well-curated collection of Maxpar and Maxpar OnDemand mouse antibodies, flow cytometry by CyTOF can significantly facilitate the mechanistical studies of mouse models and expand our understanding of age-related human diseases, infection and cancer.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0104

105 PREVALENCE OF CLAUDIN18.2 AND PD-L1 EXPRESSION IN CHINESE GASTRIC/GASTROESOPHAGEAL JUNCTION ADENOCARCINOMA

Linlin Mao*, Wei Yi, Xu-Alan Lin, Ying Gu, Zhenzhong Xia, Chuan Qi, Michael Shi, Steven Yu, Xueming Qian. *Suzhou Transcenta Therapeutics Co., Limited, Suzhou, China*

Background Claudin18.2 (CLDN18.2), a tight junction protein highly specific to gastric mucosa, is a promising target for gastric cancer (GC) treatment.[1] Immunotherapy targeting PD-1 combined with chemotherapy has been approved as the first line treatment of GC.[2] Understanding the expression profiles of CLDN18.2 and PD-L1 could offer guidance for the development of combination therapies that maximize the benefits of both agents. This study investigated the prevalence of CLDN18.2 expression in gastric/gastroesophageal junction (GC/GEJ) adenocarcinoma and its correlation with PD-L1 expression in Chinese patients.

Methods Expression of CLDN18.2 in formalin-fixed, paraffin-embedded (FFPE) GC/GEJ tissue samples was detected by immunohistochemistry (IHC) using an in-house anti-CLDN18.2 antibody (Clone14G11) on the Leica Bond III IHC stainer. Both the staining intensity (0, 1+, 2+, 3+) and the percentage of positive tumor cells were evaluated. CLDN18.2 positivity was defined as expression of CLDN18.2 in $\geq$ 10% tumor cells with intensity $\geq$ 1+. Samples with moderate-to-strong CLDN18.2 membrane staining (intensity $\geq$ 2+) in $\geq$ 40% tumor cells were also analyzed. PD-L1 expression was assessed based on combined positive score (CPS) using Agilent's PD-L1 IHC 28–8 pharmDx.

Results A total of 300 GC/GEJ resected tissue samples were assessed, 89 (30%) were histologically classified as intestinal, 158 (52%) diffuse, 33 (11%) mixed, and 20 (7%) others. 295 (98%, 286 GC, 9 GEJ) samples were from primary site, 5 (2%) samples were from metastatic site (ovary, lymph node, omentum or left adnexa). CLDN18.2 staining was positive in 216 (72%), and negative in 84 (28%) of the tissue samples. 136 (45%) samples showed moderate-to-strong CLDN18.2 membrane staining in $\geq$ 40% tumor cells. CLDN18.2 positivity prevalence was 75% (n = 119/158) in diffuse and 61% (n=54/89) in intestinal subtypes. Moderate-to-strong CLDN18.2 membrane staining in $\geq$ 40% tumor cells was observed in 48% (n=76/158) diffuse subtypes, and in 39% (n=35/89) intestinal subtypes. For PD-L1 expression, 51 (17%) had PD-L1 CPS $\geq$ 5. 19% (n=41/216) of the CLDN18.2 positive samples also showed PD-L1 CPS $\geq$ 5. In the CLDN18.2 subgroup with moderate-to-strong CLDN18.2 membrane staining in $\geq$ 40% tumor cells, 21% (n=28/136) had PD-L1 CPS$\geq$5. It appears that the distribution of CLDN18.2 expression is independent of PD-L1 status.

Conclusions High prevalence of CLDN18.2 expression in Chinese patients with GC/GEJ adenocarcinoma was observed. About 80% CLDN18.2 positive tumors had PD-L1 CPS < 5. These results support the value of CLDN18.2-targeted therapy in gastric cancer, especially for those patients who may not benefit from anti-PD-1/PD-L1 immuno-checkpoint therapy.

106 DEVELOPMENT OF RO ASSAY FOR ANTI-PD-1 MAB AND ANTI-PD-1×CD47 BSAB UTILIZING HPD-1/HCD47 DUAL HUMANIZED MICE, AT PRECLINICAL SETTING TO FACILITATE CLINICAL VALIDATION

[1]Xiaoyu An*, [1]Mingfa Zang, [2]Ke Hang, [3]Xianfei He, [3]Ruilin Sun, [3]Jian Fei, [2]Henry Li, [1]Haijuan Yu. *[1]Crown Bioscience Inc, san diego, CA, USA; [2]Hanx Biopharmaceuticals, Wuhan, China; [3]Shanghai Model Organisms Center, Inc, Shanghai, China*

Background One of the most relevant pharmacokinetic (PK) parameters for antibody-based therapy in the clinics is receptor occupancy (RO). Each specific therapeutics usually requires a tailored RO assay, an PD-1 RO assay for anti-PD-1 antibody treatment. For bispecific antibody (BsAb) treatment, the needed RO assays can include each receptor RO and total RO combining the two different receptors. Due to the complexity and challenges in developing such assays using clinical samples, it would be prudent to develop a model system to test RO assay methods *in vivo* at the preclinical stage prior to clinical validation, since it may simulate dosing process in human and also provide opportunity to correlate RO to tumor model efficacy if tumor pharmacology is also conducted simultaneously. Surface expressing CD47 and PD-1 receptors are recognized two most important checkpoints for both innate and adaptive immunity suppressing tumor immunity, and have been explored for immunotherapies, in the cases of investigational drugs, HX008 (PD-1 mAb) and HX009 (CD47×PD1 BsAb).[1–4] In order to facilitate development of RO assay for the clinics, we explored preclinical modelling RO assays using hPD-1/hCD47 dual humanized mouse model for testing these two species-restricted investigational drugs.

Methods The brief procedures are as followed: 1) Non-tumor bearing hPD1×hCD47 dual humanized mice were single administrated via *i.p.* injection with test antibodies at different dose levels; 2) PBMCs were collected and prepared from the animals at different timepoints (pre-dosing, 2 hours post dosing and 7 days post dosing; 3) one half of the PBMC samples were added into the vials containing over-saturating amount of test antibody, and the other half were added into the vials containing PBS, followed by mixing; 4) add defined amount of fluorescence-labeled test antibody, followed by washing and flow cytometry analysis, and the%RO being determined. The test antibodies could be anti-human PD-1 antibody, anti-human CD47 antibody or anti-human PD-1×CD47 BsAb for measuring the respective RO values.

Results Preliminary results demonstrated that HX008 RO assays showed anticipated dose dependent RO values at both timepoints, suggesting this assay development is highly doable and predictive using the preclinical humanized models. Further detailed to be analyzed, including HX009 RO values for PD-1 receptor only, CD47 receptor only and total for combining both receptors.

Conclusions Supposing further data from HX-009 RO modelling proven valid, RO assay using humanized mice could become a standard method of choice for RO assay development at the preclinical stage, enabling simpler/efficient clinical development.

107 TUMOR SPECIFIC MHC-I EXPRESSION DETERMINES THE LOCAL IMMUNE MICROENVIRONMENT IN BREAST CANCER

Xiaopeng Sun*, Brandie Taylor, Paula Gonzalez Ericsson, Violeta Sanchez, Justin Balko.
Vanderbilt University Medical Center, Nashville, TN, USA

Background Tumors employ various immune escape mechanisms, including downregulation of major histocompatibility complex I (MHC-I) expression, to avoid T cell-mediated antitumor immunity. Although complete MHC-I loss is possible, most tumors express MHC-I in a heterogeneous manner, with a mix of MHC-I high, mid, and low expressing tumor cells. However, the intratumor MHC-I heterogeneity and its impact on the immune microenvironment still require further study. The goal of this study is to investigate MHC-I expressional heterogeneity in breast cancer and characterize the immune landscape, with a focus on CD8 T cells, which target MHC-I expressing tumor cells, and NK cells, which target MHC-I negative/low tumor cells, in a spatial manner within the tumor microenvironment.

Methods We performed quantitative immunofluorescence for MHC-I, CD8, CD56 (NK cell marker), and pan-cytokeratin on breast cancer tumors (n=314) from diverse subtypes to obtain single-cell resolution MHC-I expression and spatial information of tumor and immune cells. Ripley's K function was used to analyze the spatial distribution of MHC-I high, mid, and low expressing tumor cells. We also performed density-based clustering to arrange neighboring tumor cells into clusters and subsequently examine the local immune cell infiltration.

Results All clinical breast cancer subtypes showed high variability in MHC-I expression, with triple-negative breast cancer (TNBC) having the highest MHC-I expression and the largest percentage of tumors with multimodal MHC-I expression (consisting of MHC-I high, mid, and low expressing tumor cells). Both MHC-I high and low expressing tumor cells, especially those in TNBC, tend to cluster and create tumoral MHC-I hot and cold spots. Meanwhile, the MHC-I high-expressing stromal cells and CD8 T cells clustered with tumoral MHC-I hot spots, while MHC-I cold spots exhibited the lowest lymphocyte infiltration and clustered with MHC-I low-expressing stromal cells. Interestingly, heterogenous MHC-I tumor clusters (those with mixed high and low expressing cells) had the highest levels of infiltrating NK cells.

Conclusions Our work reveals the heterogeneity of MHC-I expression among different breast cancer subtypes. TNBC, the immune checkpoint inhibitor (ICI)-sensitive subtype, is characterized by the highest MHC-I expression and well-defined MHC-I hot and cold spots. Additionally, the local immune landscape around MHC-I hot, cold, and heterogeneous clusters are significantly different. Increased NK cell infiltration in areas where tumor cells heterogeneously express MHC-I was also consistent with our preclinical heterogeneous MHC-I mammary tumor model. Those results suggested that immunotherapy-resistant, MHC-I heterogeneous tumors may be sensitized by combining an NK cell activation drug, such as anti-NKG2A, with already-available ICIs.

Ethics Approval Samples involved in this study are under IRB030747 and INEN 10–018

108 PREDICTION OF CANCER IMMUNOTHERAPY RESPONSE USING ULTRASOUND IMAGING OF TUMOR STIFFNESS AND PERFUSION

[1]Chrysovalantis Voutouri*, [1]Triantafyllos Stylianopoulos, [1]Fotios Mpekris, [1]Myrofora Panagi, [1]Christina Michael, [2]John Martin. *[1]University of Cyprus, Aglantzia, Nicosia, Cyprus*; *[2]Materia Therapeutics, Las Vegas, Nevada,, Las Vegas, NV, USA*

Background Solid tumors are highly heterogeneous tissues that might differ considerably between different types or even among tumors of the same type. As a result, while in some patients (responders) a particular treatment may be very effective, in other patients (non-responders) the same treatment may not be beneficial and in many cases. Emerging technologies have been used towards the development of new biomarkers mainly through analyzing the human genome or biological markers, such as the expression of PD-L1/PD-1, but so far most of them have failed to translate into clinical tools[1] and only a limited number has managed to be approved for cancer prediction.[2, 3] Here, we hypothesize that aspects of the tumor microenvironment, and particularly the tumor stiffness and perfusion can be used as biomarkers predictive of response to immune checkpoint inhibition in desmoplastic (i. e., rich in extracellular fibers) murine tumor models.

To modulate tumor stiffness and improve perfusion, strategies based on the use of drugs that inhibit CAF-stimulating signaling factors to normalize the levels of intratumor extracellular matrix have been developed. These therapeutics are known as mechanotherapeutics, because they normalize mechanical abnormalities in the TME, i.e., stiffness and blood flow.[4, 5] Towards the development of this novel therapeutic class, several generic drugs with decades of safe use in other diseases have been repurposed to act as cancer mechanotherapeutics, including the anti-hypertensives losartan and bosentan, the corticosteroid dexamethasone, the antihistamine tranilast and the antifibrotic pirfenidone.[6–11]

Methods In this study, we employed clinically-applied ultrasound shear wave elastography (SWE) and contrast-enhanced ultrasound (CEUS) to demonstrate in four orthotopic murine tumor models of breast cancer (4T1 and E0771), sarcoma (MCA205) and melanoma (B16F10) that specific measures of stiffness and perfusion can predict the efficacy of immune checkpoint inhibition.

Results Interestingly, we further show that these correlations between tumor stiffness/perfusion and therapeutic efficacy are valid even when data from all tumor models are considered together (figure 1). SWE and CEUS are non-invasive imaging modalities that are employed for diagnostic purposes in the clinical practice in oncology, cardiology and other diseases.[12–15]

Conclusions Furthermore, SWE has been investigated in patients with breast cancer as a marker of response to chemotherapy.[16] Therefore, the results of our study are highly transferable to the clinic.

Abstract 108 Figure 1 Tumor stiffness strongly correlates to perfusion markers independently of heterogeneities among tumor types. Plots of the stiffness (in terms of elastic modulus) of 4T1, E0771, MCA205 and B16F10 tumors as a function of the values of the perfusion measures of mean transit time and rise time demonstrate the strong linear correlation even when data from all tumor types are considered together. The Pearson's r value and the R2 value of the best linear fit to the experimental data is shown to quantify the strength of the correlations. A Pearson's r value>0.8 denotes a very strong correlation

109 QUANTITATIVE SPATIAL ASSESSMENT OF THE TUMOR-IMMUNE MICROENVIRONMENT IN THE METASTATIC MELANOMA LYMPH NODE

[1]Rachel Maus*, [1]Raymond Moore, [1]Alexey Leontovich, [1]Zachary Fogarty, [1]Ruifeng Guo, [1]Chathu Dona, [1]Burak Tekin, [1]Jill Schimke, [1]Betty Dicke, [2]Benjamin Chen, [1]Svetomir Markovic. *[1]Mayo Clinic, Rochester, MN, USA; [2]Bristol-Myers Squibb, Cambridge, MA, USA*

Background Lymph nodes often serve as the first site of metastasis in solid tumors despite being specialized peripheral immune organs. Evaluating tumor-immune interactions within distinct architectural regions of the lymph node has the potential to inform the clinical heterogeneity observed in metastatic cancer response to immunotherapy. Here, we applied multiplexed immunofluorescence (MxIF) to melanoma lymph node (LN) tissue specimens to quantify tumor-immune interactions contributing to recurrence risk in patients receiving anti-PD1 immunotherapy.

Methods Whole, excisional lymph node biopsies were obtained from 33 treatment-naïve patients with metastatic melanoma who underwent subsequent anti-PD1 therapy. A single 5μm formalin-fixed paraffin embedded LN tissue section was used to assess a panel of 45 analytes by cyclic MxIF. Fields of view (~1mm^2) were selected from pathologist-annotated regions of the tumor core (n=447), tumor-immune interface (n=298) and adjacent lymphoid tissue (n=339). Pixel-based single cell segmentation and a supervised classifier approach was applied to resolve 10 distinct tumor, stromal and immune cell phenotypes and functional states (e.g. PD1, PDL1, LAG3) in 5.5 million cells.

Results Stratification based on responsiveness to anti-PD1 therapy resulted in 15 patients experiencing melanoma recurrence by 12 month follow-up. Single cell quantification of the tumor cell fraction was reflective of the pathologist-annotated histology (tumor: 69.7 ± 21.7%, interface: 20.9 ± 13.0%, lymphoid: 0.7 ± 2.5%). Similarly, the distribution of T cell subsets (cytotoxic T, T helper, Tregs) followed conventional histology patterns (tumor 5.3 ± 7.0%, interface: 32.0 ± 16.2%, lymphoid: 51.6 ± 20.9%). Within tumor regions, B and T cell counts displayed a high concordance with pathologist TIL scores as calculated by ANOVA (p-value=0.012). Functional expression of PD1 on T cells was observed in all histologies (tumor: 15.1%, interface: 8.9%, lymphoid: 2.8%). Notably, the percentage of PD1+ T cells was significantly higher in the interface histology of patients that did not experience recurrence (11.5% vs 5.8%) and lymphoid tissue (4.5% vs 1.4%) and lower in the tumor core (14.3% vs 17.7%) suggesting distinctive spatial localization patterns for PD1+ T cells correlate with clinical outcomes ($p<0.001$). Ongoing analyses will evaluate the diverse cellular interactions across these histologies to determine unique spatial signatures that correlate with recurrence.

Conclusions Spatial distribution of PD1+ T cells is regionally enriched at the tumor-immune interface among patients that did not experience recurrence following anti-PD1 therapy. The metastatic lymph node represents an ideal tissue landscape to apply cyclic MxIF and study tumor-immune cellular interactions that inform recurrence risk following immunotherapy.

Acknowledgements The authors would like to thank the physicians of the Mayo Clinic Melanoma Oncology division who treated the patients included in this study. We also wish to extend our gratitude to the patients and their families for entrusting us with their tissue and for their unwavering commitment to scientific advances in metastatic melanoma.

Ethics Approval The study was approved by Mayo Clinic's Institutional Review Board, approval number 20–002866.

110 CHARACTERIZATION OF HPV-SPECIFIC T-CELLS IN BLOOD AND TISSUE IN UGANDAN WOMEN LIVING WITH HIV WITH CERVICAL LOW GRADE SQUAMOUS INTRAEPITHELIAL LESIONS

[1]Amy Codd*, [1]Scott Adams, [1]Cecilia Yeung, [1]Lauri Aicher, [2]Corey Casper, [3]Lisa Frenkel, [4]Thomas Uldrick, [1]Evan Newell. *[1]Fred Hutch Cancer Center, Seattle, WA, USA; [2]Infectious Disease Research Institute, Seattle, WA, USA; [3]Seattle Children's Research Institute, Seattle, WA, USA; [4]Regeneron, Bethesda, MD, USA*

Background Cervical cancer (CC) is the most common cancer in women living with HIV (WLWH) and the leading cause of cancer mortality in women in Uganda.[1,2] CC occurs in a fraction of unresolved high-risk human papilloma virus (hrHPV) infections. HIV is a risk factor for hrHPV infection, however, infection and early stage, low grade squamous epithelial lesions (LSIL), can be resolved by a competent immune response. Nevertheless, WLWH with immune function restored by antiretroviral therapy (ART) remain at higher risk for persistent hrHPV infection, LSIL and progression to high grade squamous epithelial lesions (HSIL).[3] Therefore, we hypothesize that the immune response differs between WLWH, on ART, who progress from LSIL to HSIL/ICC, compared to WLWH, on ART, who experience LSIL regression.

Methods Recently, a cohort (n=304) of Ugandan WLWH and HIV seronegative counterparts was established to categorize hrHPV status and examine associations with the immune response.[4] When stratified by degree of dysplasia, hrHPV infection was more prevalent in WLWH with LSIL (cervical intraepithelial neoplasia (CIN) 0/1), compared to seronegative women, than the same comparison in HSIL (CIN2/3).[4] Due to the scale of this study, immune parameters analyzed were limited to CD4 and CD8 counts and ratio. This prompted us to design a pilot study, subsampling the cohort, for in-depth interrogation of the immune response in LSIL. The study involves analysis of formalin fixed paraffin embedded (FFPE) cervical tissue and peripheral blood mononuclear cells (PBMC) from WLWH, on ART, diagnosed with LSIL associated with hrHPV infection with progression (n=4) or regression (n=4) or WLWH with no dysplasia diagnosis (n=4).

Results We developed a mass cytometry panel incorporating markers of T cell dysregulation and mucosal homing and leveraged combinatorial tetramer technology to analyze PBMC-derived T cell responses to antigens from various hrHPV types. Further functional analysis is being performed using cytokine intracellular staining (ICS) flow cytometry. FFPE-derived DNA and RNA are subject to TCR sequencing and immunology gene focused-Nanostring analysis, respectively, to complement peripheral immune response data. Owing to complexities of sample procurement, data analysis is ongoing.

Conclusions LSIL represents a reversible stage in the development of CC, with recent data[3] suggesting this may be associated with poorer resolution of hrHPV infection in WLWH, compared to seronegative women. In this pilot study, we expect to identify features of immune dysregulation underlying increased risk of malignant progression from LSIL, which could propel larger scale high dimensional analysis of the cohort.

111 INTEGRATING MULTIDIMENSIONAL MASS CYTOMETRY AND MULTIPLEX IMMUNOHISTOCHEMISTRY TO INFER SPATIAL RELATIONSHIPS BETWEEN HUMAN GLIOBLASTOMA INFILTRATING IMMUNE CELLS THAT CORRELATE WITH PATIENT OUTCOME

Todd Bartkowiak*, Asa Brockman, Sierra Lima, Madeline Hayes, Caroline Roe, Justine Sinnaeve, Akshitkumar Mistry, Nalin Leelatian, Bret Mobley, Lola Chambless, Reid Thompson, Kyle Weaver, Rebecca Ihrie, Jonathan Irish. *Vanderbilt University Medical Center, Nashville, TN, USA*

Background Glioblastomas (GBM) account for ~60% of adult primary brain tumors. With few advances in therapeutics, median overall survival remains 15-months post-diagnosis. Immunotherapies may provide therapeutic benefit; however, no predictive immune features have informed therapeutic stratification. Radiographic tumor contact with the lateral ventricle (C-GBM) correlates with 7-months worse prognosis compared to patients with ventricle non-contacting GBM (NC-GBM), yet the influence of ventricle contact on anti-tumor immunity is unknown. This study characterized the GBM immune microenvironment and identified targetable mechanisms of immunosuppression correlating with worse outcomes in C-GBM patients.

Methods Primary glioblastoma tissue was provided with written informed consent in accordance with the Declaration of Helsinki and with approval of the Vanderbilt Institutional Review Board (IRB #131870). Seventeen patients presented with primary, IDH-wildtype C-GBM and 15 with NC-GBM. Machine learning integrated 1) mass cytometry immunophenotyping, 2) metabolic phenotypes, 3) immune cytokine response patterns and induced intracellular signaling networks, and 4) matched multiplex immunohistochemistry on FFPE embedded tissue to identify phenotypic, functional, and spatial biomarkers correlating with patient outcome.

Results C-GBM tumors were enriched in STAT3-driven CD32+CD44+HLA-DR+ monocyte-derived macrophages (MDM) compared to NC-GBM (19 ± 8% vs. 6 ± 2%; $p<0.001$) and depleted in lymphocytes including subsets of T, B and NK cells (2.9 ± 1% vs. 7.6 ± 2%; $p<0.001$) and tissue-resident microglia (1.8 ± 0.3% vs. 7 ± 3%; $p<0.001$). Moreover, 45% of exhausted T cells in C-GBM co-expressed the checkpoint receptors PD-1 and TIGIT despite exhibiting metabolic activity consistent with retained functional capacity. As an orthogonal approach, we used multiplex IHC to identify the spatial distribution of immune cells throughout the GBM tumor tissue. K-means clustering identified 10 immunological niches in GBM tumors. Macrophage-tumor niches were most common in C-GBM (17.93% of niches), followed by T cell-microglia-tumor niches (17.72%). Within NC-GBM niches, T cell-T cell interactions were more prevalent in NC-GBM tumors (log odds ratio = 0.90) and correlated with improved survival outcome.

Conclusions These findings suggest that factors within the periventricular space negatively influence the immune microenvironment within GBM tumors. Clinically targetable immune biomarkers (e.g. PD-1) were identified in C-GBM. Notably, this work highlights the potential impact of radiologic assessment of lateral ventricle contact as a guide for clinical trial design for immunotherapies in neuro-oncology based on tumor proximity to the lateral ventricle wall.

Ethics Approval Primary glioblastoma tissue was provided with written informed consent in accordance with the Declaration of Helsinki and with approval of the Vanderbilt Institutional Review Board (IRB #131870).

Consent No sensitive or identifiable information is included in this study.

Background Age-associated pro-inflammatory states may result in decreased response to immune checkpoint inhibitors (ICI) in older patients (pts) with cancer. We explored the association of circulating inflammatory markers with response to ICIs, and investigate potential differences in transcriptional and TME signatures of pts ≥80-years (yr) of age and younger.

Methods We built a multicenter, international database of pts with different tumors treated with ICIs monotherapy between 2011 and 2021 from 11 academic centers in the US and Europe. Retrospective analysis of 885 pts compared objective response rates (ORR; iRECIST), median progression-free survival (mPFS) and overall survival (mOS) between pts ≥80-yr and <80-yr, and stratified them across serum pre-treatment levels of neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), monocyte-to-lymphocyte ratio (MLR) and systemic immune-inflammation index (SII=PxN/L). Optimal cut-off values for high (H) *vs.* low (L) levels were determined using receiver operating characteristic curves.

DNA (592-gene panel/whole exome) and RNA (whole transcriptome) next-generation sequencing, immunohistochemistry (IHC) and TME analysis (MCP-counter) were performed on 24,123 independent samples of non-small cell lung cancer (NSCLC), melanoma (MEL) and renal cell carcinoma (RCC) submitted to a CLIA-certified laboratory (Caris Life Sciences, Phoenix, AZ). Results were compared between pts ≥80-yr and <80-yr.

Results Table 1 summarizes pts baseline characteristics. Pts <80-yr had better ORR (*P<0.01*), but comparable mOS and mPFS to ≥80-yr (table 2). In pts ≥80-yr, NLR-L and SII-L were associated with higher ORR (*P<0.01* and *P<0.05*; figure 1). All pts with NLR-L, MLR-L and SII-L, had longer mOS (*P<0.01;* figure 2). All PLR-L and SII-L pts had significantly longer mPFS (*P<0.01*; figure 3).

Compared to pts <80-yr, NSCLC ≥80-yr had increased abundance of fibroblasts, dendritic cells and macrophages (*P<0.01*) in their TME and lower TMB-H (*P<0.001*). MEL ≥80-yr pts had fewer TME infiltrating T-lymphocytes (*P=0.02*), a1.24-fold increased expression of *IL-6*. RCC ≥80-yr pts had 0.56-fold decreased expression of *GZMB*, and lower PD-L1 (IHC-SP142, ≥2+|5%) expression (*P<0.05;* figure 4). Additional correlative biomarkers will be reported in the poster.

Conclusions Lower levels of circulating inflammatory markers associated with significantly longer survival and better response rates to ICIs. SII-L and NLR-L specifically are potential biomarkers of response to ICI in pts ≥80-yr. This is the first study to evaluate the role of serum markers of inflammation as potential biomarkers of response to ICI in older pts with cancer, along with molecular correlate. Circulating inflammatory markers, and associated gene expression and TME composition suggest potential unique, cancer-specific biomarkers of response to ICIs in this population.

Ethics Approval The study was approved by the institutional review board at each participating institution. Written informed consent was waived, given the retrospective nature of the study and the de-identified status of collected data.

113 UNCOVERING THE DARK IMMUNOPEPTIDOME OF HEAD AND NECK SQUAMOUS CELL CARCINOMA (HNSCC): RELEVANCE FOR UNIVERSAL CANCER VACCINES, IMMUNOLOGICAL MONITORING AND TIL THERAPY

[1]Noriko Iwamoto*, [1]Takashi Shimada, [2]Tarsem Moudgil, [2]Ryan Meng, [2]Tanisha Christie, [2]Alexa Dowell, [2]Rom Leidner, [2]Bryan Bell, [2]William Redmond, [2]Eric Tran, [3]Hong-Ming Hu, [3]Traci Hilton, [2]Brian Piening, [2]Yoshinobu Koguchi, [3]Bernard Fox. *[1]Shimadzu Corporation, Kyotoi, Japan; [2]Providence Cancer Institute, Portland, OR, USA; [3]UbiVac/Providence Cancer Institute, Portland, OR, USA*

Background Discoveries of the last two years have initiated a renaissance in our understanding of the targets T cells recognize on cancer cells. Identification of HLA-presented non-canonical or cryptic peptides that are non-mutated and have high interpatient sharing in AML [PMID: 33740418], coupled with their absence from the thymus, led them to be designated as alternative neoantigens with potential for being universal cancer vaccines [PMID: 33852826]. These cryptic genes, in some cases, appear to play a role in promoting malignancy, further strengthening the rationale for their identification and use as targets for immunotherapy. Our group seeks to identify the Dark Immunopeptidome of HNSCC. Over the last several months we have swithed from exome-capture RNA-Seq, which fails to detect non-canonical gene sequences, to ribo-Seq, which can capture these cryptic transcripts.

Methods HNSCC cells were lysed and recovered lysates were treated with detergent in the presence of protease inhibitor. HLA peptides were collected from HLA complexes purified by anti-HLA-I antibody (w6/32). Recovered HLA peptides were analyzed by the microLC-QTOF MS (LCMS-9030. Shimadzu Corporation). Ribo-Seq was performed on HNSCC and full cryptic protein databases were generated using a modified version of the pipeline described in Scull et al. [PMID: 34509645]. Libraries were aligned to the GRCh38 reference genome using STAR [PMID: 23104886] in two-pass mode and both a reference guided assembly and a de-novo assembly were generated using Cufflinks [PMID:22383036]. Variant calling was performed using GATK Best Practices Workflow 'RNASeq short variant discovery (SNPs + Indels)' utilizing Mutect2 [PMID:23396013] for variant calling and subsequent filtering. The reference guided assembly, de-novo assembly, and the variant calling output were turned into transcriptome assemblies utilizing gffread [PMID: 32489650], and underwent three frame translation using triple_translate (Scull et al.). The resulting three-frame translated fasta files were merged and had any duplicates or redundancies removed using squish (Scull et al.) for database generation to be used in PEAKS [PMID: 14558135].

Results We have completed ribo-Seq on 2 HNSCC cells lines and are preparing to interogate the microLC-QTOF MS-generated spectra for HLA-presented peptides of the HNSCC cell lines.

Conclusions While data are still being generated and evaluated using different assessment tools, our group considers this proteogenomic approach to assess the Dark Immunopeptidome for HNSCC holds substantial promise for uncovering targets of anti-cancer immunity. In addition to applications for immunological monitoring, this has potential therapeutic application for cancer vaccines or as vaccine boosters for patients receiving TIL.

114 CHARACTERIZATION OF SUPPRESSIVE MYELOID CELLS IN SOLID TUMORS TO REFINE DISEASE SELECTION IN A PHASE 1 STUDY OF THE MULTI-SIGLEC INHIBITOR AL009

Julie Huang*, Sam Nalle, Helen Lam, Arnon Rosenthal, Daniel Maslyar. *Alector, South San Francisco, CA, USA*

Background Inhibitory sialic acid-binding immunoglobulin-type lectins (Siglecs) are a subset of the Siglec family of cell surface receptors expressed predominantly on myeloid cells that potentiate immune suppression. Tumors increase the expression of sialic acid glycans and co-opt the immunosuppressive effects of Siglecs, driving tumor resident immune cells toward a cancer permissive phenotype. Disrupting Siglec-sialic acid signaling could confer a therapeutic benefit in cancer, particularly those cancers with high levels of myeloid derived suppressor cells (MDSCs). To accomplish this, we designed AL009, an engineered Siglec Fc fusion molecule that acts as a sialic acid trap and a multi-Siglec inhibitor, repolarizing suppressive myeloid cells and activating an anti-cancer response. The safety, tolerability, and efficacy of AL009 in patients with solid tumors will be evaluated in an upcoming Phase 1 study. Here we present data that help to refine disease selection for the Phase 1 study and efforts in testing potential predictive biomarkers for clinical use.

Methods Tissue microarrays from patients with various solid tumors were analyzed by immunohistochemistry (IHC). Markers detected included CD163, CD68, and a representative Siglec for multi-Siglec expression. IHC scoring methodology was prespecified focusing on proportion of cells expressing each of the above markers. Scoring was on a 4-point scale and based upon the number of cells stained with the marker of interest in reasonable proximity to the tumor (tissue without tumor was not scored).

Results Tumor profiling by IHC identified squamous cell lung cancer, colorectal cancer, ovarian cancer, kidney cancer as indications rich in MDSCs marked by high levels of CD163, CD68, and Siglec expression. These cancer indications may be particularly responsive to AL009. The use of PD-L1 expression data from The Cancer Genome Atlas for these various cancer indications provides further guidance on potential effective combination therapies coupled with AL009.

Conclusions We employed an IHC panel that marks CD163, CD68, and Siglecs to identify cancer indications rich in MDSCs. As AL009's mechanism of action is to disrupt the Siglec-sialic acid signaling of MDSCs, we believe that patients with these particular cancers will be most likely to respond to AL009 treatment. This IHC panel will be utilized to retrospectively explore Siglecs, CD163, and CD68 as predictive biomarkers in an upcoming Phase 1 study.

Ethics Approval The human tissue microarrays were procured from a commercial vendor that collect human samples with the following ethical considerations: informed donor consent, IRB/EC approval, fully anonymized, and compliant with current US (HIPAA) International and EU regulations.

115 SPATIAL DISSECTION OF T CELL CLONOTYPE IDENTITY, TRANSCRIPTIONAL PROFILES, AND CELL-CELL INTERACTIONS IN THE TUMOR MICROENVIRONMENT AND TERTIARY LYMPHOID STRUCTURES

[1]Bryan Iorgulescu*, [2]Sophia Liu, [3]Shuqiang Li, [3]Mehdi Borji, [2]Irving Barrera-Lopez, [2]Vignesh Shanmugam, [3]Haoxiang Lyu, [2]Julia Morriss, [2]Zoe Garcia, [2]Evan Murray, [3]David Reardon, [3]Charles Yoon, [4]David Braun, [3]Ken Livak, [3]Catherine Wu, [2]Fei Chen. *[1]MD Anderson Cancer Center, Houston, TX, USA; [2]Broad Institute, Cambridge, USA; [3]Dana-Farber Cancer Institute, Boston, MA, USA; [4]Yale, Boston, MA, USA*

Background Determining the spatial interactions of T cell clonotypes in tumor microenvironments and tertiary lymphoid structures (TLSs) is essential to understanding adaptive antitumoral immune responses, but existing spatial sequencing methods remain unable to profile the TCR repertoire at high resolution.

Methods We previously described the development of Slide-TCR-seq, which integrates Slide-seqV2 (spatially-resolved RNA capture by a DNA-barcoded bead array with 10μm resolution) with rhTCRseq (highly sensitive targeted capture of TCR sequences)[2,3,4] to facilitate amplification of the TCR transcript from CDR3 to the 3' end. This approach enables the simultaneous measurement of cellular transcriptomes, T cell clonotypes, and spatial location at 10μm resolution. We examined melanoma and renal cell carcinoma (RCC) tumors with Slide-TCR-seq to understand the spatial relationships between T cell clonotypes, tumor cells, and immune cells in the tumor microenvironment and TLSs.

Results We applied Slide-TCR-seq to melanoma and RCC metastases because of the well-characterized roles played by T cell phenotype and TCR repertoire in their immune microenvironments.[5,6] By histology and Slide-TCR-seq, we identified TLSs in both melanoma and RCC metastases. We observed that T cells located within the tumor regions were more clonally expanded than those in the TLSs. Furthermore, T cells in TLSs tended to be CD4+ T cells, while those infiltrating into tumor tended to be CD8+ T cells with an exhausted phenotype ($p<0.05$ by FDR-corrected t-test)—together suggesting unique immunological roles of TLSs in tumors.

In the melanoma metastasis, one T cell clone (CDR3 sequence CASRASNEQFF) was preferentially enriched in one of the two tumor lobes that were examined ($p=1\times10^{-102}$). Compared to other clonotypes, *GZMB* ($p=1\times10^{-8}$; associated with cytotoxic T cell function) and *STAT3* ($p=7\times10^{-7}$; associated with activated T cells' survival) were prominently upregulated in CASRASNEQFF.

CASRASNEQFF T cells additionally exhibited unique cell non-autonomous mechanisms: monocytes neighboring CASRASNEQFF T cells displayed elevated *CXCL10* chemokine expression ($p=5\times10^{-21}$), which can recruit tumor-reactive effector T cells.[7] Notably, monocytic expression of *CXCL10* was higher in the same lobe that was enriched with CASRASNEQFF T cells, implicating a preferential interaction between the two. Melanoma cells neighboring the CASRASNEQFF T cells also displayed differential gene expression, including downregulated *MGST1* expression ($p=3\times10^{-15}$).

Conclusions Slide-TCR-seq enables spatially-resolved transcriptomics and TCR clonotyping. Our findings suggest that TLS T cells' phenotype and TCR repertoire are distinct from tumor-infiltrating T cells, and that the transcriptional profiles of T cells, monocytes, and tumor cells may depend on their spatial relationships to one another in the tumor microenvironment.

116 DEEP HIGH-PLEX SPATIAL PHENOTYPING OF GLIOBLASTOMA MULTIFORME PROVIDES NEW INSIGHTS INTO THE IMMUNE LANDSCAPE AND TUMOR HETEROGENEITY

[1]Dmytro Klymyshyn*, [1]Niyati Jhaveri, [1]Yasmin Kassim, [1]Bassem Ben Cheikh, [1]Oliver Braubach, [2]Keith Black, [2]Tao Sun. [1]*Akoya Biosciences, Menlo Park, CA, USA*; [2]*Cedars-Sinai Medical Center, Los Angeles, CA, USA*

Background Highly multiplexed spatial biology technologies have become key to unveiling unique cellular phenotypes and cellular neighborhoods in healthy and diseased tissues. Glioblastoma (GBM), the most prevalent and aggressive brain tumor in adults, is characterized by high intra- and inter-tumoral heterogeneity. Along with the highly infiltrative nature of these tumors, the immunosuppressive microenvironment leads to poor clinical outcomes with median survival of less than 15 months with current standard-of-care treatments. While immunotherapies have been approved for the treatment of various types of cancer, clinical trials in GBM treatment yielded little to no success.

Methods Using the Phenocycler®-Fusion, an integrated spatial biology system, we performed deep analysis of over 50+ proteins to interrogate the immune, vascular, and tumor landscapes in primary and recurrent GBMs. Antibody panels included markers for cell lineage, immune checkpoints, tissue structure, and cellular activation states which, when analyzed, provided comprehensive information of the tumor microenvironments' phenotypic constituents as well as their spatial relationship.

Results Most of the tumor tissues exhibited high levels of glial marker GFAP, indicative of their cell-of-origin. In some tumors, GFAP expression overlapped with Vimentin and CD44, two characteristic markers for the mesenchymal subtype of GBM associated with poor prognosis. GBM tumors also showed varying degrees of proliferation and angiogenesis as evidenced by Ki67 and CD31 staining, respectively. MMP9 expression was very common in most tumors and MMP9 positive cells were found to be associated with the vasculature. Infiltrating T cells also varied significantly from almost non-detectable to a large presence in certain tumors. Both residential microglia and infiltrating monocytes/macrophages could be found across most of the tumors. Intriguingly, some GBM samples showed high expression of β-catenin and exhibited a remarkable infiltration of myeloid-derived suppressor cells (MDSCs; $CD14^{high}/HLA\text{-}DR^{low}$), a large amount of glioma-associated macrophages ($CD163^{+}$) and a high percentage of $FoxP3^{+}$ Tregs.

Conclusions Deep spatial phenotyping of GBM tumors revealed a high degree of cellular heterogeneity in both intra and inter-tumoral fashion. This unbiased, whole-slide approach of analyzing multiple proteins simultaneously within complex GBM tissue structures will greatly enhance our understanding of the immune-suppressive tumor microenvironment in GBM. Further investigation of the immune landscape before and after immunotherapy treatment will help us understand the mechanism of therapy resistance and guide new drug development.

117 HIGH-PLEX SPATIAL PROTEOMIC PROFILING OF IMMUNOTHERAPY RESPONSE GROUPS IN HEAD AND NECK CANCER IDENTIFIES TISSUE SIGNATURES ASSOCIATED WITH THERAPY RESPONSE

[1]Arutha Kulasinghe*, [1]Habib Sadeghirad, [2]Ning Liu, [1]James Monkman, [2]Chin Wee Tan, [3]Caroline Cooper, [4]Sarah Church, [5]Fabian Schneider, [5]Jeppe Thaagard, [5]James Mansfield, [3]Kenneth O'byrne, [2]Melissa Davis, [6]Brett Hughes. [1]*The University of Queensland, Brisbane, Australia*; [2]*WEHI, Melbourne, Australia*; [3]*The Princess Alexandra Hospital, Brisbane, Australia*; [4]*Nanostring Technologies, Seattle, WA, USA*; [5]*Visiopharm, Horsholm, Denmark*; [6]*The Royal Brisbane and Women's Hospital, Brisbane, Australia*

Background Immunotherapies have improved the treatment landscape for recurrent and metastatic head and neck cancers (HNC). Immune checkpoint inhibitors (ICI) have led to durable benefit in approximately 20% of HNSCC patients. Therefore, predictive biomarkers are needed to identify those likely to respond or develop resistance to ICI therapy.

Methods Our retrospective study profiled pre-treatment formalin-fixed paraffin-embedded (FFPE) tissues from metastatic HNC patients treated with immunotherapy at the Royal Brisbane and Women's Hospital. Here, we used image analytics tool (Oncotopix Discovery®) to demarcate gross structures from H&E images (tumour, stroma, tertiary lymphoid structures, muscle, fat and vasculature) and per-region cell counts, which informed our high-plex profiling of the tumour microenvironment using the Nanostring GeoMx Digital Spatial Profiler. Tumour and stromal compartments were measured for 80-proteins simultaneously spanning immune cell typing, immuno-oncology drug targets, immune activation, pan-tumour, cell death, and PI3K/AKT panels. Each GeoMx ROI (H&E and 4-plex IF (DNA, PanCK, CD8 and CD3) was analysed for percent tissue type (tumour, stroma, etc), per-subregion cell counts, simple cellular phenotypes, and spatial metrics between cell types. The protein findings were measured against response to ICI therapy (RECIST criteria) and overall survival parameters to identify tissue signatures associated with patient outcomes. High-plex validation of markers was performed using orthogonal multiplex tools.

Results Our data revealed robust structural segmentation strategies to annotate tissues using H&E, which may sit upstream of high-plex spatial proteomic assays to identify regions of interest for selection and profiling. The study identified VISTA, CD66b, CD44 which were upregulated, and PD-L1, PD-L2, IDO-1 were downregulated in the progressive disease (PD) vs partial response (PR) comparison, respectively. Within the tumour microenvironment compartment, BAD, BIM and Phospho-PRAS40 were upregulated in the PD group, whereas Cleaved Caspase 9, HLA-DR and CD68 was upregulated in the PR group. A multi-marker signature composed of Pan-CK, PD-1, PD-L2 and cleaved caspase 9, co-localised in the tumour compartment was associated with a worse overall survival.

Conclusions There is an increasing need to comprehensively profile tumour tissues from HNC using high-plex automated imaging and tissue profiling methodologies. Our study demonstrates a new combined workflow enabling the development of tissue-based signatures predictive of response/resistance to ICI therapy.

Ethics Approval This study has Human Research Ethics Approval (LNR/2020/QRBW/66744) from the Royal Brisbane and Women's Hospital Human Research Ethics Committee (RBWH HREC) and the University of Queensland

118 DELINEATION OF SPATIAL TISSUE SIGNATURES OF IMMUNOTHERAPY RESPONSE GROUPS IN NON-SMALL CELL LUNG CANCER (NSCLC)

[1]Arutha Kulasinghe*, [1]James Monkman, [2]Honesty Kim, [2]Aaron Mayer, [1]Ahmed Mehdi, [3]Marie Cumberbatch, [3]Milan Bhagat, [4]Fabian Schneider, [4]Jeppe Thaagard, [4]James Mansfield, [5]Rahul Ladwa, [6]Scott Mueller, [7]Mark Adams, [5]Kenneth O'byrne. *[1]The University of Queensland, Brisbane, Australia; [2]Enable Medicine, California, CA, USA; [3]Tristar Technologies, London, DC, UK; [4]Visiopharm, Horsholm, Denmark; [5]The Princess Alexandra Hospital, Brisbane, Australia; [6]University of Melbourne, Melbourne, Australia; [7]Queensland University of Technology, Brisbane, Australia*

Background Lung cancers remain the leading cause of cancer related mortality and have a poor 5-year survival. Immunotherapies have led to durable benefit in a cohort of non-small cell lung cancer (NSCLC) patients. Identifying those patient likely to achieve benefit remains a clinical unmet need. Whilst predictive biomarkers such as PD-L1 and tumour mutation burden (TMB) have shown utility, the underlying tumour-immune biology is unlikely represented. The composition and activation status of the cellular milieu contained within the tumour microenvironment (TME) is becomingly increasingly recognised as a driving factor dictating response to immunotherapies.

Methods In this study, we employed multiplex IHC (mIHC), and digital spatial profiling (DSP) to capture the targeted immune proteome and transcriptome of tumour and TME compartments from ICI-treated (n=41) and standard of care (n=47) NSCLC patient cohorts. Oncotopix® Discovery was also used to analyse the highplex imagery. The analysis pipeline consisted of tissue segmentation (tumor, stroma, necrosis, etc), nuclear detection using a deep-learning algorithm for DAPI, a threshold-based cellular phenotyping step, and spatial analyses.

Results Patients sensitive to ICI therapy expressed higher levels of IL2 receptor alpha (CD25, p=0.028) within the tumour compartments, which corresponded with increased *IL2* mRNA (p=0.001) within their stroma. *IL2* mRNA levels within the stroma positively correlated with the expression of pro-apoptotic markers cleaved caspase 9 (p=2e-5) and BAD (p=5.5e-4) and negatively with levels of memory T cells (CD45RO) (p=7e-4). Immuno-inhibitory markers CTLA-4 (p=0.021) and IDO-1 (p=0.023) were supressed in ICI-responsive patients. Tumour CD44 (p=0.02) was depleted in the response group and corresponded inversely with higher stromal expression of one of its ligands, *SPP1*(osteopontin, p=0.008). Cox survival analysis indicated tumour CD44 expression was associated with poorer prognosis (HR=1.61, p=0.01), consistent with its depletion in ICI sensitive patients. The SOC cohort paralleled similar roles for immune checkpoints and pro-apoptotic markers, with LAG3 (HR=3.81, p=0.04) indicating poorer outcome, and BIM (HR=0.16, p=0.014) with improved outcome.

Conclusions Through multi-modal approaches, we have dissected the characteristics of NSCLC treatment groups and provide evidence for the role of several markers including *IL2*, CD25, CD44 and *SPP1* in the efficacy of current generations of ICI therapy. The signatures are being validated in prospective larger cohort studies.

Consent This study has Queensland University of Technology (QUT) Human Research Ethics Committee Approval (UHREC #2000000494).

119 **SENSITIVE PREDICTION OF IMMUNOTHERAPY RESPONSE BY INTEGRATING IMMUNE INFILTRATION AND NEOANTIGEN PRESENTATION SCORE IN LATE-STAGE MELANOMA**

[1]Bailiang Li*, [1]Charles Abbott, [1]Lee McDaniel, [1]Rachel Pyke, [1]Fabio Navarro, [1]Hima Anbunathan, [2]Michael Synder, [3]Sekwon Jang, [1]Sean Boyle, [1]Richard Chen. *[1]Personalis, Inc, Menlo Park, CA, USA; [2]Standford University, Palo Alto, CA, USA; [3]Inova Schar Cancer Institute, Fairfax, VA, USA*

Background Single-modality biomarkers such as tumor mutational burden (TMB) often fail to reliably predict response to immune checkpoint blockade (ICB), likely due to incomplete characterization of the complex tumor-immune interactions that influence treatment efficacy. We previously developed the composite biomarker, neoantigen presentation score (NEOPS^{TM}), which integrates neoantigen processing and presentation potency and showed it outperformed TMB and other single-modality biomarkers in predicting ICB response in melanoma.[1,2] Here, we combined NEOPS with the assessment of tumor immune infiltration, and demonstrated more accurate patient stratification for ICB response.

Methods We assessed the interaction effect of 17 immune and stromal cell types on NEOPS, as measured with the ImmunoID NeXT Platform®, using logistic regression in a retrospective cohort of 45 stage III/IV melanoma patients who received anti-PD1 therapy. Next, we evaluated the impact of the resulting immune-selected phenotype on the accuracy of NEOPS, built integrated models, and validated them in a cohort of 109 anti-PD1 treated late-stage melanoma.

Results The predictive value of NEOPS was increased in patients with higher levels of naïve CD4/CD8 T cell, exhausted CD8 T cell, and CD8 T cell gene expression signatures. Correlated cell signatures were further engineered into features reflecting naïve T lymphocytes (naïve CD4/8 T) and total CD8 (exhausted and CD8 T) T cell infiltrations. Both features were shown to independently boost the accuracy of NEOPS in the validation cohort (naive: $p_{interaction}<0.05$; CD8: $p_{interaction}=0.11$). In immune-selected patients displaying both high naive and CD8 features, NEOPS achieved an improved accuracy of 77.2% (vs 69.7% baseline performance, $p<0.05$) and an AUC of 0.74 (vs 0.66, $p<0.1$) in the validation cohort (table 1). In anti-CTLA4 treatment naïve patients, NEOPS prediction in the immune-selected group was also enhanced with an accuracy of 81.8% (vs 70.6%, $p<0.05$) and an AUC of 0.89 (vs 0.68, $p<0.01$) in the validation cohort (table 1). Integrating NEOPS with naïve and CD8 features into a single composite biomarker results in an AUC of 0.82 (cross validation: 0.78 vs 0.71).

Conclusions Identifying immune-selected patients based on cellular composition of the tumor microenvironment significantly increased the accuracy of our neoantigen-based biomarker of ICB response, NEOPS. These data highlight the potential utility of integrating tumor microenvironment data with neoantigen information into an extended composite biomarker to provide more accurate prediction of immunotherapy response.

Abstract 119 Table 1 NEOPS performances in different immune groups

		Discovery		Validation	
		Full	Immune-selected	Full	Immune-selected
All	n	45	26	109	57
	Accuracy	76%	88%	70%	77%
	AUC	0.79	0.95	0.66	0.74
	C-index (PFS)	0.68	0.74	0.58	0.62
anti-CTLA4 naive	n	36	22	66	33

120 **DECODING IMMUNOTHERAPY RESPONSES WITH HIGH-DIMENSIONAL AND HIGH-THROUGHPUT SPATIAL PHENOTYPING OF NON-SMALL CELL LUNG CANCER (NSCLC)**

[1]Ning Ma*, [1]Aditya Pratapa, [2]James Monkman, [3]Ken O'Byrne, [1]Oliver Braubach, [2]Arutha Kulasinghe. *[1]Akoya Biosciences, Menlo Park, CA, USA*; *[2]University of Queensland, Brisbane, Australia*; *[3]Princess Alexandra Hospital, Brisbane, Australia*

Background Lung cancers are the leading cause of cancer-related deaths globally and have a 5-year survival of ~20%. Whilst immunotherapies have led to durable and prolonged survival, only a subset of patients remain responsive. Additional biomarkers are needed to better predict which patients will respond or develop resistance against immune checkpoint inhibitor (ICI) therapies. Spatial phenotyping of the tumor microenvironment (TME) is now recognized as a key factor in understanding immunological composition and status that are predictive of ICI therapy benefits.

Methods Here, we profiled biopsies from a cohort of non-small cell lung cancer (NSCLC) patients treated with single-agent Nivolumab. We developed high-dimensional immune profiling (57 antibody panel) and conducted whole-tissue PhenoCycler®-Fusion spatial phenotyping. Spatial features, including cellular composition and cellular neighborhoods were analyzed and compared against clinicopathological findings and response to immunotherapy.

We then expanded our spatial analysis to a larger NSCLC cohort using customizable PhenoCode™ Signature Panels (PSP) for high-throughput immunoprofiling (CD3/CD8/CD20/CD68/PanCK + CD4 add-in) and immunocontexture (CD8/CD68/PD-L1/FoxP3/PanCK + PD-1 add-in) imaging. The PSP panel content combines the barcode-based antibody chemistry from the PhenoCycler® platform with the signal amplification of Opal chemistry from the PhenoImager® platform. The PSP panel was profiled across 20 biopsies to investigate correlations between spatial phenotypic signatures, clinicopathological findings, and response to ICI therapy.

Results Our PhenoCycler®-Fusion data revealed more than 10 unique phenotypes within the TMEs of ICI therapy response groups. High-dimensional spatial analyses furthermore revealed intratumoral and intertumoral heterogeneity and cell-specific metabolic signatures. Concurrently, multispectral spatial analysis of PSP panel data uncovered putative spatial signatures within NSCLC cohorts, indicating the enrichment and significance of certain phenotypic frequencies and cellular interactions associated with therapy response.

Conclusions There is an increasing need for the development of predictive biomarkers of response to ICI therapy. We demonstrate the complementary use of high-dimensional, deep spatial phenotyping analysis with high-throughput multiplex imaging for identifying new spatial signatures with the immune landscape of NSCLC. These methods are amenable to revealing novel cell types and spatial signatures that can be associated with ICI outcomes and therefore serve as clinical biomarkers.

121 TETRASPANIN MOLECULE CD9 AS A NOVEL MARKER OF TUMOR-REACTIVE T CELLS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0121

[1]Yoshihiro Miyahara*, [1]Makiko Yamane, [1]Tae Hayashi, [1]Yuji Toiyama, [2]Kazushi Hiranuka, [3]Hiroyuki Kishi, [1]Hiroshi Shiku. *[1]Mie Univ. Graduate School of Medicine, Tsu, Japan; [2]BrightPath Biotherapeutics Co., Ltd., Kawasaki, Japan; [3]University of Toyama, Toyama, Japan*

Background Overcoming 'heterogeneity of tumor antigen' by infusion of a variety of T cells that recognize multiple tumor antigens would be beneficial for patients with solid tumor. To this end, two major approaches aiming to comprehensively obtain tumor-reactive T cells (or TCRs) from TIL/PBMC have been examined so far. One approach is to use cell surface molecules such as exhaustion marker PD-1, and the other is to utilize single cell analysis for selecting tumor-reactive T cells with characteristic RNA expression profiles. Although significant progress has been made, it is still required to deepen the understanding of anti-tumor immunity for development of an effective immunotherapy.

Methods We applied the following strategies to dissect human colorectal TIL. (1) Obtain TCRs from single cell sorted $CD8^+$ TIL ex vivo by using cell surface molecules, (2) Analyze tumor reactivity by using autologous tumor organoids, (3) Determine the specificity to neoantigens, and (4) Identify molecules preferentially expressed by neoantigen-specific T cells.

Results We obtained neoantigen-specific 5 TCRs from 4 cases among of 8 tumor-reactive TCRs from 6 cases. Notably, tumor-specific $CD8^+$ TILs were most enriched in the $PD\text{-}1^+$ and $4\text{–}1BB^+$ (DP) population in all cases, and further analysis revealed that the frequency of DP cells in $CD8^+$ TIL tend to correlate with patient survival. Interestingly, scRNA-seq and TCR-seq analysis of TIL in which about 5% of whole $CD8^+$ TILs are neoantigen-specific uncovered that CD9, a member of tetraspanin, was significantly expressed in these T cells. Indeed, addition of CD9 to DP sorting further enriched tumor-specific T cells. To our best knowledge, tetraspanin molecule has not been reported as a marker of tumor-reactive T cells. Therefore, these data prompted us to examine CD9 expression on neoantigen-specific $CD8^+$ T cells in mice. Indeed, not only CD9 but also CD81, another member of tetraspanin, is preferentially expressed on these T cells in a mouse model we previously reported.[1] Furthermore, we successfully identified tumor-reactive TCRs from splenic $CD8^+CD9^+CD81^+$ T cells in two independent tumor bearing mice models (CMS7 and CT26), in which one TCR recognized AH-1 epitope in the case of CT26 tumor bearing mice.

Conclusions We report that tetraspanin molecules would be novel markers of tumor-reactive T cells. Our data strongly indicate that tetraspanin molecules play unexpected roles in the interaction of T cells with tumor, although further analysis is required. Finally, we hope that these findings would be useful for development of an effective personalized cancer immunotherapy in near future.

122 THE NEXT GENERATION OF IMMUNOTHERAPY RESPONSE SIGNATURES REVEALED BY BIOPHYSICAL SIMULATIONS

Gregory Norris, John Pfeiffer, Joseph Peterson, Nicole Liadis, Matthew Biancalana, Dorys Lopez-Ramos, Anuja Antony, Daniel Cook*. *SiBiSys, Inc., Chicago, IL, USA*

Background Although immunotherapy has become standard-of-care for many cancers, the number of benefiting patients remains relatively small. Current biomarkers of response (e.g., PD-L1) have proven only modestly useful for distinguishing IO-responders vs. non-responders.[1] Here, we present a proof-of-concept approach for the rapid, non-invasive assessment of immunotherapy response prediction using biomarker imaging signatures.

Methods We used publicly available datasets (ISPY1 and ISPY2 non-IO-treated patients)[2,3] to calculate the expression levels of gene signatures across breast cancer subtypes. We analyzed these imaging datasets using TumorScope, a biophysical simulation engine, to identify biomarkers (features) present within IO-responsive tumors. We then correlated this response to biological processes and hallmark cancer gene signatures. TumorScope uses patient standard-of-care data, including high spatiotemporal resolution medical images (e.g., DCE-MRIs) to predict a patient's probability of achieving a pathological complete response (pCR).[4] Next, we calculated the spatial distribution of these features across tumors. To specifically identify the IO-response signatures, we calculated the feature thresholds associated with pCR in response to IO using the ISPY2 IO-treated patient dataset (linear regression of the training set, n=63). This spatial biomarker-based approach, SimbIOScope, showed comparable predictive power as the traditional biopsy-based transcriptomic approach. We further validated this approach in an independent cohort from a single center (n=12), and applied our method to a large IO-naïve population (n=292) to assess the model's predictive capability.

Results Spatially-resolved biomarkers of immune evasion in triple negative breast cancer (TNBC) and HR+/HER2- tumors identified individuals with resistance to IO therapy, and had similar predictive power to transcriptomic analysis. We found that baseline (prior to therapy) high levels of immune evasion signatures in IO non-responders are associated with hypoxia ($r=0.45$, $p<1x10–6$) and autophagy in TNBC patients, and with low angiogenesis ($r=-0.40$, $p=0.006$) in HR+/HER2- patients. When tested on an independent patient cohort (n=12), SimbIOScope correctly predicted pCR in over 91% of cases. In a larger reference cohort (n=292), SimbIOscope predictions of pCR were consistent with the empirical increase observed in clinical trials. Our analysis predicted a 14% increase in pCR for TNBC tumors over baseline with the addition of the checkpoint inhibitor pembrolizumab, as compared to the 13.6% pCR increase observed in clinical trials (Keynote 522).[5]

Conclusions SimbIOScope imaging biomarkers and analyses efficiently identify the cohort of patients likely to respond to immunotherapy. Its imaging analytic capabilities position SimbIOScope as a critical tool when planning cancer treatment options, and expands IO-response prediction beyond traditional biomarkers.

123 LANDSCAPE ANALYSIS OF THE NEOEPITOPE-SPECIFIC T CELL RESPONSES IN PATIENTS WITH AND WITHOUT CLINICAL BENEFIT FROM IMMUNE CHECKPOINT BLOCKADE THERAPY

[1]Cristina Puig Saus*, [2]Barbara Sennino, [2]Songming Peng, [2]Zheng Pan, [2]Benjamin Yuen, [2]Bhamini Purandare, [2]Kyle Jacoby, [2]Olivier Dalmas, [2]Duo An, [2]Boi Quach, [2]Clifford Wang, [3]Huiming Xia, [1]Sameeha Jilani, [2]Diana Nguyen, [2]Kevin Shao, [2]Claire McHugh, [2]John Greer, [2]Phillip Peabody, [2]Saparya Nayak, [2]Jonaathan Hoover, [2]Sara Said, [2]Susan Foy, [2]Andrew Conroy, [2]Michael Yi, [2]Christine Shieh, [2]William Lu, [2]Katharine Heeringa, [2]Yan Ma, [2]Shahab Chizari, [2]Melissa Pilling, [2]Marc Ting, [2]Ramya Tunuguntla, [2]Salemiz Sandoval, [2]Robert Moot, [2]Theresa Hunter, [3]Sidi Zhao, [1]Justin Saco, [1]Ivan Perez-Garcilaso, [1]Agustin Vega-Crespo, [1]Ignacio Baselga, [1]Gabriel Abril-Rodriguez, [1]Grace Cherry, [1]Deborah Wong, [3]Jasreet Hundal, [1]Bartosz Chmielowski, [1]Daniel Speiser, [2]Michael Bethune, [2]Xiaoyan Bao, [4]Alena Gros, [3]Obi Griffith, [3]Malachi Griffith, [5]James Heath, [2]Alex Franzusoff, [2]Stefanie Mandl, [1]Antoni Ribas. *[1]University of California, Los Angeles, Los Angeles, CA, USA*; *[2]PACT Pharma, South San Francisco, CA, USA*; *[3]Washington University School of Medicine, St. Louis, USA*; *[4]VHIO, Barcelona, Spain*; *[5]Institute for Systems Biology, Pasadena, CA, USA*

Background The primary target of T-cell responses to cancer cells are peptides derived from non-synonymous mutations presented by HLA. However, the large diversity of HLA alleles and restricted availability of clinical samples has limited the study of the antigenic determinants recognized by T cells (termed neoepitopes) at the scale needed for a landscape analysis of antitumor immune responses in patients.

Methods We applied a newly developed technology to perform a longitudinal landscape analysis of the neoepitope-specific T cells in peripheral blood and tumor from 11 patients with metastatic melanoma, 7 with response (R) or 4 with no response (NR) to immune checkpoint blockade (ICB) immunotherapy. Briefly, based on the computational prediction of patient-specific putative neoepitopes, hundreds of capture reagents were made consisting of the patient HLA class I subtypes loaded with the corresponding predicted neoepitope; neoepitope-specific T cells were then isolated, and the TCR alpha and beta sequenced. The tumor reactivity of the isolated neoepitope-specific TCRs (neoTCR) was assessed upon co-culture of autologous melanoma cell lines from each patient with primary human T cells expressing the neoTCRs generated using a CRISPR-based non-viral precision genome engineering to replace the endogenous TCRs.

Results The tumor mutation burden ranged between 2562 and 54 and 297 to 31 for patients with R and NR, respectively. We screened an average of 157 (range 243 to 17) predicted neoepitope-HLA per patient across their 6 HLA molecules, and isolated neoTCRs in all 11 patients. The number of mutations targeted ranged between 13 and 1. We assessed tumor reactivity in samples from 3 R and 3 NR; 39 of the 64 neoTCRs demonstrated specific recognition and cytotoxicity to patient-matched melanoma cell lines. Multiple T cells with different neoTCRs (T cell clonotypes) recognized a limited number of mutations in 7 patients with R (average of 31 different neoTCR clonotypes per patient). These T cell specificities were recurrently detected at different time points in blood and tumors. Samples from 4 patients with NR also demonstrated neoepitope-specific T cell responses in blood and tumor to a similarly restricted number of mutations but lacked TCR polyclonality (average 3 neoTCR clonotypes per patient) and were not recurrently detected in sequential samples.

Conclusions Effective ICB therapy is associated with polyclonal neoepitope-specific T cell responses in the tumor and blood that recognize a limited number of immunodominant mutations and are recurrently recognized over time.

Ethics Approval Patients with metastatic melanoma were selected as they signed an informed consent to collect PBMC and tumour biopsies while receiving therapy with anti-PD-1 therapy alone or in combination with other drugs. Biopsies and blood samples were collected under the University of California, Los Angeles (UCLA) Institutional Review Board approvals 11–003254.

124 IDENTIFICATION OF TUMOR ANTIGENS FROM MULTIPLE GENOMICS SOURCES USING LENS (LANDSCAPE OF EFFECTIVE NEOANTIGENS SOFTWARE)

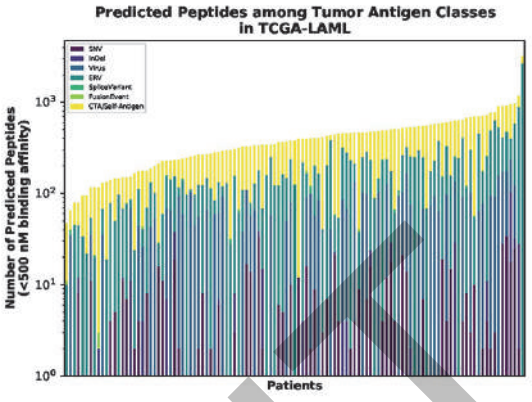
[1]Benjamin Vincent, [1]Steven Vensko*, [1]Kelly Olsen, [1]Dante Bortone, [2]Christof Smith, [3]Shengjie Chai, [1]Alexander Rubinsteyn. *[1]University of North Carolina School of M, Chapel Hill, NC, USA; [2]Brigham and Women's Hospital, Boston, MA, USA; [3]Uber, Inc., San Francisco, CA, USA*

Background Elimination of cancer cells by T cells is a critical mechanism of antitumor immunity and cancer immunotherapy response. T cells recognize cancer cells via engagement of T cell receptors with peptide epitopes presented by major histocompatibility complex (MHC) molecules on the cancer cell surface. Discovery of the full landscape of tumor antigens in any given individual will be important for understanding response to immunotherapy and optimizing strategies for antigen-specific immunotherapy development. Although T cell epitopes can be derived from antigen proteins coded for by multiple genomic sources, bioinformatics tools used to identify tumor-specific epitopes using DNA and RNA sequencing data have largely focused on epitopes derived from somatic variants.

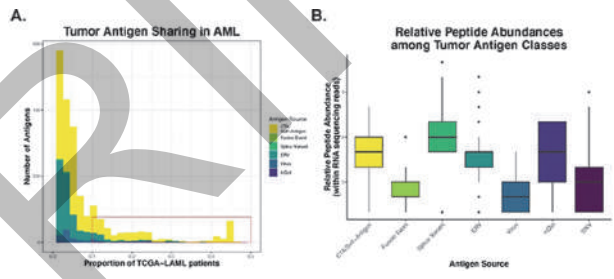
Methods We report here an open-source workflow utilizing the Nextflow DSL2 workflow manager, Landscape of Effective Neoantigen Software (LENS), which predicts tumor-specific and tumor-associated antigens from single nucleotide variants (SNVs), insertions and deletions (InDels), gene fusions, splice variants, cancer testis antigens (CTAs), overexpressed self-antigens, viruses, and human endogenous retroviruses (hERVs). The main advantage of LENS is that it extends the breadth of genomic sources of tumor antigens that may be discovered using genomics data. Other advantages include modularity, extensibility, ease of use, incorporation of phasing and germline variant information in epitope identification, and harmonization of relative expression level and immunogenicity prediction across multiple genomic sources (table 1). LENS is open-source and freely available for academic use (https://gitlab.com/bgv-lens).

Results To demonstrate the utility of LENS, we present an analysis of the predicted antigen landscape in 115 acute myeloid leukemia (AML) samples. AML was chosen due its low somatic mutation rate and dearth of classical (SNV-derived) neoantigens. Predicted tumor antigens were distributed unevenly across genomic sources (figure 1). The highest degree of antigen sharing was found in those derived from aberrantly expressed endogenous retroviral genes, which were also highly-expressed in the RNA-seq data (figure 2**).** A small number of gene fusion-derived antigens were also highly expressed with high predicted binding affinity (figure 3).

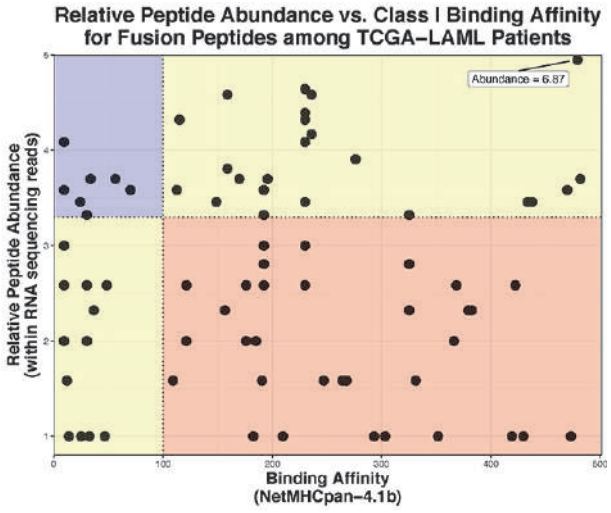
Conclusions We expect that LENS will be a valuable platform and resource for analysis of polyepitopic T cell responses across the full immunodominance hierarchy, antigen selection for therapeutic neoantigen vaccination, and T cell epitope discovery, especially in cancers with few somatic mutations and increased importance of tumor-specific epitopes from genomic sources beyond single nucleotide variants. In AML specifically, our results support further development of hERV and gene fusion-based tools for immune monitoring and therapeutics going forward.



Abstract 124 Figure 1 TCGA AML tumor antigen distribution by patient sample. Tumor antigen distributions across 115 TCGA-LAML samples are shown. Predicted neoantigen number ranges between 40 to 2,433 peptides with a median of 319 peptides per patient



Abstract 124 Figure 2 Antigen sharing in AML. (A) The number of AML antigens predicted to be presented in multiple TCGA AML samples are shown along with their genomic sources. Antigens identified in more than 10% of samples are enclosed by the red box. (B) RNA expression of predicted AML antigens by genomic source



Abstract 124 Figure 3 Fusion peptide read support vs. HLA Class I binding affinity across patients. Several predicted fusion-derived peptides show both relatively high binding affinity and high relative peptide abundance (blue). Others show either high expression and low affinity or low expression and high affinity (light red), or both low expression and low affinity (red)

Abstract 124 Table 1 Comparison between LENS and other Neoantigen workflows LENS generally offers similar or improved functionality compared to other popular neoantigen workflows. Specifically, LENS supports more tumor antigen sources, includes a harmonized estimate of antigen expression, does not require end-user pre-processing of input data, and is a both modular and extensible workflow. It is worth noting that all the included workflows are open-source and may subjectively be classified as modular and extensible as a result. We classify LENS as modular and extensible as these were desired features that drove design and development rather than consequences of code availability. The 'Hybrid' classification for nextNEOpi's containerization metric is due to some components, like pVACtools and NeoFuse, having self-contained containers while other tools (e.g. variant callers) are all contained within a single container.

125 **CHARACTERIZATION AND LABEL-FREE ISOLATION OF PHENOTYPICALLY DEFINED HUMAN IMMUNE CELLS USING GHOST CYTOMETRY, A NOVEL AI POWERED FLOW CYTOMETRY TECHNOLOGY**

[1]Keisuke Wagatsuma, [1]Hiroko Nomaru, [1]Kazuki Teranishi, [2]Satoru Akai, [1]Yuri An, [2]Kaoru Komoriya, [1]Yoko Kawamura, [2]Asako Tsubouchi, [1]Andy Wu*, [1]Sadao Ota. *[1]ThinkCyte Inc, Tokyo, Japan*; *[2]ThinkCyte Inc., San Carlos, CA, USA*

Background Background: Identification and isolation of specific human immune cell populations with technologies that are minimally disruptive to native biological states are a critical requirement in modern cellular immunotherapy approaches. For both early-stage cell therapy research and the development of autologous and allogenic cellular therapeutics, technologies that can isolate specific immune cell subsets while preserving their native biological and functional properties are needed to improve the quality and efficacy of cell therapy drug products.

Methods

Methods Here we applied Ghost Cytometry, a novel method of analyzing and sorting cells using high dimensional image information, to isolate human immune cell subsets with minimal external perturbation. Ghost Cytometry leverages a combination of proprietary optics and artificial intelligence to capture digital-optical profiles (Ghost Motion Imaging (GMI) signals) from individual immune cells. The approach generates a novel, multi-dimensional data set for individual cells, which can be leveraged to enable label-free sorting of defined phenotypic cell populations for downstream R&D

Results

Results We characterized human T-cells and generated 'ground truth' functional profiles for 1) glycolysis level (by depletion of a glucose analog), 2) exhaustion state (by PD-1 and LAG3 expression), 3) activation or resting profiles (by CD25 expression) and 4) viability (by propidium iodide exclusion and Annexin V expression) based on their unique GMI signals. From this, we developed a set of machine-learning derived classifiers for identification of unlabeled T-cell subsets. The classifiers showed area under the curve (AUC) performance ranges between 0.923 and 0.995, demonstrating high classification accuracy.

Conclusions

Conclusions Here we report on a novel method to characterize and isolate human immune cell subsets with enhanced therapeutic potential. This approach enables isolation of target T-cell subsets with defined phenotypic profiles in an unperturbed state, without the requirement of using external fluorescent markers. The results described here have practical applications for investigators and drug developers in cell therapy research and development.

126 PROGNOSTIC GENE SIGNATURE REFLECTING CD8+ T CELL ENRICHMENT IN EARLY-STAGE TRIPLE-NEGATIVE BREAST CANCER

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0126

[1]Chang Kim*, [1]Yun Suk Yu, [1]Jin Young Park, [2]Kyong Hwa Park. *[1]CbsBioscience, Daejeon, Korea, Republic of; [2]Korea university anam hospital, Seoul, Korea, Republic of*

Background Triple-negative breast cancer (TNBC) is the most challenging subtype of breast cancer, and its prognosis is poor compared to the other subtypes.[1] Immune cells have critical role in tumor rejection and prognosis of patient with TNBC.[2] In early TNBC, CD8+ T cells infiltration is positively associated with response to neo-adjuvant chemotherapy and prognosis of patients.[3] Recently, combination of immune checkpoint inhibitor, pembrolizumab, with standard chemotherapy has been approved for the neo-adjuvant setting.[4] However, there are no valid prognostic biomarkers that reflect the CD8+ T cell enriched tumor in patients with early TNBC. To establish an elaborate therapeutic strategy for TNBC, identification of biomarkers that reflecting feature of CD8+ T cell enriched TNBC is needed.

Methods 76 patients with TNBC were enrolled for gene expression profiles and GSE 169246 data were collected for single cell RNA (scRNA) profiles. Median Follow-up period of enrolled patients was 51.5 months (range: 4.6–230.8). Of the enrolled patients, 13 patients had recurrence or metastasis. Using the HiSeq 4000 sequencer, RNA sequencing was conducted to analyze the gene expression profiles of tumor samples from TNBC patients. Single cell RNA analysis was performed using Seurat package (v.4.0.5). Differentially expressed genes (DEGs) were defined as satisfying both conditions that satisfying in Cox regression analysis and Wilcoxon analysis in gene expression profiles, and that satisfying in logistic regression analysis in CD8+ t cell profiles of scRNA analysis. Gene signature was analyzed by combination of above DEGs. Gene signature was marked on t-SNE of scRNA profiles. Statistical analyses were conducted using R language (v.3.4.3).

Results We identified gene signature reflecting CD8+ T cell enriched feature that stratified patients with TNBC by risk score. Gene-set signatures related to CD8+ T cells were identified as following; GADD45B_ H2AFX_PTPRA_RILPL2_-RORA_ZC3H13_ZHX2 (sensitivity = 92.31%; specificity = 93.65%; accuracy = 93.42%). In Kaplan Meier (KM) analysis, patients with tumors with high-risk gene signatures (n=16, median iDFS = 42.7) showed significantly shorter iDFS than those with low-risk gene signatures (n=60, median iDFS not reached). CD8+ t cells related gene signature was marked on CD8+ T cell near the CD4+ T cell in t-SNE.

Conclusions the gene-set signatures reflecting CD8+ T cells enrichment showed high performance to predict prognosis of TNBC. Further analysis of gene signatures related to macrophages will be additionally presented at the conference.

127 SPATIAL-SPECIFIC GENE SIGNATURES OUTPERFORM BULK-MRNA SIGNATURES TO DEFINE RESISTANCE TO IMMUNOTHERAPY IN MELANOMA PATIENTS

Thazin Aung*, Jonathan Warrell, Sandra Martinez-Morilla, Niki Gavrielatou, Loannis Vathiotis, Nay Chan, Harriet Kluger, David Rimm. *Yale University, New Haven, CT, USA*

Background Gene signatures have been shown to predict the response/resistance to immunotherapies but with only modest accuracy.[1–3] However, gene signatures are devoid of spatial information, and the inability to distinguish tumor genes from TME genes is likely to decrease the prediction accuracy. Here we collect spatially defined genes and determine if the addition of spatial information can improve prediction.

Methods The Digital Spatial Profiling (DSP) of GeoMX Whole Transcriptome Atlas (WTA), a new technology for transcriptome-wide spatial profiling of tissues, is used to generate a transcriptomic map of 55-immunotherapy-treated melanoma samples. DSP-WTA approach enables *in situ* hybridization against 18,190 genes in several areas of interest (i.e., CD68+ macrophages, CD45+ lymphocytes and S100+ tumor cells) at high throughput using a sequencing readout. We developed a computational pipeline to discover cell-type (compartment) specific signature models. To estimate the classification accuracy, the models were built using a split sample approach with 100 different Lasso logistic regression binomial models. Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 was used to identify objective response. We then developed a compartment signature matrix to deconvolve bulk-RNA-seq into compartmentalized-RNA expression using CIBERSORTx (*in silico* tissue dissection)[4] to simulate compartment-derived gene expression data. We then compare the CIBERSORT results to actual spatially collected gene signatures.

Results We achieved AUC (area under the curve) > 0.9 for all compartment-specific signatures. The AUCs for each signature are 0.94 (CD45), 0.97 (CD68), 0.93 (S100B), 0.98 (pseudo-stroma) and 0.92 (pseudo-bulk). Cross-testing in different compartments (i.e., CD45 signature in CD68, S100B, pseudo-bulk and pseudo-stroma compartments, etc.) showed poor performance indicating the signatures are compartment-specific. Then these signatures were validated in an independent immunotherapy-treated melanoma cohort (N=90)[5] by deconvolving bulk-RNA-seq into compartmentalized gene expression. Our 8-gene pseudo-bulk signature validated with AUC:0.74 (CI:0.64–0.84), our 8-gene CD68 signature with AUC:0.83 (CI:0.75–0.91), and our S100B 8-gene signature with AUC:0.66 (CI:0.54–0.77), respectively. To evaluate the deconvolution platform with real compartment RNA-seq data, our pseudo-bulk data were deconvolved into pseudo-compartments using CIBERSORTx cell-type decomposition and tested with compartment-specific signatures. We noted poor performances with AUC:0.59 (CD45), AUC:0.56 (CD68) and AUC:0.65 (S100B), respectively.

Conclusions Compartmentalized CD45-, CD68- and S100B-signatures show strikingly high AUC compared to bulk mRNA signatures. These high spatially de novo signatures far outperform the signatures that can be achieved by computational deconvolution. We believe that the spatially informed signatures differentially evaluates the tumor vs the TME and may be much more accurate in the prediction of response/resistance to immunotherapy.

128 MULTIOMIC SPATIAL INTERROGATION OF TUMOR-INFILTRATED IMMUNE CELLS USING THE RNASCOPE™ CO-DETECTION ASSAY WITH VIVID DYES

[1]Anushka Dikshit*, [2]Sayantani Basak, [1]Emerald Doolittle. [1]*Advanced Cell Diagnostics, a Bio-Techne, Newark, CA, USA*; [2]*Bio-Techne, Newark, CA, USA*

Background Interrogating complex tumor microenvironment requires a multi-omics approach that can provide high level of sensitivity and specificity. Identifying immune cell subsets within the tumor can be vital for predicting response and determining therapeutic efficacy. Detecting target immune cell markers using immunohistochemistry/Immunofluorescence (IHC/IF) and visualizing cytokine expression with *in situ* hybridization (ISH) can provide comprehensive information about the activation states of immune cells. Here, we demonstrate a newly developed integrated ISH and IHC/IF workflow compatible with manual and automated platforms that can substantially improve RNA-protein co-detection.

Methods We demonstrate the use of our RNA-Protein Co-detection assay in combination with the automated and manual RNAscope Multiplex Fluorescent v2 assay and the RNAscope Chromogenic Duplex assay. The RNAscope Multiplex Fluorescent v2 assay was also combined with the new TSA Vivid dyes for detection of cytokines and immune cells. The co-detection assays enabled detection of T cell markers, macrophage markers and checkpoint markers in the tumor microenvironment by using a tumor microarray.

Results We identified CD4+ helper T cells and CD8+ cytotoxic T lymphocytes using CD3, CD8 and CD4 antibodies. Additionally, we determine the activation states of CD8+ T cells by visualizing *IFNG, GZMB and IL-2* RNA expression. We were also able to identify macrophages detected by CD68 protein expression, *CD163* and *ITGAM* RNA expression. We could also delineate tumor-stroma border in the samples by using the Pan-CK probe which distinctly marks the tumor cells and visualize the expression of immunoregulatory receptors PD-L1 and *CTLA4* in the tumor cells. The new TSA Vivid dyes demonstrated much brighter signals when compared to than other TSA-based dyes enabling robust detection of immune cell and low-abundance cytokine markers.

Conclusions The RNA-protein co-detection assay is enabled for multi-omic detection of target biomarkers with both chromogenic and fluorescent RNAscope assays. The new TSA vivid dyes improve the robustness of target detection using the RNAscope Multiplex V2 assay with co-detection by effectively boosting signal intensity. Overall, the new RNAscope RNA-protein co-detection workflow and reagents allow optimized simultaneous visualization of RNA and protein targets by enhancing the compatibility of antibodies with RNAscope.

129 PLATFORM TO CONDITIONALLY INDUCE LUNG TUMORS IN GENETICALLY ENGINEERED MOUSE MODELS USING CRE MRNA CONTAINING NANOPARTICLES

Vidit Bhandarkar*, Elen Torres-Mejia, Namita Nabar, Tamara Dacoba, Paula Hammond, Stefani Spranger. *Massachusetts Institute of Technology, Cambridge, MA, USA*

Background Pre-clinical models are crucial for better understanding and treating human diseases such as cancer. Autochthonous models of lung cancer are excellent tools to study tumor progression and evolution. However, current approaches rely on intra-tracheal, viral delivery of Cre recombinase to initiate tumorigenesis by activating oncogenes and deleting tumor suppressor genes.[1] Two caveats of this technique are the lack of cell-type specificity of viral vectors and the resulting immunogenicity of these vectors. We have demonstrated that lentiviral delivery of Cre recombinase (Cre-LV) to the lungs of mice results in infection of dendritic cells (DCs) and macrophages and innate immune activation. To study the immune response to naturally progressing lung cancer while controlling for the confounding immunogenicity of viral vectors, we have developed a virus-free platform to induce lung tumors in genetically engineered mice.

Methods We encapsulated Cre mRNA in polymeric nanoparticles (NPs) made from a Poly(Beta-Amino Ester) (PBAE). The resulting cationic NPs were layered with anionic poly-aspartic acid (PLD) to preferentially target epithelial cells and reduce immunogenicity by decreasing interactions with immune cells.[2] To optimize particle size and mRNA packaging for efficient *in-vivo* delivery, we screened different mRNA:PBAE ratios. Top candidates were then tested *in-vitro* on the Green-Go reporter cell line, which becomes GFP^+upon Cre expression, to determine the transfection efficiency of these NPs.[3] To induce lung tumors, we intra-tracheally injected the optimized PLD-layered Cre mRNA-NPs (PLD Cre-NPs) into $Kras^{LSL\text{-}G12D}$; $p53^{fl}$; $TdTomato^{fl}$ ($KP^{Tdtomato}$) reporter mice.[1] We compared tumor initiating capacity of these NPs to Cre-LV and analyzed tumor progression, innate immune activation and cell-type specific infection.

Results PLD Cre-NPs efficiently formed tumors in $KP^{Tdtomato}$ mice, with comparable histology to Cre-LV induced tumors. However, unlike Cre-LV induced tumors, PLD Cre-NP administration resulted in fewer lesions at late timepoints, which better recapitulates human disease. Further, PLD Cre-NPs primarily infect epithelial cells and minimally infect myeloid cells such as DCs and macrophages. Finally, compared to Cre-LV infection, PLD Cre-NP administration reduces innate immune activation.

Conclusions Current approaches to induce lung tumors in autochthonous mouse models rely on viral delivery of Cre which elicits an immune response. PLD Cre-NPs are efficient at forming lung tumors without activating and infecting innate immune cells, enabling a more controlled characterization of the immune landscape in lung cancer. This technology can also be extended to other conditional mouse models of cancer where delivery of the NPs can be localized to the tissue of origin.

130 PRECISE SPATIAL MULTIPLEXING FOR IMMUNE CELL PROFILING OF THE TUMOR MICROENVIRONMENT WITH CHIPCYTOMETRY

Thomas Campbell*, Nancy Stanslowski, Jennifer Brooks. *Canopy Biosciences – A Bruker Company, Saint Louis, MO, USA*

Background Understanding the spatial distribution of key immune cell populations is critical in advancing our understanding of cancer to inform the development of novel therapeutics. Historically, the spatial analysis of the tumor microenvironment has been limited to relatively low-plex immunohistochemical (IHC) or immunofluorescent (IF) assays, which were inadequate for deep immune cell profiling of the tumor microenvironment.

Methods Here we present the analysis of human breast carcinoma samples with a 60-plex protein assay using a novel precise spatial multiplexing technology called ChipCytometry™, which combines iterative immuno-fluorescent staining with high dynamic range imaging to facilitate quantitative phenotyping with single-cell resolution. In addition to traditional pathology review of the high-plex dataset, standard FCS files are generated from multichannel OME-TIFF images, enabling identification and quantification of cellular phenotypes via flow cytometry-like hierarchical gating.

Results The results show precise expression levels for each of the 60 markers in the assay in each individual cell in the sample, maintaining spatial information about each cell. Dozens of immune cell subtypes were identified and quantified based on protein expression profiles. Spatial analysis of the samples reveals quantifiable heterogeneity of immune cell infiltration within the tumor samples, demonstrating the utility of the ChipCytometry platform for in-depth immune profiling in clinical samples.

Conclusions The ChipCytometry platform enables simultaneous detection of multiple protein markers on a single tissue section for deep immune cell profiling in the tumor microenvironment. Combined with the single-cell spatial information, such data sets provide an opportunity for the discovery of new complex multiplexed biomarker signatures to inform therapeutic development.

131 QUANTITATIVE SPATIAL PROFILING OF THE TUMOR MICROENVIRONMENT IN NSCLC TISSUE MICROARRAY CORES USING A 6-PLEX MULTIPLEX IMAGING TECHNOLOGY AND AI-POWERED PHENOTYPING ANALYSIS

Nicole Couper*, Bethany Remeniuk, Karen McClymont, Bei Hopkins, Natalie Monteiro, Lorcan Sherry, Darren Locke. [1]*OracleBio, Glasgow, UK*; *Akoya Biosciences, Marlborough, MA, USA*

Background Non-small cell lung cancer (NSCLC) patients can have impaired immune responses within the tumor microenvironment (TME), leading to a progression of tumor growth and poorer prognosis. Accurate cell phenotyping combined with spatial profiling of the immune contexture and checkpoint expression, can provide a deeper understanding of complex cellular interactions underpinning the tumor-immune response. The aim of this study was to utilize spatial multiplexed imaging technology and associated data analysis methods to identify populations of immune cells, their functional status, as well as their interactions with the tumor in a set of NSCLC tissue cores from patients treated with first line standard-of-care chemotherapy, and second line immuno-oncology treatment.

Methods Formalin-fixed paraffin-embedded (FFPE) NSCLC tissue microarrays (TMA), comprised of n=41 cores containing a range of carcinomas and pathological Tumor-Node-Metastasis (pTNM) stages, were stained on a Leica Bond RX™ using the Akoya PhenoCode™ Signature Immuno-contexture Human Protein Panel, which includes markers for CD8, CD68, PD-1, PD-L1, FoxP3, and PanCK as a tumor indicator. Stained TMAs were scanned at 20x magnification on a PhenoImager HT multispectral imaging system. Image analysis was performed using Visiopharm software deep learning algorithms for multiplexed images to segment specific tissue regions of interest (ROI) and to perform accurate detection and classification of different cell phenotypes. Cell object data files per core were exported for spatial and heterogeneity analysis using proprietary python scripts.

Results Immune cell counts, phenotypes and spatial interactions were identified within the tumor and stroma ROI per core. Data included total and negative cell phenotype counts, cell density in tumor and stroma, as well as cell distance and clustering spatial interactions in each of the 41 cores in the TMA set. Specific immune cell subsets of interest quantified included CD8+/PD-1+, CD8+/FoxP3+/PD-1+ and CD68+/PD-L1+, FoxP3+, and FoxP3+/PD-1+. Tumor cells of interest included PanCK+ and PanCK+/PD-L1 +.

Conclusions The combination of high quality, spatial multiplex imaging data provided by the PhenoCode Panel, coupled with deep learning quantitative image analysis techniques, enables detailed characterization of the complex cellular interactions, at both the functional and spatial level, within the TME of IO-treated NSCLC tissue. This study further highlights the importance of a robust technical workflow to deliver optimal staining, imaging, cell detection and phenotyping in generating high quality data to facilitate spatial profiling and interpretation in pathologically complex tissue samples.

Ethics Approval Commercially sourced TMA from Tr-Star Technology Group

132 RACIAL DIFFERENCES IN TMB MEASURES BETWEEN PAIRED TUMOR/NORMAL AND TUMOR-ONLY SEQUENCING ACROSS ENDOMETRIAL, BLADDER, AND NON-SMALL CELL LUNG CANCERS

[1]Francisco De La Vega, [1]Yannick Pouliot, [2]Chad Reichard, [1]Rotem Ben-Shachar, [1]Brooke Rhead, [1]Kenneth Carson, [1]Matheww Cooney, [1]Kristiyana Kaneva, [3]Afshin Dowlati, [1]Justin Guinney*. *[1]Tempus Labs, Inc., Chicago, IL, USA; [2]Urology of Indiana, Indianapolis, IN, USA; [3]Case Western Reserve University, Cleveland, OH, USA*

Background Tumor mutational burden (TMB), defined as the number of somatic mutations per megabase of a tumor, is routinely used as a predictive biomarker for immunotherapy response in metastatic cancer patients. Sequencing of paired tumor and normal specimens allows for correction of TMB estimates with patient-specific germline variants. For tumor only assays, TMB estimates are corrected using germline variant annotations derived from population-scale germline variant surveys. These surveys often underrepresent minorities and individuals of non-European descent, leading to potential inaccuracies in TMB estimates in these populations.

Methods Our cohort includes patients who underwent tumor genomic profiling with the Tempus xT Next Generation Sequencing (NGS) assay and diagnosed with non-small cell lung (NSCLC, n=4,583) endometrial (n=3,084), or urothelial (n=2,806) cancer. We used 654 ancestry informative markers selected to overlap the target regions of the 648-gene Tempus xT NGS assay to infer global continental ancestry proportions and imputed race/ethnicity categories using ancestry admixture thresholds. TMB differences in paired sequencing (PS) and tumor-only sequencing (TOS) were evaluated for each imputed race/ethnicity category and cancer type. Statistical comparisons of TMB distributions were assessed using the Kruskall-Wallis test.

Results Among the entire cohort, 6,126 patients had PS performed, and 4,347 had TOS performed. The imputed ethnicities were 4% Asian (A), 10% Black (B), 5% Hispanic/Latino (H) and 81% White (W). In NSCLC, median TMB for A, B, H, and W patients was 1.9, 4.2, 3.2, and 3.8 for PS and 4.9, 7.6, 4.9, and 5.4 for TOS. Among endometrial cancers, median TMB for A, B, H, and W patients was 2.1, 2.7, 2.6, and 3.5 for PS and 5.0, 5.4, 5.4, and 5.4 for TOS. Median TMB for A, B, H, and W patients was 3.1, 3.5, 3.5, and 4.2 for PS and 7.3, 6.1, 6.9, and 5.6 for TOS in urothelial cancers. Differences across PS and TOS were significant in each cancer type ($p<0.0001$). When all cancer types were combined, the mean inflation of TMB median values was 1.7 for White whereas non-White patients was 3.4 ($p<0001$).

Conclusions Paired tumor sequencing reduces estimated TMB compared to tumpor-only sequencing across all racial groups, more significantly for non-White patients.

133 SPATIALLY DEFINED GENE SIGNATURES UNCOVER THE ASSOCIATION OF EXTRACELLULAR MATRIX GENES WITH IMMUNOTHERAPY RESISTANCE IN HEAD AND NECK SQUAMOUS CELL CARCINOMA

[1]Niki Gavrielatou*, [2]Jonathan Warrell, [1]Thazin Aung, [1]Loannis Vathiotis, [3]Panagiota Economopoulou, [4]Barbara Burtness, [3]Amanda Psyrri, [1]David Rimm. *[1]Yale School of Medicine, New Haven, CT, USA; [2]Yale University, New Haven, CT, USA; [3]Attikon University Hospital, NKUA, Athens, Greece; [4]Yale School of Medicine, Yale Cancer Center, New Haven, CT, USA*

Background Immune-checkpoint inhibition (ICI) only benefits a subgroup of patients with head and neck squamous cell carcinoma (HNSCC). Several molecular and cellular components of the tumor microenvironment (TME) have been hypothesized to drive either response or resistance. Here, spatially defined whole transcriptome data were analysed in search of associations of compartment-specific gene-signatures with HNSCC immunotherapy outcomes

Methods Pre-treatment biopsy samples from 50 immunotherapy-treated recurrent or metastatic HNSCC patients as well as 12 matched post-treatment biopsies obtained after 4 weeks of treatment, constructed in tissue microarray format (YTMA496), were included in the study. The GeoMx Human Whole Transcriptome Atlas (NanoString Technologies) assay was performed on samples to allow RNA quantification of 18,677 protein encoding genes, using in situ hybridization, in three molecularly defined tissue compartments; tumor (CK), leukocyte (CD45), macrophage (CD68). Differentially expressed genes (DEGs) ($P<0.05$) between pre- and post-treatment biopsies in each of the tissue compartments were identified. Next, these DEGs were used as a 'biological' filter for the initial 18,677 gene set and analysed using LASSO logistic regression models with the aim to obtain pre-treatment gene expression signatures for best overall response (RECIST 1.1.). The performance of each compartment signature was evaluated using the receiver operating characteristic (ROC) curve and AUCs were calculated for Best Overall Response (BOR) to ICI. Genes comprising the highest performing signature were investigated for correlations with immune cell genes extracted from the 'Single Cell RNA-Seq HNSCC' (CIBERSORTx) gene matrix.

Results A six-gene signature (*DDX4, COL17A1, HBA1, MMP1, GPNMB, TTN*) in the CD45 compartment presented the highest AUC (0.83), followed by signatures in the CK and CD68 compartments (AUC: 0.72 and 0.68, respectively). Cross-testing of the CD45 signature in the other two compartments, as well as in a third, artificially generated 'pseudo-bulk' compartment (all compartments combined), showed poor performance, indicating spatial specificity. Interestingly, the CD45 signature included three extracellular-matrix protein-encoding genes (*MMP1, COL17A1, TTN*), all associated with resistance (negative coefficients in the BOR model) to ICI. Fibroblast and dendritic cell populations, characterized using the CIBERSORTx gene matrix, were the immune phenotypes most closely associated with the CD45 signature.

Conclusions Our results indicate that CD45 molecular tissue compartment gene expression demonstrates increased association with ICI resistance in HNSCC. Extracellular matrix genes rather than immune-cell related genes dominated the CD45 compartment signature, highlighting the importance of non-immune stromal components within the TME and the importance of the use of spatial information in the understanding of ICI resistance.

134 B AND MYELOID CELL POPULATIONS DOMINATE IN THE METASTASIS COMPARED TO PRIMARY TUMORS OF PATIENTS WITH PANCREATIC CANCER

[1]Emily Greene*, [1]Deon Doxie, [1]Maria Diab, [2]Bassel El-Rayes, [1]Shishir Maithel, [1]Juan Sarmiento, [1]Olatunji Alese, [1]Jayden Kim, [3]Cameron Herting, [1]Kavita Dhodapkar, [1]Madhav Dhodapkar, [1]Haydn Kissick, [1]Chrystal Paulos, [1]Gregory Lesinski. *[1]Emory University, Atlanta, GA, USA; [2]University of Alabama at Birmingham, Birmingham, AL, USA; [3]Eli Lilly, Decatur, GA, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) is a lethal malignancy with 5-year survival rate of only 11% for patients. To date, nominal data on the immune profile within metastatic PDAC of patients exists. Since most patients present with late-stage disease, defining the immunological landscape of metastatic disease could inform next-generation immunotherapy for PDAC patients.

Methods Using a 37-marker mass cytometry panel, freshly digested tumor tissue from surgically resected primary (n=6) and untreated liver punch biopsy metastatic (n=10) PDAC samples were evaluated for various immune features at the single cell level. Stained samples were fixed, run on a Helios™ mass cytometer and analyzed via FlowJo and Cytobank software.

Results Fewer $CD45^+$ cells were present in metastatic compared to primary PDAC tumors. $CD19^+$ B Cells (3.65% ± 5.19 of live cells) dominated among other immune populations in metastases. Yet these B cells appeared less activated in metastatic PDAC, signified by fewer B cells expressing $HLA\text{-}DR^+$ (57.67% ± 26.49 of $CD19^+$) versus the primary cohort (84.95% ± 21.19 of $CD19^+$). Primary samples had significantly more myeloid, NK and T cells ($p=0.017$, $p<0.01$ and $p=0.015$, respectively) versus metastases. Moreover, primary tumors had significantly higher $CD38^+CD4^+$ and $CD38^+CD8^+$ T cells (consistent with an exhausted phenotype), while ICOS and TIGIT were elevated on T reg from primary vs. metastatic tumors. A survey of checkpoints revealed that LAG-3, TIGIT, and PD-1 were the most prevalent markers across both $CD4^+$ and $CD8^+$ T cells. Further analysis revealed proliferative ($Ki67^+$) $CD11b^+$ cells at both tumor sites. Metastatic sites had prevalent PMN-MDSC-like myeloid cells, but few M-MDSC-like myeloid cells. In-depth analysis of T cell populations revealed more $CD4^+Tbet^+$ Th1-like cells in primary (37.83% ± 34.13 of $CD4^+$) as compared to metastatic samples (12.34% ± 31.43 of $CD4^+$). Antigen-exposed $CD45RO^+PD\text{-}1^+$ T cells ($CD4^+$: 60% ± 33.28; $CD8^+$: 44.17% ± 23.38) and $TCF\text{-}1^+PD\text{-}1^+CD8^+$T cells (37.88% ± 33.27 of $CD8^+$) were also predominant in primary samples.

Conclusions These data indicate for the first time that metastatic PDAC is dominated by B and myeloid cells. While T cells were more evident in primary tumors, these cells harbored phenotypic properties of exhaustion. This work lays the foundation for a detailed spatial investigation into primary and metastatic PDAC tumors and could identify actionable targets to improve immunotherapy for PDAC patients.

135 IDENTIFICATION OF SUPER-EXHAUSTED T CELLS: A NOVEL POPULATION PREDICTIVE OF RESPONSE TO IMMUNOTHERAPY

[1]Alban Bessede, [2]Florent Peyraud*, [1]Jean Philippe Guegan, [1]Christophe Rey, [3]Sylvestre Le Moulec, [4]Fabrice Barlesi, [2]Sophie Cousin, [2]Guilhem Roubaud, [2]Mathilde Cabart, [2]Maxime Brunet, [5]Ezogelin Gruyters, [5]Ariel Savina, [6]Berengère Dadone-Montaudon, [4]Aurélien Marabelle, [4]Jean Charles Soria, [4]Yohann Loriot, [4]Jean-Yves Scoazec, [2]François Le Loarer, [2]Antoine Italiano. *[1]Explicyte, Bordeaux, France; [2]Institut Bergonié, Bordeaux, France; [3]Clinique Marzet, Pau, France; [4]Institut Gustave Roussy, Villejuif, France; [5]Astrazeneca, Rahway, NJ, USA; [6]CHU Nice, Nice, France*

Background Given that most of cancer patients treated with anti-PD1/PD-L1 immune checkpoint blockers (ICB) do not derive benefit, there is a crucial need to identify reliable predictive biomarker of responses. Besides PD-1, several key immune checkpoints, such as CTLA4, LAG3, TIM3 and TIGIT, are associated with a T cell exhausted phenotype and play a crucial role in leading to cancer immune evasion. The impact of simultaneous expression by T cells of distinct inhibitory receptors on outcome of patients treated with ICB is still unknown.

Methods We analyzed the tissue samples, collected before ICB initiation, from patients with solid tumors and included in an institutional molecular profiling program (NCT02534649). We used multiplexed-immunohistofluorescence with the following panel CD3/PD1/TIM3/LAG3/TIGIT/CTLA4, and performed immune cell characterization using multispectral images analysis. We then investigated the correlation between coexpression of T cell-associated exhaustion markers, clinical response rate, progression-free survival (PFS) and overall survival (OS) by Cox proportional hazards models.

Results Four hundred thirty five patients were included in the analysis (NSCLC: n=207, 47.6%; sarcoma: n=42, 9.7%; urothelial: n=30, 6.9%; others: n=156, 35.9%). Digital pathology analysis allowed us to identify a population of 'super-exhausted' T cells characterized by the co-expression of PD1, LAG3, TIGIT and TIM3 which was enriched in 125 cases (28.7%), and was significantly associated with better PFS (HR 1.60, CI95 1.26–2.04, p<0.001) and OS (HR 1.42, CI95 1.07–1.89, p=0.016) in the whole cohort. Patients with super-exhausted high tumors had higher objective response rate (38.4%) compared to super-exhausted low tumors (19.7%, p<0.001). The presence of super-exhausted T cells was significantly higher in responders (10%) versus non responders (4%, p<0.001). Correlation with better outcome was observed whatever the subgroup considered (NSCLC vs other tumors, CD8 T cells density and presence of tertiary lymphoid structure [TLS]). In multivariate analysis (n=372, 85.5%), increased tumor infiltration by super-exhausted T cells (>1%) was significantly associated with better PFS (HR 0.61, CI95 0.46–0.81, p<0.001) and OS (HR 0.68, CI95 0.48–0.97, p=0.033).

Conclusions The presence of super-exhausted T cells may represent a new predictive biomarker of response to ICB and pave the way for the development of effective ICB combinations. Data from an independent validation cohort will be presented at the meeting.

136 A PLASMA PROTEOMIC BASED PREDICTIVE BIOMARKER FOR RESPONSE TO IMMUNOTHERAPY IN NSCLC

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0136

[1]Michal Harel*, [1]Coren Lahav, [2]Ido Wolf, [3]Ella Tepper, [4]Maya Gottfried, [5]Raya Leibowitz, [6]Mahmoud Abu-Amna, [7]Abed Agbarya, [8]Rivka Katzenelson, [9]Michal Lotem, [10]Mor Moskovitz, [11]Alona Zer, [12]Ina Koch, [12]Niels Reinmuth, [13]Adam Dicker, [14]David Gandara, [15]Petros Christopoulos, [16]David Carbone. *[1]Oncohost LTD, Binyamina, Israel; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Yafo, Israel; [3]Assuta Ramat HaHayal Hospital, Tel Aviv Yafo, Israel; [4]Meir Medical Center, Kfar Saba, Israel; [5]Shamir Medical Center, Zerifin, Israel; [6]Emek Medical Center, Afula, Israel; [7]Bnai-Zion Medical Center, Haifa, Israel; [8]Kaplan Medical Center, Rehovot, Israel; [9]Hadassah Medical Center, Jerusalem, Israel; [10]Rabin Medical center, Petah Tikva, Israel; [11]Rambam Health Care Campus, Haifa, Israel; [12]Asklepios Klinik Gauting GmbH, Munich-Gauting, Germany; [13]Thomas Jefferson University, Philadelphia, PA, USA; [14]UC Davis Comprehensive Cancer Center, Sacramento, CA, USA; [15]Thoraxklinik Heidelberg gGmbH, Heidelberg, Germany; [16]The Ohio State University, Columbus, OH, USA*

Background To date, predicting response to immune checkpoint blockade (ICB) therapy in non-small cell lung cancer (NSCLC) patients is based on tumor PD-L1 levels. However, available assays are only moderately predictive, and most require a tumor biopsy. Here, we describe a novel machine learning-based biomarker model that analyzes proteomic profiles in blood plasma to predict ICB response in NSCLC patients.

Methods We collected plasma samples and clinical data from 339 ICB-treated NSCLC patients via a multi-center clinical study (PROPHETIC; NCT04056247; approved by local IRB committees from each site), 60% of them received combination of ICB-chemotherapy and the rest received ICB alone. Patients displaying disease progression were classified as non-responders and the rest as responders. Proteomic profiling was performed by the SOMAscan assay. A machine-learning-based model for clinical response prediction was developed based on protein expression level in patient's plasma. Using a proprietary algorithm, we identified Response Associated Proteins (RAPs), that serve as potential indicators of clinical response depending on their plasma level in the individual patient. The output of the model provides a patient-specific response probability for 3, 6, and 12 months after starting treatment.

Results The RAP-based model displayed strong predictive power over the first year of ICB-based therapy, as indicated by area under the curve (AUC) of the receiver operating characteristics (ROC) plot of 0.71, 0.77 and 0.78 for 3-, 6- and 12-months following treatment initiation, respectively, and a high goodness of fit between predicted response probability and observed response rate (R^2 = 0.97). Patients with low and high response probability predictions displayed a significant difference in overall survival and progression-free survival. The RAP-based model outperformed a PD-L1-based model (AUC of 0.5, 0.6 and 0.55 for 3-, 6- and 12- months, respectively). Notably, in a subgroup of patients with PD-L1-high tumors (>50% PD-L1) receiving monotherapy, patients with high response probability predictions survived significantly longer than patients with low response probability predictions (p-value 0.0002, 0.0036 and 0.0115 for 3-, 6- and 12-months, respectively) who had similar overall survival as patients with PD-L1-low tumors (<50% PD-L1).

Conclusions Altogether, we have developed a novel predictive model for ICB response in NSCLC patients based on proteomic profiling of blood plasma. The model offers two main clinical utilities. First, it provides response predictions for three time points over the first year of treatment. Second, it identifies a subgroup of high PD-L1 patients who may benefit more from combination therapy.

137 FCγRIIA-SPECIFIC DARPINS AS A NOVEL TOOL TOWARD SPECIFIC GENE DELIVERY INTO HIV RESERVOIR CELLS

[1]Arezoo Jamali*, [1]Vanessa Riechert, [1]Samuel Theuerkauf, [1]Sascha Hein, [2]Philipp Adams, [2]Elena Herreracarrillo, [2]Ben Berkhout, [1]Klaus Cichutek, [1]Jessica Hartmann, [1]Christian Buchholz. *[1]Paul Ehrlich Institut, Langen (Hessen), Germany*; *[2]University of Amsterdam, Amsterdam, Netherlands*

Background FcγRIIa (CD32a) has recently been identified as a cellular marker for the latent HIV-1 reservoir.[1] Its relevance as a marker has been challenged, due to technical problems complicated by T-B cell conjugates, and trogocytosis, as well as the lack of reliable antibodies, to distinguish the a and b isoforms. Thus, there remains a need for specific FcγRIIa-binders for diagnostic and therapeutic strategies, including targeted gene delivery. Receptor-targeted viral vectors can mediate highly selective gene delivery into target-receptor positive cells not only ex vivo but also in vivo.

Methods Libraries of designed ankyrin repeat proteins (DARPins) were screened for binding to human FcγRIIa using ribosomal display. Binders unable to discriminate between isoforms were eliminated by counter selection against FcγRIIb. Specific binders were identified on cell lines artificially expressing FcγRIIa or FcγRIIb and by surface plasmon resonance. The binding epitopes were localized through chimeric FcγRIIa a/b proteins expressed on SupT1 cells. The most promising DARPins were inserted into the glycoprotein of Nipah virus to generate FcγRIIa receptor-targeted viral vector. Targeting FcγRIIa receptor on pure or mixed expressing cell lines as well as primary human PBMC was monitored.

Results The identified DARPins discriminated between FcγRIIa and FcγRII b in protein and cellular binding assays with no detectable off-target activities. Their affinities for human FcγRIIa were in the low nanomolar range. In flow cytometry, the DARPins detected FcγRIIa + cells even when they made up less than 1% of the cell population. The difference between FcγRIIa and FcγRIIb is due to a single amino acid moiety. DARPins detected FcγRIIa$^+$ cells could discriminate this even when they made up less than 1% of the cell population in flow cytometry. Lentiviral vectors, displaying the DARPin mediated highly selective gene delivery into FcγRIIa + cells in the presence of a large surplus of FcγRIIb+ cells. On primary cells, between 0.03% – 1.26% (PBMC) and 0.14% – 3.46% of CD4$^+$ T cells were transduced. Such frequencies are well within expectation for FcγRIIa$^+$ cells among T lymphocytes.

Conclusions In summary, well-characterized high-affinity selected FcγRIIa- DARPins have become available offering the potential to become unique tools for the detection of and drug delivery into the latent cellular HIV-1 reservoir. Their application for cell detection supports the presence of FcγRIIa-positive T cells.

138 PLASMA YKL-40 IS ASSOCIATED WITH PROGNOSIS IN PATIENTS WITH METASTATIC PANCREATIC CANCER RECEIVING IMMUNE CHECKPOINT INHIBITORS IN COMBINATION WITH RADIOTHERAPY

[1]Astrid Johansen*, [2]Sif Novitski, [2]Jessica Hjaltelin, [3]Susann Theile, [3]Mogens Boisen, [2]Søren Brunak, [1]Daniel Madsen, [3]Dorte Nielsen, [3]Inna Chen. *[1]Center for Cancer Immune Therapy, Herlev, Denmark; [2]NNF Center for Protein Research, Copenhagen, Denmark; [3]Department of Oncology, Herlev, Denmark*

Background YKL-40, also known as chitinase-3 like-1 protein (CHI3L1), is a secreted glycoprotein produced by various cell types including stromal, immune, and cancer cells. It contributes to cancer progression through tumor-promoting inflammation. YKL-40 has been shown to inhibit the cytotoxic function of T and NK lymphocytes, and in vivo studies have demonstrated synergistic anti-cancer effects of blocking YKL-40 in combination with immune checkpoint inhibitors (ICIs). Biomarkers for the prediction of the response to ICIs are highly needed. We investigated the association between plasma YKL-40 levels clinical benefit and survival in patients with metastatic pancreatic cancer (mPC) receiving ICIs combined with stereotactic body radiotherapy (SBRT).

Methods Blood samples were collected from 84 patients with mPC who participated in the randomized phase II CheckPAC study, in which patients received nivolumab with or without ipilimumab combined with a single fraction of SBRT (15 Gy). Blood samples were collected at baseline, after 2 weeks, and then every 8 weeks until disease progression. Plasma YKL-40 was measured using a commercial ELISA kit.

Results Median plasma YKL-40 was higher after 8 weeks of treatment in patients with progressive disease than in patients with clinical benefit, defined as stable disease, partial or complete response ($p < 0.05$). Elevated baseline plasma YKL-40 was an independent predictor of shorter overall survival (OS) (HR 2.06, 95% confidence interval 1.15–3.7). A ≥40% decrease in plasma YKL-40 was associated with longer OS ($p = 0.0025$) compared to stable (<40% decrease to ≤40% increase) and >40% increasing plasma YKL-40. There was no correlation between plasma YKL-40 and the tumor burden marker CA19–9 at baseline or during treatment.

Conclusions This study contributes new knowledge regarding plasma YKL-40 as a predictor of clinical benefit from ICIs combined with radiotherapy. These exploratory results warrant further investigation of YKL-40 as a biomarker for patients treated with immunotherapies.

Ethics Approval The CheckPAC study was approved by the Danish Ethics Committee (VEK, j.nr. H-16031247) and the Danish Data Protection Agency (j.nr. 2012–58–0004; HGH-2016–112; I-Suite j.nr. 05088).

Consent Signed informed consent was obtained from each participant.

139 IDENTIFICATION OF DISTINCT TISSUE PHENOTYPES IN LUNG AND COLORECTAL CANCERS BY IMAGING MASS CYTOMETRY IS CONSISTENT ACROSS SERIAL SECTIONS

[1]Smriti Kala*, [2]Rasmus Lyngby, [2]Rasmus Sorensen, [1]Andrew Quong, [1]Sam Lim, [1]Clinton Hupple, [1]Nina Lane, [2]Jeppe Thagaard, [2]Johan Dore-Hansen, [2]James Mansfield, [2]Fabian Schneider, [1]Michelle Macpherson. [1]*Standard BioTools, San Francisco, CA, USA*; [2]*Visiopharm, Hørsholm, Denmark*

Background The growth in cancer immunotherapy agents requires an understanding of the immune contexture of the tumor microenvironment (TME). Imaging Mass Cytometry™ (IMC™) is a powerful tool for the study of complex cellular interactions in the TME and in the discovery of biomarkers that can predict disease outcome or response to therapy. The Hyperion Imaging System (Standard BioTools) utilizes CyTOF® technology to simultaneously assess 40+ protein markers at subcellular resolution without spectral overlap or background autofluorescence, thus providing unprecedented insight into the organization and function of the TME. However, despite the advances in staining and imaging methods, developments in analysis software had not kept pace, as a complete, user-defined workflow in a single software package for the analysis of highplex imaging data was lacking.

Methods This study demonstrates a tissue phenotyping workflow in highly autofluorescent lung and colorectal cancer tissues using highplex IMC, which offers the advantage of zero autofluorescence, and hence more reliable results. The data analysis pipeline uses Oncotopix® Discovery (Visiopharm) software for easy, accurate and quantifiable phenotyping. Serial sections of both tissue types were stained with a 40-marker panel comprised of structural, tumor, stroma, and immune cell markers, including immunoregulatory proteins that are targets of immunotherapy. The IMC cell segmentation kit was included in the panel for improved nucleus and plasma membrane demarcation. The analysis pipeline consisted of tissue segmentation (tumor, stroma, necrosis, etc), nuclear detection using a deep-learning algorithm pre-trained on IMC DNA channels, a threshold-based cellular phenotyping step, and spatial analyses.

Results In this work, we have shown that analysis of IMC images from lung and colorectal cancer tissues can uncover tissue phenotypic signatures of the TME through the determination of immune cell types found in the vicinity of cancerous cells and their numbers. Moreover, cell counts and tissue phenotypes were highly consistent across the serial sections, demonstrating the power of IMC in generating robust data.

Conclusions Overall, this work demonstrates that even for highly autofluorescent tissues, IMC can generate high-quality data, consistent across serial sections, which can be easily and accurately analyzed using a single software package, thus empowering IMC users to be confident in biological interpretation of high-dimensional proteomic data. This study showcases the capability of IMC technology combined with Oncotopix Discovery analysis in classification of cellular components within the TME, which is important for development of systematic digital profiling of the spatial TME.

140 ASSESSMENT OF DIFFERENCES IN TUMOR MUTATIONAL BURDEN IDENTIFIED ON LIQUID BIOPSY IN 16,870 PATIENTS NEWLY DIAGNOSED WITH METASTATIC CANCER

[1]Eugene Kwon, [1]Daniel Childs, [1]Bradley Stish, [1]Stephen Boorjian, [1]Matthew Tollefson, [1]Cameron Britton, [1]Ahmed Mahmoud, [2]Angela Thompson, [2]Reagan Barnett, [2]Leylah Drusbosky, [2]Leslie Bucheit*. *[1]Mayo Clinic, Rochester, MN, USA; [2]Guardant Health, Redwood City, CA, USA*

Background Tumor mutational burden (TMB) has emerged as a biomarker of response to immune checkpoint inhibition (ICI), with pembrolizumab approved for patients with a TMB of >10 mut/Mb regardless of solid tumor type. Predictive TMB cutoffs have not been optimized to account for differences in results based on genetic platform, manner of collection (tissue versus blood-based), or tumor type, though some data suggest disease-specific cut-offs may better identify patients who are likely to benefit from ICI. While described in tissue-based assays, blood-based TMB (bTMB) values and histology-specific differences are not well characterized for those newly diagnosed metastatic solid tumors. Here, we present results of bTMB assessment in nearly 17,000 newly diagnosed patients.

Methods Genomic results were queried for patients with newly diagnosed metastatic non-small cell lung cancer (NSCLC), colorectal, breast, prostate, gastric, melanoma or bladder cancer (as designated by ordering clinicians on requisition forms), who had Guardant360 (Guardant Health) testing between October 1, 2020, and June 1, 2022. Three factors were assessed across cancer types: 1) rate of evaluable bTMB, 2) median bTMB at diagnosis, and 3) percentage of patients whose initial bTMB value was above disease-specific cut-offs generated from prior Guardant cohorts[1] (≥80th percentile bTMB values in mut/Mb – NSCLC: 20.2, CRC: 20.1, breast: 15.3, prostate: 13.4, gastric: 13.8, melanoma: 23.8, bladder: 20.2).

Results 16,870 patients were included, most diagnosed with NSCLC (table 1). Newly diagnosed patients with prostate cancer had the lowest rate of evaluable bTMB (<75%); all other cancer types were near or above 80% evaluable. Newly diagnosed patients with bladder cancer and melanoma had the highest median bTMB, while the lowest values were observed for breast and prostate cancers. Less than 20% of newly diagnosed patients with prostate or colorectal cancers had bTMB values above the cancer-type specific cut-off; all other cancer types had >20% of patients with bTMB values above cut-offs.

Conclusions bTMB is evaluable in most patients with newly diagnosed metastatic disease, supporting the feasibility of using circulating tumor DNA to determine TMB. Approximately 20% had a bTMB value above the cancer-specific cut-offs, suggesting potential responsiveness to ICI. Notably, prostate cancer was low across all factors assessed which may reflect its 'cold' biology; assessment of bTMB over time, rather than only at diagnosis, may better inform bTMB utility for patients with certain cancers. Further studies are needed to explore the utility of serial TMB assessment and correlate bTMB values with clinical treatment and outcomes.

Abstract 140 Table 1 bTMB values in patients newly diagnosed with metast

Cancer type	bTMB evaluable	Median bTMB (mut/Mb)	Number of patients who had bTMB greater than cancer type cut-off
NSCLC	8509/10,333 (82%)	12.44	1825 (21%)
Colorectal	1978/2281 (87%)	9.57	95 (13%)
Breast	1621/1984 (82%)	7.89	298 (21%)
Prostate	856/1155 (74%)	7.99	149 (17%)
Gastric	433/525 (82%)	8.61	95 (22%)
Melanoma	274/347 (79%)	14.94	99 (26%)
Bladder	208/245 (85%)	19.36	61 (29%)

141 INDOLEAMINE 2,3 DIOXYGENASE EXPRESSION PREDICTS RESPONSE TO IMMUNE CHECKPOINT BLOCKERS IN ADVANCED NON-SMALL CELL LUNG CANCER

[1]Alban Bessede*, [2]Sylvestre Le Moulec, [1]Jean Philippe Guegan, [3]Isabelle Soubeyran, [3]Florent Peyraud, [1]Christophe Rey, [3]Antoine Italiano. [1]*Explicyte, Bordeaux, France*; [2]*Clinique Marzet, Pau, France*; [3]*Institut Bergonié, Bordeaux, France*

Background In the era of immuno-oncology, it's now crucial to identify primary resistance mechanisms to Immune Checkpoint Blockers (ICB) in order to **i)** delineate novel pathways that can be targeted to improve current rate of response and to **ii)** identify predictive biomarkers to select patients who might benefit from ICB. The Indoleamine 2,3 dioxygenase (Ido) – a tryptophan degrading enzyme – has been well described to exert immunosuppressive functions and is considered as a therapeutic target to improve ICB benefit. However, despite important drug development efforts, little is known about Ido expression and its association with clinical response to ICB.

Methods We analyzed through a digital pathology approach the tumor samples obtained at immunotherapy onset from 55 patients (pts) with stage III/IV NSCLC enrolled in an institutional molecular profiling program (BIP: NCT02534649, sponsor: Insttitut Bergonié, Bordeaux, France). A multiplexed immunohistofluorescence panel consisting of the following markers PDL1, IDO1, CD8 and PanCK was developed, validated, and applied on each available tissue sample. Images were captured through slide digitization (PhenoImager HT, Akoya Biosciences) and analyzed for correlation with clinical outcome (Progression Free Survival and Overall Survival).

Results High PDL1 expression was correlated with a better PFS (19.60 months vs 4 months, p=0,018) and OS (not reached vs 21.2 months, p=0,017) than $PDL1^{Low}$ pts. This study confirmed that pts with a higher abundance of CD8 within the stroma were more responsive to ICB than pts with a lower CD8 infiltration level. Strikingly, high levels of IDO1 expression within the tumor region – as defined through PanCK staining – was associated with a better PFS (not reached vs 4.40 months, p=0,039). Additional image analysis is currently ongoing for the evaluation of the association between the spatial distribution of PDL1+, IDO1+ and CD8 + cells and clinical outcome.

Conclusions Our results indicate that high IDO1 expression in the tumor compartment is associated with improved outcome in patients with advanced NSCLC. Inhibiting IDO may not be a relevant approach to improve ICB efficacy in NSCLC.

142 DEMONSTRATING THE ROLE OF SPATIAL CONTEXTURE IN DETERMINING RESPONSE TO IMMUNE CHECK POINT INHIBITORS USING A TUMOR HISTOCULTURE PLATFORM

[1]Satish Sankaran*, [1]Oliyarasi M, [1]Rajashekar M, [1]Ritu Malhotra, [1]Kowshik Jaganathan, [1]Gowri Shankar K, [1]Vasanth K, [2]Manjula BV, [3]MS Ganesh, [3]Amritha Prabha, [4]Prakash BV, [5]C Jaya Prakash, [1]Arjun Chakraborty, [1]Syamkumar V, [1]Biswajit Das, [1]Aditi Satish, [1]Nandini Basak. *[1]Farcast Biosciences, Bangalore, India; [2]Bangalore Baptist Hospital, Bangalore, India; [3]Vydehi Multi Speciality Hospital, Bangalore, India; [4]Sri Lakshmi Multi Speciality Hospital, Bangalore, India; [5]DBR and SK Super Speciality Hospital, Bangalore, India*

Background Baseline signatures have so far failed to accurately predict response to immune checkpoint inhibitors. A model that mimics the clinical response of tumor immune microenvironment (TiME) upon treatment in culture, would dramatically improve the chances of identifying true responders. Tumor histocultures capture the complex interactions between various tumor microenvironment components effectively. They retain the immune cell repertoire along with spatial context, both of which are adequately represented in Farcast^{TM} TiME histoculture platform.

Methods Farcast^{TM} head and neck squamous cell carcinoma histoculture platform was used to evaluate response to treatment with anti-PD1 (Nivolumab) alone or in combination with anti-CTLA4 (Ipilimumab) in culture. Multiple assays including spatial analysis was performed post-treatment.

Results Interferon gamma (INFg) cytokine release, that classically defines T- cell response, was used to stratify samples for response to treatment with Nivolumab (n=45). Histopathological evaluation revealed that 4 of 45 (9%) samples showed an increase in tumor infiltrating immune cells by 1.5 folds, with a concomitant increase in IFNg secretion ($Log_2FC \pm SD$,1.67 ± 0.8), and CD8+GranzymeB+ cells estimated by flow cytometry. Three out of these 4 samples showed an increase in tumoricidal response. To capture the complex spatial interplay between TiME components and the intra-cellular signals that determine response, a 72-protein marker GeoMx DSP (nanoString) panel was used on two samples (one recurrent and a primary) treated with Nivolumab. panCK was used for tumor segmentation. An increased expression of FoxP3 (Treg marker), IDO and phosphorylated tumor markers was observed in the recurrent sample within the tumor nest, suggestive of immune suppressive microenvironment post treatment. Interestingly, the primary sample exhibited increase in checkpoint and T-cell costimulatory molecules within the tumor nest along with a significant decrease in FoxP3 and tumor marker EGFR, suggestive of enhanced T- cell mediated tumor cytotoxicity. To map the relative spatial distribution of CD8+ and FoxP3+ cell populations, multiplex IHC assay was performed, and data analyzed using QuPath. Decrease in distance between CD8+ cells from tumor nest with a concomitant increase in distance between FoxP3+ and CD8+ cells were observed in a high IFNg and GranzymeB secreting sample.

Conclusions In summary, our data suggests that though IFNg secretion was observed in multiple samples post treatment, spatial contexture influenced T-cell response mediated tumor cytotoxicity. Farcast TiME thus provides a unique platform that can combine spatial dynamics of immune cells overlaid with bulk data, providing important insights into understanding underlying mechanisms that counter T-cell response to immune check point inhibitors.

Acknowledgements Technical support from nanoString for performing the GeoMx DSP experiment and analysis is acknowledged.

Ethics Approval All patient samples used in this study was obtained with prior approvals from individual institutional review boards of participating hospitals.

143 **A COMPREHENSIVE WORKFLOW FOR HIGHPLEX IMAGING, TISSUE SEGMENTATION, AND MULTIPLEX CELLULAR PHENOTYPING FOR TUMOR MICROENVIRONMENT ANALYSIS**

Fabian Schneider*, Rasmus Lyngby, Rasmus Sorensen, Andrew Quong, Smriti Kala, Sam Lim, Clinton Hupple, Nina Lane, Michelle Macpherson, Jeppe Thagaard, Johan Dore-Hansen, James Mansfield. [1]*Visiopharm, Horsholm, Denmark*; [2]*Standard BioTools, South San Francisco, CA, USA*

Background The growth in cancer immunotherapy agents requires an understanding of the immune contexture of the tumor microenvironment (TME). One way to understand immune contexture is to use multiplex staining, imaging, and analysis to obtain multi-marker phenotypes of specific cells and analyze their biodistribution in the TME. Imaging Mass Cytometry™ (IMC) is the method of choice for single-step staining and highplex imaging of FFPE tissues. FFPE tissue is autofluorescent, which limits the utility of immunofluorescence methods, particularly when done without amplification. Lung and colorectal tissue (and bone, skin, etc) are highly autofluorescence, and therefore are a good target for IMC imaging, which has no autofluorescence issues. However, developments in analysis software with a single-package workflow for highplex imagery have not kept pace. We present here a comprehensive workflow in the Oncotopix® Discovery platform designed specifically for highplex IMC image analysis, covering tissue segmentation, cell segmentation based on IMC DNA images, cellular phenotyping, and spatial analyses.

Methods Lung and colorectal tissue sections with a 40-marker panel comprised of structural, tumor, stroma, immune cell markers, and immunoregulatory proteins that are targets of immunotherapy, were imaged (Hyperion, Standard BioTools). Highplex image analysis was performed as a multi-step workflow in a single software package that includes: conversion of IMC images to pyramidal format; easy visualization methods for displaying different marker subsets; a paint-to-train algorithm for tissue segmentation (into tumor, stroma, necrosis, etc); deep-learning-based nuclear segmentation pre-trained specifically on IMC DNA channels; cellular phenotyping based on thresholds set based on visual assessment of positivity; spatial biodistribution metrics for cell populations; and a flexible set of outputs for further downstream analysis.

Results This study demonstrates that a simple workflow can be used to analyze highplex images of different tissue types with no programming knowledge and few changes between tissue types. Visualization templates for the marker subsets and the pre-trained IMC nuclear segmentation are reusable. A new tissue segmentation algorithm for each tissue type is required, as are new thresholds for biomarker positivity. Spatial biodistribution metrics and heatmaps were generated for each tissue type with a minimum of work required.

Conclusions IMC highplex imaging of lung and colorectal tumor samples is a simple and effective means of obtaining highplex images without interfering autofluorescence. Having a comprehensive workflow for the analysis of this complex data makes obtaining useful results from highplex images more accessible to biologists and immunologists by circumventing the requirement for expert programming for each specific application.

144 CD3 HUMANIZED MOUSE MODELS AS VALIDATED TOOLS TO ASSESS IMMUNE-RELATED ADVERSE EVENTS OF T CELL ENGAGERS

Perrine Martin-Jeantet, Gaelle Martin, Angela Pappalardo, Florence Renart-depontieu, Patricia Isnard-Petit, Yacine Cherifi, Fabiane Sônego, Kader Thiam*.

genOway, Lyon, France

Background T cell engagers show high efficacy in B cells malignances. Immune-related adverse events (IrAE), including cytokine release syndrome (CRS), is reported in patients due to on-target off-site effects of T cell engagers (TCE). Translational and predictive assays to assess IrAE of TCE are key to avoid pitfalls in clinical trials. Knock-in humanized mouse models enable the assessment of human-target antibodies in a fully immunocompetent mouse. Indeed, immune responses in CD3 humanized model have been extensively evaluated, and humanization of CD3 has not impaired immune cell distribution. Furthermore, immunization studies showed that T-B cell cooperation is functional in these mice. CD3-TCR complex is also functional, as anti-human CD3 antibodies induce T cell activation. Different classes of TCE showed tumor cell killing ex vivo, as well as tumor growth inhibition in vivo. Here we report the use of CD3 humanized models to assess CRS ex vivo and in vivo.

Methods Two CD3 humanized mice developed by knock-in were used for *ex vivo* and *in vivo* investigation of cytokine production. While one of the models is restricted to one clone of anti-human CD3, the other has been shown to bind several clones of anti-human CD3. *Ex vivo*, T-cell dependent cellular cytotoxicity assay was performed using different TCE concentrations on splenocytes from CD3 humanized mice. *In vivo*, CD3 humanized mice were treated with anti-human CD3 and cytokine release in blood, clinical monitoring, body weight and temperature were assessed.

Results Cytokine release in cytotoxicity assay showed that splenocytes from CD3 humanized mice produced IFN-g, TNF-a, IL-6, IL-1β, IL-10 and IL-12p70 in a TCE concentration-dependent manner.. *In vivo,* cytokine production was also observed in blood of CD3 humanized mice treated with anti-human CD3. Kinetic of secretion was dependent on the detected cytokine (IFN-g, IFN-a, IL-6, IL-10) and chemokine (CXCL9, CXCL10, CCL3, CCL2, CCL4). An anti-CD3 dose-effect on cytokine levels of secretion was demonstrated. In parallel, body temperature drop at early timepoints and increase in late timepoints were observed upon treatment with anti-CD3.

Conclusions Cytokine release and some clinical signs of CRS are reproduced in the two CD3 humanized models described here, validating their value to assess IrAE of TCE. Although the fully functional immune system is one of the main advantages of this model, assessment of mouse biology is a drawback. As a complementary approach, BRGSF-HIS mice, an immunodeficient mouse model reconstituted with human $CD34^+$ cells, showed to reproduce both clinical signs and cytokine production of human TCE-induced CRS.

145 NADUNOLIMAB INHIBITS IL-1α/β-INDUCED CXCR1/2 LIGAND EXPRESSION AND REDUCES SERUM LEVELS OF CXCL1 AND CXCL5 IN NSCLC AND PDAC PATIENTS

Camilla Millrud*, Elin Gyllenbäck, Petter Skoog, Annika Sanfridson, David Liberg. *Cantargia AB, Lund, Sweden*

Background Interleukin-1 receptor accessory protein (IL1RAP) is expressed on tumor cells and stromal cells in most solid tumors, including PDAC and NSCLC. IL1RAP is a co-receptor of the IL-1 receptor (IL1R1), and its dimerization with IL1R1 is required for IL-1 signaling. IL-1 is expressed in the tumor microenvironment and contribute to chemoresistance and an immune-suppressive tumor microenvironment. The chemokine receptors CXCR1 and CXCR2 and their ligands are crucial for the migration of immune-suppressive cells into the tumor and thereby influences tumor progression and metastasis. CXCR1/2 ligands can be expressed by cells in the tumor microenvironment and are downstream of IL-1 signaling. Nadunolimab is a fully humanized ADCC-enhanced monoclonal IgG1 antibody targeting IL1RAP and disrupting both IL-1α and IL-1β signaling. Currently, nadunolimab is evaluated in phase II for PDAC and NSCLC (NCT03267316) in combination with gemcitabine + Nab-paclitaxel or gemcitabine + cisplatin, respectively.

Methods Whole blood and PBMC from healthy donors as well as cancer-associated fibroblasts (CAFs) were stimulated with IL-1α or IL-1β with or without nadunolimab followed by assessment of CXCR1/2 ligands. Serum samples collected before start of treatment and after 2 weeks of treatment from 11 NSCLC patients treated with nadunolimab in combination with gemcitabine + cisplatin, and 16 PDAC patients treated with nadunolimab and gemcitabine + Nab-paclitaxel, were analyzed for the presence of CXCL1, CXCL5 and CXCL8.

Results The inhibitory effect of nadunolimab on IL-1α and IL-1β induced CXCR1/2 ligands was evaluated in different cell systems. IL-1α and IL-1β induced the secretion of the CXCR1/2 ligands CXCL1, CXCL2, CXCL5, CXCL6 and CXCL8 in CAFs. This increase was normalized with the addition of nadunolimab. In a similar fashion, nadunolimab significantly blocked the IL-1α and IL-1β induced levels of CXCL1, CXCL5 and CXCL8 from PBMC and whole blood. Therefore, CXCL1, CXCL5 and CXCL8 were evaluated as potential biomarkers in serum from patients treated with nadunolimab. Similar to the in vitro results, serum levels of CXCL1 and CXCL5 were significantly decreased in patient on treatment with nadunolimab and chemotherapy. However, levels of CXCL8 were not affected after 2 weeks of treatment.

Conclusions Nadunolimab was demonstrated to decrease the levels of CXCR1/2 ligands across different cell systems, and a reduction in CXCL1 and CXCL5 was detected in both NSCLC and PDAC patients during treatment with nadunolimab. This is in line with an effect of nadunolimab on the tumor microenvironment and indicates the potential of CXCL1 and CXCL5 as serum biomarkers for treatment with nadunolimab.

Trial Registration NCT03267316

Ethics Approval The study was approved by the Ethics committees of the concerned countries and an informed consent was obtained from all individuals included in this study. Clinical trial number NCT03267316.

146 TRANSCRIPTOME AUGMENTATION PROVIDES ACCURATE AND SENSITIVE QUANTIFICATION OF GENES ASSOCIATED WITH THE TUMOR MICROENVIRONMENT

Fabio Navarro*, Pamela Milani, Koichi Hashikawa, Shruti Bhide, Upasana Dutta, Dave Delano, Charles Abbott, Robin Li, Zeid Rusan, John West, John Lyle, Sean Boyle, Richard Chen. *Personalis, Inc, Menlo Park, CA, USA*

Background Tumors harbor a complex and dynamic ecosystem of malignant, immune, and stromal cells. While malignant cells dictate much of the tumor biology, there is evidence that the tumor microenvironment (TME) also plays a significant role in disease progression and response to therapy. The role of the immune cells is particularly relevant in immunotherapy, and multiple transcriptome-based biomarkers have shown utility in predicting the efficacy of immune checkpoint blockade. However, little is known about the benefits of enhancing the depth and uniformity of transcriptome sequencing coverage for quantifying the TME cell type composition.

Methods We have developed the ImmunoID NeXT Platform®, which combines high-quality exome and transcriptome sequencing with advanced informatics designed for immune-oncology to comprehensively characterize the tumor and TME from a single FFPE tumor sample. Proprietary augmentation technology was applied to bolster sequencing depth in regions of low coverage across approximately 20,000 genes, enhancing transcriptome coverage uniformity. We processed and sequenced 32 PBMC samples, in-vitro cell mixtures (CD8, CD4, Tregs, B-cells), and over 100 purified cell types to assess the biases and performance of gene expression quantification using the augmented transcriptome. Immune cell composition was validated using flow cytometry. Using purified cell types, we applied differential expression analysis to identify genes preferentially expressed in target cell types. Finally, we confirmed the augmented transcriptome identifies well-established cell-type marker genes and novel cell-type enrichment genes fit for deconvolution.

Results We observed that the ImmunoID NeXT Platform benefits read coverage and uniformity for the majority of genes as compared to both PBMC (PolyA+) and tumor samples (rRNA-depletion). We identified genes preferentially expressed in immune, stromal and granulocyte cell types, showing high overlap with previous literature, and we describe over 1,000 new potential markers fit to assess cell type enrichment in reference samples. To demonstrate that coverage augmentation did not introduce biases disrupting the collinearity between cell fractions and gene expression, we profiled in-vitro cell mixtures. We found that marker genes for Tregs, CD4, CD8, and B-cells are linearly correlated with the fraction of cells mixed and verified by flow cytometry. For instance, well-established CD8 markers show a strong correlation between cell fraction and expression (CD8A corr=0.947 p-value=2.55e-12).

Conclusions We show that ImmunoID NeXT® accurately captures and augments the transcriptome of PBMC and FFPE samples. Applying augmented transcriptome coverage to the assessment of the TME benefited the identification of marker genes for cell type enrichment analysis without introducing bias.

147 COMPREHENSIVE *IN SITU* IMMUNE PHENOTYPING WITH THE COSMX™ HIGH PLEX PROTEIN ASSAY

[1]Tien Phan-Everson*, [1]Jianji Chen, [1]Zachary Lewis, [1]Gary Geiss, [1]Yan Liang, [1]Emily Brown, [1]Liuliu Pan, [1]Stefan Phelan, [1]Charlie Glaser, [1]Mithra Korukonda, [1]Carl Brown, [1]Dwayne Dunaway, [1]Joseph Phan, [1]Alyssa Rosenbloom, [1]Brian Filanoski, [1]Rhonda Meredith, [1]Kan Chantranuvatana, [1]Brian Birditt, [1]Giang Ong, [1]Hye Son Yi, [1]Erin Piazza, [1]Jason Reeves, [2]Subham Basu, [1]Christine Kang, [1]Vik Devgan, [1]Edward Zhao, [1]Michael Rhodes, [1]Joseph Beechem. *[1]NanoString, Seattle, WA, USA; [2]Abcam, Cambridge, UK*

Background The spatial interactions between the immune system and tumor cells greatly influence antitumoral immunity, patient prognosis, and therapeutic efficacy. However, few methods exist to query large numbers of immune biomarkers at subcellular spatial resolution. Launched earlier this year, the CosMx™ Spatial Molecular Imager (SMI) platform captures high-plex single cell and subcellular detection of proteins from FFPE tissues. To detect these key drivers of cancer progression and immune cell activation states and functions, we designed and validated a high-plex protein panel for the CosMx SMI platform. This panel contains 4 markers for cell segmentation and pre-experimental imaging and 64 barcoded antibodies emphasizing immuno-oncology focused targets.

Methods The CosMx protein assay uses antibodies conjugated with oligonucleotides, which are detected using universal, multi-analyte CosMx readout reagents. The fully automated CosMx instrument carries a widefield water immersion objective with 1.1 NA. The CosMx Human Immuno-oncology panel was optimized to comprehensively phenotype lymphoid and stromal lineages within the tumor microenvironment. The CosMx protein assay reagents were validated on multi-organ FFPE tissue microarrays covering prevalent solid tumor types and matched controls, and 52 human FFPE cell lines, including overexpression lines for key targets such as GITR, CD278, PD-L1, and PD-1.

Results We achieved 86% sensitivity and 90% specificity across well-characterized human cell lines compared to GeoMx spatial profiling, and further benchmarked to multiple orthogonal datasets (e.g., the Human Protein Atlas, low-plex IHC). Within the tissue sample profiled, we captured immune cell localization across and within the tumor, key signaling markers related to lymphoid and myeloid activation such as checkpoint engagement, and myeloid cell polarization and antigen cross-presentation markers. We made the data from the study profiling cancer tissue freely available online. This includes the protein images, AI-based cell segmentation, and the per-cell protein abundance profiles.

Conclusions CosMx SMI is a high-plex spatial multiomics platform that enables detection of more than 64 proteins at subcellular resolution in real-world FFPE tissues. Our 64-plex human immuno-oncology protein panel enables in-depth study of the tumor microenvironment, including markers covering cell typing and lineage, immune activation, and checkpoints. This new platform will enable researchers to collect high-plex protein immunophenotyping data and understand immune molecular mechanisms with full spatial context.

FOR RESEARCH USE ONLY.

148 TAP2 DEFICIENCY MEDIATES ADAPTIVE IMMUNE EVASION AND IMMUNOTHERAPY RESISTANCE IN HUMAN NON-SMALL CELL LUNG CANCER

[1]Kishu Ranjan*, [1]Imad ud Deen, [1]Miguel López de Rodas, [1]Nicole Gianino, [2]Soldano Ferrone, [1]Kurt Schalper. *[1]Yale University School of Medicine, New Haven, CT, USA; [2]Massachusetts General Hospital, Boston, MA, USA*

Background The recognition of cancer-cells by T-cells and the therapeutic efficacy of PD-1 axis blockers for cancer treatment are dependent on a fully functional HLA class-I antigen processing machinery (APM). The APM has been found to be defective in many types of human malignancies; however, there is limited information in non-small cell lung cancer (NSCLC). Here we studied cancer-cell APM defects in NSCLC focusing on transporter associated with antigen processing proteins TAP1 and TAP2.

Methods We utilized quantitative and spatially resolved multiplex quantitative immunofluorescence (mQIF) to simultaneously analyze the markers DAPI, cytokeratin (CK), CD8, TAP1 and TAP2 in >1,100 primary NSCLCs from 6 independent cohorts represented in tissue microarrays. Three cohorts (Cohorts #1–3) included 881 tumors from patients treated with standard of care non-immunotherapy and two cohorts included 139 cases treated with PD-1 axis blockers (Cohorts #4–5). One additional cohort included 130 primary lung adenocarcinomas clinically tested for oncogenic mutations in *EGFR* and *KRAS* (Cohort #6). The association between cancer-cell selective TAP1 and TAP2 protein downregulation, clinicopathologic variables and outcomes were studied. To investigate the functional consequences of TAP1 and/or TAP2 deficiency in lung cancer cells, we analyzed the surface peptide-HLA complex levels, functional phenotype/transcriptomic profile, and sensitivity to tumor-antigen specific T-cell killing of cultured tumor cells with targeted TAP1 and/or TAP2 silencing using siRNA or CRISPR-Cas9 based targeted gene deletion.

Results mQIF analysis revealed cancer-cell selective downregulation of TAP1 and TAP2 proteins in ~5% and ~45% of immunotherapy naïve primary NSCLCs, respectively. Cases with TAP2 downregulation showed lower CD8+ T-cell infiltration and shorter survival after PD-1 axis blockers. This effect was not seen in tumors with cancer-cell selective TAP1 downregulation or in cases treated without immunotherapy. Targeted silencing or genetic deletion of *TAP2*, but not *TAP1* in human $HER2^{+}/HLA^{+}$ A549 lung cancer cells reduced the baseline and cytokine induced surface levels of the peptide-HLA complexes formed by the $HER2_{369–377}$ nonamer and HLA-A2 recognized using flow cytometry. In addition, *TAP2* silencing was associated with a marked reduction in tumor cell killing after co-culture with human HLA-A2-positive CD8 + T-cells expressing the T-cell receptor recognizing the $HER2_{369–377}$ peptide. Targeted immune transcriptomic analysis of *TAP2* deficient A549 cells revealed prominent alterations in IFNg sensitivity and cytokine/chemokine expression.

Conclusions Cancer-cell selective TAP2 downregulation is common in NSCLC and mediates immune evasion and immunotherapy resistance *via* reduced antigen presentation and defective IFNg responses. TAP2 deficiency in NSCLC has prominent biomarker and therapeutic potential.

Ethics Approval This study was carried out in accordance with the principles of the Declaration of Helsinki and all tissue and clinical information were used in a de-identified fashion after approval from the Yale Internal Review Board (Yale Human Investigation Committee) protocols #9505008219 and #1608018220 or local institutional protocols, which approved the patient consent forms or waiver of consent.

149 COMPLEMENTARY PHENOCODE SIGNATURE PANELS COMPREHENSIVELY MAP CELL INTERACTIONS AND IDENTIFY SPATIAL PHENOTYPIC SIGNATURES IN THE TUMOR MICROENVIRONMENT

Bethany Remeniuk*, Bei Hopkins, Natalie Monteiro, Darren Locke. *Akoya Biosciences, Marlborough, MA, USA*

Background Spatial biology using multiplexed imaging provides advantages over other biomarker modalities by enabling deeper interrogation of cellular- and protein-level co-expression, localization, and arrangements within the tumor microenvironment (TME). An emerging new biomarker class in the TME are Spatial Phenotypic Signatures (SPS), defined by the measurement of the interactions between, and cell densities of, tumor and immune cells. Akoya's PhenoCode™ Signature Panels have been designed to enable comprehensive mapping of the TME and to help identify SPS. Three PhenoCode Signature Panels were used to investigate SPS for immune checkpoint inhibitor (ICI) therapy in non-small cell lung cancer (NSCLC) patients where ICI have shown durable benefit.

Methods PhenoCode Signature Panels provide off-the-shelf multiplexed imaging customization (6-plex Panel via 5-plex core plus 1 open channel configuration) with minimal user development requirements. PhenoCode uses barcode-based antibody chemistry from Akoya's PhenoCycler® platform integrated with the signal amplification capabilities of Opal chemistry from Akoya's PhenoImager® platform. A tissue microarray (TMA) comprising 41 formalin-fixed paraffin-embedded (FFPE) pre-treatment samples from second-line PD-L1/PD-1 ICI-treated NSCLC cohorts (Durvalumab, Nivolumab, or Pembrolizumab, 16 responders and 25 non-responders) was screened with three PhenoCode Signature Panels. The PhenoCode Signature Panels were: Immuno-contexture Human Protein Panel (CD8/CD68/PDL1/FoxP3/CK core + CD20 or PD1 in the open channel) and Immune Profile Human Protein Panel (CD3/CD8/CD20/CD68/CK core + CD4 in the open channel). FFPE TMAs were stained on a Leica Bond RX™. Slides were imaged on a Phenoimager HT multispectral imaging system and analysis algorithms were developed using inForm®, with cell counts, densities, and spatial parameters calculated using PhenoptrReports.

Results Meta-analysis[1] on anti-PD-1/PD-L1 therapy data pooled from 50+ studies (10+ tumor types and 8,000+ patients) examined the predictive value of single-marker immunohistochemistry (PDL1), tumor mutation burden (TMB), gene expression profiling (GEP) and multiplexed imaging; findings revealed that spatial approaches performed significantly better compared to the other assay types. Multispectral spatial analysis of FFPE TMA samples using PhenoCode Signature Panels uncovered putative SPS within ICI-sensitive NSCLC, indicating enrichment and significance of cell frequencies and cell interactions in responder/non-responder cohorts.

Conclusions A new frontier of biomarker discovery based on spatial biology presents a path toward the use of multiplexed imaging in the clinic, as multiplexing technologies and workflows become more practical, high-throughput, and analytically robust. The ability to deploy Signature Panels supported by PhenoCode chemistry to investigate the immune landscape of the TME will accelerate the finding of SPS that may reliably predict response for ICI therapy.

150 **CIRCULATORY PLASMA PROTEOMIC BIOMARKERS PREDICT RESPONSE TO IMMUNOTHERAPY IN MELANOMA PATIENTS AND REVEAL BIOLOGICAL INSIGHTS INTO THE TUMOR MICROENVIRONMENT**

[1]Arnav Mehta*, [2]Marijana Rucevic, [2]Emmett Sprecher, [3]Nir Hacohen, [4]Genevieve Boland, [3]Milan Parikh, [1]Jiajia Chen, [4]Dennie Frederick, [4]Elliot Woods, [3]Lynn Bi, [3]David Lieb, [2]Lina Hultin-Rosenberg, [2]Jamey Guess, [3]Ryan Park, [3]Alexis Schneider, [4]William Michaud, [4]Benchun Miao, [4]Gyulnara Kasumova, [4]Michelle Kim, [4]Xue Bai, [4]Russell Jenkins, [4]Samuel Klempner, [4]Anna Gonye, [5]Keren Yizhak, [3]Moshe Sade-Feldman, [1]David Liu, [4]Ryan Sullivan, [4]Keith Flaherty. *[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]Olink Proteomics, Boston, USA; [3]Broad Institute of MIT and Harvard, Boston, USA; [4]Massachusetts General Hospital, Boston, MA, USA; [5]Technion Israel Institute of Technology, Haifa, Israel*

Background The majority of patients treated with immunotherapy do not have durable treatment responses. Therefore, there is an urgent need to identify early non-invasive biomarkers for treatment response.

Methods In this study, we performed plasma proteomic analysis of >700 proteins at three timepoints on 174 metastatic melanoma patients treated with immune checkpoint blockade (ICB). We then expanded our analyses to >3000 proteins performed on a larger cohort of 250 patients for deeper exploration of baseline and early on-treatment predictive biomarkers for response to ICB treatment. As a result, we built a predictor of immunotherapy response that outperforms several tissue-based approaches.

Results From the differentially expressed proteins between ICB responders (R) and non-responders (NR), we identified a co-regulated module of proteins associated with treatment resistance comprising IL-6, IL-8, MIA, LIF and GDF-15 enriched in certain NR patients. By analyzing single-cell RNA-sequencing data of tumor biopsies from 32 patients and bulk RNA-sequencing data from 70 patients, we determined the relative contribution of cells in the tumor to proteins in circulation, and associated plasma protein levels with tumor immune microenvironment (TME) phenotypes. The major TME subsets driving the expression of the non-response module proteins were tumor and myeloid cells. Amongst myeloid cells, a subset of tumor-associated macrophages (TAMs) with a suppressive phenotype were identified as potential key drivers of non-response, having the highest expression of all the proteins in the co-regulated NR module.

Conclusions In summary, an integrated longitudinal analyses of circulatory plasma proteins, combined with TME transcriptomics, provides deeper insight into the biology of immunotherapy resistance, and demonstrates prognostic significance and utility of plasma proteomics in biomarker discovery for cancer immunotherapy.

151 USING ADDITIONAL MORPHOLOGY MARKERS IN NANOSTRING® GEOMX® WHOLE TRANSCRIPTOME ATLAS ASSAY TO ASSESS NSCLC TUMOR SUBTYPE

Jessica Runyon*, Christian Nievera, Vijay Baichwal. *Canopy Biosciences, St. Louis, MO, USA*

Background Recent publications have discussed techniques to identify tumor subtypes and a potential correlation with tumor immunity and immunotherapy success. Several techniques have been used for tumor subtype identification including RNA Seq, NanoString® nCounter®, and newer multi-omics approaches. NanoString's GeoMx® DSP platform provides spatial context about cells and their interactions within a tumor while also producing high-plex gene expression data. Expansion of existing morphology markers used with GeoMx DSP enables more precise segmentation of tumors based on key characteristics and provides a better understanding of the tumor's interaction with surrounding tissue. The subsequent transcriptomic profile from the Whole Transcriptome Atlas (WTA) panel may help identify characteristics that impact immunotherapies and the development of treatment screening tests. Lung cancer is still the leading cause of cancer death in the United States.[1] As classified by the WHO/International Association for the Study of Lung Cancer (IASLC),[2] there are three main subtypes of malignant NSCLS including squamous cell carcinoma (25% of lung cancers) and adenocarcinoma (40% of lung cancers).

Methods To evaluate the capability of this technology to selectively enrich specific cell types, we stained sections of non-small-cell lung cancer tumor (NSCLS) subtypes. Since molecular subtyping of NSCLC tumors is critical for targeted therapy and IHC biomarkers play a key role in the diagnosis and subclassification of lung cancer, we investigated if a histological approach combined with molecular profiling could assess both subtypes while identifying unique markers to each tumor subtype. NSCLC tissue was stained with P40 and TTF-1 antibodies to differentiate between squamous cell carcinoma and adenocarcinoma subtypes.[3, 4] For all experiments, transcriptional profiles were assessed with the WTA panel for GeoMx DSP, covering over 18,000 genes and enabling oncology pathway analysis to profile the tumor, tumor microenvironment, and immune response. Analysis of this data set was performed using the GeoMx DSP Analysis Suite software.

Results The transcriptional profiles of these samples were then compared, and significant differences were revealed between these two tumor cell types.

Conclusions The findings support the notion that custom morphology markers enable better tumor stratification providing more meaningful gene expression analysis data. This gene expression data can then be integrated with gene signatures which are being developed for key targets of IO treatments to predict the utility of various immunotherapies for individual patient tumors. Studies with additional tumor types and markers are ongoing to further explore the utility of this technology for analyzing gene expression in different tumor types.

152 THE IMMUNE EXPRESSION LANDSCAPE OF SOLID TUMORS WITH TERTIARY LYMPHOID STRUCTURES

Maria-Fernanda Senosain*, RJ Seager, Erik Van Roey, Shuang Gao, Mary Nesline, Jeffrey Conroy, Sarabjot Pabla. *Labcorp/Omniseq, Nashville, TN, USA*

Background Tertiary lymphoid structures (TLS) are lymphoid organs that develop in non-lymphoid structures in chronically inflamed areas such as tumors. These organized aggregates of T and B cells have the potential to be used as prognostic and predictive cancer factors and could even be targeted for activation and differentiation to increase the antitumor immune response. One current challenge is to identify TLS biomarkers that can discriminate between tumors with strong immune infiltration and those with true TLS structures. In this study, In this study, we identified genes and pathways that could potentially be used to categorize tumors as TLS-positive.

Methods Targeted RNA-seq of 398 immune genes was performed on 167 FFPE tumors representing 5 histologies, composed of melanoma (51.5%), lung cancer (29.9%), kidney cancer (16.2%), bladder cancer (1.8%), and head and neck cancer (0.6%). These tumors had different degrees of T-cell immune infiltration patterns as determined by H&E and CD8 IHC review: TLSs (14.4%), strongly infiltrating (7.2%), infiltrating apparent (29.9%), infiltrating not apparent (22.2%), and not infiltrating (26.3%). We then identified differentially expressed genes comparing TLS-positive tumors with TLS-negative tumors (including infiltration patterns), and TLS-positive tumors with strongly infiltrated tumors, followed by pathway analysis with the REACTOME database.

Results When comparing TLS-positive with TLS-negative tumors, TLS-positive tumors were significantly enriched in pathways associated with the adaptive immune system and T cell receptor signaling, whereas TLS-negative tumors were enriched in cytokine and interferon signaling. Crucially, when comparing TLS-positive tumors with strongly infiltrated tumors, we observed that TLS-positive tumors were significantly enriched in pathways associated with cell cycle, mitosis, and proliferation signaling hinting at active antigen recognition and anti-tumor response.

Conclusions Our results suggest that tumors with TLS have an upregulation of pathways associated with cell cycle and proliferation, and downregulation of interferon and cytokine signaling pathways compared to strongly immune infiltrated tumors without TLS. Genes associated with these pathways could be potential biomarkers for use in identifying TLS-positive tumors. Future directions are to continue the refinement of these signatures using larger datasets, and explore their value in predicting clinical outcomes in patients treated with immune checkpoint therapy.

153 CLINICAL IMPLICATION OF EXHAUSTIVE T-CELL ENVIRONMENT IN UVEAL MELANOMA PATIENTS

[1]Mithalesh Singh*, [2]Seema Kashyap, [2]Nikhil Kumar, [2]Jayanti Jha, [2]Neiwete Lomi, [2]Lata Singh. [1]*University of California, Irvine, CA, USA*; [2]*All India Institute of Medical Sciences, New Delhi, India*

Background Despite recent advancements in the clinical use of immunotherapies, the role of exhausted T cells in the immunobiology of uveal melanoma is still unclear. Exhausted T lymphocytes in the tumor microenvironment exhibit activation of inhibitory receptors, decreased effector cytokine production, and cytolytic activity, resulting in failure of cancer cell elimination. Therefore, the goal of this study was to examine the predictive value of LAG3, CTLA-4, and T-cell markers (CD4, CD8, CD3, and FOXP3) expression in UM patients.

Methods Prospective analysis of 54 UM tumor and blood specimens were taken for this study. Immunohistochemical analysis of exhausted T-cell targets (LAG3 and CTLA-4), and T-cell markers (CD3, CD4, CD8, and FOXP3) were performed on formalin-fixed paraffin-embedded specimens, and expression of exhausted T-cell targets were validated by western blotting. Transcriptional analysis was investigated by qRT-PCR on all the cases for *LAG3* and *CTLA-4* genes. We also checked the expression of CTLA-4, CCR8, and LAG3 at serum levels by sandwich-ELISA assay. Statistical analysis was performed to correlate tumor targets with clinicopathological parameters and patient outcomes.

Results CD3, CD4, CD8, and FOXP3 expression was found in 41%, 35%, 50%, and 39% of the patients, respectively. TIL-positive UM appears to have more CD8-positive cells than other TIL markers. Furthermore, patients lacking nBAP1 who had these TILs exhibited aggressive behavior, which may be associated to shorter metastasis-free survival (MFS). LAG3 and CTLA-4 expression was found in both tumor cells and the lymphocytic environment of UM tissues. Higher LAG3 expression was found to be statistically significant with the presence of epithelioid cells ($p=0.033$), a high mitotic count ($p=0.006$), CD34 positive ($p=0.001$), and nBAP1 loss ($p=0.007$), respectively. While CTLA-4 expression was associated with ciliary body invasion ($p=0.013$) and CD34 positivity ($p=0.031$). Similarly, to protein expression, increased mRNA expression of *LAG3* and *CTLA-4* gene was found in high-risk UM. sLAG3 was considerably higher in metastatic UM (MUM) than in primary UM (PUM) ($p<0.001$). sCCR8 levels were significantly lower in MUM ($p<0.05$) than in PUM. Our data suggest that MFS rates were 60% and 57% in patients having LAG3 immunoexpression and BAP1 loss, respectively. MFS rates were 80% and 56%, respectively, for those who had mRNA expression of *LAG3* and *CTLA-4* with nBAP1 loss.

Conclusions Our findings suggest LAG3 as a promising biomarker to specifically identify functionally exhausted T cells and has a prognostic significance in UM.

154 GENERATION OF HUMANIZED MOUSE MODELS FOR THE PRECLINICAL EVALUATION OF NOVEL IMMUNE CHECKPOINT INHIBITORS, IMMUNE CELL ENGAGERS AND CELL THERAPIES

Maria Stecklum, Annika Wulf-Goldenberg, Bernadette Brzezicha, Christian Rupp*, Wolfgang Walther, Jens Hoffmann. *Experimental Pharmacology and Oncology Berlin-Buch GmH, Berlin-Buch, Germany*

Background The preclinical evaluation of many novel immune therapies requires the use mouse models with a functional human immune system. In previous studies we have demonstrated that either peripheral blood mononuclear cells (PBMCs) or subpopulations of PBMCs such as T- and NK-cells or hematopoietic stem cells (HSC) can be used to establish a humanized immune system in immunodeficient mice system with functional T-, B-, and NK cells as well as monocytes and dendritic cells. By transplanting either cell-line or patient-derived tumor xenografts into humanized mice, we successfully generated a fully human tumor-immune-cell model for several tumor entities. Finally, we validated the functionality of these models using either immune-checkpoint inhibitors, cell therapies, or immune cell engagers.

Methods HSC-humanized mice were generated by i.v. injection of CD34+ stem cells into immunodeficient NOG mice. PBMCs or enriched T- or NK-cell populations from a curated set of blood donors were used to humanize mice by either single or multiple i.v. injections. CDX and PDX models from different entities (i.e. lymphoma, neuroblastoma, and breast cancer) were transplanted into these humanized mice which were used to evaluate novel immune therapy options. The presence of immune cells and their activation status was analyzed by flow cytometry in blood and tumor samples

Results Injected HSCs successfully engrafted and established a functional human immune system with proliferating and differentiating immune cell populations. Fourteen weeks after injection, up to 20% of the human immune cells in the blood were functional T-cells. Several CDX and PDX models successfully engrafted in these humanized mice without significant differences regarding tumor growth compared to non-humanized mice. Checkpoint inhibitor treatment led to tumor growth delay in selected models and flow cytometry analysis of tumor samples revealed a high number of tumor infiltrating T-cells. A comparison of checkpoint inhibitor activity in a pancreatic cancer PDX model using four different humanized mouse models in parallel (HSC, PBMC, T-or NK cell humanized) revealed most convincing results in terms of tumor growth inhibition for the HSC humanized model.

Conclusions We have established fully human tumor-immune-cell models for different tumor entities in combination with different donor derived immune cell subsets as effector cells and have demonstrated successful long term engraftment of HSCs. All models have been used for the evaluation of either novel checkpoint inhibitors, cell therapies or immune cell engagers and will allow preclinical and translational studies for the identification of novel therapy options, drug combinations and biomarkers.

155 MHC CLASS I ANTIGEN PRESENTATION IS ASSOCIATED WITH AN INFLAMED SCLC TUMOR MICROENVIRONMENT CHARACTERIZED BY A HIGHER DENSITY OF CYTOTOXIC T-CELLS IN CLOSER PROXIMITY TO TUMOR CELLS

Markus Schick*, Miljenka Vuko*, Mingchao Xie, Monica Azqueta Gavaldon, Felix Segerer, Andreas Spitzmüller, Harald Hessel, Marco Testori, Johannes Zimmermann, Michael Surace, Mari Heininen-Brown, Jaime Rodriguez Canales, Shashank Saran, Helen Angell, Guenter Schmidt, Hadassah Sade, J Carl Barrett, Giulia Fabbri. *AstrZeneca, Munich, Germany*

Background Small cell lung cancer (SCLC) is generally known to exclude immune cells and durable responses to immunotherapies are rare. Only very few biomarkers to inform immuno-oncology (IO) treatments are established in clinical practice thus far. Recently, four major SCLC subtypes (SCLC-A, SCLC-N, SCLC-P and SCLC-I) were described. Whereas the first three are characterized by activation of specific transcription factors, the SCLC-I (inflamed) subtype is characterized by an inflamed gene signature, high expression of MHC class I (MHC-I) antigen presentation and shows the greatest benefit from addition of immunotherapy to chemotherapy treatment [1,2]. Importantly, MHC-I is epigenetically silenced in the vast majority of SCLC and the presence of MHC-I could serve as a biomarker for the identification of SCLC-I cases. [2]. Here, we aimed to assess the biology of MHC-I high SCLC cases to investigate its role as a biomarker to inform cancer immunotherapies.

Methods We combined the power of artificial intelligence (AI)-driven computational pathology with multiplex immunofluorescence (mIF) to gain critical insight into the tumor microenvironment (TME) of SCLC. 125 SCLC formalin-fixed, paraffin-embedded tissue samples were stained with a mIF panel consisting of six markers: PanCK, CD8, CD68, PD-1, PD-L1, and Ki67. We assessed the phenotype and spatial location of each cell in the pathologist-annotated tumor center and within the AI-segmented stroma and tumor epithelium. Pathologists classified immunohistochemically stained MHC-I slides from the same tissue blocks as MHC-I high, medium, or low according to their H-scores (low: ≤30; medium: 31–139; high: ≥140). TME characteristics between those groups were compared.

Results In all measured regions, we found higher densities of CD8+ and particularly PD-1/CD8 double positive T-cells in the MHC-I high group. Moreover, we observed the highest proportion of PD-1 positivity among cytotoxic T-cells in the tumor epithelium of MHC-I high samples, which also showed a high density of PD-L1+ tumor cells. Average distance of PD-1+ T-cells to their nearest tumor cell was lowest in the MHC-I high group. In the same group, an average of 19.3% of tumor cells in the epithelium had at least one PD-1+ T-cell within a 50 μm radius, while in the MHC-I low group this average was only 8.9%.

Conclusions We utilized cutting-edge computational pathology to establish MHC-I as orchestrator of the composition and spatial arrangement of an inflamed SCLC TME. Beyond that, our findings corroborate the role of MHC-I as a potential biomarker for inflamed SCLC cases, which benefit most from cancer immunotherapies.

156 ESTABLISHMENT OF AN IMMUNE CELL PHENOTYPING MULTIPLEXED IMMUNOFLUORESCENCE ASSAY AND DIGITAL IMAGE ANALYSIS WORKFLOW TO INVESTIGATE THE TUMOR MICROENVIRONMENT IN SOLID TUMORS

Dirk Zielinski, Suso Platero*. *Discovery Life Sciences, Kassel, Germany*

Background The advent of immune-oncology had a significant impact on the stratification of cancer patients, in the past few years. Immune phenotyping of the tumor microenvironment is becoming a tool for the identification of novel predictive biomarkers for cancer immunotherapy. One promising approach is the usage of multiplexed immunofluorescence (mIF) assays for the semi-quantitative assessment of spatial distribution patterns.

Methods Akoya's Opal fluorophores were optimized for the Ventana Discovery ULTRA for use with human control tissues as well as several cancer tumors. The panel consisted of CD4 (clone SP35), CD8 (clone C8/144B), CD68 (clone PG-M1), FoxP3 (clone SP97), PD-L1 (clone SP263) and pan-Cytokeratin (clones AE1/AE3). Each marker was independently validated using single plex bright field immunohistochemistry and adequate stripping efficiency, of the previous applied primary and secondary antibody complex, was confirmed.

Automated image analysis was performed using a workflow of several custom Visiopharm applications, after optimization of segmentation in regions of interest, like tumor invasive margins, or surrounding microenvironment.

Results 6-plex mIF, followed by automated image analysis, was performed in controls and cancer tissue. The ability to multiplex allows for the detection of new immunophenotypes in the tumor and surrounding microenvironment. Such phenotypes, together with the validation of the markers and the image analysis workflow will be presented.

Conclusions Individual mIF immune marker panels and automated image analysis identify a broad number of different immune phenotypes, including rare double- or triple-positive cell subtypes, yielding new insights into the complexity of the tumor microenvironment. Such results could in the future improve cancer patient stratification in immunotherapy.

157 INTERROGATION OF THE TUMOR IMMUNE MICROENVIRONMENT AND *EX VIVO* PROFILING OF PD-1 BLOCKADE USING THE 3D-EXPLORE *EX VIVO* PLATFORM OF FRESH PATIENT TUMOR TISSUE

Brittney Ruedlinger*, Jasmin D'Andrea, Jared Ehrhart, Soner Altiok. *Nilogen Oncosystems, Tampa, FL, USA*

Background The patient derived 3D-EXplore *ex vivo* platform that incorporates features of the tumor microenvironment provides the multifaceted approach required to model the dynamic response to immune checkpoint blockade. For many patients resistance to PD-1/PD-L1 blockade remains a challenge and new approaches are needed to guide treatment. Here, we demonstrate feasibility of the 3D-EXplore platform utilizing fresh patient tumoroids to interrogate the impact of PD-1 blockade on the tumor immune microenvironment in Non-Small Cell Lung Cancer (NSCLC).

Methods Tumoroids measuring 150 μm in size were generated using a proprietary mechanical process without any enzymatic digestion or propagation from fresh NSCLC samples (n=70). This study was approved by Vanderbilt University Ethics Board; approval number 031078 and Ohio State University Ethics Board: 2014J0130. 3D-EXplore *ex vivo* studies were performed with anti-PD-1 monoclonal antibodies nivolumab or pembrolizumab and multiparameter flow cytometry analysis was carried out to assess the treatment-mediated changes in the tumor resident T lymphocytes, Tregs, NK/NKT and myeloid cell populations. Furthermore, we performed multiplex cytokine release assays with supernatants collected from the *ex vivo* treated tumoroid cultures.

Results Multiplex flow cytometric analysis demonstrated the heterogeneity of the tumor immune cell populations including myelomonocytic and leukocyte lineages in different patient tumor samples. 3D *ex vivo* samples treated with nivolumab and pembrolizumab demonstrated PD1 occupation on CD3 T-cells, while approximately 20% of tumors showed increased CD8 T-cell activation upon *ex vivo* treatment that correlated with proinflammatory cytokine release in the conditioned media. The *ex vivo* response to PD1 inhibitors was correlated with changes in the expression of other immune checkpoint proteins, such as CTLA4, immune scoring, tumor mutation burden, tumor pathologic stage, and PD-L1 expression assessed by E1L3N IHC in FFPE tumor sections.

Conclusions Our data demonstrated that 3D-EXplore is as a clinically relevant platform for examining the efficacy of immunotherapeutic interventions. As shown here, PD-1 blockade had tumor and donor specific treatment efficacies with respect to overcoming the suppressive tumor environments. Furthermore, the 3D-EXplore platform provides keen insight into the intact tumor microenvironments, facilitating the development and efficacy of immunotherapeutic agents in cancer.

Ethics Approval All tissues in the study were collected under patient consent approval by Vanderbilt University Ethics Board; approval number 031078 and Ohio State University Ethics Board: 2014J0130

158 A NOVEL, HIGHLY ACCURATE LIQUID BIOPSY-BASED GLYCOPROTEOMIC PREDICTOR OF CHECKPOINT INHIBITOR TREATMENT BENEFIT IN ADVANCED NON-SMALL CELL LUNG CANCER

Klaus Lindpaintner*, Apoorva Srinivasan, Alan Mitchell, Apurva Dixit, Gege Xu, Xin Cong, Daniel Serie. *InteVenn Bioscience, South San Francisco, CA, USA*

Background Protein glycosylation is the most abundant and complex form of post-translational protein modification. Glycosylation profoundly affects protein structure, conformation, and function. The elucidation of the potential role of differential protein glycosylation as biomarkers has been limited by the technical complexity of generating and interpreting this information. We have recently established a novel, powerful platform that combines liquid chromatography-mass spectrometry with a proprietary artificial-intelligence-based data processing engine that allows, for the first time, highly scalable interrogation of the glycoproteome. Here we report the performance of this platform to predict likely benefit from immune-checkpoint inhibitor (ICI) therapy in advanced non-small cell lung cancer (NSCLC).

Methods Our platform was utilized to assess 532 glycopeptide (GP) and peptide signatures representing 75 serum proteins in pretreatment blood samples from a cohort of 125 individuals (54 females, 71 males, age range 60 to 75 years). Inclusion criteria were as follows: a diagnosis of unresectable stage 3 or 4 NSCLC, treatment with pembrolizumab monotherapy (27 patients), or treatment with combination pembrolizumab-chemotherapy (98 patients). Overall survival (OS) data were available for all patients. Samples and de-identified clinical data were obtained from Tempus Labs (Chicago, IL).

Results A multivariable-model-based classifier for OS was created utilizing 70% of the cohort as a training set and seven glycopeptide and non-glycosylated peptide biomarker features selected from a generalized additive model. The classifier yielded a hazard ratio (HR) for prediction of likely ICI benefit of 3.96 at $p < 0.0001$. Additionally, the classifier was validated using a test set comprised of the withheld 30% of patients, yielding a HR of 3.86 at $p < 0.01$ which separated patients likely benefiting from ICI therapy from those likely not benefiting from ICI therapy (median OS of 23.2 vs. 5.9 months, respectively, based on classifier score above/below cutoff).

Conclusions The glycoproteomic classifier described here predicts with high sensitivity which patients are likely to benefit from ICI therapy. In addition to potentially reducing the use of ICIs in a safe manner in patients who would be unnecessarily subjected to possible adverse drug reactions, our classifier simultaneously has the potential of reducing the burden of health care expenditures. Our results indicate that glycoproteomics holds a strong promise as a predictor for ICI treatment benefit which appears to significantly outperform other currently pursued biomarker approaches.

Ethics Approval The study was conducted under IRB approval obtained by Tempus Labs, with all patients involved providing informed consent for the use of their blood samples for biomarker research.

159 XERNA TUMOR MICROENVIRONMENT SUBTYPES AS A BIOMARKER IN LUNG CANCER PATIENTS

[1]Mark Landers*, [1]Patrick Eimerman, [1]Steve Mastrian, [1]Tracey White, [1]Janine LoBello, [1]Gargi Basu, [1]Szabolcs Szelinger, [1]Jessica Aldrich, [1]Matthew Halbert, [1]Jess Hoag, [1]David Hall, [2]Farjana Fattah, [3]Daniel Pointing, [3]Luka Ausec, [3]Anze Gregorc, [4]Seema Iyer, [4]Mark Uhlik, [4]Laura Benjamin, [1]Rick Baehner. *[1]Exact Sciences, Madison, WI, USA; [2]Simmons Comprehensive Cancer Center, UT Southwestern, Dallas, TX, USA; [3]Genialis Inc., New York, NY, USA; [4]OncXerna Therapeutics, Waltham, MA, USA*

Background Despite immune checkpoint inhibitor (ICI) monotherapy approvals in NSCLC, SOC predominately utilizes combinations of ICI with non-targeted chemotherapy or precision therapies targeting oncogenic drivers. Biomarkers guiding these clinical decisions rely on tumor genotyping to identify actionable mutations, tumor mutational burden (TMB) and on immunohistochemistry for PD-L1 expression. Currently, neither PD-L1 nor TMB perform adequately for ICI patient selection.[1] Emerging evidence indicates a more complete profile of the tumor microenvironment (TME) may improve selection of patients likely to respond to ICI.[2] The Xerna machine learning-based RNA sequencing biomarker assay classifies tumors into four TME subtypes; Immune Active (IA), Immune Suppressed (IS), Immune Desert (ID) and Angiogenic (A) . This classification identifies tumors likely to benefit from ICI (IA and IS) or anti-angiogenic agents (ID and A).[3] We examined the distribution of actionable oncogenic driver mutations across Xerna TME subtypes to investigate the potential use for therapy selection.

Methods Biomarker prevalence, and Xerna TME subtype classification, were determined for 104 metastatic lung cancer cases previously analyzed using the Oncomap™ ExTra test, tumor-normal whole-exome and whole-transcriptome sequencing. DNA variants and high TMB (≥10 mut/Mb) were identified from DNA sequencing, and RNA expression levels were used to assign tumors to Xerna subtypes. Biomarker and associations were compared using Fisher's Exact Test. The study was approved by WCG IRB Ethics Board, approval number 20181863.

Results In total, 53% of cases had high (IA+IS) vs. low (ID +A) Xerna immune subtypes and 60% harbored targetable oncogenic driver mutations (table 1). Actionable *EGFR* and *KRAS* mutations were detected in 31% and 20% of cases respectively, while high TMB was detected in 27% of cases. High TMB was significantly higher in IA (62%) vs. IS (14%) or A (13%) categories ($p<0.05$). Although no significant associations between Xerna subtype and oncogenic drivers were observed, *EGFR* mutations were least frequent in IA tumors (15%) while 33% of the IS subtype contained KRAS mutations (10% G12C).

Conclusions The Xerna TME panel identified a high prevalence of patients who may benefit from ICI (IA+IS) and harbored actionable oncogenic drivers. Within this group, the prevalence of targetable oncogenic drivers within the IS phenotype, such as *KRAS* G12C, may represent the potential for novel ICI combination therapies.[4] These findings further highlight the importance of adding TME analysis to comprehensive biomarker testing in NSCLC

160 NOVEL, HIGH-PLEX, AND FLEXIBLE BIOMARKER PANELS FOR RAPID DEVELOPMENT OF SPATIAL SIGNATURES TO IMPROVE STRATIFICATION OF RESPONSE TO COMBINATION THERAPIES

Rachel Schaefer*, Jacob Circelli, Oscar Perez, Linying Liu, Michael McLane, Yi Zheng. *Akoya Biosciences, Marlborough, MA, USA*

Background Pre-clinical and clinical studies into new checkpoints as therapeutic targets have raised the possibility that combining immune checkpoint inhibitors or other immunotherapies may be an effective strategy in improving both the response and survival rates. The development of clinically useful biomarkers to select responders for combination therapies will be critical for the advancement of such treatments. Profiling the tumor microenvironment (TME) by assessing spatial relationships and protein co-expression within specific cellular subsets could lead to improved patient stratification of response to these combination therapies. To provide researchers with an end-to-end, automated workflow for the functional evaluation of tumors in the context of patient immunity, we have developed a new single-cell multiplexed staining method.

Methods PhenoCode Signature panels utilize barcode-based antibody labeling chemistry, allowing primary antibodies to be applied as a cocktail in a single incubation step followed by amplified detection using Opal fluorescent dye technology. These panels feature a flexible design component allowing for the easy integration of a novel checkpoint or immune cell marker into a 5-plex panel, resulting in the detection of up to six biomarkers simultaneously on a single tissue section. Human formalin-fixed, paraffin-embedded (FFPE) lung cancer tissues were stained using the PhenoCode Signature panels and DAB. Staining was performed on the Leica BOND RX™ automated stainer. Multispectral imaging was performed on the PhenoImager® platform, and image analysis was performed with a phenotyping algorithm in inForm® software. Intensity analysis was performed in R using Phenoptr and PhenoptrReports.

Results Three PhenoCode Signature 6-plex panels were developed and applied to lung cancer samples to help characterize distinct immune landscapes. We demonstrate a fully automated, yet robust and flexible workflow for assessing spatial relationships and profiling the tumor microenvironment. The staining of each marker within the panels qualitatively matches chromogenic DAB staining. High assay reproducibility was demonstrated by both qualitative and quantitative analysis of staining quality. Single markers were substituted from each panel to show the flexibility of the panel design.

Conclusions In this study, we demonstrate the utility of three 6-plex PhenoCode Signature panels for easy and reproducible profiling of the TME. The flexible design component of the panels allows for the substitution of a single biomarker enabling the rapid assessment of additional cell phenotypes. The flexible configuration combined with shortened assay development time are designed to enable researchers to rapidly develop more predictive spatial phenotypic signatures, aiding in the development of more targeted combination immunotherapies

161 SINGLE-CELL SPATIAL IN SITU TRANSCRIPTOMICS UNRAVELS VULVAR HSIL COMPOSITION ASSOCIATED WITH COMPLETE RESPONSE TO THERAPEUTIC VACCINATION

[1]Ziena Abdulrahman*, [2]Mariette IE van Poelgeest, [2]Marij JP Welters, [1]Sjoerd H van der Burg. *[1]Leiden University Medical Center, Oncode, Leiden, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands*

Background Vulvar High-grade Squamous Intraepithelial Lesion (vHSIL) is predominantly induced by high-risk Human Papilloma Virus type 16 (HPV16). In two independent trials, therapeutic vaccination against the HPV16 E6 and E7 oncoproteins resulted in objective partial and complete responses in half of the HPV16+ vHSIL patients at 12 months follow-up. Here, the pre-vaccination vHSIL tumor microenvironment in relation to the vaccine-induced clinical response was in-depth investigated.

Methods A unique novel high-plex spatial molecular imaging technique, CosMx (Nanostring), was applied, which for the first time allows the visualization of 1000 RNA transcripts at a subcellular resolution in situ on FFPE pre-immunotherapy tissue, using cyclic fluorescent in situ hybridization. This allowed both the discovery of new cell types in the tumor microenvironment of vHSIL, as well as the investigation of their spatial interactions. We studied a cohort of 20 pre-immunotherapy vHSIL samples, 6 complete responders, 7 partial responders and 7 non-responders. Data was analyzed with the R Giotto package for spatial transcriptomics, applying unsupervised clustering for cell identification and machine learning to unravel spatial patterns in the tissue.

Results The tumor microenvironment of complete responders is characterized by the presence of distinct pro-inflammatory dendritic cells, macrophages and T cells, whereas these cells are scarce in non-responders. Moreover, also the spatial composition of these patient groups differed significantly, the tumor microenvironment of complete responders harbors direct spatial interactions between pro-inflammatory innate and adaptive immune cells indicating an adequate ongoing anti-tumor immune response, which is lacking in non-responders.

Conclusions Single-cell in situ transcriptomics identified the key importance of multiple pro-inflammatory immune cell types for response of vHSIL to therapeutic vaccination, as well as the importance of the spatial organisation of these immune cells in order to be able to execute their pro-inflammatory function. This indicates that a well coordinated immune response on multiple levels, i.e. having sufficient numbers of both pro-inflammatory myeloid and lymphoid cells, as well as their spatial architecture, is pivotal for successful response to immunotherapy.

Ethics Approval Ethics approval was provided by the Leiden University Medical Center. Patients were included in this study after providing written informed consent. This study was conducted in accordance with the Declaration of Helsinki and in accordance with Dutch law.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0161

162 DETECTING T-CELL REINVIGORATION AND PERSISTENCE USING PATIENT DERIVED EX VIVO THREE-DIMENSIONAL SPHEROID MODELS

Katy Lassahn*, Ashley Elrod, Tessa DesRochers, Kathryn Appleton. *Kiyatec, Greenville, SC, USA*

Background Immune checkpoint blockade is shifting the paradigm for cancer treatment. However, this class of therapeutics is limited by insufficient or dysfunctional antitumor T-cells with impaired memory formation. Adoptive cell therapy is a treatment option for patients with exhausted resident T-cells, yet the effective use of this immunotherapy for the treatment of solid tumors is still in early stages. A durable patient response is possible when T-cell products successfully persist following recursive tumor cell exposure and resist differentiation and exhaustion.[1] Due to the variability of personalized cellular immunotherapies, verification of T-cell function would facilitate selection of the most desirable product for clinical use. Herein, we report a tissue agnostic ex vivo three-dimensional model which recapitulates the tumor microenvironment for the assessment of T-cell performance.

Methods Spheroids were generated using primary patient-derived tumor cells or patient-derived xenografts and cultured with immune cells, expanded tumor-infiltrating lymphocytes or CAR-Ts. Reinvigoration was determined via increased T-cell activation and proliferation as detected by flow cytometry. Low effector to target ratios were utilized to mimic a high tumor burden. T-cell persistence was tested following multiple rounds of tumor cell challenge in a repetitive antigen exposure assay. Granzyme B levels, degranulation and annexin V were evaluated to measure antitumor efficacy. T-cell susceptibility to differentiate was determined by detecting memory markers CD62L and CCR7. Finally, T-cell products that were prone to exhaustion were identified by monitoring expression of checkpoint proteins.

Results Patient samples capable of reinvigoration responded to PD-1 blockade as determined by increases in T-cell proliferation, 4–1BB, and degranulation. Decreased expression of the memory markers CD62L and CCR7 was observed on CD45RO+/CD8+ T-cells when challenged with high tumor burden, but not with low tumor burden exposure. Responding T-cells persisted with higher absolute numbers compared to low tumor burden models. Using our repetitive antigen challenge platform, we detected no significant change in T-cell function with a single rechallenge of tumor cell exposure. Upon multiple challenges, varying degrees of T-cell degranulation, granzyme B levels, and T-cell viability were observed compared to lesser challenged T-cells demonstrating inherent differences in donor T-cell persistence.

Conclusions This complex three-dimensional platform has the ability to 1) test patient-specific T-cell reinvigoration and 2) closely monitor and assess candidate cell therapy products during development. This platform can provide a cost-effective method to expedite new cell therapy products through preclinical pipelines.

163 IMMUNE-BASED BIOMARKER ACCURATELY PREDICTS RESPONSE TO IMIQUIMOD IMMUNOTHERAPY IN CERVICAL HIGH-GRADE SQUAMOUS INTRAEPITHELIAL LESIONS

[1]Ziena Abdulrahman*, [2]Natasja Hendriks, [2]Arnold J Kruse, [3]Antonios Somarakis, [4]Anna JM van de Sande, [4]Heleen van Beekhuizen, [5]Jurgen MJ Piek, [3]Noel FCC de Miranda, [2]Loes FS Kooreman, [2]Brigitte FM Slangen, [1]Sjoerd H van der Burg, [2]Peggy J de Vos van Steenwijk, [5]Edith MG van Esch. *[1]Leiden University Medical Center, Oncode, Leiden, Netherlands; [2]Maastricht University Medical Center, Maastricht, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Erasmus University Medical Center, Rotterdam, Netherlands; [5]Catharina Hospital, Eindhoven, Netherlands*

Background The complete response rate of cervical high-grade squamous intraepithelial lesion (cHSIL) patients to imiquimod immunotherapy is 60%. Consequently, many patients are exposed to unnecessary adverse effects of imiquimod. On the other hand, conventional surgical large loop excision therapy is associated with increased risk of premature births in subsequent pregnancies. An in-depth analysis of the cHSIL immune microenvironment was performed in order to identify and develop a predictive biomarker for response to imiquimod, to maximize therapy efficacy and avoid adverse effects in patients unlikely to respond.

Methods Biopsies of 35 cHSIL patients, before and 10 weeks on imiquimod treatment, were comprehensively analyzed by two multispectral seven-color immunofluorescence panels for T cell and myeloid cell composition in relation to treatment response. Based on these results a simplified immunohistochemical detection protocol was developed. Samples were scanned with the Vectra multispectral imaging system, and cells were automatically identified using machine learning.

Results The immune microenvironment of complete responders (CR) prior to imiquimod is characterized by a strong and coordinated infiltration by T helper cells (activated $PD1^+$/type 1 $Tbet^+$), M1-like macrophages ($CD68^+CD163^-$) and dendritic cells ($CD11c^+$). The lesions of non-responders (NR) displayed a high infiltration of $CD3^+FOXP3^+$ regulatory T cells. At 10 weeks on imiquimod treatment, a strong influx of intraepithelial and stromal $CD4^+$ T cells was observed in CR but not NR patients. A steep decrease in macrophages occurred both in CR and NR patients, leveling the pre-existing differences in myeloid cell composition between the two groups. Based on the pre-existing immune composition differences, the sum of intraepithelial CD4 T cell, macrophage and dendritic cell counts was used to develop a quantitative simplified one color immunohistochemical biomarker, the CHSIL Immune Biomarker for Imiquimod (CIBI), which can be automatically and unbiasedly quantified and has an excellent predictive capacity (ROC AUC 0.95, $p<0.0001$).

Conclusions The capacity of cHSIL patients to respond to imiquimod is associated with a pre-existing coordinated local immune process, fostering an imiquimod-mediated increase in local T cell infiltration. The CIBI immunohistochemical biomarker has strong potential to select cHSIL patients with a high likelihood to experience a complete response to imiquimod immunotherapy.

Ethics Approval Ethics approval was provided by all the participating hospitals: Maastricht University Medical Center, Erasmus University Medical Center Rotterdam and Catharina Hospital Eindhoven. Patients were included in this study after providing written informed consent. This study was conducted in accordance with the Declaration of Helsinki and in accordance with Dutch law.

164 EVALUATION OF LIQUID BIOPSY-BASED PLASMA COPY NUMBER BURDEN, DNA METHYLATION AND PERSONALIZED MINIMAL RESIDUAL DISEASE APPROACH FOR MONITORING MOLECULAR RESPONSE TO DIFFERENT DRUG REGIMENS IN METASTATIC COLORECTAL CANCER PATIENT

[1]Zheng Feng*, [2]Neil Smith, [3]Giancarlo Bonora, [2]Juergen Scheuenpflug, [3]Pan Du. [1]*EMD Serono, A business of Merck KGaA, Darmstadt, Germany, Billerica, MA, USA*; [2]*Merck Healthcare KGaA, Darmstadt, Germany, Darmstadt, Germany*; [3]*Predicine, Inc, Hayward, CA, USA*

Background Liquid biopsy (LBx) based low pass whole genome sequencing (LP-WGS) derived blood copy number burden (bCNB) with defined clinical cut-offs provides a genome-wide overview for monitoring molecular reponse. LBx DNA methylation analysis promises sensitivity for monitoring treatment response and possibly provides tissue of origin (TOO) insights. The potential clinical utility of the multi-faceted approaches to monitor molecular response using bCNB and DNA methylation in the metastatic colorectal cancer (mCRC) palliative treatment setting were investigated.

Methods Seventy longitudinal (baseline, on-treatment, and end of treatment (EOT)) plasma samples were collected from 14 mCRC patients treated with chemotherapy (CTx) alone or in combination with one or more targeted agents and PD-L1 blockade (figure 1). bCNB and DNA methylation were analyzed at all timepoints, respectively. bCNB is calculated based on the genome-wide copy number abnormalities, normalized by the LP-WGS profiles from healthy donors. Furthermore, a clinical applicable cut-off can be defined for molecular response monitoring. DNA methylation provides whole-genome methylation profiles using input amounts as low as 1 ng. Personalized MRD which uses patient-specific mutation and fixed panels, was utilized to generate MRD data for the 11 baselines, time points and EOT samples.

Results Using bCNB, eight patients treated with CTx in combination with different therapies such as targeted agents and PD-L1 blockade showed a consistent reduction in tumor burden compared to baseline, with post-treatment bCNB values below the cut-off of 5.2 (log2) derived from healthy donors (figure 2). DNA Methylation determined TOO, exemplified by the preliminary data detected the enrichment of SMAD4-associated hypermethylated DNA fragments in a patient with metastasis. A cut-off of 9.5 (log2) was defined based on abnormally methylated fragments, which correlated with bCNB (R^2=0.83; figure 2). Additionally, indication specific tiered cut-offs for molecular responses can be defined. Tumor fraction estimates using Personalized MRD showed a correspondence with both bCNB (patient-wise correlation, Pearson r=0.87) and abnormal DNA Methylation cut-offs (patient-wise correlation, Pearson r = 0.82) for patients with matching data points, respectively.

Conclusions bCNB is a feasible approach for assessing molecular response with cut-off determination, and its low cfDNA input requirement enables clinical utilities. Preliminary data supported that DNA methylation assay detected TOO and demonstrated potential clinically applicable cut-off definitions. bCNB, DNA methylation and Personalized MRD demonstrated concordance and provided a comprehensive suite of solutions for molecular response and MRD monitoring. Collectively, the holistic LBx approaches with clinical applicable cut-off definition would possibly facilitate the selection of patient-centric tailored treatments.

Ethics Approval The study protocol was in accordance with the tenets of the Declaration of Helsinki. Commercial samples used in this study were procured from Indivumed GmbH following protocols approved by the local Institutional Review Board (IRB) committee. Informed consent forms were obtained from all the human subjects in this study.

Consent Written informed consent was obtained from the patient for publication of the abstract and any accompanying images. A copy of the written consent is available for review by the Editor of this journal.

165 PAHR: THE PAN-CANCER AHR SIGNATURE PIPELINE

[1]Peter Schulz-Knappe, [1]Christiane Opitz*, [2]Saskia Trump, [1]Ahmed Sadik. *[1]DKFZ, Heidelberg, Germany; [2]Charite, Berlin, Germany*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0165

Background The ligand-activated transcription factor, AHR (aryl hydrocarbon receptor) is an important regulator of different biological process including angiogenesis, hematopoiesis, drug and lipid metabolism, cell motility, and immune modulation. AHR activating ligands are found in the environment (e.g., dioxin), but are also generated endogenously, for example by tryptophan catabolizing enzymes (e.g., IDO1, TDO2, IL4I1).[1,2,3] AHR activation can lead to immunosuppression, thus limiting response to therapy. AHR activity is increased in cancer and efforts are ongoing to decipher the AHR-mediated immune modulation in the crosstalk between cancer and the tumor microenvironment.

Methods By combining analysis of gene expression data from over 10,000 tumors in 32 different cancers and natural language processing we developed a pan-cancer AHR transcriptional gene signature (PAHR) that allows detecting the status of AHR activation in a cell and ligand independent manner. We built a plug & play pipeline using PAHR, which employs multiple machine learning methods for AHR target biomarker discovery.

Results Using PAHR, we profiled transcriptomics and amino acid metabolic profiles of 32 different cancers that associate with the production of AHR activating ligands. Furthermore, we used PAHR to characterize AHR specific cancer subtypes showing various AHR-mediated immunosuppressive functions.

In most cancers, the AHR cancer subtypes reflected worse overall survival outcome with increasing AHR activity. Functional characterization of bladder cancer AHR subtypes showed that AHR mediates different transcriptional programs leading to similar survival outcomes using different immunosuppressive modules. Some cancer subtypes showed better survival outcome associated with high AHR activity, indicating that AHR can play both tumor promoting and suppressive roles.

Conclusions PAHR integrative analysis detects different patterns of AHR activities across cancers with significant induction of immunosuppression in cancers leading to the development of distinct patient strata on a pan-cancer level.

We conclude that assessment of AHR-activity by way of PAHR presents as a new stratification strategy in immune oncology. PAHR will improve patient selection in clinical trials, and therapy selection of todays and future cancer immunotherapies to improve response to treatment for the individual patient.

167 COMPREHENSIVE PROFILING OF CANCER-ASSOCIATED FIBROBLASTS IN CD8+T CELL-EXCLUSIVE NON-SMALL CELL LUNG CANCER TUMOR MICROENVIRONMENTS USING THE NANOSTRING GEOMX® DIGITAL SPATIAL PROFILER

Christina Cho*, Gavitt Woodard, Francesc Lopez-Giraldez, Ti Badri, Matthew Vesely, Lieping Chen. *Yale School of Medicine, New Haven, CT, USA*

Background Cancer-associated fibroblasts (CAFs) are a major component of the non-small cell lung cancer (NSCLC) tumor microenvironment (TME).[1–4] Recent studies indicate that CAFs play a role in generating a CD8+T cell (CTL)-exclusive TME.[5–9] Given that immune-checkpoint inhibitors (ICIs) rely on CTLs, an abundance of CAFs in the TME may result in reduced ICI efficacy. Although CAFs are considered potential targets for therapy, attempts to deplete CAFs have largely failed.[10] This is due to the fact that CAFs are a heterogenous population of cells and depletion of the wrong subpopulation could worsen disease.[1] Thus, to enhance ICI efficacy and improve patient outcome, we must identify and target CAF subtypes that promote CTL exclusion. Single-cell RNA sequencing (scRNAseq) has improved our understanding of CAF heterogeneity[11–13]; yet this technology cannot provide a comprehensive profile of CAF subtypes within the TME. For scRNAseq, tumor tissues are digested, causing cell death, and the resultant transcriptomic profile is incomplete. To generate a holistic profile of CAF subtypes within NSCLC, and identify the subpopulation that promotes CTL exclusion, we have utilized the GeoMX® Digital Spatial Profiler (DSP)[14–17], a state-of-the-art platform that allows for spatially resolved, high-plexed molecular profiling of intact tumor tissues.

Methods We performed digital spatial profiling on a tissue microarray (TMA) slide containing fifty-five cores of human lung tumors. We performed in-situ hybridization (ISH) on the slide with the GeoMx Whole Transcriptome Atlas (WTA), a mixture of photocleavable oligo-linked RNA probes that covers 18,000+ protein-coding human genes. Next, we stained the slide with fluorescent antibodies against Vimentin (VIM, a CAF marker), CD8, and SYTO (nuclear dye). Each core was a region of interest (ROI), and UV-light was masked to focus on CD8+ and VIM+ areas within each ROI to generate distinct areas of illumination (AOI) that were read out separately. NSG data was analyzed with DESeq2 to identify genes that were differentially expressed in CAFs living in CTL-exclusive tumors.

Results We identified 441 genes that were differentially expressed in CAFs residing in CTL-exclusive tumors compared to CAFs in CTL-inclusive tumors. Ingenuity Pathway Analysis (IPA) of those genes revealed several pathways which were inactivated in CTL-exclusive CAFs, including Leukocyte Extravasation Signaling and Ephrin Receptor Signaling, both of which could contribute to reduced CTL migration and infiltration.

Conclusions The GeoMX DSP can be used to identify CAF subpopulations that contribute to the formation of immune-exclusive TMEs and reveal novel molecular targets for immunotherapy.

168 EXPLORING FEATURES AND PARAMETERS FOR NEIGHBORHOOD ANALYSIS IN HUMAN CANCER MULTIPLEXED IMMUNOFLUORESCENCE DATA

[1]Ian Dryg*, [1]Madison Turner, [1]Ann-Elizabeth Le, [1]Anne Carlisle, [1]Kathleen Pfaff, [1]Jason Weirather, [1]F Stephen Hodi, [2]Scott Rodig. *[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]Brigham and Women's Hospital, Boston, MA, USA*

Background The tumor microenvironment (TME) contains an elaborate mixture of varied cell phenotypes, whose spatial organization plays an important but incompletely understood role in disease outcome and response to therapy. Neighborhood Analysis is a promising new spatial analysis method used to extract broad features from a spatial dataset and summarize recurring regions that may be important in the TME [Schürch et al 2020, Griffin et al 2021, Patel et al 2019, Oyler-Yaniv et al 2018].[1–4] However, it remains unclear which neighborhood sizes provide the best insights. Schürch et al 2020 used 19 nearest neighbors plus self, which is a small spatial neighborhood. Our group has previously used a circular area with radius of 75 microns, which is a larger spatial neighborhood. Primarily, we aim to explore how neighborhood size can affect neighborhood analysis results and interpretations. Secondarily, we propose to explore other new features in neighborhood analysis.

Methods The Human Tumor Atlas Network's (HTAN) efforts to establish a cancer atlas 3-dimensionally and over disease progression presents the opportunity to mine spatial datasets across cancer types and explore parameters used in neighborhood analysis. As part of the HTAN consortium, DFCI focused on three diseases to investigate with paired sequencing and spatial analyses: metastatic breast, melanoma, and colorectal cancers. Patient FFPE samples were stained and imaged using Akoya Biosciences Phenoptics mIF platform. Two panels were used: a macrophage-oriented panel including CD3, CD68, Tumor marker (SOX10 or Cytokeratin), PDL1, CD163, and Ki67; and a T cell-focused panel including CD8, PDL1, PD1, FOXP3, and Tumor marker. mIF images were thresholded and phenotyped using inForm software from Akoya Biosciences. Pythologist python package [https://github.com/dfci/pythologist] was used to ingest inForm outputs and to perform neighborhood analysis.

Results A pilot comparison of 'r'=45 microns (r45) and 'r'=75 microns (r75) revealed that r45 neighborhoods contained approximately 1/3 the number of cells of r75 neighborhoods and were more susceptible to one cell of a certain phenotype influencing that entire neighborhood cluster.

Conclusions Primarily, we postulate that smaller neighborhoods may lead to more granular results, perhaps describing small locales better, but leading to less interpretable overall conclusions than larger neighborhoods. Secondarily, we hypothesize that new features measured from neighborhoods may be used to identify boundaries in different tissue regions such as the tumor/margin/stroma borders. By exploring parameters and features for neighborhood analysis, we aim to improve interpretability of these analyses, to provide new features to use, and to strengthen rationale for picking certain neighborhood sizes in future spatial studies.

169 IMMUNOTHERAPEUTIC POTENTIAL OF THE HUMANIZED ANTI-MUC16 ANTIBODY AR9.6 AGAINST PDAC

[1]Christabelle Rajesh*, [1]Satish Sagar, [2]Cory Brooks, [1]Michael Hollingsworth, [1]Prakash Radhakrishnan. [1]*University of Nebraska Medical Center, Omaha, NE, USA*; [2]*California State University Fresno, Fresno, CA, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease with poor overall survival, owing partly to its late-stage presentation and resistance to standard of care.[1] Mucins are largely glycosylated proteins that have been found to be aberrantly expressed in multiple adenocarcinomas, including PDAC.[2] Mucin-16 (MUC16/CA125) is one such heavily glycosylated member that is overexpressed in >65% of PDACs and has been shown to correlate to poor prognosis.[3] This study investigates the tumor mitigating mechanisms and thereby, therapeutic potential of the humanized anti-MUC16 monoclonal antibody (huAR9.6) in models of PDAC.

Methods The enzyme-linked immunosorbent assay (ELISA) was performed using recombinantly produced MUC16 epitopes to assess the binding affinity of huAR9.6, as described previously.[4] The wound healing assay using isogenic PDAC cell lines treated with huAR9.6, isotype control huIgG and vehicle was performed to assess the effect on cell migration. To determine the *in vivo* therapeutic potency, PDAC cells were orthotopically implanted into the pancreas of athymic nude mice which were then randomized to huAR9.6, isotype control huIgG, and vehicle treatment groups. Furthermore, *in vitro* functional assays to assess the antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) capacity of huAR9.6 were performed using PDAC cell lines.

Results huAR9.6 showed a strong binding affinity to the tandem repeat region of the SEA domain 5 of MUC16. Treatment of PDAC cells with huAR9.6 reduced their migratory potential, indicating its anti-tumorigenic role. Mice treated with huAR9.6 showed a significant decrease in tumor weight and volume as compared to the huIgG and vehicle treated groups. The proliferative marker Ki67 was also significantly lowered in the pancreatic tumors of huAR9.6 treated mice, as compared to controls. Further, *in vitro* ADCC assays using freshly isolated human peripheral blood mononuclear cells (PBMCs) as effector cells showed an increase in cell death of PDAC cells treated with huAR9.6, as compared to cells treated with huIgG control. CDC assays using human serum also showed increased cytotoxicity of PDAC cells in the presence of the huAR9.6 antibody as compared to controls.

Conclusions The results strongly suggest that huAR9.6 binds to MUC16 and limits PDAC growth via cytotoxicity mechanisms including ADCC and CDC. This validates the therapeutic potential of huAR9.6 in models of PDAC and adds value to the previously established diagnostic ability of this antibody [5]. These studies are conducted with the overarching goal of facilitating the translation of huAR9.6 to treat PDAC in the clinic.

171 **TUMOR MICROENVIRONMENT IMMUNE CELL LANDSCAPE VARIES AMONG MOLECULAR SUBTYPES IN GASTRIC CANCER**

Sanyog Dwivedi*. *UNAM, Mexico City, Mexico*

Background Immune interactions in the tumor microenvironment (TME) are a major factor in deciding the fate of immunotherapy. Heterogeneity and molecular subtypes, especially in solid tumors like gastric cancer (GC), involve substantial modification in TME. Hence understanding the immune cell populations infiltrating the TME of different molecular subtypes will help to develop more effective and targeted therapies

Methods **CBioPortal**[1,2] was used to extract and analyze The Cancer Genome Atlas (TCGA) Stomach Adenocarcinoma Pan-Cancer Atlas Data (STAD). Immune Metagene signatures from previous publications[3] were used to analyze the immune infiltration landscape in different GC molecular subtypes- chromosomal instability (CIN)(n=223), microsatellite instable (MSI) (n=73), genomically stable (GS)(n=50), Epstein–Barr virus (EBV) associated (n=30). GraphPad Prism9 and MS Excel were used to analyze the data and generate the figures.

Results We analyzed the infiltration landscape of Natural Killer (NK) cells, T cells ($CD4^+$, $CD8^+$, Th1, Th2, Th17), immune suppressive Myeloid-derived suppressor cells (MDSC), and Regulatory T cells (Tregs) in GC molecular subtypes. The results showed that $CD8^+$ cytotoxic T cells and $CD4^+$ helper T cells were highly downregulated in the GS subtype in comparison to other molecular subtypes (figure 1). Cytokine secreting T helper cell subsets, Th1, Th2, and Th17 demonstrate a dissimilar infiltration pattern among subtypes (figure 2). Th1 cells were highly expressed in the EBV subtype as compared to Th1 infiltration in the other subtypes (figure 3). GS and EBV both depict higher infiltration of Th2 cells and lower infiltration of Th17 cells in comparison to CIN and MSI subtypes (figure 2). GS subtype along with EBV has a superior infiltration of immune suppressive MDSC and Tregs (figure 3). Both cytotoxic NK^{56dim} and cytokine secreting immune modulating $NK^{56bright}$ cells were the lowest infiltrating the GS molecular subtype (figure 4). Intriguingly, $NK^{56bright}$ infiltration markers don't differ significantly between subtypes. It was worth observing that in general, there is more infiltration of NK^{56dim} over $NK^{56bright}$ cells in GC patients (figure 4).

Conclusions TME of the GS molecular subtype of GC contains less cytotoxic cells ($NK56^{Dim}$ and $CD8^+$ T) and higher infiltration of immune suppressive cells (Tregs and MDSCs).

172 BODY MASS INDEX (BMI) AND SERUM ALBUMIN LEVEL AS A PREDICTOR OF SURVIVAL OUTCOMES IN ADVANCED-STAGE MELANOMA PATIENTS TREATED WITH ANTI-PD1 THERAPY

Yusuf Mohamoud*, Yeonhee Park, Dahlia Tesfamichael, Vincent Pozorski, Vincent Ma.
University of Wisconsin, Madison, WI, USA

Background Body mass index (BMI) and serum albumin are common measurements used to evaluate nutritional status. Recent studies have shown conflicting results correlating nutritional status with immune checkpoint inhibitor (ICI) therapy outcomes.[1,2] In this study, we investigate if baseline and change in BMI and serum albumin levels correlate with survival outcomes in advanced stage melanoma patients treated with anti-PD-1 therapy.

Methods We conducted a single-center, retrospective review of unresectable stage III and IV melanoma patients treated with anti-PD-1 monotherapy (nivolumab or pembrolizumab) or ipilimumab/nivolumab (I/N) between 2011 and 2022. Overall survival (OS) and progression-free survival (PFS) were measured from the first dose of treatment to date of death and clinical or radiographic progression, respectively. The effect of baseline BMI, serum albumin levels, and their respective percentage change at 3 months from treatment initiation on PFS and OS was assessed on a continuum level. Multivariate analyses were performed using Cox proportional hazard models, accounting for the following covariates: Age, gender, anti-PD-1 therapy type, primary melanoma type, pre-treatment LDH, BRAF status, presence of brain or liver metastasis, and prior adjuvant or non-anti-PD-1 treatment for advanced-stage melanoma.

Results 202 patients were identified. Mean BMI was 30.1 and mean albumin level was 3.63 g/dL. Higher baseline BMI (HR 0.9825, 95% CI: 0.9657–0.9996, p=0.0445) and lower baseline albumin level (HR 2.4498, 95% CI: 1.2606–4.7619, p=0.0082) was associated with worse PFS [table 1]. Change in BMI and albumin level at 3 months was not associated with PFS outcomes. Lower baseline albumin level was associated with worse OS outcomes [HR 2.4814, 95% CI: 1.1161–5.5157 p=0.0258]. Higher change in albumin level at 3 months was also associated with worse OS [HR 0.9389, 95% CI: 0.9109–0.9677, p=0.00004]. Our univariate analysis showed lower baseline albumin level and decreasing albumin change from the baseline mean at 3 months was associated with worse PFS and OS [figure 1].

Conclusions Nutritional status may have a predictive role on survival in advanced melanoma patients treated with anti-PD-1 therapy. Baseline albumin and decreasing albumin levels at 3 months is associated with worse survival. Unlike previous studies, we found that higher baseline BMI may lead to worse PFS outcomes in immunotherapy treated patients. Interventional studies are warranted to see if nutritional status optimization prior to and during anti-PD-1 therapy can affect clinical outcomes.

173 SENSITIVITY AND CONCORDANCE OF *CD274* EXPRESSION BY RNA SEQUENCING (RNA-SEQ) IN COMPARISON WITH THREE PD-L1 IMMUNOHISTOCHEMISTRY METHODS IN HEAD AND NECK SQUAMOUS CELL CARCINOMA (HNSCC)

[1]Mary Nesline*, [1]Sarabjot Pabla, [1]Jeffrey Conroy, [1]Paul DePietro, [1]Shengle Zhang, [1]Roger Klein, [2]Achyut Bhagelu, [2]Rebecca Previs, [2]Prasanth Reddy, [2]Shakti Ramkissoon, [2]Eric Severson. *[1]OmniSeq, Inc., Buffalo, NY, USA*; *[2]Labcorp, Durham, NC, USA*

Background PD-L1 expression by immunohistochemistry (IHC) is associated with HNSCC immunotherapy response.[1] The performance of different PD-L1 IHC clones has shown variability and poor concordance for immune vs. tumor cell scoring in HNSCC. Crucially, this leads to poor reproducibility in the combined positive score (CPS) method by the PD-L1 IHC 22C3 companion diagnostic.[2] We explored the clinical sensitivity and concordance of *CD274* (PD-L1) expression by RNA-sequencing compared to three PD-L1 IHC methods.

Methods A retrospective cohort of HNSCC patients (n=258) with FFPE tissue was tested by comprehensive immune profiling[3](2017–2022), including *CD274* by RNA-seq (normalized percentile rank 0–100). IHC was performed with either the 28–8 or 22C3 PD-L1 clones. 28–8 was scored with% tumor cells stained (TC, n=34), while 22C3 was scored with either tumor proportion score (TPS, n=61) or combined positive score (CPS, n=163). For 22C3, CPS$\geq$1 is low positive, and $\geq$20 is high positive. For 28–8 TC and 22C3 TPS, $\geq$1 is low positive, and $\geq$50 is high positive. ROC models for each IHC method were constructed for 5 sets of patients with different pairwise interpretation groups and used to determine RNA-seq cutoffs based on individual PD-L1 IHC scoring methods and accuracy at those cutoffs. Concordance between standard IHC scoring methods and *CD274* by RNA-seq was also assessed.

Results PD-L1 IHC results varied depending on the clone and scoring method used. Not surprisingly, CPS had the fewest negative cases (2.7%) and most high cases (47.2%). Tumor cell scoring by TPS (29.5% negative, 24.6% high) and TC (17.6% negative, 26.5% high) was similar for high vs. not high. For all three IHC approaches, PD-L1 RNA-seq classified IHC high v negative, high v low, and high v not high status with at least fair range of AUC (0.758–0.981), sensitivity (0.636–1.00), and specificity (0.785–1.00). RNA-seq could not discern between IHC low v negative status for any method. Pairwise comparisons showed significant concordance between median RNA-seq percentile ranks for IHC high v low and high v negative status for all IHC methods. By RNA-seq, the frequency of PD-L1 high cases for each scoring method increased from 47% to 55% (CPS), 24.6% to 42.6% (TPS) and 26.5% to 47.1% (TC) based on modeled RNA-seq cutoffs.

Conclusions RNA-seq accurately discerns PD-L1 high vs. not high HNSCC tumors based on IHC scoring methods and may more reliably identify patients for frontline immunotherapy.

174 SINGLE CELL FFPE AND SPATIAL TRANSCRIPTOMIC PROFILING OF AN INVASIVE DUCTAL CARCINOMA ENHANCES CELLULAR AND SPATIAL INSIGHTS

Ryan Stott*, Jawad Abousoud, Stephen Williams, Shamoni Maheshwari, Valeria Giangarra, Sarah Taylor, Andrew Kohlway. *10x Genomics, Pleasanton, CA, USA*

Background Invasive ductal carcinoma (IDC) is the most common type of breast cancer, accounting for 80% of all breast cancer diagnoses. Formalin-fixed paraffin-embedded (FFPE) samples are a valuable resource for diagnosing breast cancers. FFPE samples are often available with patient metadata and clinical outcomes, thus providing a critical sample resource for disease studies. Here we demonstrate the potential of single-cell transcriptomics on dissociated FFPE tissues. We also assessed the same FFPE breast IDC tissue block using the Chromium Single Cell Fixed RNA Profiling and Visium Spatial Gene Expression assays for more accurate estimation of cell-type proportions for each Visium spot.

Methods FFPE scrolls (2 x 25-µm) of human breast IDC were dissociated into a single cell suspension using a combination of enzymatic digestion and mechanical dissociation. Cells were then processed using the Chromium Fixed RNA Profiling workflow. A section from the same FFPE IDC block was processed using the Visium Spatial Gene Expression Solution for FFPE.

Results Clustering analysis of the single cell FFPE data identified 17 distinct cell populations, including luminal epithelial progenitors, mature luminal epithelia, basal cells, fibroblasts, pericytes, and immune cells. Applying the Prediction Analysis of Microarray 50 (PAM50) subtype predictor to these clusters, we identified one cluster showing a strong correlation with a basal-like cancer subtype whereas all other clusters correlated with a normal signature. To compare single cell and spatial data, we utilized Robust Cell Type Decomposition to estimate cell-type proportions for each Visium gene expression spot. Distinct regions were observed for mature and progenitor luminal cells. Interestingly, the mature luminal cells mapped specifically to the region annotated by a pathologist as invasive carcinoma while T and B cells colocalized outside of the carcinogenic region, which may have implications on the patient's prognosis.

Conclusions Our studies show that transcriptome-wide gene expression at a single-cell resolution on FFPE-preserved tissue adds a whole new axis of information to clinical studies, providing new opportunities for the analysis of large biobanked cohorts and longitudinal samples of clinical relevance. Additionally, assessing the same FFPE tissue blocks by combining Chromium Single Cell Fixed RNA Profiling with Visium Spatial Gene Expression assays enables a comprehensive dataset with more precise cell type profiling in the spatial context.

Cell Therapies

175 CAR-T ENGAGER PROTEINS OPTIMIZE ANTI-CD19 CAR-T CELL THERAPIES FOR LYMPHOMA

Paul Rennert*, Lihe Su, Lan Wu, Roy Lobb, Christine Ambrose. *Aleta Biotherapeutics, Natick, MA, USA*

Background B cell lymphoma therapy has been transformed by CD19-targeting cellular therapeutics that induce high clinical response rates and impressive remissions in relapsed and refractory patients. However, approximately half of all patients who respond to CD19-directed cell therapy relapse, the majority within six months. One characteristic of relapse is loss or reduction of CD19 expression on malignant B cells. We designed a novel biologic, a CAR T Engager, that binds CD20 and displays the CD19 extracellular domain. This approach increases the apparent CD19 antigen density on CD19-positive/CD20-positive lymphoma cells, and prevents antigen-loss induced relapse, as CD19 bound to CD20 remains present on the cell surface. We demonstrate that this novel therapeutic prevents and reverses lymphoma relapse *in vitro* and prevents CD19-negative lymphoma growth and relapse *in vivo*.

Methods The CTE biologic has three functional domains: a modified CD19 ECD, an anti-CD20 binding domain and an anti-albumin binding domain. The protein, termed a CAR-19-CD20 T cell Engager (CTE-19.20), binds to CD20 and displays the CD19 ECD and increases CD19 antigen density on target lymphoma cells regardless of their level of CD19 expression.

Results CTE-19.20 proteins potently triggered CD19-negative lymphoma cell death in the presence of CAR-19 T cells *in vitro* and prevented antigen-loss relapse in an *in vitro* model of lymphoma escape from CAR-19 therapy. Using *in vivo* modeling we show that CTE-19.20 protein given alongside CAR-19 T cells prevented CD19-negative lymphoma expansion, eliminated disease, and significantly impacted survival. CTE-19.20 was readily expressed and secreted by transfected mammalian cells, was efficiently purified and demonstrated favorable biophysical properties.

Conclusions Patient relapse from CAR-19 therapy occurs rapidly, often within the first months following therapy. The kinetics of relapse offer the potential to intervene using CTE-19.20 protein, using several different clinical designs. In the first instance we are developing this molecule with the goal of treating patients who have already received a CAR-19 therapy, by evaluating their clinical response through the first few months post CAR infusion. Diverse biomarkers can be used to track response and risk of relapse. PET imaging and ctDNA analyses have emerged as sensitive means of tracking lymphoma and leukemia regression. This is an optimal and straightforward approach to productive and sustained activation of CAR-19 T cells, using a potent CD19-anti-CD20 bridging protein with an extended half-life.

176 IMMUNE ACTIVATION BY ANTIGEN-SPECIFIC T CELLS ELICITED IN PATIENTS RECEIVING STANDARD THERAPY FOR PEDIATRIC SOLID TUMORS

Jillian Smith*, Amy Hont, Catherine Bollard. *Children's National Hospital, Washington, DC, USA*

Background Immunotherapy in the form of immune checkpoint inhibitors and chimeric antigen receptor (CAR) T-cells has revolutionized the treatment of select malignancies.[1–2] However, beyond CD19+ cancers, clinical responses to CAR-T have been modest in pediatric cancers, likely due to lower mutational burden. Antigen spreading, an expanded anti-tumor immune response through exposure to neoantigens, has been observed in patients following treatment with immunotherapy agents or chemotherapy for malignancies with typically higher mutational burdens.[3–6]]. However, this has not been observed in pediatric patients with solid tumors after standard treatment. We demonstrated the safety of autologous tumor-associated antigen-specific T lymphocytes (TAA-T) specific for WT1, PRAME, and Survivin in Phase I studies.[7] We also identified antigen spreading post-infusion with increased T cells specific for non-targeted antigens MAGE-A3, MAGE-A4, SSX-2, and SOX-2, all expressed on solid tumors.[8–12] We hypothesized that antigen spreading would be greater in patients who received TAA-T than in those who received standard chemotherapy or radiation therapy.

Methods Fourteen patients with pediatric solid tumors who received standard-of-care therapy were enrolled on the standard chemotherapy arm and compared to fourteen relapsed/refractory patients who received TAA-T infusion. Peripheral blood samples were taken prior to therapy, during therapy, and off therapy if available, and these were evaluated for the presence of T cells specific to MAGE-A3, MAGE-A4, SSX-2, and SOX-2 as measured by IFN-γ ELISPOT.

Results Our results demonstrate the presence of antigen spreading in newly diagnosed patients who receive standard therapy as evidenced by T cells specific for MAGE-A3 (mean: 28.2, range: 0–137 IFN-y SFC/1e5 cells (SFC)), MAGE-A4 (mean: 31.8, range: 0–270 SFC), SSX-2 (mean: 22.8, range: 0–100 SFC) and SOX-2 (mean: 7.2, range: 0–46 SFC). Similar levels of antigen spreading were also identified in relapsed/refractory patients post TAA-T infusion detecting T cells specific for MAGE-A3 (mean: 30.7, range: 0–249 SFC). MAGE-A4 (mean: 27.6, range: 0–230 SFC), SSX-2 (mean: 33.9, range: 0–200 SFC) and SOX-2 (mean: 39.5, range: 0–270 SFC).

Conclusions These results demonstrate immune activation as evidenced by antigen spreading in newly diagnosed pediatric patients with solid tumors receiving standard-of-care chemotherapy and radiation therapy, the majority of which remain in remission following treatment. Similar levels of antigen spreading were also observed in responding patients who received TAA-T for relapsed/refractory disease. This data provides further support for the role of immunotherapy in the treatment of pediatric solid tumors and the strong anti-tumor response these therapies can potentiate.

177 **PRECLINICAL CHARACTERIZATION OF CYT-100 IPSC DERIVED NK CELLS ALONE AND IN COMBINATION WITH CYT-303 NK CELL ENGAGER FOR HEPATOCELLULAR CARCINOMA (HCC)**

Liang Lin*, Andrea Chambers, Marshall Chao Ma, Hao-Ming Chang, David Zou, Preeti Ashok, Elizabetta Burchi, Armin Rath, Stanley Frankel, Jean Kadouche, Daniel Tepper, Nejmi Dilmac, Antonio Arulanandam, Wei Li. *Cytovia Therapeutics, Natick, MA, USA*

Background CYT-100 is a first-generation iPSC derived NK cell product in development for use in combination with NK cell engager antibody (NKE) CYT-303 targeted against NKp46 activation receptor on NK cells and Glypican-3 (GPC3) expressed in the tumor for treatment of hepatocellular carcinoma (HCC). The combination of CYT-100 and CYT-303 is expected to activate endogenous NK cells and provide additional functional NK cells in the HCC microenvironment. Here we describe preclinical characterization of CYT-100 alone or in combination with CYT-303. In addition, we compared CYT-100 expansion capacity potential to PBNKs (peripheral blood natural killer cells).

Methods CYT-100 immunophenotyping was conducted by flow cytometry using a panel of NK cell directed antibodies. Intracellular signaling following stimulation of CYT-100 with rIL-2 or rIL-15 was assessed using a phospho STAT-5 antibody by flow cytometry and cell growth monitored by counting cells using the flow cytometer or a cell counting kit (CCK8). Hep3B tumor spheroids were formed in special U-bottom adhesive plates and tumor spheroid killing assays were conducted using the Incucyte^{TM} Live Cell Analysis System. Serial killing assays were conducted by repeatedly adding the same CYT-100 cells to fresh tumor cells following each round of tumor killing. The chromosome telomere length was assessed by a q-PCR assay.

Results CYT-100 immunophenotyping results showed > 95% expression of CD56/CD45, high expression of all activating receptors, except CD16, and some chemokine receptors including CXCR3, and minimal expression of most inhibiting receptors. Stimulation with rIL-2 or rIL-15 resulted in tyrosine phosphorylation of STAT-5 and increased cell growth over a period of 6 days, comparable to PBNKs, demonstrating the capacity of these cells to expand in the presence of cytokines. CYT-100 showed increased time-dependent killing of Hep3B tumor spheroids that peaked 2–3 days following of initiation of killing. This killing was enhanced in the presence of CYT-303 in a dose dependent manner. Furthermore, CYT-100 showed serial killing of Hep3B tumors and this was enhanced in combination with CYT-303. Chromosome telomere length analysis of CYT-100 showed greater telomere length compared to that of PBNKs, suggesting greater expansion capacity potential of these cells.

Conclusions The allogeneic IPSC derived NK cell product CYT-100 demonstrates cytotoxicity against hepatocellular carcinoma Hep3B cells, sensitivity to cytokine activation and expansion potential. The cytotoxicity of this iNK product is further enhanced by combination with the NK cell engager antibody CYT-303. These data support further development of the combination of iNK cells and NKEs as therapeutics for HCC.

178 TARGETING ER-MITOCHONDRIAL DYNAMICS TO IMPROVE RESPONSES TO IMMUNE CHECKPOINT BLOCKADE

Katherine Cook, Elizabeth Stirling, Jessica Mackert, Mitra Kooshki, Adam Wilson, Wei Zhang, Pierre Triozzi, David Soto-Pantoja*. *Wake Forest School of Medicine, Winston-Salem, NC, USA*

Background One of the top challenges in cancer immunotherapy is 'understanding the molecular and cellular drivers of primary vs. secondary immune escape to immune checkpoint blockade therapies.' Although durable responses indicating immunologic memory are reported, most patients do not respond with tumor regression. In addition, recurrences are observed after initial response, suggesting the emergence of acquired resistance. Therefore, novel therapeutics are needed to enhance ICB treatment to halt melanoma progression and increase patient survival rates. Oxidative stress and hypoxia in the tumor microenvironment resulting in endoplasmic reticulum (ER) stress signaling associated with cancer therapy resistance. PKR-like endoplasmic reticulum kinase actions in the tumor microenvironment can occur by activation of the Unfolded Response (UPR). However, PERK also has functions that are not linked to canonical activation of UPR signaling. PERK is involved in the maintenance of ER with mitochondria-associated membranes (MAMs). This is important in glucose sensing and could impair metabolic reprogramming during T cell activation if disrupted.

Methods To determine ER-stress markers of patient response, we analyzed Peripheral Blood Mononuclear Cells by single-cell RNA sequencing (scRNAseq), 3D electron, and confocal microscopy to determine mitochondria/ER interactions. Antigen-mediated CD8+ T cell toxicity assay was performed using Pmel-1 transgenic mice. LC-MS Metabolomics and Seahorse mitochondrial respiration assays were used to determine CD8+ cellular energetics treated with anti-PD-1 in the presence or absence of PERK blockade. An in vivo murine tumor model (B16) was developed to determine whether PERK blockade sensitizes tumors to anti-PD1 therapy.

Results UMAP clustering of our scRNAseq data indicates a ~3-fold increase in PERK expression after the first treatment cycle in patients who did not respond to anti-PD-1 therapy ($n=12$, $^*p<0.05$). This was confirmed by plasma ELISA assay in a different cohort of patients ($N=50$, $^*p<0.001$). Furthermore, the expression of PERK in non-responder patients was associated with increased expression of TOX1 in the T-cell population, and induction of ER stress caused a transcriptional increase in TOX1 in T cells suggesting that ER stress may be associated with T cell dysfunction. Induction of ER stress limited antigen-mediated CD8+ T cell killing; however, blockade of PERK enhanced the cytolytic capacity of CD8+ T cells over 4-fold, clearing tumor cells even under ER stress-induced circumstances ($n=4$, $^*p<0.01$). Examination of ER-mitochondria interactions by confocal and 3D electron microscopy suggested increased co-localization of these two organelles in lymphocytes of responder patients to anti-PD1 therapy. Blockade of PERK in combination with anti-PD1 treatment resulted in a 64% reduction in tumor volume compared to control and an over 40% reduction compared to anti-PD1 monotherapy ($n=7$, $^*p<0.002$). This suggests that blockade of PERK enhances αPD-1 efficacy. PCA from metabolomics of tumor-infiltrating T cells suggested a differential metabolic signature that separates the PD1 treated group from control, PERK blockade, and combination-treated animals. Furthermore, blockade of PERK increased glycolytic flux and mitochondrial respiration of CD8+ T cells. Thus, blockade of PERK supports metabolic reprogramming to support T cell effector function under ER stress conditions.

Conclusions Our data show that PERK expression may serve as a potential clinical marker of ICB response. Our preliminary evidence indicates that Targeting PERK improved the efficacy of anti-PD1 therapy by modulating metabolic signaling of CD8+ T cells. Thus, targeting PERK in the tumor microenvironment may inhibit pro-oncogenic and immunosuppressive signaling from enhancing ICB responsiveness.

179 **T-CELLS DERIVED FROM MALIGNANT PLEURAL EFFUSIONS (MPE) ARE READILY EXPANDABLE, POLYFUNCTIONAL AND CYTOTOXIC TO AUTOLOGOUS TUMOR**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0179

[1]Vera Donnenberg*, [1]Albert Donnenberg, [1]James Luketich, [1]Shannon Puhalla, [1]Yasa Mutlu, [2]David Bartlett. [1]*University of Pittsburgh, Pittsburgh, PA, USA*; [2]*Ahn Research Institute, Pittsburgh, PA, USA*

Background We have shown that malignant pleural effusions (MPE) are characterized by a distinct and complex pleural secretome[1–3] dominated by IL-6, sIL-6Rα, CCL2, CXCL10, TGFβ, CCL22, IL-8. These cytokines favor tumor epithelial to mesenchymal transition, invasion and suppression of anti-tumor response among the abundant infiltrating T cells. The goal of this study was to determine whether brief ex vivo activation could induce potent effector activity.

Methods Pleural T cells were isolated from freshly drained pleural effusions from 6 breast cancer patients. Autologous pleural tumor was expanded in vitro using the Mammary Epithelial Growth Medium (Lonza). Pleural T cells were stimulated using antiCD3CD28 Dynal beads and low dose IL-2 (60 Cetus U/ml) for 2,4,7, 14 or 21 days. Expanded tumor targets (p0 and p1) were plated at 10,000 cells/96well cultured overnight before the addition of pleural effector T cells at effector to target ratios of 0.1, 3, 6, 12.5, 25 and 50. Cytotoxicity was assessed using a colorimetric assay for lactate dehydrogenase (LDH) release (PromegaCytox-96). Pleural T cells phenotype and activation/exhaustion markers. Cytokine secretion was measured by flow cytometry and (Luminex).

Results Ex vivo expanded pleural T cells were effector-memory phenotype (CD45RA-CD27-) and were highly cytotoxic against autologous tumor (89–100% Specific Lysis). Even a 2-day ex vivo activation generated highly cytotoxic T cells. The effectors were mostly CD4+ cells (62–90%). Majority of CD8+ T cells were central memory (CD45RA-/CD27-) or effector memory (CD45RA+/CD27-); a majority co-expressed intracellular granzyme B and perforin, 20–60% expressed PD-1. Most CD4+ co-expressed granzyme B and perforin, suggesting cytotoxic CD4+ T cells and were PD-1+. The in vitro cytotoxicity of expanded pleural T cells was highly reproducible among patients of significantly varied age (37 – 94) as well as patients with different molecular subtypes (triple negative, ER+PR+Her2-, ER+PR-Her2+, ER+PR+Her2+, ER+AR+PR-Her2-). Supernatants from cytotoxicity cultures evidenced secretion of G-CSF, IL-6, CXCL10, IFNgamma, MCP-3, MIP1alpha and beta, IL-13, IL-2 and TNFalpha in a dose dependent fashion. Polyfunctional T cells (single cells secreting IL-2, TNFalpha, IFNgamma, but not IL-10) were detectable among ex vivo expanded T cells.

Conclusions Pleural T cells are not exhausted and can be stimulated to become potent anti-tumor effectors that may be useful for adoptive cellular therapy.

180 THE IN-VITRO MEASURE OF T CELL AVIDITY BETWEEN TUMOR-EFFECTOR PAIRS, NOT AFFINITY, PREDICTS OPTIMAL ANTI-TUMOR RESPONSE IN VIVO

Justin Moser*, Yotam Bar–Ephraim, Jens Eberlein, Keith Bailey, Song-My Hoang, Andrea Candelli, Will Singleterry. *LUMICKS, Waltham, MA, USA*

Background With the increasing complexity of cell therapy construct design, novel methodologies to accelerate screening and improve evaluation of lead candidates for clinical benefit are needed. Several methods are currently employed including receptor-ligand affinity measurements. However, affinity between T cell receptors (TCRs) and peptide-MHC complexes (pMHC) has shown to be a poor predictor of T cell functional capacity.

Methods We have developed the z-Movi Cell Avidity Analyzer to directly measure the overall binding strength, or cellular avidity, of effector to their target. Unlike affinity, cellular avidity is driven by the overall strength of dynamic surface interactions between effector cells and their targets; this novel biomarker integrates receptor density, the sum of individual affinities, and engagement of the multitude of co-receptors within the immunological synapse to characterize the interaction in a more biologically relevant context.

Results We will discuss how increased specific cellular avidity, i.e., TCRs with the strongest antigen binding and the lowest background binding, correlated with improved effector function in vitro and in vivo. Another application of measuring cell avidity explored the effect of changes to the glycosylation pattern on the cell surface of BMDC on T cell activation. Here, altered glycosylation patterns on BMDC increased avidity towards T cells leading to enhanced T cell function upon Ag recognition. These results demonstrated the benefits of understanding cell avidity to predict and select potent T cell candidates or bispecific antibodies.

Conclusions These results demonstrated the benefits of understanding cell avidity to predict and select potent T cell candidates or bispecific antibodies.

181 HIGH THROUGHPUT SCREENING STRATEGIES IN THE DEVELOPMENT OF LOGIC GATED CELL THERAPIES

Rona Harari-Steinfeld*, Laura Lim, Angela Boroughs, Sofia Kyriazopoulou Panagiotopoulou, Cate Sue, Jamie Thomas, Jon Chen, Aaron Cooper, Ryan Fong, Mary Chua, Ed Yashin, Christine Shieh, Sophie Xu, Nicholas Haining. *Arsenal Biosciences, South San Francisco, CA, USA*

Background Generating potent clinical responses against solid tumors remains a challenge for CAR T cell therapy. This lack of efficacy is likely due in part to reduced on-tumor activity in the tumor microenvironment and the lack of appropriate target antigens that are expressed on tumor cells but not on critical healthy tissues. We addressed the second of these challenges by engineering T cells to target tumors only upon recognition of two antigens through AND Boolean logic.

Methods In our efforts to develop logic gated cell therapies we generated hundreds of binders for the priming receptor (PrimeR) and the CAR receptor. Here we demonstrate two strategies used for functional screening of PrimeR binders to identify binders with desired sensitivity and fidelity in driving the specific on-target expression of a fixed CAR.

In an arrayed strategy, we engineered T cells from 4 donors in multiwell plates using CRISPR-mediated, non-viral, site-specific integration of circuits bearing ~1000 PrimeR binders and receptor architectures with a fixed MSLN CAR. In addition, we employed a pooled screening strategy in which we engineered 2 donors of T-cells with a pool containing a subset of >300 unique PrimeR binders with a fixed MSLN CAR, using a similar engineering protocol.

Engineered T cells from both strategies were co-cultured with target cell lines to evaluate targeting fidelity and on-target functionality. In the arrayed setting, functional readouts (activation markers, cytokine secretion) were measured and reported directly. In the pooled setting, sorting based on functional markers was performed at end-point and sequencing was used to determine the enrichment of specific binders. Circuit fidelity was assessed by the lack of CAR expression and/or T-cell activation in response to target cell lines expressing the cytolytic antigen alone, or neither target antigens. On-target functionality was assessed by quantifying secretion of key cytokines in response to dual antigen stimulation.

Results We combined these metrics to filter out PrimeRs that allowed for CAR expression in the absence of logic gate activation, and to rank the remaining binders by their ability to drive CAR expression in the presence of both antigens. To account for multiple criteria when ranking binders, we used desirability functions, scaling each measurement to a (0–1) range, and using geometric means to combine desirabilities across different criteria.

Conclusions As each strategy comes with a different set of limitations and advantages, both serve as important tools for the effective selection of binders and receptors in the development of novel cell therapies.

182 DISCOVERY OF TSC-203-A02: A PRAME-SPECIFIC TCR-T CELL THERAPY CANDIDATE FOR THE TREATMENT OF SOLID TUMORS

Mollie Jurewicz, Elizabeth Hall, Alexandra Luther, Kimberly Cirelli, Vivin Karthik, Kenneth Jahan, Tary Traore, Maytal Bowman, Victor Ospina, Sonal Jangalwe, Shubhangi Kamalia, Sadie Lee, Daniel Pollacksmith, Sida Liao, Amy Virbasius, Kristen Murray, Jillian Oliveira, Lisa Nip, Christina Lam, Livio Dukaj, Danielle Ramsdell, Jin He, Joel Sher, Ribhu Nayar, Qikai Xu, Yifan Wang, Antoine Boudot, Cagan Gurer, Gavin MacBeath*. *TScan Therapeutics, Waltham, MA, USA*

Background The cancer/testis antigen PRAME exemplifies an ideal TCR-T cell therapy target due to its high expression in multiple malignancies and its absence in normal tissues. Initially identified in metastatic cutaneous melanoma,[1] PRAME is highly expressed in various additional solid tumors including lung, head & neck, and ovarian cancers. PRAME plays a pivotal role in multiple cellular processes and has been demonstrated to exhibit protumorigenic function primarily through inhibition of retinoic acid receptor signaling.[2] Targeting of PRAME in solid tumors, particularly when performed as part of a TCR-T multiplexing strategy, represents a promising therapeutic approach in the treatment of many cancer indications

Methods We discovered TCRs specific for 5 different A*02:01-restricted PRAME-derived epitopes using TScan's proprietary ReceptorScan platform. Using an activation-based screening technology termed ActivScan, we identified the most functional TCRs from a library of 1300 PRAME-specific TCRs to select for TCRs with greatest avidity and expression. These highly active TCRs were examined for their cytotoxic function using a panel of PRAME-expressing A*02:01-positive cell lines. Lead TCRs were assessed for potential off-target reactivity using our proprietary SafetyScan platform, in which off-target recognition of antigens derived from all proteins that comprise the human proteome is evaluated. Safety was further confirmed by examining alloreactivity to high-frequency class I HLAs and by testing TCR reactivity to a panel of normal primary human cells. Lastly, we tested TCR-T cells for their ability to control tumor growth *in vivo* using PRAME-expressing xenograft mouse models.

Results We screened 871 million naïve $CD8^+$ T cells from 16 unique healthy donors in ReceptorScan to identify 5706 TCRs specific for 5 PRAME epitopes. $PRAME_{425–434}$-specific TCRs demonstrated superior recognition of a PRAME-expressing cell line compared to all other PRAME epitopes tested. Following selection of high-expressing and high avidity $PRAME_{425–434}$-specific TCRs in ActivScan, TCRs were evaluated for their cytotoxic function, and two TCRs compared favorably to a clinical-stage benchmark TCR with respect to cytotoxicity, cytokine release, and T cell proliferation. Safety assessment demonstrated that few off-target peptides were recognized by lead TCRs, minimal alloreactivity was observed to 110 allotypes tested, and no reactivity to normal primary human cells was found. $PRAME_{425–434}$-specific TCR-T cells were also able to control tumor growth *in vivo* following infusion into immunodeficient mice implanted with PRAME-expressing xenografts.

Conclusions Based on its demonstrated activity *in vitro* and *in vivo*, this autologous TCR-T cell therapy candidate, TSC-203-A02, has been advanced to IND-enabling studies.

183 CANCER-MUTATION-SPECIFIC T CELLS: NOVEL IMMUNOTHERAPY APPROACH FOR LOW MUTATIONAL BURDEN PATIENTS

Alfred Slanetz*, Walter Barry, Benjamin Schwarz, Farzonai Muzaffar, Ryan Campbell, Abenezer Abera. *Geneius Biotechnology, Inc., Natick, MA, USA*

Background Immune checkpoint inhibitors, such as anti-PD1 antibodies, have revolutionized cancer immunotherapy. Their success demonstrates that a patient's own T cells recognize and treat cancer. However, anti-PD1 therapy is most effective in the treatment of cancers with high mutational burden, ~5% of all malignancies. Therefore, an alternative strategy is necessary to target cancer with lower mutational burden. Importantly, the efficacy of PD-1 blockade is associated with the recruitment of new T cells from the blood rather than the activation of pre-existing tumor infiltrating lymphocytes (Yost K.E., *et al*. Nat. Med. 2019).

Methods Our approach is to prime and expand T cells from the blood to cancer-specific mutations *ex vivo*.

Results We can generate T cell populations reactive to as few as 8 and as many as 40 cancer-specific mutant proteins in a single production run. *In vitro*, these T cells have mutation-specific cytotoxicity and do not kill the normal cells. These T cells express homing receptors that allow them to infiltrate the tumor and express high levels of TNFaand IFNg, both of which are associated with effective tumor cytotoxicity and pro-inflammatory modification of the tumor microenvironment. The predominant immunophenotype of these cells is consistent with central and effector memory, CD4+ and CD8 + T cells, with almost no regulatory or exhausted T cells.

Conclusions We believe these T cells can be used as a cellular therapy in conjunction with, or as an alternative to, immune checkpoint inhibitors to treat lower mutational burden cancers that comprise most patients' tumors.

184 **DISCOVERY, CLONING AND FUNCTIONAL VALIDATION OF A NEOANTIGEN SPECIFIC PATIENT DERIVED TCR ON THE BERKELEY LIGHTS PLATFORM, WITH IMPLICATIONS IN PERSONALIZED CANCER IMMUNOTHERAPY**

[1]Joseph Valdez*, [1]Guido Stadler, [1]Pei-Yu (Kate) Lin, [1]Milton Quintanilla, [1]Tyler Helmann, [2]Xiuli Zhang, [2]S Peter Goedegebuure, [2]Malachi Griffith, [2]William Gillanders, [3]William Hoos, [1]Yiyang Xu. *[1]Berkeley Lights, Emeryville, CA, USA; [2]Washington University in St. Louis, St. Louis, USA; [3]Jaime Leandro Foundation, Scotts Valley, CA, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) has the poorest prognosis of all human cancers and requires new therapeutic options. Several immune-based treatments including personalized neoantigen vaccines and adoptive T cell transfer are currently being investigated. Recently, complete clinical response was reported in a patient with HER2+ metastatic PDAC treated with a neoantigen vaccine in combination with radiation and dual checkpoint (https://doi.org/10.1101/2021.12.16.21267326). Here we describe a sensitive method for post-vaccination functional characterization of neoantigen-specific T cells from minimal quantity of patient peripheral blood at the single cell level using a microfluidic device on the Beacon® optofluidic system from Berkeley Lights.

Methods Peripheral blood was obtained from a patient with metastatic PDAC in complete response following neoantigen DNA vaccine therapy. T cells were pre-enriched by stimulating with a cocktail of peptides corresponding to 7 neoantigens. Subsequently, single T cells were investigated over 2 days using a microfluidic device featuring nanoliter-scale NanoPen® chambers in co-culture with autologous dendritic cells or partially HLA-matched allogeneic antigen presenting cells (APCs) pulsed with the neoantigen peptides. Antigen-responsive T cells were isolated based on expression of CD137, a known T cell activation-associated marker, cytokine secretion and cytotoxicity profile. TCRs of selected T cells were recovered, synthesized, cloned into a lentiviral expression vector, expressed in primary T cells from an unrelated donor, and validated using peptide pulsed APCs.

Results A quantitative dataset including CD137 expression, IFN-y secretion and real time cytotoxicity was generated for single T cells from the peripheral blood of a cancer patient in co-culture with single APCs. Candidates were ranked based on strength of phenotype, isolated and TCR sequences were generated. The top TCR candidate, restricted to HLA-A*02:01, post-engineering was effective in recapitulating the same potency criteria (99% cytotoxicity, 74% CD137+ as compared to <1% for controls and >15,000 fold enrichment of IFNy/TNFa/IL-2 as compared to controls) against a lymphoma derived cell line presenting a single peptide from the cancer vaccine. Importantly, this TCR was not active against the other neoantigen peptides or a well characterized oncogenic peptide MART-1 demonstrating specificity.

Conclusions We demonstrate the ability to characterize T cells in co-culture with APCs at single cell resolution. A TCR which exhibited strong functional behavior during screening was also effective and specific to a single neoantigen peptide post engineering. This workflow may enable personalized TCR to be realized by reducing the timeframe and finding better candidates to be used independently or in combination with cancer vaccines and other interventions.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0184

185 TUNING THE CELL-CELL DISTANCE VIA THE NON-SIGNALING EXTRACELLULAR SPACER DOMAIN OF CHIMERIC ANTIGEN RECEPTORS IS CRITICAL FOR OPTIMAL ACTIVITY

[1]Jason Yokoyama*, [1]Lisa Song, [2]Quinn Walker, [2]Bijan Boldajipour, [1]Howell Moffett, [1]Brian Weitzner, [1]Scott Boyken, [1]Marc Lajoie. *[1]Outpace Bio, Seattle, WA, USA; [2]Lyell Immunopharma, San Francisco, CA, USA*

Background Chimeric antigen receptors (CARs) are synthetic receptors that target engineered immune cell effector functions against target cells expressing specific antigens. CAR activity can be significantly improved by optimization of multiple parameters, including geometry of the immunologic synapse, biophysical properties of the extracellular domains, and signaling properties of the intracellular domains. Native T cell activation is driven by adhesion molecules and T cell Receptors (TCRs) binding to peptides displayed on the Major Histocompatibility Complex (MHC) of target cells, with a well-defined cell-cell distance of 14–15 nm in synaptic contact areas. However, the optimal synaptic distance, and the importance of cell-cell synaptic distance for CAR activity has not been systematically determined. Here we investigate the role of spacer length on the recognition of clinically relevant tumor antigens using a panel of 4 previously-published spacers and 41 novel spacers derived from human extracellular proteins and ranging in length from 3.6–30.6 nm.

Methods We tested all of these spacers with five known CAR targeting domains that bind epitopes at varying distances from the cell membrane on the target cells, including three ROR1 CARs (R11, R12, 2A2), one CD19 CAR (FMC63) and one HER2 CAR (herceptin). Additionally, we developed a model system in which a single linear epitope could be systematically presented at different distances from the target cell membrane using our spacer sequences. In this model, an anti-HA scFv (clone 2E2) was used as the CAR binding domain and an HA peptide (YPYDVPDYA) was used as a model epitope. We tested all possible CAR constructs in vitro by evaluating cytokine production and target cell killing kinetics (primary and serial restimulation).. Addtionally, we tested whether our in vitro observations are predictive of in vivo performance by choosing five spacers that cover a wide range of performance for two CARs with different predicted optimal spacer lengths in the in vitro study (R12, FMC63) and tested them in mouse xenograft models.

Results We demonstrate that both in vitro and in vivo CAR activity is dependent on spacer length, with optimal activity observed at a synaptic distance of about 20 nm, substantially longer than the 14–15 nm TCR:MHC complex. Furthermore, the optimal range of synaptic distances is far narrower than previously appreciated.

Conclusions We identified spacers that led to improved activity over the current state-of-the-art CAR sequences, suggesting that our biophysically-optimized spacers can be used to rapidly create optimal CAR constructs for arbitrary binder-epitope pairs.

Ethics Approval All animal procedures and housing were conducted in accordance with the Lyell/Explora umbrella IACUC protocol ID EB17–010–117.

186 TUMOR REACTIVE, CYTOKINE INDUCED, ENGINEERED HUMAN NATURAL KILLER CELLS DEMONSTRATE SERIAL CYTOTOXICITY AGAINST LIQUID AND SOLID TUMOR CELL TARGETS

[1]Ting Lu*, [1]Christian Bustillos, [1]Zhiyao Li, [1]Jianying Zhang, [2]Lei Zhang, [2]Li Chen, [1]Jianhua Yu, [1]Michael Caligiuri. *[1]City of Hope National Medical Center, Los Angeles, CA, USA; [2]CytoImmune Therapeutics, Inc., Monrovia, CA, USA*

Background Expression of PD-L1 on human natural killer (NK) cells identifies a subset that are selectively reactive to tumors. PD-L1(+) NK cells have increased CD107a expression, cytotoxicity, and interferon-gamma secretion vs. the PD-L1(-) fraction. PD-L1(+) NK cells are manufactured for patient administration using cytokine stimulation under GMP conditions and in vivo survival sustained by engineering these tumor-reactive, cytokine-induced killer (TRACK) NK cells to express soluble (s)IL-15. Cryopreserved, off-the-shelf allogeneic TRACK NK cells expressing sIL-15 are being assessed in a phase 1 trial in patients with relapsed/refractory non-small cell lung cancer (NSCLC; NCT05334329). Here, we assess phenotype and function of human TRACK NK cells and demonstrate serial natural cytotoxicity and antibody-dependent cellular cytotoxicity (ADCC) lymphoma and NSCLC targets.

Methods TRACK NK cells were manufactured from umbilical cord blood NK cells by activation and expansion of NK cells over a feeder cell line, engineering to secrete sIL-15, followed by cytokine activation before cryopreservation. Serial TRACK NK cell cytotoxicity was measured as killer frequency, defined as the average number of tumor target cells killed per single TRACK NK cell over 8–40 hours.[1]

Results Fresh TRACK NK cells expressed >90% CD16 immediately prior to cryopreservation; following thaw, resting NK cell CD16 expression was >60% at T_0 but rose significantly to >75% following culture at 37C for 6h and >82% at 24h ($p<0.05$), mimicking upregulations as would likely occur in vivo. Similar statistically significant upregulation of NKp44 and NKp46 ($p<0.05$) was observed on TRACK NK cells, whereas very high expression of NKp30, NKG2D, and DNAM-1 remained stable. CD57 and PD-1 expression remained low (~1–5%). TRACK NK cells performed robust ADCC against both CD20(+) at various E:T in the presence of anti-CD20 and anti-EGFR, respectively, significantly better than NK killing of either target. Substantial TRACK NK cell cytoreduction of NSCLC was also demonstrated in vivo. In addition, antibody independent serial cytotoxicity and antibody-depended serial cytotoxicity by TRACK NK cells was demonstrated against both lymphoma and NSCLC lines.

Conclusions Under various conditions, each TRACK NK cell was able to kill a multitude of lymphoma cells via ADCC in the presence of anti-CD20 mAb or a multitude of NSCLC in the absence or presence of antibody. These data support the use of the TRACK-NK cells in the clinic using both their natural cytotoxicity and their ADCC mechanism of action against both liquid and solid tumors.

187 A LIVE TUMOR FRAGMENT PLATFORM SUITABLE FOR ASSESSING RESPONSE TO T-CELL THERAPIES

Christopher Zahm*, Laura Hrycyniak, Ellen Wargowski, Dinesh Joshi, Team Adstamongkonkul, Greg Ochs, Gabriella Stueber, Debra Bloom, Ryan Fischer, Christina Scribano, Christin Johnson, Anura Shrestha, Nathan Marhefke, Ariah Law, Jonathan Oliner. *Elephas Bio, Madison, WI, USA*

Background T-cell therapies have shown efficacy in numerous clinical settings. However, predictive biomarkers of response are lacking, and determining which T-cell therapy each cancer patient will respond to has been hindered by the absence of model systems that maintain the specific immunosuppressive features of each patient's tumor microenvironment (TME). The Elephas live tumor fragment (LTF) platform is designed to enable prediction of clinical response to many types of immunotherapies, including cellular therapies and checkpoint blockade. The experiments described here examine T-cell activation, cytokine production, and tumor-cell killing following co-culture of LTFs with T-cell therapies.

Methods Transgenic T-cells: LTFs were generated from two tumors that differ only by the presence or absence of a recombinantly expressed protein selectively recognized by targeted transgenic T cells. Transgenic and wildtype (WT) T-cells were isolated and co-cultured at 1:1, 5:1, and 10:1 T-cell:target-cell ratios using LTFs from both tumor types and assessed for T-cell activation and tumor cell viability using flow cytometry and cytokine/chemokine secretion profiling.

TILs: Tumors were collected and processed for TIL expansion, which was conducted in the presence of IL-2 for 10 days. Following expansion, CD8 T-cells were isolated and co-cultured for 48h at a 1:1 ratio with LTFs from the same tumor. Tumor killing and T-cell activation were measured by flow cytometry.

All animal studies were carried out in accordance with animal welfare guidelines and approved by the IACUC at Excelsior Labs.

Results Transgenic T-cells: Flow cytometry revealed an increase in activation markers (CD25, CD69, ICOS, PD1, and CD137) on the surface of transgenic CD8 T-cells incubated with target-positive tumors, but not target-negative tumors, while WT T-cells displayed no increases when incubated with either tumor type. Secretome profiling demonstrated similar changes, with an increase in cytokine and chemokine secretion (IFNg, CXCL1, CCL4, and CXCL5) as the ratio of transgenic CD8 T-cells to target-cells increased, using target-positive, but not target-negative, LTFs. Decreases in tumor cell viability were also detected at higher T-cell:Target-cell ratios and were again only observed with target-positive LTFs.

TILs: CD8 T-cells isolated from TILs, but not WT T-cells, that were co-cultured with LTFs demonstrated increased activation and resulted in a decrease in tumor cell number following 48h of culture.

Conclusions We have verified target-specific transgenic T-cell activation, as well as reduced tumor viability in expanded TILs following co-culture with LTFs. These data lay the groundwork for future studies using the Elephas LTF platform to predict individual clinical responses to various T-cell therapies.

Ethics Approval All animal studies were carried out in accordance with animal welfare guidelines and approved by the IACUC at Excelsior Labs.

188 ARGININE PRE-CONDITIONING ENHANCES T-CELL POTENCY AND METABOLIC FITNESS

Rashmi Pillai*, Xiaoyu Zhang, Brandon Lamarche, Yama Abassi. *Agilent, San Diego, CA, USA*

Background Enhanced T-cell performance is imperative for the success of adoptive T-cell-based therapies. Here we assessed the killing efficiency of MART-1 specific TCR T-cells after Arg, Gln, and Leu pre-conditioning using the Agilent xCELLigence RTCA eSight (eSight). The eSight system can simultaneously capture live-cell images and measure cellular impedance, which determines the changes in cell number, morphology, and attachment. In parallel, the status of metabolism of the pre-conditioned T-cell was determined by Seahorse XF assays.
Methods Briefly, $CD3^+$ T-cells (Hemacare, Seattle, WA) were transduced with retrovirus SAMEN-DMF5 with a CD34 marker gene, against MART-1. The T-cells were pre-conditioned in a range of concentrations varying between 0–6mM with Arg, Glu and Leu for 7 days, followed by a killing assay using MART-1 expressing melanoma cell line as target cells (624.38) engineered to express a red-fluorescent nuclear protein, and Seahorse XF Cell MitoStress and T-cell metabolic profiling assays. The comparison was made with the controls, including transduced T-cells grown in RPMI but with no amino acids during pre-conditioning (TCR_RPMI), and non-transduced T-cells (Non_TCR).
Results Our data show Arg supplementation enhanced T-cell killing of target cells while Leu and Gln suppressed T-cell mediated killing. Specific cytolysis (5:1, E:T ratio) at 60h for TCR_RPMI and 6 mM Arg pre-conditioned T cells (TCR_ARG) were 35% and 76%, respectively. We further determined the impact of the duration of pre-conditioning. 2 and 4 days of pre-conditioning with 6 mM Arg were done along with the 7-day method. The percentages of cytolysis of TCR_ARG (6 mM) at 60 hr were 29, 68, and 81 on days 2, 4, and 7, respectively, indicating that improved killing potency of the T-cells started as early as 4 days with Arg. The Seahorse XF assays were performed to determine metabolic fitness and persistence. Arg (6mM) supplementation increased the spare respiratory capacity 1.7 and 2.6 times compared to TCR_RPMI control on days 4 and 7 respectively.
Conclusions In summary, Arg at 6mM concentration was effective with the highest percentage of cytolysis and a higher spare respiratory capacity and Gln and Leu conditioning suppressed T-cell killing. Consistently, Arg fuels the TCA cycle and thus, shifts metabolism towards mitochondrial respiration.

189 CRISPR-MEDIATED METABOLIC REPROGRAMING OF ADOPTIVELY TRANSFERRED T CELLS TO POTENTIATE ANTITUMOR RESPONSE

Soraya Zorro Manrique*, Yunfei Wang, Ana Dominguez, Debra Armendariz, Patrick Hwu.
Moffitt Cancer Center, Tampa, FL, USA

Background The signaling of key metabolic pathways in T cells within the tumor microenvironment (TME), strongly impacts their antitumor response. Cancer cells compete with T cells for essential nutrients such as glucose and amino acids; in addition, cancer cells produce T-cell inhibitory metabolites such as lactate and adenosine. Therefore, metabolic reprograming of T cells to confer adaptability to the TME is a promising therapeutic strategy for advanced cancers.

Methods To identify detrimental metabolic genes for T-cell tumor infiltration, we performed an *in vivo* shRNA screen with a pooled metabolome library (~300 genes) in Pmel CD8 T cells adoptively transferred into B16 tumor-bearing mice. We identified genes whose disruption in T cells resulted in increased infiltration in B16 melanoma.

Results We found that disruption of the PDHB gene enhances T-cell tumor infiltration. Pdhb encodes for the E1 Subunit Beta of the Pyruvate Dehydrogenase (PDHB), an enzyme linking glycolysis and the tricarboxylic acid cycle. We validated this result using CRISPR/Cas9 RNP transfection (>90% knockout efficacy) to knockout (KO) Pdhb in Pmel CD8 T cells. Our *in vivo* studies showed that PDHB KO improves T-cell infiltration and tumor rejection, vs non-targeting control T cells. PDHB KO cells produced higher IFNg levels and displayed improved tumoricidal capacity. The functional metabolomic analyses (seahorse assays) indicated that PDHB KO cells have an impaired mitochondrial function (reduced respiratory and FAO capacities) while having an increased glycolytic activity. The transcriptome and pathway analyses indicated that PDHB disruption, strongly induced lipid biosynthesis. Analyzing the most upregulated metabolites in the PDHB KO cells revealed that inosine, a product of adenosine metabolism, reported to serve as an alternative carbon source for T cells, was within the top 5 upregulated metabolites. The integrated transcriptome, metabolomics and pathway analyses indicated that PDHB KO cells display a metabolic reprograming with upregulation of unsaturated fatty acid biosynthesis, glycolysis/gluconeogenesis, pyruvate metabolism, chemokine signaling and purine metabolism. Remarkably, the transcriptome analysis suggests that the PDHB KO T cells have an expression pattern of Tscm/Tcm cells which might be associated with their capacity to survive within tumors.

Conclusions In tumors characterized by glucose deprivation, the inosine upregulation by PDHB KO T cells might support T-cell function. Overall, our data suggests that PDHB disruption in T cells could contribute improving adoptive cell therapy. Thus, our study indicates that CRISPR-mediated metabolic reprograming of T cells could be a powerful approach for generating T cells able to overcome tumor-driven metabolic restrictions.

Ethics Approval Animal protocol was approved by the University of South Florida, IACUC IS00008501.

190 NOVEL CELLULAR IMMUNOTHERAPY WITH ANTI-MESOTHELIN CAR-KILLER LYMPHOCYTES AGAINST ADVANCED CHOLANGIOCARCINOMA

[1,2]Annamaria Massa*, [3]Valeria Leuci, [2]Federica Galvagno, [2]Chiara Donini, [2]Francesca Vita, [2]Ramona Rotolo, [2]Alessia Proment, [4]Letizia Vitali, [3]Elisabetta Fenocchio, [2]Elisa Vigna, [3]Giuliana Cavalloni, [5]Massimo Aglietta, [2]Dario Sangiolo. *[1]University of Turin, Orbassano (Torino), Italy; [2]University of Turin, Turin, Italy; [3]Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy; [4]Univerisity of Turin, Candiolo, Italy; [5]Università di Turin, Turin, Italy*

Background Cholangiocarcinoma (CCA) is a biliary epithelial tumor with poor prognosis, for which there are not effective therapeutic options in advanced stages.[1] Innovative therapeutic strategies are highly needed. Cellular immunotherapy holds great promise for the treatment of solid tumors.[2] Among various cellular immunotherapy approaches, our group contributed to the development and testing of Cytokine Induced Killer lymphocytes (CIK) endowed with intrinsic MHC-unrestricted tumor killing activity.[3] Recently, it was reported that CIK may be engineered with Chimeric Antigen Receptors (CARs) generating immune effectors with double antitumor potentiality,[4,5] strategically important to counteract the frequent heterogeneity of tumor antigen expression. To this end, in the context of CCA mesothelin (MSLN) is emerging as a promising CAR target.[6,7]

Here, we hypothesized to generate a novel and effective cell therapy strategy against CCA redirecting patient-derived CIK, with a CAR against MSLN acting as relevant CCA target.

Methods

MSLN-CAR CIK were generated from patients' PBMC and were transduced with a lentiviral vector encoding for the second generation anti-MSLN CAR including the co-stimulatory domain 4–1BB. CAR expression and extended phenotype of mature CAR-CIK were assessed by flow cytometry. The expression of MSLN, were assessed in CCA cell lines and CCA surgical specimens. In parallel, target molecules recognized by CIK (MICA/B, ULBPs) were evaluated.

Tumor killing in 2D models was evaluated at different effector:target ratio by flow-cytometry and bioluminescence-based essays. In order to increase the complexity of CCA models 3D tumor spheroids were generated from different CCA cells bearing a reporter gene (RFP) and co-incubated with effector cells at ratio 2:1. Fluorescence images were acquired at different times using fluorescence microscopy.

Results We successfully generated MSLN-CAR.CIK from peripheral blood of tumor patients (n=5) (figure 1A). CAR.CIK immunophenotype was comparable to unmodified controls (NTD.CIK): (42±5)% CAR+, (49±8)% CD3+CD56+, (77±6)% CD3+CD8+ and (83±7)% NKG2D+. We found high (>90%) membrane expression of MSLN in 6/7 CCA cell lines that were all effectively killed by MSLN-CAR.CIK in 2D assays. The observed tumor lysis was significantly enhanced (n=12) compared to NTD.CIK: 80% vs 30% (E/T 2.5:1), 70% vs 20% (E/T 1:2, p< 0.0001) (figure 1B). The intense activity, along with tumor infiltration, by MSLN-CAR.CIK was observed also against CCA 3D spheroids.

Conclusions We report that MSLN-CAR.CIK effectively targets CCA cells in both 2D assays as well as in 3D models. Our findings provide translational bases to support clinical cellular immunotherapy studies with MSLN-CAR.CIK in the challenging field of advanced CCA.

191 TARGETING MYELOID-DERIVED SUPPRESSOR CELLS (MDSCS) IN BLADDER CANCER TO ENHANCE EFFICACY OF ADOPTIVE CELL THERAPY (ACT)

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0191

Sarah Bazargan Candidate*, Brittany Bunch, Jamie Blauvelt, Annick Landin, Johannes Ali, Dominique Abrahams, Amy Hall, Matthew Beatty, Michael Poch, Shari Pilon-Thomas. *Moffitt Cancer Center, Tampa, FL, USA*

Background MDSCs are a significant barrier to adoptive cell therapy (ACT) due to their suppressive effects on T-cells. We predict that there is an enrichment of MDSCs within bladder tumors and depletion of MDSCs may augment anti-tumor responses after intravesical ACT with tumor reactive T-cells.

Methods For murine studies, orthotopic MB49-OVA bladder tumors were collected, stained for MDSCs, and analyzed by flow cytometry. Urine samples from bladder cancer patients were also collected and stained for MDSCs. From mice, purified MDSCs and OT-I T-cells were cocultured and from bladder cancer patients, purified urine MDSCs and CD3-stimulated peripheral blood T-cells were cocultured to assess suppression of T-cell proliferation or IFN-gamma secretion. Mice bearing MB49-OVA tumors were treated with intravesical instillation of gemcitabine and/or OT-I T-cells and tumor growth was monitored via ultrasound.

Results In mice bearing MB49-OVA tumors, the levels of polymorphonuclear (PMN)-MDSCs averaged between 11.1–23.5% of live cells and monocytic (M)-MDSCs averaged 7.6% of live cells, demonstrating that nearly 20–30% of live cells within murine bladder tumors are MDSCs. In the urine of bladder cancer patients, PMN-MDSCs predominantly make up the live cell population, averaging 71.7%, demonstrating an enrichment for MDSCs within the microenvironment of human bladder cancer. In murine coculture assays, MDSCs reduced the proliferation of OT-I T-cells and in human cocultures, MDSCs reduced T-cell IFN-gamma production to a fourth of control levels. Therefore, MDSCs from bladder tumors suppress anti-tumor T-cells by inhibiting proliferation and reactivity. In mice bearing large MB49-OVA tumors (>50mm3), pretreatment with gemcitabine improved anti-tumor response in combination with intravesical ACT with OT-I T cells in comparison to treatment with gemcitabine only ($p=0.0387$), OT-I only ($p=0.0148$), and untreated ($p=.0039$). In smaller MB49-OVA tumors (<50mm3), gemcitabine pretreatment provided little added benefit to ACT in comparison to treatment with gemcitabine only ($p>0.05$) and OT-I only ($p>0.05$). All p-values generated by performing Mann-Whitney tests on tumor volumes at final time points.

Conclusions MDSCs make up a significant proportion of the immune population within bladder tumors and exert suppressive effects on T-cells. Our studies support the selective targeting of MDSCs via gemcitabine to improve the anti-tumor effects of ACT. While we show that a single instillation of gemcitabine and ACT improves anti-tumor responses, we predict that this effect will be further enhanced with multiple instillations of T-cells.

192 CHARACTERIZATION OF ANTIBODIES AGAINST BTN2A1 FOR Vδ2$^+$ γδ T CELL-BASED TUMOR IMMUNOTHERAPY

[1]Kok Fei Chan*, [1]Simone Ostrouska, [2]Ranjeeta Prasad, [2]Daria Kurtov, [2]Andrew Hammet, [3]Marc Rigau, [3]Adam Uldrich, [1]Andreas Behren. *[1]Olivia Newton-John Cancer Research Institute, and School of Cancer Medicine, La Trobe University, Heidelberg, Victoria, Australia, Melbourne, Australia; [2]CSL Limited at the Bio21 Molecular Science and Biotechnology Institute, The University of Melbourne, Parkville, Victoria 3010, Australia, Melbourne, Australia; [3]Department of Microbiology and Immunology at the Peter Doherty Institute for Infection and Immunity, The University of Melbourne, Parkville, Victoria 3010, Australia, Melbourne, Australia*

Background Human γδ T cells are ideal candidates for tumor immunotherapy because of their natural tropism for tumor microenvironment, elicit rapid innate-like immune responses upon tumor recognition and the ability to orchestrate other tumor-infiltrating immune cells for tumor cell killing.[1] Our group has recently defined aspects of the mechanism of T-cell receptor (TCR) dependent activation of Vγ9Vδ2$^+$ T cells by tumors following the presentation of phosphoantigens via the B7 immunoglobulin family-like butyrophilin 2A1 (BTN2A1) and BTN3A1.[2] Dysregulation of the mevalonate pathway in tumors can cause activation of Vγ9Vδ2$^+$ T cells via phosphoantigen accumulation and induces γδ T cell chemotaxis toward tumor cells.[3, 4] Most clinical studies so far have used aminobisphosphonates (to promote accumulation of phosphoantigens in cells) or synthetic phosphoantigen analogues such as bromohydrin pyrophosphate (BrHPP) and 2-methyl-3-butenyl-1-pyrophosphate (2M3B1PP) to activate Vγ9Vδ2$^+$ T cells in cancer patients.[5–8] More recently, agonist antibodies against BTN3A (e.g., clone 20.1, ICT-01 and CTX-2026) have been identified and used as a phosphoantigen-independent approach to activate Vγ9Vδ2$^+$ T cells for targeted cell killing.[1]

Methods We are currently characterizing a number of anti-BTN2A1 antibodies that can potentially be used to modulate the activity of Vγ9Vδ2$^+$ T cells in *in vitro* assays.

Results We have also established a pre-clinical humanized tumor model using NOD scid gamma (NSG) mice and showed delayed tumor growth in mice that received 4 rounds of human Vδ2$^+$ γδ T cell adoptive cell transfer in combination with clone 20.1 agonist antibody, which will allow further characterization of our anti-BTN2A1 antibodies.

Conclusions Taken together, our study has demonstrated the potential to target BTN2A1 and BTN3A1 for Vγ9Vδ2$^+$ T cell-based cancer immunotherapy development.

193 CAR-T MANUFACTURED FROM FROZEN PBMC YIELD EFFICIENT FUNCTION WITH DELAYED *IN VITRO* EXPANSION

[1]Julieta Abraham-Miranda*, [1]Meghan Menges, [1]Reginald Atkins, [2]Mike Mattie, [2]Justyna Kanska, [1]Joel Turner, [1]Melanie Hidalgo-Vargas, [1]Frederick Locke. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Kite Pharma, Santa Monica, CA, USA*

Background Chimeric antigen receptor (CAR)-T cells are engineered T cells that can identify and eliminate cells expressing a target antigen. Cryopreservation of CAR-T cells preceding infusion is a widely used practice since it allows flexible scheduling time of patient infusions.[1] Using frozen PBMCs from patients prior to standard therapies could impact the fitness and function of the final CAR-T product[2] but provides flexibility in scheduling both leukapheresis and manufacture.[3] The impact of cryopreserved PBMCs on the quality of the final CAR-T product is incompletely characterized and needs to be further studied.

Methods We performed a prospective study using PBMCs from 20 healthy donors (HDs) to examine if manufacture of CAR-T cells using frozen (2X) vs. fresh (1X) PBMCs affects the quality and functionality of the product. The CAR-T manufacturing process is detailed in figure 1. We analyzed second generation CD19-targeted human CAR-T cells with CD28 (h1928z) co-stimulation for transduction efficiency, product expansion, immune-phenotype, activation induced cell death (AICD) and metabolic fitness (MF). We compared functionality by measuring markers of activation (4–1BB, CD107a and pAKT measured by flow cytometry, and cytokine release measured by ELLA) and their cytotoxic capacity (measured by xCELLigence Real-Time Cell Analysis) against hCD19 target-expressing cells.

Results We found that freezing PBMCs delayed expansion during manufacture, with a doubling time 1.25-fold higher in 2X h1928z compared to 1X h1928z CAR-T cells (figure 2B). Transduction efficiency (figure 2A), CD4/CD8 ratio (figure 2C), CAR-T cell phenotype (figure 2D-E), AICD (figure 2F) and MF (figure 2G) were not affected by freezing PBMCs prior to CAR-T manufacture. Moreover, freezing PBMCs did not affect expression of 4–1BB (figure 2H), CD107a (figure 2I) or pAKT (figure 2J) after CAR engagement. IFN-γ and TNF-α production was reduced in 2X h1928z CAR-T cells after hCD19 mediated activation (figure 2K) without compromising their cytotoxic capacity (figure 2L-M).

Conclusions Freezing PBMCs prior to CAR-T production slows cell expansion during manufacture and decreases IFN-γ and TNF-α production, without disturbing CAR-T cell immune-phenotype, activation, or *in vitro* anti-tumor function. As CAR-T immunotherapy continues to expand, the necessity to store PBMCs to improve manufacturing logistics as well as to allow collection from patients at an early clinical stage will grow. This study supports the concept that cryopreservation of PBMCs is a valid solution to these issues without compromising the quality of the final product.

194 PRE-CLINICAL DEVELOPMENT OF CT-1119, A MESOTHELIN TARGETING CHIMERIC ANTIGEN RECEPTOR MACROPHAGE (CAR-M), FOR SOLID TUMOR IMMUNOTHERAPY

Nicholas Anderson*, Michael Klichinsky, Kerri Ciccaglione, Stefano Pierini, Brinda Shah, Alison Worth, Rashid Gabbasov, Brett Menchel, Daniel Blumenthal, Sabrina DeLong, Sascha Abramson, Thomas Condamine. *Carisma Therapeutics, Philadelphia, PA, USA*

Background Despite significant success in treating hematological malignancies, adoptive cell therapies have yielded limited efficacy in solid tumors.[1] Macrophages are myeloid cells of the innate immune system and are naturally recruited to solid tumors,[2] where they have the potential to phagocytose tumor cells, activate the tumor microenvironment (TME), and prime a broad anti-tumor adaptive immune response via T cell recruitment and activation. We have previously developed chimeric antigen receptor macrophages (CAR-M) targeting HER2 and showed efficacy in a variety of pre-clinical models,[3] with a Phase I clinical trial ongoing. Mesothelin is overexpressed in a variety of solid tumors, including mesothelioma, lung, pancreatic, and ovarian cancers.[4] Here, we present preclinical data summarizing the development of CT-1119, a mesothelin targeted CAR-M for solid tumors.

Methods Using the chimeric adenoviral vector Ad5f35, we engineered primary human macrophages to express a CAR comprising a human scFv targeted against human mesothelin. To assess the activity of CT-1119, *in vitro* cell based assays and *in vivo* murine xenograft models were utilized. Donor-matched untransduced (UTD) macrophages served as controls.

Results Primary human CAR-M engineered with an Ad5f35 vector demonstrated high CAR expression, high viability, upregulated M1 (anti-tumor) macrophage markers, and downregulated M2 (pro-tumor) macrophage markers. CT-1119 demonstrated increased resistance to repolarization by M2 (pro-tumor) polarizing cytokines as compared to donor matched UTD macrophages. CT-1119 specifically bound mesothelin and binding was not impacted by mesothelin shedding. CT-1119 specifically phagocytosed multiple mesothelin expressing tumor cell lines in a CAR-dependent and antigen-dependent manner. CT-1119 demonstrated robust *in vitro* killing of the relevant tumor cell lines A549 and MES-OV expressing mesothelin. CAR engagement also induced the release of pro-inflammatory cytokines such as TNFα following stimulation with mesothelin in both cell-free and cell-based contexts in a dose-dependent manner. *In vivo*, CT-1119 significantly reduced tumor burden in a murine xenograft model of lung cancer. Similarly, human monocytes targeting mesothelin were successfully generated using the same Ad5f35 vector and demonstrated specific activity against mesothelin positive tumor cells.

Conclusions The presented results demonstrate that CT-1119, an autologous human anti-mesothelin CAR-M, can cause phagocytosis, tumor cell killing, and pro-inflammatory cytokine release in response to stimulation with mesothelin. These results show that CAR-M is a feasible approach for the treatment of mesothelin expressing sold tumors via the potential for induction of a systemic anti-tumor response.

195 **CHARACTERIZATION OF WU-NK-101, A FEEDER CELL-FREE EXPANDED ALLOGENEIC MEMORY NK CELL PRODUCT WITH POTENT ANTI-TUMOR ACTIVITY**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0195

[1]Laura Arthur*, [1]Mary Mathyer, [1]Celeste Dufour, [1]Bryan Cruz, [2]Melissa Berrien-Elliot, [2]Mark Foster, [1]Nitin Mahajan, [1]Alun Carter, [1]Matthew Cooper, [1]Ryan Sullivan. *[1]Wugen Inc., Saint Louis, MO, USA; [2]Washington University in St. Louis, St. Louis, MO, USA*

Background Cytokine-induced memory NK cells, like WU-NK-101, offer several advantages over conventional NK cells.[1, 2] These advantages include enhanced functional persistence, efficacy, and metabolic fitness that improve their survival and activity in liquid and solid tumor microenvironments.[3, 4] Additionally, unlike conventional NK (cNK) cells derived from iPSC, cord blood, or adult peripheral blood, WU-NK-101 does not require engineering to enable anti-tumor activity.

The Moneta™ Platform is a feeder cell-free system of fusion protein complexes to generate, expand, phenotypically maintain, and cryopreserve memory NK cells for an 'off-the-shelf' allogeneic drug product. Here we define the molecular characteristics of WU-NK-101, through RNA and protein phenotyping, and elucidate pathways involved in memory NK cell expansion and activity.

Methods WU-NK-101 was generated from previously frozen NK cells derived from healthy donor whole blood using the Moneta™ platform. We evaluated pre- and post-expansion phenotype by flow cytometry, CyTOF, and RNA-Seq. We further assessed post-thaw functionality by cytokine secretion and cancer cell cytotoxicity in the absence or presence of monoclonal antibodies.

Results CyTOF analysis revealed that WU-NK-101 have an expression profile distinct from cNK. Compared to cNK, WU-NK-101 have elevated expression of Memory NK markers (CD25, CD69, NKG2A), cytotoxic molecules (GzmB, TRAIL), activating receptors (NKp30, NKp44, NKG2D), and nutrient transporters (CD71, CD98), providing mechanistic rationale for their enhanced anti-tumor activity and metabolic flexibility. Flow cytometry and RNAseq analysis confirm this phenotype. When stimulated by cancer cells, WU-NK-101 have enhanced secretion of IFN-γ, MIP-1α, and TNFα; and also demonstrate improved cytotoxicity compared to cNK. WU-NK-101 is able to utilize monoclonal antibodies to effectively drive antibody-dependent cellular cytotoxicity against solid tumor cancer cell lines.

Conclusions The Moneta™ platform expands memory NK cells while maintaining their cytokine-induced memory phenotype, as identified by RNA-Seq, flow cytometry, and CyTOF. As a result, WU-NK-101 demonstrates improved anti-tumor activity compared to cNK cells, even within the adverse tumor microenvironment. These data support the clinical development of WU-NK-101, an allogeneic Memory NK cell therapy in both liquid and in solid tumors, as a monotherapy and in combination with monoclonal antibodies, solid tumor engagers, or other anti-tumor modalities.

196 **EXPANSION OF TUMOR-INFILTRATING LYMPHOCYTES FROM COLORECTAL CANCER LIVER METASTASIS; CHARACTERISTICS AND POTENTIAL HISTOLOGIC MARKER OF SUCCESSFUL CELL EXPANSION**

[1]Jina Baek*, [2]Hyun Lee, [1]Gyungyub Gong, [2]Chae-Lyul Lim, [1]Hee Jin Lee. *[1]University of Ulsan College of Medicine, Seoul, Korea, Republic of; [2]NeogenTC Corp, Gyeonggi-do, hanam-si, Korea, Republic of*

Background Colorectal cancer is the 3rd most common cancer worldwide. In recent years, adoptive cell therapy (ACT) of tumor-infiltrating lymphocytes (TILs) has been successful in treatment of metastatic melanoma. We cultured TILs from colorectal cancer liver metastasis. We evaluated the numbers and subsets of expanded TILs and their relationship with the original tumors' histologic findings.

Methods Fifteen samples of colorectal cancer liver metastasis were collected at a single institute. Cancer tissues were cut into 1 to 2-mm fragments and underwent initial expansion of TILs for 2 weeks. The number of the TILs per fragment was counted and checked for successful expansion at cutoff of 0.8x10^5 cells per fragment. Their characteristics were evaluated by flow cytometry. Remnant cancer tissues were made into hematoxylin and eosin-stained slides. The slides were reviewed for histologic findings including the level of stromal TILs and inflammatory cell infiltrate at the invasive margin, using the Klintrup-Makinen (KM) assessment. KM score was assessed in a 4-point scale, from 0 (no increase) to 3 (florid infiltrate at invasive edge with cancer cell destructions).

Results The median number of expanded TILs per fragment after initial expansion was 1.1x10^5 cells (range: 0.16 – 8.75 x10^5) With cutoff value of 0.8x10^5 cells per fragment, successful culture rate was 66.7% (10 of 15 cases). The mean proportion of CD4+ and CD8+ T cells were 69.4% and 32.5%, respectively. The mean proportion of effector memory, effector, central memory, and naïve T cells were 73.1%, 7.8%, 1.4%, and 0.8%, respectively. Number of expanded TILs per fragment and the level of stromal TILs showed no statistical correlation (Kruskal-Wallis test, p=0.258). However, number of expanded TILs per fragment and KM score showed significant association (p=0.006). Histologically, intratumoral percentage of tumor cells, stroma, necrosis, and mucin showed no statistical correlation to expanded TILs per fragment (p=0.36, p=0.286, p=0.563, and p=0.27, respectively), and tumor size also did not show statistical correlation to expanded TILs per fragment (simple regression, p=0.122). We also reviewed patients' MSI status and history of chemotherapy after metastasis, and neither showed statistical correlation (Mann-Whitney U test, p=0.782 and p=0.661, respectively).

Conclusions Expansion of TILs from colorectal cancer liver metastasis was successfully performed, and assessment of inflammatory cell infiltrate at the invasive margin may be helpful in estimating the number of obtainable TILs before the initial expansion. Together, these data could be used for further studies to establish the effective ACT in colorectal cancer patients.

197 **PRELIMINARY SAFETY AND EFFICACY OF AUTOLOGOUS ANTI-MSLN T CELL ENGAGER-LOADED T CELLS (CAB-T) IN PATIENTS WITH MESOTHELIN-EXPRESSING ADVANCED SOLID TUMORS**

[1]Xuanwen Bao, [1]Lulu Liu, [2]Jialin Gu, [2]Mei Li, [1]Zhou Tong, [1]Hangyu Zhang, [2]Yalin Li, [2]Xinjiang Gong, [2]Peng Wang, [3]Andy Tsun, [4]Guoqiang Hu, [4]Chuan-Chu Chou*, [2]Zhiyuan Li, [1]Weijia Fang. *[1]The First Affiliated Hospital, Hangzhou, China; [2]CABT-Bio, Haikou, China; [3]Biotheus Inc, Zhuhai, China; [4]Biotheus Inc., Shanghai, China*

Background Mesothelin (MSLN) is highly expressed in various solid tumor types with low levels of expression in some normal healthy tissues. Our CAB-T platform is a novel, proprietary T cell based anti-CD3 bispecific T cell engager (TCE) delivery system. Our preclinical studies indicated its superior anti-tumor efficacy over traditional 2nd-generation CAR-T formats. Here, we report the preliminary safety and efficacy of MSLN-targeting CAB-T (MSLN-CAB-T) in patients with MSLN-expressing advanced solid tumors during an investigator-initiated trial (IIT).

Methods This is an open-label, single-center study with an accelerated dose titration followed by a 3+3 design. Patients were enrolled with MSLN+ advanced or metastatic solid tumors (detected by IHC; 2+/3+ $\geq$30% in viable tumor cells). MSLN-CAB-T cells were manufactured using autologous PBMC that were freshly isolated from leukapheresis. Following lymphodepletion, MSLN-CAB-T cells were administrated intravenously followed by safety and efficacy observations, and the detection of MSLN-CAB-T expansion and cytokine/TCE levels in patient sera. Primary objectives included safety and tolerability to determine the maximum tolerated dose (MTD). Secondary objectives included overall safety, preliminary efficacy, and PK.

Results From Apr, 2021 to Nov, 2021, seven patients had enrolled (4, ovarian cancer; 1, colon cancer; 2, duodenal carcinoma). 4/7 received $\geq$4 prior lines of therapy, 2/7 received anti-PD1 treatment. Dose levels included 3×10^5 cells/kg (n=1); 1×10^6 cells/kg (n=1); 3×10^6 cells/kg (n=3); 5×10^6 cells/kg (n=1), and 1×10^7 cells/kg (n=1). There were no dose-limiting toxicities (DLT) or treatment-related deaths. Treatment-related adverse events (TRAEs) of $\geq$ Grade 3 were reported in two patients (1×10^6 cells/kg and 1 x 10^7 cells/kg). Grade 1 cytokine release syndrome (CRS) was reported in all of the patients $\geq$ 3×10^6 cells/kg and only one patient dosed at 1×10^7 cells/kg developed Grade 3 CRS (quickly recovered after treatment with corticosteroid and tocilizumab). Post-infusion, MSLN-CAB-T expansion peaked in peripheral blood within 5–19 days. In five evaluable patients (4, ovarian cancer; 1, colon cancer), the best overall response was stable disease (n=1); two ovarian cancer patients dosed at 3×10^6 cells/kg showed tumor shrinkage with one patient whose tumor reduced in size of ~26.89% at the first assessment. Dose-dependent PK and TCE levels correlated with MSLN positivity and tumor burden.

Conclusions MSLN-CAB-T showed good preliminary safety in subjects with MSLN+ solid tumors, and MTD has not yet been reached. This provides the rationale to expand the study, especially for patients with tumors expressing higher levels of MSLN ($\geq$60% in viable tumor cells) as a monotherapy or in combination with other agents.

198 **INNATE-ENHANCED CHIMERIC ADAPTORS (CAD): A NEWLY-DESCRIBED APPROACH FOR AUGMENTING POTENCY OF γδ T CELL IMMUNOTHERAPY**

Marissa Herrman*, Taylor Barca, Xue (Cher) Yang, Maryam Tabrizizad, Morgan Smith-Boeck, Louise Kiru, Jonathan Wong, Ramandeep Kaur, Smitha Gundurao, Gauri Lamture, Aruna Azameera, Kevin Nishimoto, Arun Bhat, Blake Aftab. *Adicet Bio, Inc., Menlo Park, CA, United States*

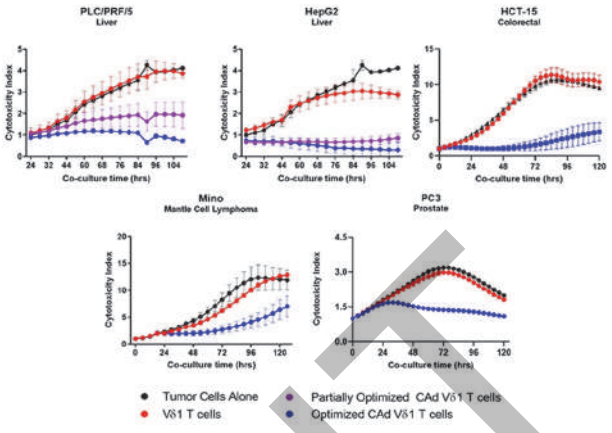
Background γδ T cells are a clinically active cytotoxic effector subtype with intrinsic tumoricidal activity and are correlated to improved survival in solid and hematologic malignancies. γδ T cells target tumors through innate and adaptive mechanisms. Notably, the innate receptor NKG2D is highly expressed on γδ T cells and recognizes a family of target proteins commonly upregulated on tumors. NKG2D specifically associates with intracellular DAP10, a binding partner necessary for signal transduction and activation. Here we describe a novel form of cell engineering incorporating an enhanced intracellular DAP10 chimeric adaptor (CAd) protein, comprising DAP10 domain modifications and inclusion of 4–1BB and modified CD3ζ co-stimulation, designed to amplify potency for tumor targeting via endogenous NKG2D receptors.

Methods Vδ1 T cells were expanded from donor PBMCs and transduced with enhanced DAP10 CAds. CAd expression and association with NKG2D were confirmed by western blot and blocking studies. In vitro characterization included co-culture assays, flow cytometric phenotyping, and cytokine production by multiplexed immunoassay. Anti-tumor potency of CAd Vδ1 T cells was evaluated in a panel of human tumor xenograft models. Xenograft and murine tissues were analyzed for Vδ1 homing and proliferation by flow cytometry.

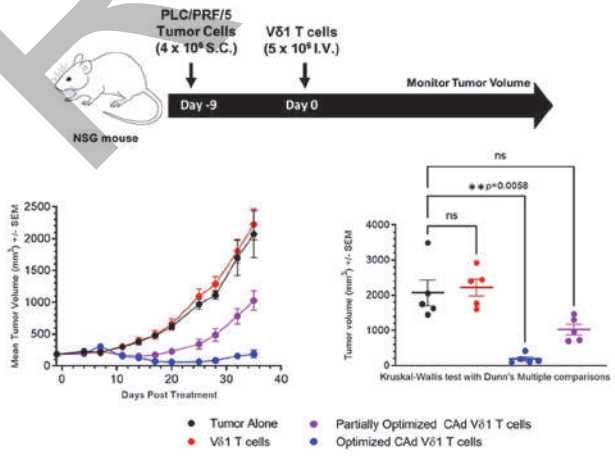
Results CAd-enhanced Vδ1 T cells showed robust expansion and transduction, routinely reaching >80% Vδ1 purity prior to depletion steps, while maintaining a primarily naïve-like phenotype. CAd-enhanced Vδ1 T cells displayed robust in vitro proliferation, cytokine production, and cytotoxic activity across a broad array of solid and heme tumor lines with significantly increased potency compared to unmodified Vδ1 T cells (figure 1). *In vivo*, CAd-enhanced Vδ1 T cells primarily accumulated and specifically proliferated in tumors, with a single dose demonstrating control of tumor burden (figure 2).

Conclusions Innate-enhanced Vδ1 T cells engineered with a newly-described DAP10-based chimeric adaptor technology represents a potent and potentially broadly-applicable 'off-the-shelf' cell therapy with marked increase in cytolytic activity via endogenously expressed innate cytotoxicity receptors. These data support continued development and further investigation in the clinic across a range of hematologic and solid tumor indications.

Ethics Approval All mouse experiments were performed in accordance with the Guide for the Care and Use of Laboratory Animals and followed all institutional and national guidelines with appropriate protocol review and approval.



Abstract 198 Figure 1 in vitro cytotoxicity with innate-enhanced Vδ1 T cells
An array of tumor cell lines across multiple indications were cocultured with unmodified Vδ1 T cells or innate-enhanced DAP10 CAd Vδ1 T cells and tumor cell growth was tracked using Incucyte. The cell line and tumor origin are indicated in the title of each graph. The difference between partially optimized CAd Vδ1 and optimized CAd Vδ1 groups is incorporation of additional DAP10 modifications into the CAd construct design



Abstract 198 Figure 2 in vivo efficacy in hepatocellular carcinoma model

199 3D *EX VIVO* PATIENT TISSUE PLATFORM FOR IMMUNO-ONCOLOGY DRUG TESTING

[1]Sander Basten*, [1]Nataliia Beztsinna, [2]Fanny Grillet, [1]Kuan Yan, [1]Niels Meesters, [2]Donny van der Meer, [1]Emma Spanjaard, [2]Willemijn Vader, [1]Leo Price. *[1]CrownBioscience, Leiden, Netherlands; [2]vitroscan B.V., Leiden, Netherlands*

Background Many immuno-oncology drugs fail in clinical trials, which is partly due to the lack of *in vitro* and *in vivo* models that sufficiently recapitulate the tumor microenvironment (TME). To bridge this gap in translational model systems, a 3D *ex vivo* patient tissue platform was developed which uses 3D *ex vivo* tumor cultures, where tumor endogenous cells of the TME are preserved. These TME components can affect tumor drug responses with potentially novel targets for drug development, making them a crucial component to be presented upon drug efficacy evaluations.

Methods Patient tumor tissues, both solid resection and liquid biopsies from metastatic disease, were processed within 24 hours of surgery or fluid drainage. Following minimal processing small tumor clusters and single cells remain, that were manipulated in liquid handling robotics. The material was embedded in a protein-rich hydrogel and exposed to panels of drug treatments in a 384-well format for 5–7 days until samples were fixed. Tissue responses were quantified using a Crown Bioscience proprietary high content image (HCI)-based analysis platform. In addition, histology and FACS were used to characterize primary samples at baseline. Cytokine measurements were performed on the tumor supernatants.

Results Freshly isolated tumor cells from various cancer patients were exposed to tissue relevant treatments, such as standard of care, targeted therapies, and immunomodulatory drugs. Endpoint analysis of fixed and stained material allowed for phenotypic measurement of responses such as tumor cell volume reduction, indicating cell killing, and more in-depth effects including growth arrest, and immune cell proliferation. Differential responses of tumor tissues to various classes of drugs targeting the tumor and/or the TME were demonstrated. In addition, validation of the various TME components for different cancers was confirmed. Using FACS, the presence of tumor cells accompanied by immune-profiling of the TME, including presence of tumor infiltrating lymphocytes, macrophages, and other immune cells was observed. Similarly, biomarker staining using IHC indicated the presence of tumor cells, fibroblasts, and various immune cell types. Cytokine measurement at experimental endpoint aligns with the measured responses of tumor reduction upon certain drug treatments.

Conclusions The 3D *ex vivo* patient tissue platform offers a rapid, reliable and patient-relevant approach to test preclinical drug candidates (e.g., antibodies, antibody-drug conjugates and small molecules) for different solid tumour types. It has the potential to significantly improve the preclinical evaluation of drugs and support the decision-making process during progression of drug candidates to the clinic.

200 **A UNIQUE CRISPR-BASED NUCLEASE WITH A NON-NGG PAM EFFICIENTLY TARGETS MULTIPLE EXCLUSIVE GENOMIC SITES FOR IMMUNO-ONCOLOGY BASED THERAPY**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0200

Rachel Diamant*, Lior Lior Izhar, Ira Gotliv, Yonit Ben David, Sigal Cohen, Maya Noff, Nir Shahar, Rafi Emmanuel, Bar Ben Baruch. *Emendo Biotherapeutics, Rehovot, Israel*

Background Chimeric antigen receptor (CAR)-T cell therapy is a recent clinically successful approach to tackling cancer, in which T cells are genetically modified to allow specific recognition and efficient killing of cancer cells via tumor associated antigens.[1] Current CAR-based treatments require costly and time-consuming autologous cell transfer. Patients' own cells are frequently of low quality and difficult to obtain, further supporting the advantage of an allogeneic transplantation. To prevent graft versus host reactions and avoid host-mediated rejection of healthy donor-derived allogeneic cells, these cells must be adjusted by eliminating the expression of endogenous recognition components, such as T cell receptor alpha constant (TRAC or TCR) and CD3, and of HLA class I molecules such as β-2 microglobulin (B2M).[2,3] In this study, we tested the feasibility of gene editing in allogeneic cells using our novel high-fidelity CRISPR-associated nuclease OMNIA4. OMNIA4 is a highly active nuclease with a unique non-NGG PAM recognition domain. The unique PAM allows gene-editing in exclusive genomic sequences that are not accessible by commonly used nucleases. Our strategy involves disrupting endogenous T cell recognition elements as well as checkpoint receptors and exhaustion genes that restrict anti-tumor T cell response.

Methods RNA guides (gRNAs) were designed for several of such genes of interest and their editing via OMNIA4 nuclease was evaluated by NGS in HeLa cells. Ribonucleoproteins (RNPs), including OMNIA4 and gRNAs designed to target distinctive sites in either TRAC, CD3e or B2M genes, were applied to primary T cells. The resulting editing outcome was evaluated by measuring T cell receptor (TCR), CD3e or B2M surface expression by flow cytometry. In addition, an unbiased analysis was performed to identify 'off-targets' edited by the nuclease.

Results Our gRNA screening yielded at least one (and up to five) active gRNA for each gene of interest, with editing level >70%. Flow cytometric analysis showed that editing in primary T cells resulted in about 94% TCR negative cells, about 85% CD3e negative cells and about 95% B2M negative cells. An unbiased assay revealed no off-targets for neither of the guides.

Conclusions These findings demonstrate efficient, accurate and safe impairment of a self-presenting element and endogenous T cell recognition components. Our approach offers gene editing at unique targets as a tool to generate universal allogeneic T cells that could be employed in the development of 'off-the-shelf' 'ready-to-use' CAR-T therapeutic agents for large-scale clinical applications.

201 DEVELOPMENT OF GUCY2C-TAC T CELLS FOR THE TREATMENT OF COLORECTAL CANCER

Tania Benatar*, Ling Wang, Thanyashanthi Nitya-Nootan, Heather MacGregor, Suzanna Prosser, Philbert IP, Prabha Lal, Stacey Xu, Laura Shaver, Sadhak Sengupta, Christopher Helsen, Andreas Bader. *Triumvira Immunologics, Inc., Hamilton, ON, Canada*

Background The T cell antigen coupler (TAC) is a novel, proprietary chimeric receptor that facilitates the re-direction of T cells to tumor cells and activates T cells by co-opting the endogenous T cell receptor complex with the goal to elicit safe and durable anti-tumor responses. TAC01-HER2, a first-in-class TAC T product targeting HER2 (ERBB2), has entered a phase I/II clinical trial in patients with HER2-positive solid tumors. Here, we present the development of a new TAC T product targeting guanylyl cyclase 2C (GUCY2C) to treat colorectal cancer. GUCY2C belongs to a family of membrane-bound mucosal guanylate cyclase receptors and is selectively expressed on the apical brush border of intestinal epithelia, a site inaccessible to T cells. In cancer, however, GUCY2C is frequently overexpressed in primary and metastatic colorectal carcinomas and, thus, a preferred antigen for the specific targeting of tumor cells via TAC T cells.

Methods GUCY2C-TAC receptor functionality was characterized using a variety of *in vitro* and *in vivo* assays. *In vitro* assays were based on flow cytometric analysis of TAC surface staining, CD69 upregulation and T cell proliferation. Cytotoxicity was assessed via real-time microscopy co-culture assays. *In vivo* studies examined the anti-tumor effect of TAC-engineered T-cells against established GUCY2C-expressing tumor xenografts.

Results The GUCY2C-TAC receptor showed strong surface expression and specific activation when co-cultured with a variety of cancer cells expressing GUCY2C *in vitro*. Upregulation of the activation-induced CD69 marker was comparable with levels induced by activated control TAC T cells. Proliferation of GUCY2C-TAC T cells was induced by co-culture with naturally expressing GUCY2C target cell lines as well as GUCY2C-engineered cell lines. *In vitro* cytotoxicity assay demonstrated a strong anti-GUCY2C response and killing of GUCY2C-expressing target cell lines. No increases in T cell activation, proliferation and no cytotoxicity were observed in non-transduced T cells and GUCY2C-TAC T cells co-cultured with GUCY2C-negative target cells, indicating that the T cell response is specific to the GUCY2C antigen. Intravenous administration of GUCY2C-TAC T cells in mice carrying GUCY2C -positive tumor xenografts led to a sustained anti-tumor response.

Conclusions The *in vitro* and *in vivo* data confirm strong and specific activity of GUCY2C-targeted TAC T cells against GUCY2C-expressing tumor models and highlight the versatility of the TAC platform for therapeutic applications in solid tumors.

Ethics Approval AUP number 20–10–37, approved by McMaster University's Animal Research Ethics Board.

202 SINGLE STEP KNOCK-IN OF NEXT GENERATION INDUCIBLE IL-12 ARMORED CAR T CONSTRUCTS

Alexander Benton*, Anze Smole, Mathilde Poussin, Monika Eiva, Daniel Powell. *University of Pennsylvania, Philadelphia, PA, USA*

Background While CAR-T cell cancer immunotherapy has been successful in treating hematological malignancies, there have been significant difficulties in adapting these therapies for the treatment of solid tumors. Several factors are responsible for this challenge including increased tumor burden, immunosuppression in the tumor microenvironment, and heterogeneity of tumor associated antigens. Various approaches have been developed to address these challenges, including endowment of CAR T cells with expression of accessory molecules that enhance their function, such as IL-12, to make "armored CARs". These approaches currently rely on constitutive IL-12 expression, or in case of inducible systems, use of multiple viral vectors, resulting in unregulated delivery or product heterogeneity respectively. Either of these methods can add significant risk of poor activity or toxicity.

Methods To resolve these issues, we developed genetic systems that combine antigen-induced production of an accessory molecule via a synthetic nuclear factor of activated T cells (NFAT) promoter, along with constitutive CAR expression, in a single lentiviral vector referred to as Uni-Vect. We demonstrate the therapeutic application of Uni-Vect *in vivo* by transient activation-dependent expression of IL-12 in an ovarian cancer model. In a previous clinical trial tumor infiltrating-lymphocytes engineered with NFAT inducible IL-12 expression were tested and clinical activity was observed.[1] However, severe toxicity accompanied by high serum levels of IL-12 and IFN-γ limited further development. We address this challenge by eliminating endogenous TCR-driven activation, which may lead to triggering of undesired NFAT-inducible IL-12 expression. Further, we utilize a genome-editing approach with homology-directed repair as a means of gene integration, to achieve single-step generation of TCR disrupted-inducible IL-12 armored CAR T cells.

Results We compare the Uni-Vect platform to standard methods for armoring CAR-T cells and demonstrate enhanced control over accessory molecule expression *in vitro*. Further, we demonstrate the functionality of our lentiviral and knock-in products in our *in vitro* and *in vivo* models of ovarian cancer. We found that knock-in inducible IL-12 CAR T cells were able to eliminate tumors in all mice while avoiding lethal toxicity due to dysregulated T cell activation.

Conclusions We demonstrate the feasibility of non-viral knock-in of large Uni-Vect constructs that share the benefits if inducible armoring and gene disruption. The modular Uni-Vect platform will set a foundation for potent next generation CAR T cellular products. Our added safety layers and an optimized manufacturing process will support clinical translation for patients with ovarian cancer and beyond.

203 PRECLINICAL DISCOVERY AND CHARACTERIZATION OF ALLOGENEIC ANTI-PSMA γδ CAR T THERAPY FOR PROSTATE CANCER

Nitya Ramadoss*, Aruna Azameera, Alexander Teague, Jonathan Wong, Atrish Bagchi, Tonya Capillo, Morgan Smith-Boeck, Michael Salum, Erika Meaddough, Elizabeth Speltz, Matthew Hoopes, Katherine Wang, Ramandeep Kaur, Smitha Gundurao, Marissa Herrman, Yvan Chanthery, Blake Aftab, Kevin Nishimoto, Arun Bhat. *Adicet Bio, Inc., Redwood City, CA, USA*

Background Prostate-specific membrane antigen (PSMA) is a transmembrane glycosylated homodimer overexpressed in >80% of prostate cancers. PSMA expression is increased in advanced stages of the disease, making it an attractive therapeutic target. Clinically, autologous anti-PSMA αβ CAR T cells have shown initial efficacy with significant CRS-like dose-limiting toxicities. Compared to αβ T cells and other innate cells, γδ T cells are associated with multifunctional innate and adaptive targeting and differentiated biodistribution into tumor-associated tissues. Additionally, γδ CAR T cells have demonstrated enhanced tumoricidal activity and tailored activation-induced cytokine profiles that may decrease toxicities associated with CRS. We characterized γδ T cells modified from a set of novel scFv-based CARs targeting PSMA for prostate cancer.

Methods We used phage panning to identify a library of anti-PSMA scFv sequences, which were reformatted into CARs in VH-VL and VL-VH orientations and screened in Jurkat-Lucia™ NFAT cells to assess CAR expression and activation in the context of target cell-based stimulation. We transduced a set of functional CARs into Vδ1 T cells, a primarily tissue-resident subset, activated and expanded from healthy donor PBMCs. We performed *in vitro* cell-based cytotoxicity assays and phenotypic assessments of CAR Vδ1 T cells using flow cytometry. Potency was also assessed in NSG mice bearing subcutaneous PSMA-expressing xenografts.

Results Anti-PSMA scFvs ranged in apparent affinities from the low nanomolar to the sub-micromolar range. CAR-expressing Jurkat cells showed target-specific NFAT activation and low tonicity. CAR-engineered Vδ1 T cells demonstrated robust expansion, *in vitro* cytotoxicity and antigen-specific proliferation against $PSMA^+$ cell lines in a manner comparable to, or greater than, J591 scFv-based Vδ1 CAR. *In vitro* potency correlated with the release of multiple effector cytokines. Notably, IL-6 and IL-10 production by anti-PSMA Vδ1 CAR T cells was negligible, while TNFα production was low, further supporting the potential of the γδ CAR T platform to demonstrate a favorable cytokine-associated safety profile. Anti-PSMA Vδ1 CAR T cells were also found to be predominantly naïve, with low levels of exhaustion marker expression. Additionally, *in vitro* (figure 1) and *in vivo* (figure 2) potency of anti-PSMA Vδ1 CAR T cells was investigated upon co-expression of dominant negative TGFβRII (dnTGFβRII). In xenograft models, anti-PSMA Vδ1 CAR T cells demonstrated potent anti-tumor efficacy.

Conclusions We have engineered, screened and demonstrated preclinical efficacy for "off-the-shelf" PSMA-targeting γδ CAR T cells. Resulting γδ CAR T constructs identified here are candidates for further preclinical and clinical development in the context of armoring technologies.

Ethics Approval All mouse experiments were performed in accordance with the Guide for the Care and Use of Laboratory Animals and followed all institutional and national guidelines with appropriate protocol review and approval.

204 **COMBINING FT536, A PAN-TUMOR TARGETING CAR NK CELL THERAPY, WITH CD16 ENGAGERS PROVIDES A COORDINATED TARGETING STRATEGY TO OVERCOME TUMOR HETEROGENEITY**

[1]John Goulding*, [1]Bryan Hancock, [1]Robert Blum, [1]Wen-I Yeh, [1]Chia-Wei Chang, [1]Mochtar Pribadi, [1]Yijia Pan, [1]Hui-Yi Chu, [1]Shohreh Sikaroodi, [1]Thomas Dailey, [1]Miguel Meza, [2]Lucas Ferrari de Andrade, [1]Peter Szabo, [1]Sarah Cooley, [1]Jeffrey Chou, [3]John Powderly, [1]Yu-Waye Chu, [1]Tom Lee, [1]Ryan Bjordahl, [4]Kai Wucherpfennig, [1]Bob Valamehr. *[1]Fate Therapeutics, San Diego, CA, USA; [2]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [3]Caroline BioOncology Institute, Huntersville, NC, USA; [4]Dana Farber Cancer Institute, Boston, MA, USA*

Background The hurdles of tumor antigen heterogeneity, a paucity of tumor-specific antigens, and pervasive immune evasion remain as significant challenges to the successful development of solid tumor immunotherapies. Despite clinical success against hematological malignancies, broader clinical application and efficacy of autologous chimeric antigen receptor (CAR)-T cell therapy remains limited. To remedy these intrinsic challenges, CAR-T cell therapy, immune checkpoint inhibition, and bi-specific engagers are being utilized in combination to extend their therapeutic application to solid tumors.

Methods We have previously presented FT536, a multiplex-engineered clonal master induced pluripotent stem cell (iPSC)-derived NK cell product candidate that incorporates a novel CAR targeting the pan-tumor associated MICA and MICB (MICA/B) stress proteins (3MICA/B CAR). FT536 has been shown to overcome multiple tumor immune evasion mechanisms, to elicit significant and broad CAR-mediated anti-tumor cytotoxic effector function, and to provide multi-antigen targeting capability through expression of a high-affinity, non-cleavable CD16 (hnCD16) Fc receptor.

Results In addition to innate cytotoxicity and MICA/B-specific activity against multiple solid tumor targets, we here demonstrate that the combination of FT536 with multiple Fc receptor engagers results in potent ADCC as well as CAR activity. ADCC was established using monoclonal antibodies (mAbs) targeting EGFR and HER2, a bi-specific c-met/EGFR mAb (amivantimab), and bi-specific NK cell engagers. Combining FT536 with conventional mAbs,bi-specific mAbs such as amivantamab, and/or bispecific NK cell engagers provides additional non-clinical evidence that multi-antigen-specific tumor targeting affords potent cytotoxicity responses in preclinical models that recapitulate patient tumor heterogeneity and antigen expression variation. We hypothesize that multi-antigen targeting of solid tumors could provide a novel approach to minimize antigen selection and immune escape.

Conclusions To assess the clinical translation potency of multi-antigen targeting and combinatorial therapeutic application of FT536 in humans, a phase I first-in-human, dose-escalation clinical study of FT536 as monotherapy and in combination with tumor-targeting mAb therapy, including amivantamab, for the treatment of multiple solid tumor indications was designed and is currently enrolling (NCT05395052).

205 **SPECIFIC AMPK AGONISM DURING CART *IN VITRO* EXPANSION ENHANCES OXIDATIVE METABOLISM AND IMPROVES *IN VIVO* LEUKEMIA CLEARANCE**

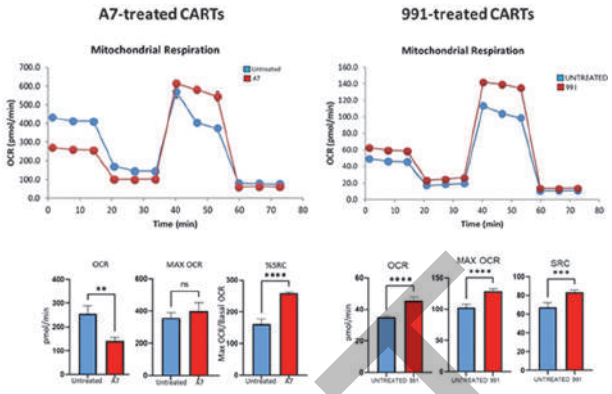
Erica Braverman*, Harrison Brown, Manda Ramsey, Craig Byersdorfer. *University of Pittsburgh, Pittsburgh, PA, USA*

Background While chimeric antigen receptor (CAR)T therapy has seen great success in pediatric leukemia, relapses continue to occur in up to 1/3 of patients.[1] CART persistence *in vivo* correlates with ongoing remission, and promoting oxidative metabolism and mitochondrial health during *in vitro* expansion creates more functional and persistent CARTs *in vivo*.[2] AMP-activated protein kinase (AMPK) is a cellular energy sensor with prominent roles in mitochondrial health and biogenesis.[3] We hypothesized that promoting AMPK activity during CART expansion would enhance mitochondrial metabolism, leading to improved anti-leukemia clearance *in vivo*.

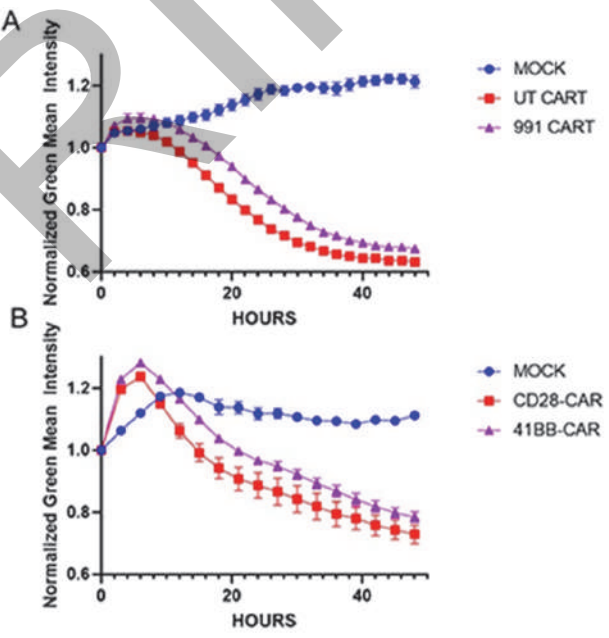
Methods Healthy human T cells underwent lentiviral transduction with a CD19-targeting CAR containing the CD28 costimulatory domain. Transduced CARTs were expanded in complete media supplemented with IL2 and either AMPK agonist Compound 991 (991), AMPK agonist A769662 (A7), or DMSO (control). After expansion, cells were assessed for metabolic function *in vitro* using the Seahorse Metabolic Analyzer. *In vitro* cytotoxicity against NALM6 targets expressing zzGreen was measured by monitoring mean fluorescence intensity using the Incucyte. For *in vivo* studies, NSG mice were injected on Day -7 with luciferase+ NALM6 leukemia cells followed by CARTs +/- agonist on Day 0, with luminescence followed weekly by IVIS imaging.

Results 991 treatment enhanced CART oxidative metabolism over DMSO-treated controls, while A7 treatment significantly reduced initial oxygen consumption, leading to 991 treatment being chosen for further study (figure 1). Despite this potential metabolic advantage, 991-treated CARTs showed reduced *in vitro* cytotoxicity against NALM6 targets compared to DMSO-treated controls, which interestingly mimicked the cytotoxicity advantage of CD28-costimulated CARTs compared to 41BB-costimulated CARTs (figure 2). Given 41BB-CARTs show enhanced persistence over CD28-CARTs *in vivo* (2), we pursued further *in vivo* studies with our agonist-treated CARTs. Indeed, despite the slower killing *in vitro*, 991-treated CARTs outperformed the DMSO-treated control CARTs *in vivo*, with significantly reduced luminescence by IVIS imaging and improved overall survival (figure 3).

Conclusions AMPK agonism during *in vitro* expansion of CARTs with 991, but not A7, creates metabolically desirable CARTs for immunotherapy. This was demonstrated by increased oxidative metabolism after expansion *in vitro* and improved leukemia clearance *in vivo*. However, anti-leukemia activity appeared decreased with *in vitro* assessments. These studies identify AMPK as an attractive target in immunotherapy, with attention paid to how this pathway is activated, and also suggest the potentially limited utility in using *in vitro* cytotoxicity as a predictor of *in vivo* function in leukemia.



Abstract 205 Figure 1 991 treatment, but not A7 treatment, enhances CART cell oxidative metabolism. Human CART cells were generated from healthy human donor T cells through lentiviral transduction, and then expanded in either DMSO (untreated), A769662 (A7), or Compound 991 (991). CARTs then underwent restimulation overnight before assessment utilizing the mitostress kit for the Seahorse Metabolic Analyzer. ** p<0.01, *** p<0.001, **** p<0.0001



Abstract 205 Figure 2 AMPK-agonist treated CARTs show decreased cytotoxicity vs untreated CARTs in vitro, which is mimicked by the cytotoxicity of 41BB vs CD28 CARTs. (A) CD28-costimulated CARTs were generated and expanded with or without 991. After expansion, cells were placed in the Incucyte against zzGreen+NALM6 targets, with green fluorescence followed to measure cell killing over 48 hours. (B) The experiment was repeated using CD28-costimulated and 41BB-costimulated CARTs. In both experiments, mock transduced human T cells were plated against NALM6 targets as a control.

NOVEL INTERMEDIATE-AVIDITY GLYPICAN-3 SPECIFIC CARTS RESIST EXHAUSTION AND MEDIATE DURABLE ANTITUMOR EFFECTS AGAINST HUMAN HEPATOCELLULAR CARCINOMA

[1]Leidy Caraballo-Galva, [1]Xiaotao Jiang, [1]Mohamed Hussein, [2]Huajun Zhang, [1]Rui Mao, [1]Pierce Brody, [1]Yibing Peng, [3]Alwu He, [1]Mercy Kehinde-Ige, [1]Ramses Sadek, [2]Xiangguo Qiu, [1]Huidong Shi, [1]Yukai He*. [1]*Augusta University, Augusta, GA, USA*; [2]*University of Manitoba, Winnipeg, Canada*; [3]*Georgetown University, Washington DC, USA*

Background Despite intensive effort, current chimeric antigen receptor modified T cells (CARTs) do not work well for solid tumors. In blood cancers, CARTs easily access to target cells and can "take a break" after each killing of individual tumor cells. In contrast, solid tumor mass limits CART infiltration and create a persistent and multi-dimensional engagement between CART and tumor cells. After CARTs manage infiltrate into tumor mass, they are surrounded by tumor cells, and their movement is further restrained by tumor stroma matrix, which force them under constant stimulation and drive them into exhaustion and death. Conventionally, most CARTs are built from high-affinity monoclonal antibodies (mAb). While such high-avidity CARTs may detect and kill tumor cells of low antigen, they are more prone to exhaustion and death in solid tumors. The aims of this study is to develop proper intermediate-affinity mAbs and intermediate-avidity CARTs for hepatocellular carcinoma (HCC), the 3rd leading cause of cancer death and to test the hypothesis that intermediate-avidity CARTs can resist exhaustion and apoptosis and maintain functions in solid tumors, generating more durable antitumor effects.

Methods We developed 3 new human glypican-3 (hGPC3)-specific mAbs from immunized mice. The mAbs only stained HCC tumors, but not the adjacent normal liver tissues. One of them, 8F8, bound an epitope close to that of GC33, the frequently used high-affinity mAb, but with ~17 fold lower affinity. We then built and compared the intermediate-avidity 8F8 CARTs to high-avidity GC33 CARTs for their *in vitro* function and antitumor effects (1).

Results *In vitro*, 8F8 CARTs killed both hGPC3^{high} and hGPC3^{low} HCC cells to the same extent as GC33 CARTs, but produced lower cytokines. However, the expansion of 8F8 CARTs was 3-5 folds more than GC33 CARTs after engaging with target cells. 8F8 CARTs were less exhausted and less apoptotic than high-avidity GC33 CARTs. The expansion advantage of 8F8 CARts was maintained under hypoxia culture condition. Importantly, the 8F8 CARTs also expanded and persisted to a greater extent than GC33 CARTs *in vivo*, resulting in durable responses against HCC xenografts. Compared to GC33 CARTs, there were 5 folds more 8F8-BBz CARTs in the tumor mass for a longer period of time (figure 1). Remarkably, the tumor infiltrating 8F8 CARTs were much less exhausted and apoptotic, and more functional than GC33 CARTs.

Conclusions The novel intermediate-avidity 8F8-BBz CART resists exhaustion and apoptosis inside solid tumors, demonstrating a greater and durable therapeutic potential than high-avidity CARTs.

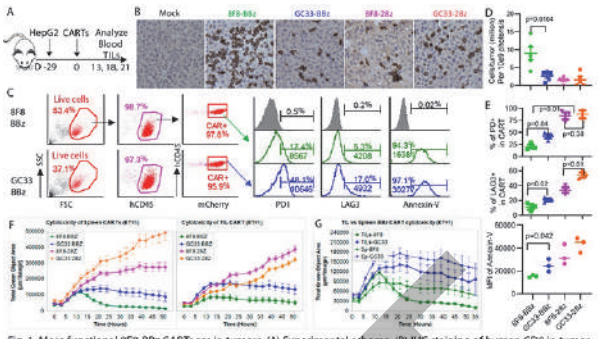

Fig. 1. More functional 8F8-BBz CARTs are in tumors. (A) Experimental scheme. (B) IHC staining of human CD8 in tumor. (C) Gating strategy of analyzing TIL CART's exhaustion and apoptosis. (D) CART number was calculated by dividing the total CARTs in the single cell suspension of each tumor by tumor BLI. (E) A summary of the % of PD1+, LAG3+, and MFI of Annexin-V on CARTs. (F) 8F8 CARTs have stronger cytotoxicity than GC33 CARTs, and BBz CARTs have better function than 28z CARTs. (G) BBz CARTs in the spleen had better function than BBz CARTs in the tumor.

207 CLAUDIN18.2-TARGETING CAB-T CELLS HAVE SUPERIOR SAFETY OVER TRADITIONAL CAR-T, WHILE MAINTAINING POTENT *IN VIVO* ANTI-TUMOR EFFICACY

[1]Jitian Chai, [1]Weifeng Huang, [1]Shaogang Peng, [1]Zhenqing Zhang, [2]Yao Yan, [2]Chuan-Chu Chou*, [2]Andy Tsun, [1]Zhiyuan Li. [1]*Biotheus (Suzhou) Co., Ltd., Suzhou, China*; [2]*Biotheus Inc., Zhuhai, China*

Background We have developed a proprietary T cell-based anti-CD3 T cell engager delivery platform (named CAB-T), which includes two elements: a chimeric CD3e/signaling component and a CD3-based bispecific T cell engager (TCE). We have previously shown the efficacy *vs.* safety advantages of the CAB-T system over a traditional second-generation CAR-T format by targeting claudin18.2 (CLDN18.2) (poster no. 206, SITC2021). However, a comprehensive comparison between CAB-T *vs.* CAR-T had not been investigated. Here, in multiple independent *in vivo* tumor mouse models, we aimed to assess the safety and efficacy of our CAB-T platform using CLDN18.2-CAB-T cells.

Methods A sequence encoding for an anti-human CLDN18.2 scFv was engineered into CAB-T (CLDN18.2-CAB-T) and CAR-T (CLDN18.2-CAR-T) expression systems and generated via lentiviral transduction of T cells followed by cell expansion. Cytokine release and TCE levels were determined by ELISA and a cytometric bead array, while T cell killing was tested by the detection of LDH release. *In vivo* studies using CLDN18.2+ tumor cells were tested in humanized mouse models (NCG or NOG mice). T cell infiltration into tumors or normal gastric tissue were detected by immunohistochemistry with an anti-FLAG antibody.

Results Both CLDN18.2-targeting CAB-T and CAR-T cells displayed excellent dose-dependent *in vivo* anti-tumor efficacy towards CLDN18.2-positive tumor cells. However, CLDN18.2-CAB-T cells had a superior safety profile over its CAR-T equivalent. More specifically, mid (1 x 10^6 cells) to high (5 x 10^6 cells) single doses of CLDN18.2-CAR-T cells were lethal to mice, whereas all the dose levels of CAB-T cells were safe. CLDN18.2-CAB-T cells released less inflammatory cytokines than CLDN18.2-CAR-T, including IL-6, TNFα and IL-2, in *in vitro* co-culture assays with NUGC4 tumor cell targets. Mice treated with CLDN18.2-CAB-T also showed higher levels of serum GM-CSF and IFNγ compared to those treated with CLDN18.2-CAR-T. Meanwhile, CLDN18.2-CAR-T induced severe immune cell infiltration in normal gastric tissue, whereas CLDN18.2-CAB-T did not. This suggests that CAB-T may provide a wider therapeutic dosing window than traditional CAR-T platforms.

Conclusions We show that CLDN18.2-CAB-T has superior safety traits over CLDN18.2-CAR-T while maintaining high levels of *in vivo* anti-tumor efficacy, suggesting that CAB-T cells may offer better safety for patients in the clinic. CLDN18.2-CAB-T is currently undergoing an investigator-initiated trial to test its safety and efficacy for subjects with CLDN18.2+ solid tumors.

Ethics Approval All mice were maintained under specified pathogen-free conditions, and all studies were approved by the Animal Care and Use Committee of HUST-Suzhou Institute for Brainsmatics.

208 **T-SIGN VECTOR-MEDIATED ANTIGEN "SPRAY PAINTING" AND TUMOR MICROENVIRONMENT (TME) REPROGRAMMING TO ENABLE CAR-T CELL TARGETING OF SOLID TUMORS**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0208

Maria Stella Sasso, Rachel Bergin, Manuela Zonca, Eva Vainiute, Tae Hyun Jang, Zahra Oubihi, Meg Snowden, Alice Muntzer, Carla Cerqueira, Rochelle Lear, Katy West, Brian Champion*. *PsOxus Therapeutics Ltd, Abingdon, UK*

Background Multiple barriers in the tumor microenvironment (TME) have hampered development of CAR-T cell therapies for solid tumors. These challenges include an immunosuppressive TME, poor trafficking of CAR-T cells to the tumor and shortage of highly expressed tumor-specific antigens. We recently demonstrated that Tumor-Specific Immuno-Gene (T-SIGn) viral vectors encoding immunostimulatory cytokines, costimulators and chemokines can reprogram the TME towards a pro-inflammatory phenotype resulting in a markedly increased therapeutic efficacy of CAR-T cells in a A549 human tumor xenograft and lung metastasis model.[1] Here we further explored the potential of the T-SIGn platform in combination with CAR-T cell therapy by developing and characterizing a T-SIGn viral vector that simultaneously expresses immunostimulatory cytokines/chemokines and a secreted bispecific protein incorporating a CAR-T cell target antigen. This secreted ligand binds to ("spray paints") tumor cells to enable recognition by CAR-T cells.

Methods We used a T-SIGn virus (NG-1125) expressing a secreted anti-HER2-CD19 fusion protein (saH2-19), as a model "spray paint" antigen, encoded together with IFNa and CXCL9 as example cytokine/chemokines. *In vitro*, human tumor cell lines were used to assess the ability of T-SIGn viruses to induce tumor-specific expression and activity of saH2-19 as CAR-T cell target antigen. We quantified T-SIGn vector-encoded CD19 expression on tumor cell surfaces using flow cytometry and CAR-T mediated killing via xCELLigence. *In vivo*, expression of CD19 fusion protein and transferred CD19 CAR-T cells in tumors were assessed by flow cytometry analysis and immunohistochemistry of A549 tumor xenografts.

Results Using *in vitro* human cell culture models, the NG-1125 vector led to efficient expression of saH2-19 on tumor cell surfaces, both on vector-infected and non-infected or non-permissive cells. This enabled effective antigen-specific tumor cytotoxicity by CD19-specific CAR-T cells. Using an *in vivo* human A549 lung tumor xenograft model adoptively transferred with human CD19-specific CAR-T cells, NG-1125 induced tumor-specific CD19 expression on both vector infected and non-infected cells (demonstrating antigen "spray painting") together with accumulation of activated T cells. This accumulation of T cells was not seen with a vector only expressing the saH2-19 transgene.

Conclusions Together, our data provide a proof of concept that T-SIGn vectors can be designed to deliver TME-modifying immunomodulators together with "spray paint" antigens that effectively enable tumor cell recognition and destruction by CAR-T cells specific for target antigens not endogenously expressed by tumors. Further studies are exploring the full potential of this "spray painting" approach to enable CAR-T cell therapy for of solid tumors.

209 ANTI-ALPP CAR-T CELL IMMUNOTHERAPY FOR OVARIAN AND ENDOMETRIAL CANCER

[1]Si Li*, [2]Qi-Jing Li, [1]Nicole Palmer, [1]Johnny Guan, [3]Zhenbo Su, [1]Peter Alexander, [1]Rui Chen, [1]Lixia Zhao. *[1]TCRCure Biopharma Corp., Los Angeles, CA, USA; [2]A*STAR, Proteos, Singapore; [3]Guangdong TCRCure Biopharma Technology C, Guangzhou, China*

Background Ovarian and endometrial cancers are commonly occurring cancers in women with very limited treatment options for relapse and metastasis. While immune checkpoint inhibitors have generated unprecedented responses in certain other cancer types, results from early attempts in ovarian and endometrial cancers have been suboptimal. To develop a CAR-T therapy against these cancers, multi-omics data mining identified ALPP (alkaline phosphatase, placental), a cell surface protein with expression restricted to female reproductive tissues, as a potential target.

Methods To validate its tumor-specific expression, immunohistochemical arrays were performed to assess cell surface display of ALPP in normal and cancerous tissues. An anti-ALPP CAR (TC-A101) was developed and validated for its targeting specificity against multiple ALP homologs, as well as its killing efficacy in vitro. The pre-clinical efficacy of TC-A101 was validated in an animal model of ovarian cancer peritoneal metastasis. The CAR structure was further optimized through alternative hinge and transmembrane domains for lower tonic signaling and better stability of CAR expression.

Results Preclinical models demonstrate that TC-A101 T cells specifically recognize and kill ALPP-expressing tumor targets, and their administration significantly reduces tumor burdens and extends the survival of mice bearing metastatic SiHa tumors and ascites. CAR structure optimization, particularly incorporating a CD28 hinge domain (TC-A103), further potentiates CAR-T cells with stabilized CAR surface expression, lowered tonic signaling, and augmented antitumor efficacy.

Conclusions The preclinical findings reported here indicate that ALPP could be a good target and anti-ALPP CAR-T cell immunotherapy is potentially safe and efficacious against female reproductive cancers expressing ALPP.

Ethics Approval All in vivo experiments in this study were conducted according to guidelines under a protocol approved by Mispro Biotech Services Institutional Animal Care and Use Committee.

210 GENERATION OF HYPOIMMUNOGENIC ALLOGENEIC CAR T CELLS BY INACTIVATION OF TRANSCRIPTIONAL REGULATORS OF HLA CLASS I AND II GENES

Hsinyuan Cheng*, Michael Yi, Michael Bethune, Eric Gschweng, Melinda Au, Duy Nguyen, Kristen Zhang, Tanu Shenoy, Barbra Sasu, Thomas Van Blarcom, Cesar Sommer. *Allogene Therapeutics, South San Francisco, CA, USA*

Background Autologous CAR T cell therapies have revolutionized the treatment landscape in hematological malignancies. Using the patient's own T cells for manufacturing, however, poses limitations on the widespread use of these therapies. Off-the-shelf allogeneic CAR T cells could potentially address these issues by using healthy donor T cells as starting material, consistency of product, immediate availability, and cost and convenience of scalable manufacturing. However, expansion and persistence of infused allogeneic CAR T cells may be limited by immune rejection. Immune "cloaking" strategies centered on deletion of β2-microglobulin can avoid rejection by CD8 T cells but may elicit strong NK cell rejection. Moreover, HLA Class II expression can be induced upon T cell activation to increase the risk of CD4 T cell rejection. Here, we propose an alternative approach to immune evasion by selectively targeting NLRC5 and RFX5, transcriptional regulators controlling expression of HLA molecules.

Methods CRISPR/Cas9 technology was used to knockout NLRC5, RFX5, B2M, CIITA, and/or TRAC. Survival of hypoimmunogenic cells was assessed in mixed lymphocyte reaction (MLR) assays with allogeneic T cells, NK cells, or PBMCs. For in vivo evaluation, mice were engrafted with human T cells and Raji tumor cells followed by administration of hypoimmunogenic CD19 CAR T cells, and CAR T cell persistence and tumor growth were monitored over time.

Results Deletion of NLRC5 and RFX5 resulted in substantial and stable downmodulation, but not complete ablation, of HLA Class I expression. RFX5 KO cells also exhibited downregulation of HLA Class II expression. NLRC5 KO and RFX5 KO T cells showed enhanced survival against allogeneic T cells but elicited only minor NK cell reactivity. When co-cultured with HLA-mismatched PBMCs, NLRC5 KO and RFX5 KO cells effectively mitigated rejection, whereas uncloaked control and B2M KO cells were eliminated by allogeneic T and NK cells, respectively. These findings were replicated in T cells expressing a CD19 CAR. Inactivation of NLRC5 or RFX5 did not impact CAR T cell phenotype or cytotoxic activity. In vivo, hypoimmunogenic CAR T cells demonstrated superior persistence and antitumor efficacy compared to uncloaked control CAR T cells in the presence of allogeneic T cells.

Conclusions Hypoimmunogenic CAR T cells can be successfully generated by targeted deletion of NLRC5 or RFX5, which reduces T cell rejection without triggering substantial NK cell rejection and does not affect CAR T cell function. The improved persistence of hypoimmunogenic allogeneic CAR T cells may increase the therapeutic efficacy of off-the-shelf products.

211 CHEMICAL PRIMING OF NATURAL KILLER CELLS FOR CANCER IMMUNOTHERAPY

Seung Hee Choi*, Eun-Su Ko, Joo Dong Park, Kyung-Soon Park. *CHA University, Seongnam, Republic of Korea*

Background Due to their powerful immune surveillance activity and ability to kill and clear cancer cells, natural killer (NK) cells are an emerging anticancer immunotherapeutic agent.[1,2] Therefore, there is much interest in developing efficient technologies that further enhance the therapeutic antitumor efficacy of NK cells. One of these technologies is a priming strategy that pre-activates NK cells using a cytokine cocktail or cancer cell lysates.[3,4]

Methods Chem_NK refers to ex vivo NK92MI or primary NK cells that have been chemically primed by 25KDa branched polyethylenimine (25KbPEI). The priming activity of 25KbPEI was evaluated by receptor expression, perforin accumulation, chemotaxis and the antitumor efficacy of Chem_NK. The priming mechanism was studied regarding 25KbPEI mediated calcium influx and subsequent activation of multiple signaling pathways.

Results Chem_NK showed increased perforin accumulation, interferon-γ expression and activating/adhesion/chemokine related receptor expression. In line with these phenotypes, Chem_NK had potent in vivo antitumor efficacy toward ovarian cancers and triple negative breast cancers. The major mechanism for 25KbPEI to prime NK cells was identified as a calcium influx via the Ca^{2+}-permeable nonselective cation channel transient receptor potential melastatin 2 (TRPM2). We confirmed that 25KbPEI mediated calcium-influx is associated with activation of ERK and mTOR signaling, which is directly linked to the translational initiation of immune response-related proteins of NK cells (figure 1).

Conclusions NK cells can be chemically primed with 25KbPEI to become 'ready to fight' state. Because PEI is a biocompatible and FDA-approved chemical for biomedical use, our results suggest a cost-effective and simple method of producing therapeutic NK cells.

212 ADOPTIVELY TRANSFERRED TH17 CELLS COOPERATE WITH HOST B CELLS TO MEDIATE ROBUST IMMUNITY TO TUMORS

[1]Anna Cole*, [2]Hannah Knochelmann, [3]Amalia Rivera-Reyes, [4]Aubrey Smith, [1]Megan Wyatt, [2]Guillermo Rangel RIvera, [1]Jeremy Boss, [1]Gregory Lesinski, [1]Chrystal Paulos. *[1]Emory University, Atlanta, GA, USA; [2]Medical University of South Carolina, Charleston, SC, USA; [3]University of Colorado, Aurora, CO, USA; [4]Orange Grove Bio, Cincinnati, OH, USA*

Background Adoptive T cell transfer therapy mediates potent immunity in some patients with aggressive malignancies, but many individuals do not respond, or may relapse. One reason for therapy failure is due to lack of T cell persistence. To overcome this problem, we aimed to generate a cell product that will lead to long term antitumor immunity in aggressive models. Accordingly, our team reported that a subset of $CD4^+$ T cells termed Th17 cells, persist long term and can eradicate solid tumors when infused into mice. However, how Th17 cells mediate tumor immunity is unclear.

Methods To model Th17 cell adoptive T cell transfer therapy, we use a transgenic mouse model in which $CD4^+$ cells express a T cell receptor (TCR) that recognizes tyrosinase-related protein 1 (TRP-1) expressed on melanoma, and polarized naïve $CD4^+$ T cell to Th17 cells. These cells are infused into mice bearing B16F10 melanoma tumors that received non-myeloablative lymphodepleting total body irradiation. Tumor growth is measured over time or tumors, spleen, and lymph nodes are analyzed 12 days post cell transfer.

Results To understand how Th17 cells elicit robust antitumor activity, we performed an unbiased analysis of RNA transcripts on tumor-draining lymph nodes of mice treated with Th17 cells. Surprisingly, we found that mice infused with anti-tumor Th17 cells have increased transcripts associated with B cells, and factors that trigger B cell maturation, antibody-secretion, and enhanced antigen presentation. Furthermore, host B cells, but not $CD8^+$ T cells, were surprisingly critical in sustaining long-term immunity, as their depletion significantly impaired survival. B cells enhance Th17 cell persistence and promote their differentiation into IFN-g producers and away from regulatory IL-10 production. Th17 cells induce B cell activation and maturation in an IL-21-dependent manner, causing the production of class switched antibodies which can alone partially protect against tumor challenge. Finally, we found that IL-21, ICOS, and IFN-g are required for this antitumor response as inhibition of any of these three abrogates durable tumor immunity.

Conclusions Altogether, this suggests a cooperative relationship between transferred Th17 cells and host B cells in mediating long term tumor immunity. Our novel findings highlight Th17 cell therapy as a way to harness both T and B cell responses against cancer. Ongoing experiments will further determine the mechanism of how B cells collaborate with Th17 cells to mediate superior antitumor activity.

213 DESIGN, CHARACTERIZATION AND PRECLINICAL VALIDATION OF A COMBINATORIAL CAR-BASED IMMUNOTHERAPY AGAINST COLORECTAL CANCER WITH HER2 AMPLIFICATION

[1]Marco Cortese*, [2]Erica Torchiaro, [2]Simonetta Leto, [2]Consalvo Petti, Alice D'Andrea, [2]Master Degree, [2]Federica Invrea, [1]Sabrina Arena, [1]Enzo Medico. *[1]University of Turin, Turin, Italy*; *[2]Candiolo Cancer Center, Turin, Italy*

Background Adoptive immunotherapy based on chimeric antigen receptor (CAR)-T cells has led to successful treatment of different hematological malignancies. However, it remains extremely challenging for solid tumors, mostly because of "on-target off-tumour" toxicity, as observed in the case of anti-HER2 CAR-T treatment of HER2-amplified colorectal cancer ($HER2_{amp}$ CRC).[1] To enable adoptive immunotherapy against $HER2_{amp}$ CRC, we therefore considered a combinatorial strategy based on the synNotch-based artificial regulatory network. A synthetic Notch receptor including anti-HER2 scFv as extracellular domain and the GAL4-VP64 artificial transcription factor as intracellular domain was employed.[2] Engagement of the anti-HER2 domain by target cells drives GAL4-VP64 cleavage and translocation to the nucleus, leading to the expression of a CAR under a GAL4-responsive promoter. In this way, only cells co-expressing both HER2 and the CAR target are killed. As a CRC-specific CAR target we selected CEA, product of the CEACAM5 gene. CEA expression is restricted to the digestive tract and is increased in cancer.

Methods For the generation of HER2-synNotch CEA-CAR effectors, we chose the natural killer cell line NK-92 and transduced it with two lentiviral vectors, encoding respectively the HER2 synNotch and the second-generation anti-CEA CAR with CD28 costimulatory domain.Transduced cells were repeatedly sorted in the ON and OFF state to select those with the best CAR induction after synNotch engagement; cloning of sorted cells led to identification of an optimally responsive clone (clone 5F).

Results *In vitro*, the 5F clone showed no basal CEA-CAR expression and massive induction in the presence of $HER2_{amp}$ cancer cells. It also displayed selective cytotoxicity against $HER2_{amp}/CEA_{pos}$ CRC cells, with minimal killing activity against $HER2_{amp}/CEA_{neg}$ breast cancer cells, or against CRC cells expressing CEA but without HER2 amplification. In vitro 3D models highlighted better recruitment and infiltration by clone 5F respect to NK-92 WT cells, only of $HER2_{amp}$ organoids. *In vivo*, the clone 5F significantly impaired tumor growth in two different $HER2_{amp}$ CRC models.

Conclusions The observed selective efficacy both in vitro and in vivo of the HER2-synNotch/CEA-CAR approach opens a perspective for possible clinical applications for $HER2_{amp}$ CRC displaying primary or secondary resistance to HER2/EGFR blockade.

214 INVESTIGATING THE CONSEQUENCES OF TIM-3 EXPRESSION ON MTOR ACTIVATION AND NK CELL CYTOTOXICITY AGAINST GLIOBLASTOMA

Tram Dao*, Sandro Matosevic. *Purdue University, West Lafayette, IN, USA*

Background Natural killer (NK) cells hold potential as one of the next generation adoptive cell therapy candidates due to their allogenecity, capability to lyse target without prior sensitization, and low risk of host-versus-graft disease. Thus, being able to utilize NK cell receptors to drive their cytotoxicity remains crucial. Additionally, for treatments of solid tumors, NK cells need to retain their viability against the suppressive tumor microenvironment. One method to modulate NK cell immunometabolism is to leverage the surface receptor TIM-3, which lies at the intersection of NK cytotoxic functions and metabolism – the mTOR-associated pathways.

Methods NK cells were isolated from healthy adult peripheral blood, and expanded in K562-based feeder media. Flow cytometry was used to phenotype TIM-3 expression and phosphorylation of mTOR, Akt, and ribosomal protein S6 (rpS6). CCK-8 assay was used to assess mTOR inhibition against patient-derived glioblastoma cells (GBM43). NK co-operative activities with mTOR inhibitors against GBM43 were evaluated through target lysis, degranulation, and cytokine secretion. TIM-3 *knock-out* (TIM-3 KO) NK cells were generated by electroporating CRISPR/Cas9 ribonucleopreotein complexes.

Results We first explored the link between TIM-3 expression on NK cells and mTOR proteins, including mTOR itself, rpS6, and Akt, which were linked to TIM-3 regulation in T cells. Previously, we had reported that TIM-3 downregulation was associated with lower IFN-γ production. As changes in phosphorylation of rpS6 was linked to lower IFN-γ mRNA levels, we hypothesized that TIM-3 expression leads to increased rpS6 phosphorylation, thus encouraging higher IFN-γ production. Here, we report changes in phosphorylation levels of Akt and rpS6 as consequences of TIM-3 KO, and how these changes can affect NK cell cytotoxicity against GBM43. We also cross-examine these findings using specific pharmacological inhibitors of mTOR, including rapamycin, JR-AB2-011, and torin-1, against mTORC1, mTORC2, and both complexes, respectively, to demonstrate that TIM-3 expression could provide some functional protection against activities these inhibitors through retention of NK cell activity. Lastly, to show that these inhibitions would not compromise NK cell functions, we show GBM43 lysis by NK cells with mTOR inhibitor adjuvants.

Conclusions We have found that TIM-3 expression can exert some control over the mTOR pathway on *ex vivo* NK cells, and this affects NK cells' cytokine production capacity. Since the tumor microenvironment is highly immunosuppressive, the protection against mTOR inhibition by TIM-3 allowed tumor-infiltrating NK cells to remain metabolically and functionally viable, and affords an opportunity to leverage mTOR inhibitors as adjuvants with NK cell therapy against GBM.

215 TARGETING OVARIAN CARCINOMA WITH GDT002, A FIRST-IN-CLASS γδTCR-BASED T CELL THERAPY

Esther Drent, Sabine Middendorp*, Andrea Bisso, Sjoerd Baardman, Dagmar Verweij, Estefania Salcedo, Chris Coomans, Steven Braem, Sander van de Weg, Menno Meijer, Natalie Proost, Marieke van de Ven, Haakan Norell, Marleen van Loenen, Nia Emami, Sara Melief, Stefania Gobessi, Mark Throsby. [1]*Gadeta, Utrecht, Netherlands*; *The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background Broad application of cell therapies like CAR-T have been hampered by a lack of tumor-specific targets. Gadeta leverages the natural HLA-independent tumor recognition capabilities of γδTCRs combined with the proliferative capacity and robust tumor killing of αβT cells to develop tumor-specific cell therapies.[1] The most abundant peripheral γδT cells express Vγ9Vδ2 TCRs, which sense the presence of phosphoantigens (pAgs) upregulated in malignant cells due to a dysregulated mevalonate pathway.[2-4] The Vγ9Vδ2 TCR expressed by GDT002 was selected for its broad and strong tumor reactivity.[5] In addition, GDT002 demonstrated effective control of tumor growth in an aggressive systemic xenograft MM mouse model.

Currently GDT002 is being evaluated in a multicenter first-in-human phase 1/2 study for the treatment of multiple myeloma (NCT04688853). This ongoing FIH trial has completed the first dose cohort of 7E7 GDT002 cells without any safety concerns. To broaden the applicability of GDT002, we conducted preclinical studies to identify potential solid tumor indications.

Methods The specificity and anti-tumor activity of GDT002 was evaluated in various cell lines from solid cancer types and primary cells from healthy tissues. Tumor reactivity was tested in 2D co-cultures in the presence or absence of pamidronate, a clinically approved aminobisphosphonate that boosts pAgs levels. Target killing was determined by an xCELLigence-based cytotoxicity assay and T cell activity by cytokine release. Furthermore, GDT002 tumor reactivity and infiltration capacity was assessed in more complex 3D co-culture systems, such as a broad panel of patient-derived tumor organoids and ovarian carcinoma tumoroids, which were subjected to high-content imaging.

Results Significant GDT002 reactivity was observed against 10/15 adherent tumor targets in the presence of pamidronate. In contrast, no GDT002 reactivity was observed against primary cells from healthy tissue. In 3D organoid co-culture assays, GDT002 displayed significant reactivity towards most organoids, with an exceptionally high (90%) response rate towards ovarian cancer organoids. In addition, high-content quantitative imaging showed efficient aminobisphosphonate- and CD277-dependent cytotoxic activity of GDT002 in tumoroids with evidence of infiltration and expansion of GDT002 in the 3D cellular matrix.

Conclusions We demonstrate that GDT002 has potent anti-tumor activity across a broad spectrum of solid tumors. Based on the unmet clinical need and preclinical studies, recurrent ovarian cancer was selected as the first solid tumor indication to evaluate the efficacy of GDT002.

216 DUAL TARGETING OF CAR-NK CELLS TO PD-L1 AND ERBB2 FACILITATES SPECIFIC ELIMINATION OF CANCER CELLS OF SOLID TUMOR ORIGIN AND OVERCOMES IMMUNE ESCAPE BY ANTIGEN LOSS

[1]Jiri Eitler*, [1]Kristin Freudenberg, [1]Paola Ortiz Montero, [1]Wiebke Rackwitz, [2]Winfried Wels, [1]Torsten Tonn. *[1]Carl Gustav Carus, Dresden, Germany; [2]Goethe University, Frankfurt, Germany*

Background Retargeting of natural killer (NK) cells with chimeric antigen receptors (CARs) can be a powerful approach to overcome NK-cell resistance of tumor cells. However, targeting a single tumor-associated antigen may be insufficient for some tumors to trigger effective NK-cell activation or result in the selection of antigen-loss variants and tumor immune escape.

Methods To overcome this hurdle, here we generated CAR-NK cells carrying two CARs that target the tumor-associated antigens PD-L1 and ErbB2 (HER2), respectively (figure 1A). NK-92 cells were transduced with lentiviral CAR constructs, and their cytotoxicity against cancer cell lines of different solid tumor origins was compared to that of parental NK-92 and corresponding single-target CAR variants.

Results Dual targeting significantly increased *in vitro* cytotoxicity against PD-L1 and ErbB2 double-positive tumor cell lines including breast, ovarian, pancreatic and gastric cancer cells when compared to single-target CAR variants (Figure 1B,C). These results were also confirmed with 3D spheroid tumor models. Off-target cytotoxicity was not observed. On a molecular level, this enhanced cell killing may be explained by synergistic activation of PLCγ and MAPK pathways. Incubation of cancer cells with IFN-γ further improved killing efficacy due to upregulation of PD-L1 expression. Furthermore, blocking experiments revealed that dual PD-L1/ErbB2-CAR NK-92 cells can overcome immune escape based on loss or inacessibility of a single target antigen.

Conclusions Altogether, we showed that dual targeting of PD-L1 and ErbB2 improves efficacy of CAR-NK cells against otherwise difficult to treat tumors, and counteracts potential resistance and immune escape mechanisms of cancer cells.

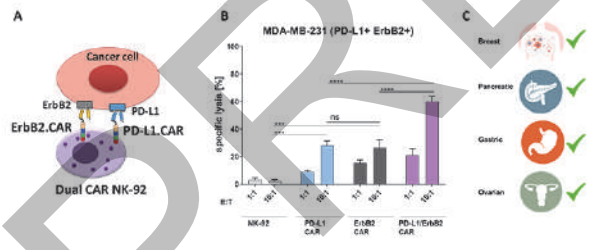

Figure1: A) schematic representation of Dual CAR NK-92 targeting ErbB2 and PD-L1 molecules on human cancer cell. B) Functional killing assay against human breast carcinoma cell line MDA-MB-231. C) Specific cytotoxicity of PD-L1/ErbB2.CAR NK-92 was confirmed against cancer cell lines of different origin.

217 MULTI-ARMORED ALLOGENEIC MUC-1 CAR T-CELLS EFFICIENTLY CONTROL TRIPLE NEGATIVE BREAST CANCER TUMOR GROWTH

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0217

Piril Erler*, Tomasz Kurcon, Jordan Skinner, Chantel Dixon, Steven Grudman, Ben Mumford, Shipra Das, Alexander Boyne, Alexandre Juillerat, Roman Galetto, Julien Valton, Hana Cho, Laurent Poirot, Beatriz Aranda-Orgilles. *Cellectis, New York, NY, USA*

Background CAR T-cell therapy success in solid tumors has been limited due to their complex biology. In solid tumors, lack of tumor-specific antigens, tumor heterogeneity, and immuno-inhibitory nature of tumor microenvironment (TME) demand an optimal therapeutic window where CAR T-cells can be highly efficient while ensuring safety. To address these challenges, we engineered CAR T-cells that i) use the tumor-specific MUC-1 antigen as a discriminatory target and ii) have enhanced therapeutic properties provided by multiple attributes. We focused on TNBC due to poor prognosis and over-expression of MUC1 (~67%) [1]. Here, we describe a universal CAR T-cell therapy for TNBC that can overcome both the host immune rejection and key inhibitory signals from the TME.

Methods We first screened several tumor-specific scFVs for MUC-1 CARs, assessing their binding and safety profiles. Then, we generated allogenic CAR T-cells by leveraging our TALEN® technology. TCR-alpha and B2M were knocked-out to prevent host-versus-graft disease, and to evade host T-cell attack. HLA-E was knocked-in at the B2M-KO site to provide resistance to host NK cell rejection. To increase activity and to overcome inhibitory signals from the TME, we introduced a PD-1 knock-out, a tumor-specific IL-12 release, and TGFBR2 knock-out. We tested these CAR T-cells *in vitro* using target specificity and cytotoxic assays, and *in vivo* by assessing tumor growth, survival, and tumor infiltration.

Results Three scFVs we prioritized showed efficient dose-dependent killing of breast cancer cells *in vitro*. Next, we used subcutaneous and orthotopic models to test CAR T-cells armored with IL-12 inducible release *in vivo*. Efficient tumor control and increased CAR-T cell infiltration extended mice survival, and notably antitumor response followed a dose-dependent pattern. Importantly, we introduced multiple edits in CAR-T cells with a high degree of efficacy, and precision using TALEN®. Functionally validating these edits, we demonstrated that TGFBR2-KO circumvents the inhibitory effects of TGFβ1, and IL-12 release follows a CAR T-cell activation pattern restricting it to the tumor site for increased safety.

Conclusions Overall, our data demonstrate that we can efficiently generate allogeneic CAR T-cells and equip them through complex engineering to overcome key challenges of solid tumors. We show that MUC-1 CAR T-cells control tumor growth, while infiltrating tumors more efficiently when enhanced with attributes catered towards the TME of TNBC tumors. Altogether, these pre-clinical data suggest that enhanced MUC-1 CAR T-cells could address some of the current challenges in development of CAR-Ts for TNBC patients with unmet medical needs.

218 IMMUNOGENIC LANDSCAPE AND THERAPEUTIC TARGETING OF MUTANT *NRAS* "PUBLIC" NEOANTIGENS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0218

Inaki Etxeberria*, Lauren Banks, Smita Chandran, Arianna Correa, Bryan Novak, Jessica Fleischman, Alexander Drilon, Jedd Wolchok, Taha Merghoub, Christopher Klebanoff. *Memorial Sloan Kettering Cancer Center (MSKCC), New York, NY, USA*

Background The NRAS driver oncogene is frequently mutated in diverse cancer types of high unmet medical need, including colorectal cancer, thyroid cancer, and ~25% of cutaneous melanomas. Most colorectal and thyroid cancers fail to respond to immune checkpoint inhibitors. Further, unlike other genomic variants of melanoma, those that harbor mutant NRAS respond poorly to current immunotherapies. Public neoantigens (NeoAgs) represent an elite class of clonally conserved, cancer-specific epitopes derived from recurrently mutated driver genes. Because public NeoAgs are restricted by prevalent HLA alleles they are shared among cancer patients and can be therapeutically targeted using off-the-shelf reagents. Here, we report on the immunogenic landscape and T cell responses to public NeoAgs resulting from recurrent NRAS (Q61) hotspot mutations in cancer patients.

Methods We combined a mass spectrometry screen, dextramer-based T cell detection, single-cells RNA sequencing, and functional immune validation assays to determine the immunogenicity of NRAS(Q61) epitopes. As part of these efforts, we assembled and performed comprehensive immune monitoring of peripheral blood and tumor samples from $n=26$ HLA-A*01^{+}patients with an NRAS(61) mutated cancer.

Results We discovered that neoepitopes derived from the three most common NRAS(Q61) hotspot substitutions (R, K, and L) are naturally processed and presented in the context of HLA-A*01, an allele expressed by ~25% of North Americans. Immune monitoring demonstrated that NRAS public NeoAg-specific T cell responses occur in ~50% of patients, including subjects with melanoma and non-melanoma cancers. Responses occurred at comparable frequencies whether the mutated NRAS residue was basic or aliphatic. Using single-cell sequencing, we retrieved and functionally validated a panel of $n=18$ TCRs from patient samples that confer specific recognition to cancer cells that express an NRAS Q61 public neopeptide. All of the patient-derived TCRs are high-affinity and function in a CD8 co-receptor-independent manner. Moreover, a subset TCR candidates demonstrate "cross-protection" towards multiple NRAS Q61 mutated variants, allowing a single receptor to provide therapeutic coverage for >90% of NRAS mutations. Mechanistically, we demonstrate that NRAS public NeoAg TCR cross-protection is tuned by expression of the CD8αβ co-receptor and requires recruitment of LCK.

Conclusions Collectively, our results demonstrate that multiple NRAS(Q61) hotspot mutations give rise to immunogenic public NeoAgs that can be studied across patients and therapeutically targeted using a TCR-based approach. These findings establish the foundation for an innovative new class of precision immune-genomic treatments for mutant NRAS cancers.

Ethics Approval All patients provided written informed consent for tumor and white blood cell sequencing and review of patient medical records for demographic, pathological and treatment information under a Memorial Sloan Kettering Cancer Center (MSKCC) institutional review board-approved biospecimen umbrella protocol (protocol 12-245; ClinicalTrials.gov ID: NCT01775072).

219 THE FUNCTIONAL ACTIVITY OF GAVO-CEL TRUC-T CELLS IS NOT IMPAIRED BY SOLUBLE MESOTHELIN

Michael Lofgren*, Robert Tighe, Robert Hofmeister, Jian Ding, Nate Bagge, Alec Andrews, Michelle Fleury, Courtney Anderson. *TCR2 Therapeutics, Cambridge, MA, USA*

Background Gavo-cel is an autologous and HLA-independent **T**-Cell **R**eceptor **Fu**sion **C**onstruct (TRuC^{TM}) T cell therapy that targets mesothelin-expressing tumors and is under Phase 2 evaluation for treatment-resistant MPM, NSCLC, cholangiocarcinoma, and ovarian cancer tumors (NCT03907852). Mesothelin (MSLN) is a 71 kDa GPI-anchored membrane protein that undergoes proteolytic membrane shedding to generate soluble mesothelin-related peptides (sMRPs) whose levels are correlated with tumor burden in MPM. sMRPs contain the juxtamembrane epitope of that is recognized by the MH1 binder domain of the gavo-cel TRuC and whose levels are correlated with tumor burden in MPM. Because shed MLSN has been implicated as a potential obstacle to successful anti-MSLN therapies, including cell therapies, we assessed the impact of soluble MSLN (sMSLN) on the function of gavo-cel and or allogeneic anti-MSLN TRuC, MH1gd.

Methods In this study, we generated primary human TRuC-T cells modeling MSLN-targeting clinical agent gavo-cel or that express MH1gd TRuC, and then measured the impact of soluble MSLN on the *in vitro* activation, cytotoxicity, and cytokine response of gavo-cel or MH1gd during acute and chronic challenge with antigen-expressing tumor cells. We also evaluated whether sMRP in human serum impacts the *in vitro* cytotoxicity and cytokine response of gavo-cel in response to MSLN-expressing tumor cell lines.

Results High, supraphysiological levels of the full-length shed domain of MSLN, sMSLN, does not impair, block, or disrupt the effector function of gavo-cel or MH1gd TRuC-T cells with respect to *in vitro* cytotoxicity or cytokine production. Furthermore, gavo-cel demonstrates potent efficacy *in vivo* in a tumor model characterized by circulating sMSLN.

Conclusions Our data indicate that both gavo-cel and allogeneic MSLN-targeting TRuC-T cells are not susceptible to functional suppression by sMRPs, even at supraphysiological levels that far exceed those found in cancer patients.

220 LUCIFERASE REPORTER CANCER CELL LINES FACILITATE CAR-T DEVELOPMENT

John Foulke*, Luping Chen, Brian Della Fera, Hyeyoun Chang, Kevin Tyo, Zhizhan Gu, Fang Tian. *ATCC (American Type Culture Collection), Gaithersburg, MD, USA*

Background Chimeric antigen receptor (CAR)-T cells have displayed remarkable efficacy in treating malignant cancers, particularly liquid tumors. CAR-T cells have proven to be a new type of "living" therapeutic by harnessing the patient's immune system to recognize specific tumor associated antigens and redirect the engineered T cells to more specifically targeted tumor cells. Considerable research efforts have been invested into developing new CAR structures to increase the scope of targeted cancer types and raise their anti-tumor efficacy. Evaluating the biofunction of CAR-T cells in vitro typically involves a series of labor-intensive co-culture experiments and immunoassays, where reproducibility remains a challenge during the validation of new CAR-T cells due to donor-to-donor variations and other possible factors. In this study, we present a panel of luciferase reporter tumor cell lines that can be utilized to examine the function of CAR-T cells. The panel of selected human tumor cell lines naturally express high levels of clinically relevant CAR-T target antigens on cell surface, such as CD19, CD20 and HER2.

Methods The panel of selected human tumor cell lines naturally express high levels of clinically relevant CAR-T target antigens on cell surface, such as CD19, CD20 and HER2. Antibiotic selection and single cell sorting were performed to isolate stable clones with high luciferase expression via the introduction of a Lenti-LUC2 luciferase reporter into the parental cell lines. The target antigen and luciferase were verified to have expression stability by comparing the low passage and the high passage reporter cells. In addition, these reporter cell lines were characterized and authenticated using cell morphology, growth kinetics, and STR profile. To verify the performance of the target luciferase reporter cell lines, we used the cancer and T cell co-culture experiments. Commercially available CAR-T cells targeting CD19, CD20, and HER2 were employed in this study, with which empty vector-transduced T cells from the same donor were paired as controls. The cytotoxicity of the CAR-T cells against target tumor cells was measured using a luciferase assay, a commercially available potency assay, and a bright field and fluorescence live cell imaging assay.

Results Our results demonstrate that the luciferase reporter system is a simple, robust, and highly sensitive means to measure biological processes in cancer and T cell ex vivo co-cultures.

Conclusions In summary, CAR-T target antigen luciferase reporter cell lines from ATCC provide the well-characterized tools with high reproducibility for studying CAR-T biofunction and validating new CAR-T agents for cancer immunotherapy.

221 SENTI-401, AN ALLOGENEIC LOGIC-GATED AND MULTI-ARMED CAR-NK CELL THERAPY FOR THE TREATMENT OF CEA-EXPRESSING SOLID TUMORS WITH ENHANCED SELECTIVITY AND EFFICACY

Alba Gonzalez Junca*, Nicholas Frankel, Maelig Morvan, Assen Roguev, Michelle Hung, Russell Gordley, Miguel Palermo, Tyler Santomaso, Pearley Chinta, Aldo Sotelo, Marcus Gainer, Derrick Lee, Tony Hua, Andrew Banicki, Mengxi Tian, Niran Almudhfar, Atahualpa Contreras, Chen-Ting Lee, Timothy Lu. *Senti Biosciences, South San Francisco, CA, USA*

Background Chimeric Antigen Receptor (CAR)-based cell-therapies have demonstrated clinical benefit in select blood cancers. Unfortunately, their success has yet to be translated to solid tumors. Poor antigen specificity and immune-suppressive mechanisms in the tumor microenvironment (TME) pose key challenges for cell-therapies in the treatment of solid tumors.

Methods SENTI-401, a CAR-NK cell-therapy with NOT Logic Gating and Multi-Arming gene circuits, is designed to overcome the above challenges. SENTI-401 targets CEACAM5 (CEA), a tumor-associated antigen (TAA) highly expressed in solid tumors, including colorectal, pancreatic and lung cancers. SENTI-401 also incorporates NOT Gate technology to overcome on-target off-tumor toxicity from CEA expression by healthy epithelial cells, which has been previously reported when targeting CEA in the clinic.[1] Senti is evaluating the effects of multi-arming CAR-NK cells with immunostimulatory payloads to potentially overcome the immunosuppressive TME.

Senti's novel NOT-Gate technology incorporates an activating (aCAR) targeting a TAA, paired with an inhibitory (iCAR) that recognizes a safety antigen (SA) uniquely expressed on the surface of healthy cells. The NOT-Gate significantly reduces CAR-mediated killing of target cells in a SA-dependent manner, thus mitigating on-target, off-tumor toxicity and allowing targeting of tumor antigens that are broadly expressed by healthy cells.

Results Using our Tumor-Associated Antigen and Safety Antigen Discovery Platform, we discovered and validated VSIG2, a protein on the surface of CEA-expressing healthy epithelial cells and not on tumor cells.

NK cells expressing CEA-targeting aCARs and VSIG2-targeting iCARs receptor pairs had significantly reduced CAR-mediated killing of target cells expressing both CEA and the SA VSIG2, in vitro and in vivo.

To enhance persistence and activity of CAR-NK cells, we developed, calibrated release (cr) technology, which can be coupled to cytokines such as IL-15, resulting in a desired ratio of secreted and surface-bound cytokine to provide autocrine and paracrine functions. The combination of crIL-15 and IL-21 resulted in increased survival and activation of anti-CEA CAR-NK cells, and leading to significantly increased target-cell killing in serial-killing assays. In vivo, anti-CEA CAR-NK cells expressing the both cytokines had superior activity and longer persistence compared to anti-CEA CAR-NK cells. Similarly, we optimized gene-circuits to confer resistance to the immunosuppressive effects of TGFb; anti-CEA CAR-NK cells armed with TGFb-blocking constructs sustained target-cell killing in the continuous presence of TGFb.

Conclusions SENTI-401 incorporates NOT-Gating and Multi-Arming gene-circuits into CAR-NK cells in order to improve the therapeutic window and efficacy of CEA-targeting cell-therapies for the treatment of solid tumors.

222 DEVELOPING AN ADOPTIVE CELL TRANSFER IMMUNOTHERAPY FOR PEDIATRIC HIGH-GRADE GLIOMAS

Stephen Frederico*, Chaim Sneiderman, Ian Pollack, Gary Kohanbash. *University of Pittsburgh, Pittsburgh, PA, USA*

Background Pediatric high-grade gliomas (HGGs) are one of the deadliest brain tumors that arise in children, with an average five-year survival for this disease being less than 20%.[1] HGGs expresses glioma-associated antigens (GAAs) which can be targeted by the immune system. These include IL-13Ra2, Survivin, and EphA2 [2]. Previously, our research group conducted a clinical trial where HLA-A2 positive pediatric patients were vaccinated with these GAA epitopes when newly diagnosed with HGG [2]. Our group observed many patients enrolled in the study showed positive anti-GAA immune responses to IL-13Ra2, EphA2, and Survivin. The findings from this trial highlighted that the sparsity of T-cells within the tumor microenvironment may pose a major challenge to improving immuno-therapeutic outcomes.

Methods In this study we engaged in identifying TCR sequences targeted to IL-13Ra2, Survivin, or EphA2. To accomplish this, a single cell-suspension of CD8 T-cells tetramer stained for Survivin, IL13Ra2, or EphA2 were obtained using FACS from PBMCS taken from individual patients who underwent vaccination. Single-cell RNA-sequencing (ScRNA-Seq) was performed on these samples to determine the phenotype of the T-cells. We also assessed T-Cell expansion and obtained the nucleotide sequence for the CDR3 region. Following acquisition of the nucleotide sequence, we developed retroviral TCR-vectors and viral particles to enable transduction of T cells. We confirmed the presence of TCRs on the T-cell surface via tetramer staining and flow cytometric analysis. We then performed in vitro killing assays by co-culturing transduced T-cells with U87 cells and assessed for LDH within our samples.

Results ScRNA-seq allowed us to identify a cluster of T-cells consisting of PRF1+ (Perforin) & GZMB+ (Granzyme b), as well as a cluster of PDCD1+ (PD-1) & TIGIT+ cells. Our tetramer staining confirmed the presence of our TCRs on the T-cell surface. In vitro killing assays demonstrated T-cell cytotoxicity as T-cells with U87 cells in 10:1, 4:1 and 1:1 ratios had a percentage cytotoxicity of 30.95%, 22.59% and 9.37% respectively. When pairing T-cells with U87 cells while blocking HLA-A2, there was a marginal decrease in cytotoxicity.

Conclusions TCRs targeted to IL-13Ra2, Survivin, or EphA2 were positively identified on the surface of transduced T-cells and demonstrated a cytotoxic response during *in vitro* killing assays. We now intend to grow these cells into large numbers and adoptively transfer them into tumor-bearing mice in hopes this will provide a survival benefit.

223 ANTI-TNMUC1 CAR-T CELLS THAT ARE CONDITIONALLY ARMED WITH IL12 ELIMINATE ADENOCARCINOMAS IN PRECLINICAL MODELS

Albert Gacerez, Eytan Herzig, Tiger Ren, Nicole Grant, Jay Danao, Daniel Roche, Daeun Nam, Krista McNally, Ben Wang, Melissa Fardy, Gus Zeiner*. *Chimera Bioengineering, South San Francisco, CA, USA*

Background Chimeric antigen receptor T (CAR-T) cell therapeutics have been successful at driving remissions in several B cell malignancies, but their efficacy against most tumor types remains limited. An emerging strategy to increase CAR-T efficacy against solid tumors is to arm CAR-T cells with additional transgenes encoding immunomodulatory payloads such as IL-12, that weaken the tumor and its supportive microenvironment, and enhance the anti-tumor effector functions of T cells. However, several clinical trials investigating the use of armed T cell therapeutics have demonstrated that immunomodulatory payload arming necessitates stringent payload expression control to prevent systemic payload exposures, which can limit therapeutic efficacy and persistence, and simultaneously drive toxicity and severe adverse events.

Methods Here we report the repurposing of a native T cell gene regulatory node, that operates post-transcriptionally to prevent effector cytokine expression in quiescent T cells, as a cellular engineering platform that conditionally affects transgenic payload expression exclusively in activated CAR-T cells. We have applied this cellular engineering platform develop aTnMuc1 CAR-T cells armed conditionally with IL-12. TnMuc1 is a hypoglycosylated variant of MUC1, an antigen expressed by many Adenocarcinomas but not by healthy cells.

Results Our anti-TnMuc1 CAR-T cells armed conditionally with IL-12 dramatically outperformed cognate unarmed aTnMuc1 CAR-T cells *in vitro* and *in vivo*. anti-TnMuc1 CAR-Ts armed conditionally with IL-12 exhibit very low levels basal IL-12 expression in quiescent states, and efficiently cleared tumors at low CAR-T doses in multiple preclinical Adenocarcinoma models; cognate unarmed anti-TnMuc1 CAR-T cells were unable to clear these tumors at any dose level. Additionally, tumor-bearing mice dosed with anti-TnMuc1 CAR-T cells armed conditionally with IL-12 demonstrated no weight loss and had low serum IL-12 levels.

Conclusions These data demonstrate the utility of applying a native T cell gene regulatory mechanism to produce highly efficacious, conditionally armed CAR-T cells. Based on the results of our preclinical data, we are advancing anti-TnMuc1 CAR-T cells armed conditionally with IL-12 for clinical trials to confirm these results in humans.

224 GENERATION OF CELL THERAPIES FOR DIVERSE APPLICATIONS USING MICROFLUIDIC CELL SQUEEZE® MANUFACTURING TECHNOLOGY

Jonathan Gilbert*, Maisam Dadgar, Scott Loughhead, Ipsita Roymoulik, Devin Bridgen, Howard Bernstein, Armon Sharei. *SQZ Biotechnologies, Watertown, MA, USA*

Background Cellular therapies require precise and versatile biological engineering at scale to generate effective and accessible products. However, current cell delivery approaches are often limited in the types of biology and range of cells they can engineer and have significant scale-up challenges. Microfluidic deformation using the Cell Squeeze® technology effectively delivers a variety of payloads to diverse cell types at scale while preserving cell health and function.

Methods We tested preclinically the performance of the Cell Squeeze technology in many cell types including T cells, PBMCs, HSCs, iPSCs, red blood cells, and TILs. We evaluated the efficiency of delivery of many materials including mRNA, gene editing factors, transcription factors, and membrane-bound cytokines. We further investigated the integration of our scaled cGMP process into an integrated manufacturing system for the rapid and cost-effective production of cell therapy drug products (point-of-care system).

Results We showed highly efficient mRNA delivery (>80%) to T cells, iPSCs, PBMCs, HSCs, and TILs while also maintaining cell function. Cell Squeeze technology also demonstrated efficient gene editing in multiple cell types. The technology further demonstrated engineering ~10B cells/minute and has been used in 3 clinical trials generating distinct investigational products. Furthermore, our point-of-care system demonstrated a fully closed automated unit for manufacturing cell therapies that integrates cell isolation, cell washing, cell delivery and bag filling. This portable system used a single-use sterile disposable tubing set and has the potential to be operated outside of a clean room. Our point-of-care system also reduced our operator hours by 90% and process time by ~50% to < 6 hours.

Conclusions Cell Squeeze technology has shown differentiated capabilities in applications such as therapeutic vaccines, immune tolerance, effector cell engineering, and directed differentiation of iPSCs. These results support a continued expansion of clinical impact of the Cell Squeeze technology leveraging the flexibility of the delivery platform. Our automated, point-of-care system incorporating the Cell Squeeze® technology could potentially further streamline manufacturing time and costs to achieve greater cell therapy accessibility and therapeutic impact potential.

225 KILLER CELL IMMUNOGLOBULIN-LIKE RECEPTOR 2DL2 (KIR2DL2) IMMUNE CHECKPOINT AS A MODULATOR OF T-CELL EFFECTOR FUNCTION

Miguel Gomez Fontela*, Sebastian Snedal, Daniel Abate-Daga. *H. Lee Moffitt Cancer Center, Tampa, FL, USA*

Background Killer immunoglobulin-like receptors (KIRs) are a family of regulatory cell surface molecules expressed on natural killer (NK) cells and in subsets of memory T cells.[1,2] Interaction of KIR2DL2 with its HLA-C1 ligands leads to inhibition of NK cell activation and decoupling of T cell effector function by inhibiting actin cytoskeleton rearrangement and modifying T cell transcriptional profile.[3-5] Here we assess the effect of KIR2DL2 on CAR-T cell effector function both *in vitro* and *in vivo* and propose KIR2DL2 as an immune checkpoint. We have developed a strategy for genomic ablation of KIR2DL2 during T cell manufacturing as a method for enhancement of adoptive cell immunotherapy (ACT).

Methods We generated prostate stem cell antigen (PSCA)-CAR-T cells, alone or in combination with KIR2DL2, using a bicistronic retroviral vector. We tested KIR2DL2 *in vitro* inhibitory role in presence or absence of HLA-C1 using real time cytotoxicity assays at different effector:target ratios (2.5:1, 1:1, 0.5:1, 0.25:1). We evaluated IFN-γ production by ELISA. To assess the inhibitory role of KIR2DL2 *in vitro* we used a mouse model bearing HLA-C1$^+$ or HLA-C1$^-$ subcutaneous xenografts of human pancreatic adenocarcinoma (HPAC) cells, treated with 5x10^6 KIR2DL2$^+$ or KIR2DL2$^-$ CAR-T cells. We used GFP-transduced T cells as a negative control. CRISPR/Cas9 genome editing was used for *KIR2DL2* ablation in CAR-T cells.

Results *In vitro*, KIR2DL2 impaired CAR-T cell responses in an HLA-C1-dependent manner. KIR2DL2$^+$ PSCA-CAR-T cells were significantly less cytotoxic in presence of HLA-C1 and secreted less IFN-γ than their KIR2DL2$^-$ counterparts. *In vivo*, KIR2DL2$^+$ PSCA-CAR-T cells injected in NSG mice harboring PSCA$^+$/HLA-C1$^+$ pancreatic tumors were not able to eliminate tumors in the presence of HLA-C1. In contrast, KIR2DL2$^+$ CAR-T cells transferred to mice harboring PSCA$^+$/HLA-C1$^{-/-}$ tumor cells performed as well as their KIR2DL2$^-$ counterparts. We designed guide RNAs targeting KIR2DL2 and developed a strategy for KIR2DL2 abrogation during adoptively transferred CAR-T cell manufacturing.

Conclusions We evaluated for the first time the biological and molecular function of KIR2DL2 within adoptively transferred T cells. Engagement of KIR2DL2 with its HLA-C1 ligand(s) impaired CAR-T cell effector function both *in vitro* and *in vivo*, as CAR$^+$/KIR2DL2$^+$ cells were less cytotoxic and secreted less IFN-γ than their CAR$^+$/KIR2DL2$^-$ counterparts. KIR2DL2 abrogation in CAR-T cells may enhance ACT by limiting its inhibitory signaling. Current efforts are focused on evaluating the impact of KIR2DL2 ablation on the therapeutic effect of CAR- and TCR-T cells.

227 HUNTR™: A HYPERPLEX PLATFORM FOR THE DISCOVERY OF NEOANTIGEN-REACTIVE T-CELL RECEPTORS

Guowei Gu*, Julissa Simmons, Kristen Rimaila, Gaby Garland, Ugochi Ibekwe, Donghyun Joo, An Lu, Amanda Montoya, Pretty Mathew, Hao Zhao, Beatriz Santillan, Matthew Collinson-Pautz, Drew Deniger. *Alaunos Therapeutics, Houston, TX, USA*

Background Solid tumors harbor mutations that can give rise to neoantigens recognized by T-cell receptors (TCRs) expressed on tumor infiltrating lymphocytes (TILs). We have developed a library of TCR-T cells targeting hotspot mutations based on the non-viral *Sleeping Beauty* transposon/transposase system, which is presently being evaluated in a first-in-human phase 1/2 study in patients with non-small cell lung, colorectal, endometrial, pancreatic, ovarian, and bile duct cancers. Current methods of TCR discovery require large volume blood draws or immortalization of primary cells with live viruses to make antigen presenting cells (APCs), limiting the ability to efficiently discover new TCRs and is only applicable to some patients. We developed hunTR™ (**hu**man **n**eoantigen **T**-cell **R**eceptor), a rapid, hyperplex platform for the discovery of neoantigen-reactive TCRs from limited starting material.

Methods TILs sorted from dissociated tumor specimens were processed to obtain TCR sequences and gene expression profiles on a single cell basis. These data were fed into a novel bioinformatics pipeline that identifies TCRs with predicted neoantigen reactivity. TCRs were reconstructed in *Sleeping Beauty* transposon plasmids and expressed in TCR cells, an engineered cell line capable of detecting TCR reactivity to both class I and class II HLA-restricted neoepitopes. Somatic single nucleotide variants, short insertions/deletions, and germline class I and II HLA alleles were called for each patient. neoAPCs were engineered to express relevant patient-derived neoantigens and HLA molecules. TCR cells were cocultured with a matrix of neoAPCs, and conditions yielding a neoantigen reactivity were identified.

Results A total of $3.1x10^5$ TCR+HLA+neoantigen combinations were evaluated in seven patients with a mean plexity of $4.4x10^4$ per patient. All specimens screened (colorectal n=3, endometrial n=2, breast n=2) yielded at least one neoantigen-reactive TCR. The 57 neoantigen-reactive TCRs (19% of 304 total TCRs screened) identified targeted 20 mutations, including one shared *KRAS* and 19 personal mutations. Of these, 81% were restricted by HLA class II while 19% were restricted by class I. A median reactive hit rate of 14% was achieved per patient (range 5-31%) with an average of three unique neoantigen specificities (range 1-6).

Conclusions In conclusion, hunTR is a hyperplex screening platform that identifies neoantigen-reactive TCRs. hunTR allows for the expansion of our hotspot mutation-targeted TCR library, increasing the addressable population of solid tumor patients (with matching hotspot mutation and HLA allele) eligible for TCR-T cell treatment. In addition, hunTR is applicable for personalized TCR-T therapy such that most solid tumor patients could be eligible for mutation-targeted cell therapy.

Ethics Approval Human-derived specimens were obtained through a commercial source that adheres to all applicable regulations and guidelines of the relevant countries including the US.

228 MULTI-ARMING AND REGULATOR DIAL GENE CIRCUITS TACKLE KEY CHALLENGES IN SOLID TUMORS

Marcela Guzman Ayala*, Michelle Hung, Deepika Kaveri, Rebecca Cottman, Elizabeth Leitner, Priscilla Wong, Ronni Ponek, Enping Hong, Manan Shah, Andrew Banicki, Lawrence Naitmazi, Kelly Lee, Wesley Gorman, Russell Gordley, Philip Lee, Timothy Lu. *Senti Biosciences, South San Francisco, CA, USA*

Background Chimeric antigen receptor (CAR) cell therapy for solid tumors is hampered by the immunosuppressive tumor microenvironment (TME), which can inhibit the function of endogenous and therapeutic immune cells, as well as a paucity of targets. The use of potent immunomodulators to transform the TME, such as interleukin (IL)-12, is limited by the need for regulation to avoid systemic toxicities.

Methods To address these challenges, Senti Bio is developing CAR-NK therapies that include Multi-Arming with calibrated release (cr)IL-15 and a Regulator Dial gene circuit to control the expression of crIL-12. Senti's proprietary calibrated release technology enables cytokines to be expressed in both membrane-bound and secreted forms, providing multi-factorial activity via autocrine and paracrine stimulation to increase CAR-NK cell function and activation of endogenous immune cells in the TME. In addition, we have designed a Regulator Dial gene circuit that expresses crIL-12 under the control of grazoprevir (GRZ), an FDA-approved small molecule drug.

Results We have tested our Multi-Arming and Regulator Dial gene circuits in combination with a CAR targeting GPC3, a hepatocellular carcinoma (HCC)-relevant target. We observed crIL-15 to promote NK cell persistence and proliferation in an autocrine fashion, while also activating other immune cells in a paracrine manner. In addition, crIL-15 was observed to enhance GPC3 CAR-NK tumor killing in a serial killing assay compared to wild-type secreted IL-15 and showed enhanced antitumor function and increased survival over control groups in vivo.

GPC3 CAR-NK cells containing the Regulator Dial gene circuit expressed low crIL-12 levels in the absence of GRZ (<100 pg/1e6 cells/48h), while induction with GRZ led to a 1000-fold increase of crIL-12 expression under the same conditions. The ON and OFF kinetics of crIL-12 induction were determined in vitro. 4 hours of GRZ-treatment was sufficient to induce >600-fold increase in crIL-12 concentrations. By day 3 post-GRZ removal, crIL-12 reverted to basal levels. Lastly, the role of crIL-12 in reversing immunosuppression was validated in a co-culture assay. Specifically, GRZ-induced crIL12 restored CAR-NK cells that were suppressed in the presence of M2 macrophages.

Conclusions We have engineered off-the-shelf CAR-NK cell therapies that target GPC3 and express crIL-15. To increase the therapeutic window of the potent immune effector IL-12 in the TME, we have designed a Regulator Dial gene circuit to controllably produce crIL-12. These gene circuits have complementary mechanisms of action to enhance CAR-NK antitumor function and potentially overcome the immunosuppressive TME in solid tumors such as HCC.

229 A2B530, AN AUTOLOGOUS CEA-DIRECTED TMOD T-CELL THERAPY WITH AN INHIBITORY RECEPTOR GATED BY HLA-A*02 TO TARGET COLORECTAL, PANCREATIC, AND LUNG CANCER

[1]J Randolph Hecht, [2]Mark Sandberg, [2]Xueyin Wang, [2]Aaron Martin, [2]Daniel Nampe, [2]Grant Gabrelow, [2]Chuck Li, [2]Michele Mcelvain, [2]Wen-Hua Lee, [2]Sanam Shafaattalab, [2]Sara Martire, [2]Fernando Fisher, [2]Yuta Ando, [2]Edwin Liu, [2]David Ju, [2]Jing-Ping Hsin, [2]Alexandre Zampieri, [3]Diane Simeone, [4]Scott Kopetz, [4]Maria Pia Morelli, [5]Mitesh Borad, [3]Theodore Welling, [6]Sandip Patel, [1]Edward Garon, [7]Kedar Kirtane, [7]Frederick Locke, [2]John Welch, [2]Eric Ng, [2]William Go, [2]Armen Mardiros*, [8]David Maloney, [2]Lu-Min Wong, [2]Alexander Kamb, [2]Han Xu, [9]Julian Molina. *[1]University of California at Los Angeles, Los Angeles, CA, USA; [2]A2 Biotherapeutics, Inc., Agoura Hills, CA, USA; [3]New York University Langone Health, New York, NY, USA; [4]The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [5]Mayo Clinic Cancer Center, Scottsdale, AZ, USA; [6]University of California San Diego, La Jolla, CA, USA; [7]H. Lee Moffit Cancer Center, Tampa, FL, USA; [8]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [9]Mayo Clinic, Rochestser, MN, USA*

Background Nearly all colorectal and most pancreatic and lung cancers express carcinoembryonic antigen (CEA). However, due to its expression in normal gut epithelial cells, CEA-targeted therapies have resulted in on-target, off-tumor toxicity. To overcome this, we have developed Tmod™, a logic-gated T-cell therapy platform. Tmod constructs are composed of an activating CAR or T-cell receptor that targets a tumor antigen and an inhibitory receptor recognizing an antigen expressed on normal healthy tissues, but not on tumor cells due to loss of heterozygosity (LOH).[1,2] A2B530 is a CEA-directed Tmod construct utilizing an LIR-1-based inhibitory receptor (blocker) targeting human leukocyte antigen A*02 (HLA-A*02).

Methods To generate CEA Tmod, T cells from HLA-A*02(+) donors were transduced with a single lentivirus to express i) the CAR, ii) the blocker, and iii) an shRNA targeting β2M. Cytotoxicity was measured by culturing CEA(+) target cell line pairs (A*02[-] and A*02[+]), expressing either GFP or RFP, with engineered T cells and quantifying live target cells over time. *In vivo* activity was examined using NSG mice subcutaneously implanted with "normal" (CEA[+]A*02[+]) and tumor cells (CEA[+]A*02[-]), in the right and left flanks. Mice were treated intravenously with CEA Tmod cells or control T cells.

Results Control CEA CAR T cells killed CEA(+) target cell lines *in vitro* irrespective of HLA-A*02 expression. In contrast, CEA Tmod cells selectively killed tumor cells (CEA[+]A*02[-]) while sparing "normal" cells (CEA[+]A*02[+]). In mixed target cell cultures, CEA Tmod cells killed only the A*02(-) target cells, whereas the CEA CAR T cells killed both the A*02(-) and A*02(+) cell lines. Further, CEA Tmod cells exhibited bidirectional control between the activated and blocked states. While mice treated with control CEA CAR T cells experienced a reduction in volume and bioluminescence of both normal and tumor grafts, CEA Tmod cells specifically cleared A*02(-) tumors in mice (table 1). Finally, although expansion of Tmod cells in peripheral blood trended lower than CAR and TCR controls, anti-tumor activity was comparable in these groups.

Conclusions A2B530 is an autologous CEA Tmod cell product that exploits common LOH at the HLA locus in cancer cells, enabling these engineered T cells to discriminate between normal and tumor cells. BASECAMP-1 (NCT04981119), an observational study identifying patients with somatic HLA LOH, is recruiting. Eligible patients with metastatic colorectal, pancreatic, or non-small cell lung cancer will be apheresed for a future A2B530 EVEREST-1 interventional study.

230 TCR-LIKE CHIMERIC-ANTIGEN-RECEPTOR TO RECOGNIZE NEOEPITOPES DERIVED FROM DRIVER MUTATIONS

David Hou, Yafei Hou*. *Immunosynth, LLC, San Carlos, CA, USA*

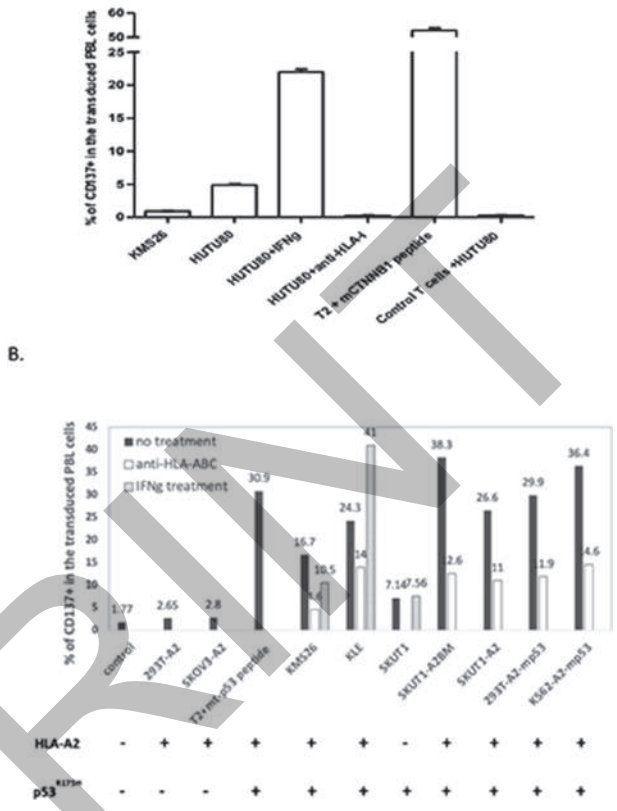
Background T cell receptor (TCR)-based cell therapy to treat solid tumors by targeting tumor neoantigens is gaining momentum. While there is an urgent need for discovering novel TCRs, one challenge is that the exogenous TCR may compete with the endogenous TCR for CD3 signaling components and form mixed dimers with potential toxicities. Additionally, the activity of T cells highly depends on signaling machinery only present in T cells, which restricts the scope of eligible therapeutic cells. We developed a TCR-like chimeric-antigen-receptor to both overcome the mispairing of TCR α/β chains and to expand the scope of TCR-based cell therapy to other immune cells.

Methods To identify novel TCRs, a monoclonal TCR discovery platform was developed. A high avidity TCR of a neoepitope-specific CD8+ T cell clone (CTL) that was generated from donor PBMCs was isolated and sequenced. A chimeric-antigen-receptor comprising an antigen binding domain (which is a portion of the identified TCR), a CD28 segment containing the hinge/transmembrane domain, and a cytoplasmic signaling domain containing a Dap10 and a Dap12 intracellular domains. To augment the avidity of the antigen receptor, a chimeric co-receptor was constructed by combining HLA-I binding domains of CD8α with the hinge/transmembrane/cytoplastic domains of CD4. T cell line (J.RT3-T3.5) and NK cell line (KYGH-1) were transduced by a lentivirus encoding the chimeric-antigen-receptor and co-receptor to assess their expression and function.

Results Two novel TCRs specific for CTNNB1^{S37F} peptide (YLDSGIHFGA) and for p53^{R175H} peptide (HMTEVVRHC) respectively were identified; both are high-avidity and can recognize the endogenous neoepitope presented by HLA-A2 in tumor cells (figure 1A and B). A chimeric-antigen-receptor specific for CTNNB1^{S37F} neoepitope/HLA-A2 was expressed on the surface of 293T cells independent of endogenous CD3 (figure 2A). However, its avidity to recognize CTNNB1^{S37F} neoepitope was approximately 5 folds lower than that of the native TCR (figure 3A). Co-expression of the co-receptor could significantly enhance the avidity of the chimeric-antigen-receptor and make it capable of recognizing endogenously presented neoepitope in tumor cells (figure 3B). In addition, NK cells re-directed with the chimeric-antigen-receptor could also recognize the neoepitope peptide in the context of HLA-A2 (figure 2B and 4).

Conclusions We validated a TCR-like chimeric-antigen-receptor that can be expressed on cells independent of endogenous CD3 and can recognize neoepitope/HLA-A2. We also designed and tested a co-receptor that can enhance the avidity of the chimeric-antigen-receptor. To further leverage the avidity of the chimeric-antigen-receptor, testing of new configurations of the chimeric-antigen-receptor and co-receptor is underway.

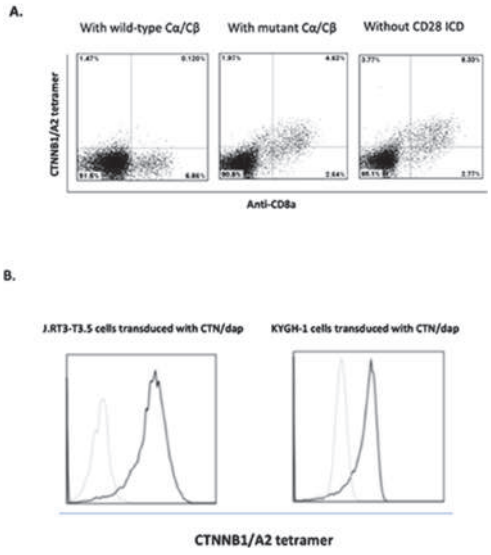
Figure 1.



Abstract 230 Figure 1 TCRs specific for a neoepitope peptide presented by HAL-A2

PBLs re-directed to express a specific TCR can be activated by the endogenous neoepitope peptide/HLA-A2+ in tumor cells. Fig. 1A shows T cells transduced with a TCR specific for a CTNNB1S37F neoepitope peptide in the context of HLA-A2 can be activated to express CD137 against HLA-A2+ tumor cell line (HuTu80 cells pre-treated with IFN?) with the CTNNB1S37F mutation. Fig. 1B shows T cells transduced with a TCR specific for a p53R175 neoepitope peptide in the context of HLA-A2 can be activated to express CD137 against HLA-A2+ tumor cell lines with the p53R175 peptide mutation.

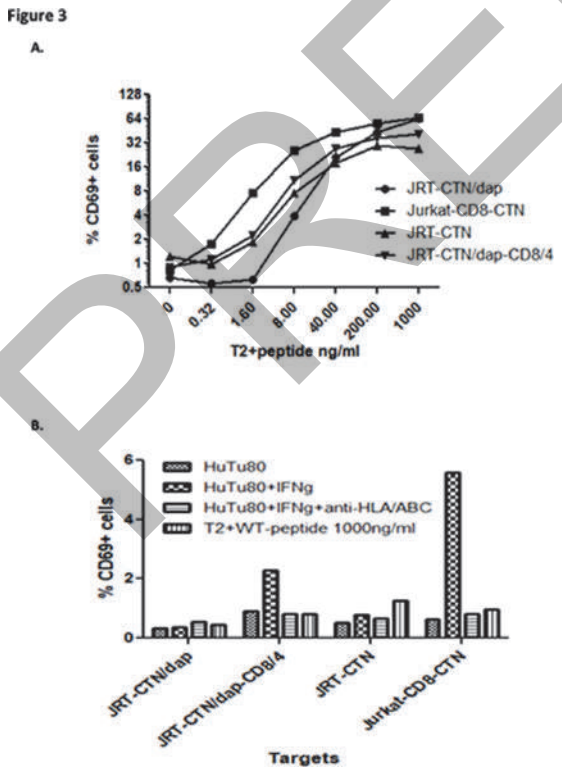
Figure 2



Abstract 230 Figure 2 Expression of a TCR-like chimeric-antigen-receptor.

TCR-like chimeric-antigen-receptor can be expressed on cell surface independent of endogenous CD3 components. Fig. 2A shows that a chimeric-antigen-receptor specific for the CTNNB1S37F neoepitope peptide in the context of HLA-A2 can be expressed on 293T cells. The additional disulfide bond formed between Ca and Cßs of the TCR is essential for the stable expression of the chimeric-antigen-receptor while the intracellular domains of CD28 have no effect. Fig. 2B shows that both T cells (J.RT3.5) and NK cells (KYGH-1) can be re-directed to express exogenous TCR-like chimeric-antigen-receptor to bind the epitope peptide/HLA-I

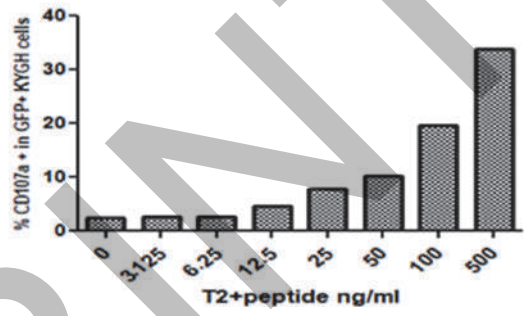
Figure 3



Abstract 230 Figure 3 Function of a TCR-like chimeric-antigen-receptor on T cells

TCR-like chimeric-antigen-receptor on T cells can functionally recognize the neoepitope peptide presented by HLA-I. Fig. 3A shows that a chimeric-antigen-receptor specific for the CTNNB1S37F neoepitope peptide in the context of HLA-A2 (JRT-CTN/dap) can be activated by the neoepitope peptide and its avidity can be enhanced by a co-receptor which is a CD8a/CD4 fusion receptor (CD8/4). Fig. 3B shows that with the help of the co-receptor, the avidity of the chimeric-antigen-receptor is comparable to the native TCR and capable of recognize the neoepitope peptide presented by HAL-A endogenously in tumor cells

Figure 4



Abstract 230 Figure 4 Function of a TCR-like chimeric-antigen-receptor on NK cells

TCR-like chimeric-antigen-receptor on NK cells can functionally recognize the neoepitope peptide presented by HLA-I. NK cells (KYGH-1) that re-directed to express a chimeric-antigen-receptor specific for the CTNNB1S37F neoepitope peptide in the context of HLA-A2 (JRT-CTN/dap) can be activated by the neoepitope peptide presented by HLA-A2 on the target T2 cells

231 DYSFUNCTIONAL IMMUNE SYNAPSES RESTRAIN ANTI-DIPG ACTIVITY OF CAR T CELLS

Jorge Ibanez*, Haley Houke, Michaela Meehl, Jennifer Ocasio, Nikhil Hebbar, Paulina Velasquez, Suzanne Baker, Giedre Krenciute. *St. Jude Children's Research Hospital, Memphis, TN, USA*

Background Diffuse intrinsic pontine gliomas (DIPGs) are highly lethal pediatric brain tumors. Thus, there is an urgent need for novel therapeutics. While chimeric antigen receptor (CAR) T-cell therapy has the potential to meet this need, early phase clinical studies with CAR T cells has shown limited anti-tumor activity for brain tumors. T cells require three signals for optimal activity, being (1) T cell activation, (2) costimulation, and (3) cytokines. While numerous investigators have focused on improving signals 2 and 3, the goal of this study was to investigate the role of immune synapse (IS) formation, which is critical for proper T cell activation, in the context of DIPG-targeted CAR T cell therapy.

Methods We generated GRP78-CAR T cells by expressing a 2nd generation CAR with a CD28.z signaling domain, which recognize an endoplasmic reticulum chaperone protein that is broadly expressed on the cell surface of DIPGs. We compared the effector function of GRP78-CAR T cells against U87 glioma and the patient-derived DIPG007 cell line, which are both positive for GRP78. Then we evaluated *in vitro* CAR T cell effector functions by MTS-based assays (cytotoxicity), repeated stimulation assays (persistence), and Milliplex (cytokine secretion). To gain mechanistic insight into tumor and CAR T cell interaction, we analyzed IS formation by live cell imaging confocal microscopy.

Results Our *in vivo* studies demonstrated that GRP78-CAR T cells eradicate orthotopic U87 brain tumors but have no anti-tumor activity against DIPG007, despite that GRP78-CAR T cells efficiently killed U87 and DIPG007 cells *in vitro*. However, the total cytokine production was significantly lower post DIPG007 activation (28 fold) when compared to U87 activation with IFNg, GM-CSF, TNFa, IL-2 and IL-13 being the most significantly suppressed in DIPG setting. In concordance, CAR T cells were only able to expand and retain their cytolytic activity in the presence of U87 cells. When we look at the CART:DIPG007 IS resulted in a significantly lower calcium flux in comparison to CART:U87 synapses. Likewise, the recruitment of lysosomes to CART:DIPG007 IS was significantly diminished. Importantly, we observe the same dysfunctional IS formation regardless of CAR T cell specificity and targeted antigen expression level indicating that the suppressive effect is DIPG-tumor mediated.

Conclusions Our study demonstrates that DIPG tumors suppress CAR T cell effector function by damping T cell activation through dysfunctional immune synapse formation. We are now testing other CARs and genetic engineering approaches directed at improving IS formation to overcome the suppressive effects of DIPGs.

232 INCREASED POTENCY AND FUNCTIONAL PERSISTENCE *IN VITRO* OF A NEXT-GENERATION NY-ESO-1-SPECIFIC TCR THERAPY INCORPORATING GEN-R™ GENETIC REPROGRAMMING TECHNOLOGY

[1]Helle Jensen*, [1]Rachel Fukuda, [1]Megan Murt, [1]Xiao Wang, [1]Lora Zhao, [1]Sheila Lou, [1]Purnima Sundar, [1]Christopher Navas, [1]Andrew Jimena, [1]Amanda Sims, [1]Travis Beckett, [1]Shobha Potluri, [1]Rowena Martinez, [1]David Chian, [1]Candace Sims, [1]Quinn Walker, [1]Abira Bandyopadhyay, [1]Breanna Pamintuan, [1]Bijan Boldajipour, [1]Chang-Chih Wu, [1]Martin Wohlfahrt, [1]Byoung Ryu, [1]Viola C Lam, [1]Rachel C Lynn, [1]Hajime Hiraragi, [2]Johannes Breuning, [2]Ashley Hamilton, [2]Fotini Kouri, [2]Jack Euesden, [2]Sara Brett, [1]Blythe Sather. *[1]Lyell Immunopharma, Inc, South San Francisco, CA, USA; [2]GSK, Stevenage, UK*

Background Letetresgene autoleucel (lete-cel; GSK3377794) is a first-generation (1st gen) NY-ESO-1-specific T-cell receptor (TCR) therapy with demonstrated clinical activity in solid tumors.[1-2] Next-generation T-cell therapies are in development with the goal of further improving response rates and durability. Gen-R is an *ex vivo* genetic reprogramming technology in which T cells are engineered to overexpress c-Jun, a member of the activator protein 1 (AP-1) family of transcription factors. Dysregulation of AP-1 family members is implicated in chimeric antigen receptor (CAR) T-cell exhaustion, and previous studies demonstrate that overexpressing c-Jun can delay functional exhaustion, thereby improving anti-tumor efficacy and CAR T-cell persistence in pre-clinical solid tumor models.[3] LYL331 (GSK4349560) is a next-generation NY-ESO-1-specific TCR therapy that incorporates Gen-R technology. Here we show pre-clinical data for LYL331 evaluating the impact of c-Jun overexpression on primary and long-term durable T-cell functions *in vitro*.

Methods Donor T cells were transduced with a lentiviral vector encoding EF1α_NY-ESO-1 (1st gen NY-ESO-1 TCR control) or EF1α_c-JunWT_NY-ESO-1 (LYL331) and characterized for primary functional activities (cytotoxicity, cytokine secretion, and proliferation) and NY-ESO-1 antigen sensitivity. In addition, we used an *in vitro* serial re-stimulation assay as a model for measuring features of T-cell exhaustion and evaluating long-term durable functions.

Results LYL331 displayed stable and high expression of c-Jun and showed multiple enhancements to primary T-cell functions *in vitro* compared to the control, including superior cytotoxic activity, as well as increased cytokine secretion (IFNγ and IL-2), proliferative capacity, and sensitivity towards the NY-ESO-1 peptide. Enhanced proliferation was observed in both CD4+ and CD8+ T cell populations, indicating that overexpressing c-Jun can improve T-cell functions in CD4+ T cells transduced with an HLA class I restricted NY-ESO-1 TCR. In addition, while the control displayed characteristics of exhaustion (i.e., loss of cytotoxic activity and cytokine secretion and increased expression of multiple exhaustion markers) in the serial re-stimulation assay, LYL331 maintained the ability to kill and secrete cytokines and displayed reduced expression of exhaustion markers TIGIT, PD-1, and CD39.

Conclusions In addition to supporting the hypothesis that genetic reprogramming with Gen-R technology can delay the onset of exhaustion and improve the long-term durable functions of LYL331, these data show that c-Jun overexpression can provide immediate benefits to the NY-ESO-1-specific TCR therapy during primary stimulation *in vitro*. Based on these promising pre-clinical data, LYL331 may have the potential to improve clinical responses in patients with solid tumor malignancies.

233 A REAL-WORLD CASE OF SECOND CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY

Jacinth Joseph, Dennis Marjoncu, Kori Holman, Sara Leidy*. *Methodist University Hospital, Memphis, TN, USA*

Background CD19-directed Chimeric Antigen Receptor T-Cell (CAR-T) therapy has emerged as a promising and novel treatment for relapsed and refractory (r/r) B-cell malignancies. Efforts are directed towards increasing persistence of CAR-T cells, which is known to lead to durable responses. Repeat CAR-T infusions have been explored in clinical trials.[1-14] Here, we report a second CD19-directed CAR-T treatment in a patient with diffuse large B-cell lymphoma (DLBCL).

Methods A 60-year old man diagnosed with r/r DLBCL received a CAR-T infusion with tisagenlecleucel having a cell viability of 75%, not meeting FDA specifications of $\geq$80%. After relapse, the same patient received a second CAR-T with axicabtagene ciloleucel (axi-cel). For both infusions, the patient received appropriate lymphodepletion. Throughout and following both infusions, the patient was monitored for cytokine release syndrome (CRS) or immune effector associated neurotoxicity syndrome (ICANS). mEASIX scores (figure 1) were calculated to evaluate association with developing CRS/ICANS and disease response. Appropriate imaging and additional follow-up of response was completed.

Results Following the patient's first CAR-T, he had no CRS or ICANS. He was discharged on day +9, then presented on day +84 with cough and dyspnea. Imaging showed an increase in lung lesion and pleural effusion. Biopsy of the lesion confirmed active lymphoma. Due to progression following CAR-T, he received two cycles of polatuzumab vedotin and rituximab for salvage. He then received his second CAR-T cell with axi-cel. On day +4, he developed grade 1 CRS, consisting of fever. CRS symptoms resolved on day +5 and he was discharged on day +12 without complications. Positron Emission Tomography (PET) scans on day +30, 3 and 6-months showed complete metabolic response (CMR), with persistently avid lesion at the L1 spine. This was biopsied showing no active lymphoma. Nine-month PET and 12-month CT showed no new findings to suggest active lymphoma and the patient remains in remission.

Conclusions Here, we present a case of a patient with r/r DLBCL who received two infusions of CAR-T cells. A second CAR-T treatment with a different product was used to treat relapse after first CAR-T in order to harness potential benefit from inherent differences between the 2 available commercial products, achieve adequate CAR-T cell dose, and avoid the higher-risk associated with the alternative treatment of allogeneic hematopoietic stem cell transplantation. As of 1-year post-second CAR-T the patient remains in a remission. This report reflects the benefit of a second infusion of CAR-T therapy in certain cases.

234 BEAD-BOUND ANTIBODY-ACTIVATION OF T CELLS PROVIDES SUB-OPTIMAL METABOLIC PROGRAMMING AND TUMOUR CONTROL COMPARED TO DENDRITIC CELL-ACTIVATED T CELLS

Meghan Kates*, Gavin Yuen, Michael St Paul, Alisha Elford, Pamela Ohashi, Sam Saibil. *University Health Network, Toronto, ON, Canada*

Background Adoptive cell therapies (ACT), including chimeric antigen receptor (CAR) or T cell receptor (TCR) transgenic T cells, have demonstrated impressive efficacy for the treatment of cancer. Unfortunately, ACT still does not result in durable responses for many patients.[1] Much investigation has centered around defining the characteristics of T cells that drive the clinical efficacy of ACT. Metabolic programming, and particularly oxidative metabolism, has emerged as a hallmark of T cells associated with superior performance in ACT due to important associations with *in vivo* persistence and metabolic resiliency in nutrient limiting environments.[2–7] However, further investigation is required to define the optimal *ex vivo* activation conditions to impart optimal metabolic programming on the T cells used for ACT. We therefore interrogated the difference in metabolic programming resulting from activation with antibody-coated beads versus peptide-pulsed dendritic cells (DCs).

Methods CD8+ T cells were isolated from P14 TCR transgenic mice (recognizing H2-D^b gp33 peptide from lymphocytic choriomeningitis virus). T cells were activated with either bone-marrow derived DCs pulsed with gp33 peptide (1:10 DC:T cells) or with bead-bound anti-CD3/anti-CD28 antibodies (1:1 beads:T cells). Oxidative and glycolytic metabolism were measured by Seahorse Extracellular Flux analyzer. These data were used to calculate ATP production rate. *In vivo*, we examined the performance of these differentially activated P14 T cells to control the growth of subcutaneously implanted B16-gp33 melanoma tumours.

Results DC-activated T cells showed increased oxidative and glycolytic metabolism compared to bead-bound antibody-activated T cells. This resulted in an enhanced rate of ATP production in the DC-activated T cells. These metabolic data were associated with efficacy in the B16-gp33 model of ACT. Mice treated with DC-activated T cells had significantly diminished tumour growth and improved survival when compared to the bead-bound antibody-activation treatment condition. The latter treatment provided little advantage over the control (no treatment) group.

Conclusions Bead-bound antibody activation of T cells at a ratio of 1:1 (beads:T cells) provides sub-optimal metabolic priming which is associated with decreased performance in ACT, particularly when compared to DC-activated T cells. Further investigation into the metabolic programming of T cells by different activation conditions may reveal metabolic or signaling modules that can be modified in these conditions to improve therapy. This is relevant to the efficacy of CAR T cell therapy which often uses bead-activation of T cells for clinical protocols.

235 CRISPR-MEDIATED INSERTION OF IL-12 INTO THE *PDCD1* LOCUS IMPROVES THE ANTITUMOR ACTIVITY OF TCR-T CELLS AGAINST SOLID TUMORS

Segi Kim*, Choi Park, Sunhwa Lee, Hyeongryeol Choi, Chan Hyuk Kim. *Korea Advanced Institute of Science and Technology, Daejoen, Republic of Korea*

Background Interleukin-12 (IL-12) is a powerful immunostimulatory cytokine that has been expressed ectopically in genetically engineered T cells to enhance their antitumor activity. However, the constitutive production of IL-12 by engineered T cells caused severe adverse effects in patients. Thus, to fully harness the immunostimulatory potential of IL-12 while avoiding systemic toxicity, we inserted *IL-12* gene into the *PDCD1* locus in T cell receptor (TCR)-engineered T cells using the CRISPR/Cas9-based genome editing tool, which allows for IL-12 secretion to be induced strictly in a T cell activation-dependent manner.

Methods As a model TCR, we used a monoclonal TCR that is specific to the NY-ESO-1 (SLLMWITQV) peptide. The PD1-edited NY-ESO-1-specific TCR-T cells were generated by sequential lentiviral transduction and Cas9 RNP/AAV6-based knock-in into human primary T cells. The resulting TCR-T cells were co-cultured with an A375 cell line expressing NY-ESO-1 antigen to evaluate cytokine production, cytotoxicity, and proliferation *in vitro*. *In vivo* antitumor activity of the TCR-T cells was investigated in A375 xenograft models using NSG mice.

Results The *PDCD1* locus was successfully edited in NY-ESO-1 TCR-T cells by replacing the endogenous PD-1 gene with a single-chain IL-12 transgene, without affecting the viability or expansion of the engineered T cells. Upon recognition of the target cells, the IL-12 transgene was expressed successfully, resulting in the strong phosphorylation of STAT-4 in the TCR-T cells. As compared to control TCR-T cells, these ΔPD-1-IL-12 NY-ESO-1 T cells displayed enhanced *in vitro* effector function, including increased secretion of IFNγ, TNF, and IL-10 as well as faster tumor cell lysis. In addition, ΔPD-1-IL-12 NY-ESO-1 T cells expanded more robustly after repeated challenges with PD-L1 overexpressing target cells. In xenograft models, ΔPD-1-IL12 NY-ESO-1 T cells potently eliminated established tumors and demonstrated increased tumor infiltration compared to control TCR-T cells.

Conclusions Using the CRISPR/Cas9 system, we demonstrated that the upregulation of PD-1, an immune-suppressive event in T cells, could be reprogrammed to secrete immunostimulatory IL-12 in TCR-T cells. In both *in vitro* assays and *in vivo* mouse xenograft studies, these PD-1-edited TCR-T cells demonstrated enhanced cytotoxic activity. Our approach may offer a novel engineering option for adoptive T cell therapy against solid tumors.

236 EXPANSION OF TUMOR-INFILTRATING LYMPHOCYTES FROM HEAD AND NECK SQUAMOUS CELL CARCINOMA TO ASSESS THE SUCCESSFUL EXPANSION FACTORS FOR DEVELOPING ADOPTIVE CELL THERAPY

[1]Mofazzal Hossain*, [1]Jong Hyeok Kim, [2]Hyun Lee, [2]Chae-Lyul Lim, [3]Gyungyub Gong, [3]Hee Jin Lee. *[1]University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]NeogenTC corp, Gyeonggi-do, hanam-si, Republic of Korea; [3]Asan Medical Center, Seoul, Republic of Korea*

Background Adoptive transfer of *in vitro* expanded tumor-infiltrating lymphocytes (TILs) has been effective in regressing several types of malignant tumors, which was first applied to metastatic melanoma more than three decades ago. Promising results of such adoptive cell therapies have intrigued us to evaluate their feasibility in unexplored cancer types that are difficult to treat with existing treatment options. Hence, we evaluated the possibility of TIL expansion from head and neck squamous cell carcinoma (HNSCC), the factors affecting their successful expansion, and the immune phenotypes of expanded TILs.

Methods We tried to expand TILs from 51 specimens (36 patients) of surgically resected HNSCC of three different anatomical location groups, including primary tumors and their metastasized lymph nodes (LNs). Cancer tissues were cut into small pieces (1-2 mm each) and underwent initial expansion for 2 weeks with gentamycin (400-1600 μg/ml). The cutoff value of successful expansion was 0.8 × 10^5 TILs per fragment. Factors affecting the successful expansion or contamination were determined mainly by focusing on the location of the samples. The characteristics of expanded cells were evaluated by flow cytometry.

Results TILs were successfully expanded from 35% of the samples (18 of 51). Mean number of TILs per fragment in successful cases of LNs was 6.1±4.6 × 10^5 (n=9), whereas the value was 4.3±3.8 × 10^5 (n=9) in primary tumors. Among three location groups of the primary tumors, the success rate was higher in samples of oropharynx & larynx than those of oral cavity (44%, 33%, and 19%, respectively). Mean percentage of CD4+ T cells was 60% in compared to 30% for CD8+ T cells. Mean proportion of T_{EM}, T_{EFF}, T_{CM}, and T_{NAIVE} were 88.5%, 4.7%, 4.8%, and 1.8% in CD4+ T cells, while 80.0%, 13.4%, 3.6%, and 2.9%, respectively in CD8+ T cells. However, 27% of the total samples were contaminated, and the rate was higher in tumor samples than in LN samples, 36%, and 11%, respectively.

Conclusions We could expand TILs from a third of primary tumors and LN samples of HNSCC. LN samples generated slightly more TILs per fragment than primary tumors while getting less contaminated. To use primary HNSCCs as a source of TIL therapy, a setting of clinically applicable antibiotic treatment during the manufacturing process is necessary. Varied success rates were observed according to the location of the cancer tissues, but those remain to be checked statistically with a large number of samples.

237 NEOANTIGEN-SPECIFIC EXPANSION OF TUMOR-INFILTRATING LYMPHOCYTES ENABLES EFFECTIVE TREATMENT OF P53-MUTANT CANCER IN MICE

Peter Kim*, Noam Levin, Nolan Vale, Steven Rosenberg. *NCI, Bethesda, MD, USA*

Background Adoptive cell therapy (ACT) targeting neoantigens can achieve durable clinical responses in patients with advanced solid cancer.[1-3] However, many T cells among the tumor infiltrating lymphocytes (TIL) are not specific for tumor antigens.[4-6] Additionally, *ex vivo* expansion of TILs often results in further reduction and differentiation of TILs specific for neoantigens.[7] The low frequencies and/or differentiated phenotype of TILs can contribute to ineffective ACT.

Methods We developed a protocol to selectively expand neoantigen-specific TILs by *in vitro* stimulation of target neoantigens, termed NeoExpand. As a proof-of-concept we performed NeoExpand on p53 neoantigen-specific TILs. TILs were incubated with antigen presenting cells either electroporated with tandem minigene RNAs encoding multiple p53 neoantigens in 25mers or pulsed with mutant peptides (25mers or minimal epitopes) and cultured in media containing 300-1000 IU interleukin (IL) 2 and 30 ng/mL IL-21 for 14 days.

Results We retrospectively determined the frequencies of neoantigen-reactive TILs in 10 patient infusion products by *CDR3B* deep sequencing. 62% (41/61) of neoantigen-reactive clones were <1% in the infusion products. TILs from patient 4196 initially containing ~2% of TILs recognizing $p53^{R175H}$, one of the "hotspot" p53 mutations, were subjected to NeoExpand and the rapid expansion protocol (REP) with feeder cells, OKT3 and IL-2. Following REP, 0.4% of 4196 T cells were reactive with $p53^{R175H}$, indicating that REP decreased the frequency of the $p53^{R175H}$-reactive clones. In contrast, the 4196 TILs following NeoExpand contained 8% TILs reactive with $p53^{R175H}$, which was a 4-fold increase in the $p53^{R175H}$-reactive cells relative to the starting population and 20-fold higher than that of REP. While conventional TIL screening identified 3 T-cell receptors (TCRs),[8-10] NeoExpand enabled identification of 7 TCRs including the 3 TCRs identified by conventional screening. *In vivo*, 4196 TIL expanded through REP was ineffective in treating established TYK-nu human ovarian cancer cells that naturally expressed $p53^{R175H}$,[7] while the 4196 NeoExpand TILs effectively regressed the tumor in NSG mice. Single cell transcriptome analysis demonstrated that NeoExpand led to expansion of central memory/stem-like populations among the mutant p53-reactive clones in the 4196 TILs, while REP led to the depletion of the central memory/stem-like population. In total, we identified 18 TCRs recognizing various p53 neoantigens, including 7 uniquely identified by NeoExpand from 6 patient samples.

Conclusions In conclusion, these data indicate that TILs specific for neoantigens can be preferentially expanded by NeoExpand, enabling effective TCR isolation and treatment of p53-mutant cancer in mice.

Trial Registration Patient samples and healthy donor peripheral lymphocytes were obtained through the tissue procurement protocol NCT00068003.

238 EXOGENOUS GOT2 IN CAR-T CELLS IMPROVES METABOLIC FUNCTION AND PRESERVES EARLY MEMORY T CELL SUBSETS

John Hinds*, Sujatha Muralidharan, Ann Ranger, Jennifer Coccia, Thomas Giordano, Emily Kuiper, Pratirodh Koirala. *SOTIO Biotech Inc., Cambridge, MA, USA*

Background To overcome the challenges of a hostile solid tumor microenvironment, we have engineered CAR-T cells to co-express mitochondrial enzyme glutamic-oxaloacetic-transaminase 2 (GOT2). GOT2 is hypothesized to improve CAR-T cell fitness by maintaining cellular redox balance under oxidative stress and fueling the tricarboxylic acid (TCA) cycle via glutaminolysis. *In vivo* preclinical studies have shown improved anti-tumor activity of glypican-3 (GPC3)-targeting CAR-T cells co-expressing GOT2 (BOXR1030) compared to Control GPC3 CAR-T cells. In this study, we have characterized the cellular phenotype and mitochondrial function of BOXR1030 T cells compared to Control CAR-T cells to better understand the contribution of GOT2 to improved CAR-T function.

Methods Phenotype and function of BOXR1030 and Control CAR-T cells (n=3 donors) were assessed at the end of standard CAR-T cell manufacturing process, after repetitive stimulation with anti-idiotype antibody (up to 5 stimulations over 15 days) and co-culturing with GPC3-expressing Hep3B cells (2D) or Hep3B spheroids (3D) in standard or low glucose culture conditions. T cell differentiation status was assessed by flow cytometry using CD45RA, CD45RO, CCR7, CD27, CD28 and CD95. Mitochondrial health was measured by analyzing mitochondrial mass, membrane potential and reactive oxygen species (ROS) generation. Cytotoxic function in terms of tumor cell killing and Granzyme B secretion in culture supernatant were measured by Incucyte and MSD respectively.

Results At the end of manufacturing, BOXR1030 T cells have a higher frequency of T stem cell memory (CD45RA+CCR7+CD27+CD95+) and T central memory (CD45RO+CCR7+CD27+) in CD8+ populations relative to Control CAR-T cells. BOXR1030 T cells also have a lower frequency of terminally differentiated CD27-CD28- T cells. Following *in vitro* stimulation or Hep3B co-culture in standard and low glucose culture conditions, BOXR1030 T cells showed preservation of early memory populations, reduced CD27-CD28- senescent cells and improved cytotoxic function relative to Control CAR-T cells. Since changes in mitochondrial function are associated with T cell differentiation and senescence, we explored mitochondrial health of BOXR1030 T cells *in vitro*. In low glucose culture conditions, BOXR1030 T cells showed reduced ROS levels and reduced loss of mitochondrial membrane potential compared to Control CAR-T cells.

Conclusions BOXR1030 CD8+ T cells contain a higher frequency of early memory cells with fewer terminally differentiated senescent cells and show improved mitochondrial health compared to Control CAR-T cells. These data suggest potentially increased fitness of BOXR1030 T cells enabling enhanced *in vivo* T cell persistence and antitumor activity. BOXR1030 is currently in Phase 1 trials to assess safety and preliminary efficacy (NCT05120271).

239 ENGINEERING OF POTENCY-ENHANCED TCR-EDITED T CELLS FOR SHARED NEOANTIGEN-TARGETED CANCER IMMUNOTHERAPY

Lianne Kok*, Sander Eshuis, Paula Kroon, Vanessa Tubb, Xiangjun Kong, Carsten Linnemann, Gavin Bendle, Jeroen van Heijst. *Neogene Therapeutics, Amsterdam, Netherlands*

Background Human cancers can express both private and shared mutation-associated neoantigens, the latter being derived from recurrent cancer driver gene mutations, with the R175H mutation in the human *TP53* tumor-suppressor gene being the most frequently shared between patients across cancer types. This makes the generation and subsequent adoptive transfer of TCR-engineered T cells reactive to an HLA-A*02:01-restricted $TP53^{R175H}$ epitope a highly attractive cancer immunotherapy approach. However, the combined immunosuppressive tumor-microenvironment and the low levels of neoantigen presentation by solid cancers compromise the activation and reactivity of TCR-engineered T cells, posing a major hurdle for these cells to eradicate tumor lesions. A substantial body of work has highlighted that inactivation of negative regulators of TCR signaling can augment T cell functionality and anti-tumor reactivity.

Methods Aiming to develop a highly potent anti-cancer T cell product, we applied CRISPR genome engineering to specifically introduce a $TP53^{R175H}$-specific TCR into the TRAC locus of primary human T cells, while simultaneously inactivating negative regulators of TCR signaling. After validating successful introduction of the $TP53^{R175H}$ TCR and inactivation of endogenous TCR chains and the TCR inhibiting genes of interest, the ability of edited T cells to proliferate, produce cytokines and control tumor growth were assessed in vitro.

Results We found that inactivation of TCR signaling inhibitory genes significantly enhanced the ability of TCR-edited T cells to proliferate and produce the cytokines IFN-γ, TNF and IL-2, both in response to anti-CD3/anti-CD28 stimulation and HLA-A*02:01^{+} tumor cell lines that express the $TP53^{R175H}$ mutation. Notably, T cells that had lost expression of negative regulators of TCR signaling were also superior in serial killing of $TP53^{R175H}$-positive tumor cells in vitro, while these T cells did not inhibit tumor cells that overexpressed a TP53 R175 WT epitope.

Conclusions Taken together, our findings show that inactivation of negative regulators of the TCR signaling pathway can enhance the reactivity of TCR-edited T cells against shared neoantigen-expressing tumor cells, thereby providing a promising new approach to increase the efficacy of TCR therapy directed against solid human cancers.

Ethics Approval Samples were obtained through a supply agreement with Sanquin Bloedvoorziening Amsterdam. These samples were collected only from voluntary, non-remunerated, adult donors who provided written informed consent as part of routine donor selection and blood collection procedures, that were approved by the Ethics Advisory Council of Sanquin Blood Supply Foundation.

240 HUMANIZED CD30 CHIMERIC ANTIGEN RECEPTOR T CELLS WITH A NOVEL 4–1BB DERIVED SPACER HAVE IMPROVED ACTIVITY AND SAFETY AGAINST CD30-POSITIVE LYMPHOMAS

Lindsay Kua*, Chee Hoe Ng, Jin Wei Tan, Richard Ong, Cheah Chen Seh, Fiona Wong, Don Sim, Ivan David Horak, Lionel Low, Kar Wai Tan. *Tessa Therapeutics, Singapore, Singapore*

Background Autologous T cells expressing chimeric antigen receptors (CARs) against CD30 have demonstrated high clinical efficacy in the treatment of relapsed or refractory CD30-positive classical Hodgkin lymphoma (cHL) [1]. In the allogeneic setting, we have treated nine CD30-positive lymphoma patients in an ongoing Phase 1 study (NCT04288726) with Epstein-Barr virus specific T cells (EBVST) expressing a CD30-specific CAR derived from the murine HRS-3 antibody. These allogeneic CD30.CAR EBVSTs show promising signs of efficacy with a favorable safety profile and no evidence of graft versus host disease (GVHD). However, low levels of infused CD30.CAR EBVSTs were detected in the peripheral blood of most patients seven days post infusion, suggesting that durable persistence of these cells remains a challenge. In this study, we seek to improve the persistence of the CD30.CAR EBVSTs with the humanization of the murine HRS-3 scFv to minimize immunogenicity, and the replacement of the current IgG1 spacer with a novel 4-1BB derived spacer to eliminate any off-target interactions.

Methods CD30.CARs with humanized scFvs and novel spacers were designed and evaluated on their *in vitro* cytolytic potency and cytokine secretion profile. Top candidates were further tested for *in vivo* efficacy and safety in CD30-high tumor models.

Results CD30.CARs with humanized scFvs preserved specificity and efficacy, and exhibited improved stability as compared to the parent HRS-3 CAR. We found that HRS-3 binds to the cysteine-rich domain 5 of the CD30 molecule, which enabled informed design of novel spacer candidates. In combination with the murine HRS-3 scFv, the novel spacer derived from the 4-1BB receptor decreased basal cytokine secretion compared to the current IgG1 spacer, while retaining cytolytic activity *in vitro*. Humanized CD30.CARs combined with the 4-1BB-derived spacer did not exhibit any nonspecific interactions with CD16+ immune cells, while displaying superior efficacy *in vitro*, better persistence *in vivo* in various humanized mouse models, and more importantly an improved safety profile in a leukemia model with high tumor burden.

Conclusions Our re-engineered CD30.CAR construct, consisting of a humanized CD30.CAR and a 4-1BB-derived spacer, is likely to improve allogeneic CD30.CAR EBVST performance.

241 DEVELOPMENT OF A PERSONALIZED NEOANTIGEN-SPECIFIC TCR DISCOVERY PLATFORM

[1]Robbert Spaapen*, [1]Thomas Kuilman, [1]Bo Schrikkema, [1]Jules Gadiot, [1]Raquel Gomez, [1]Julia Walker, [1]Laura Bies, [1]Oscar Krijgsman, [1]Yvonne Claassen, [1]Milena Viyacheva, [1]Demi Houg, [1]Manuel Soarnil, [1]Huiwen Ding, [1]Bas Stringer, [1]Gavin Bendle, [1]Carsten Linnemann, [2]Ton Schumacher. [1]*Neogene Therapeutics, Amsterdam, Netherlands*; [2]*Netherlands Cancer Institute, Amsterdam, Netherlands*

Background Tumor-infiltrating lymphocyte (TIL) therapy can mediate tumor regression in a range of solid cancers, most notably in melanoma. However, its wider application and efficacy has been limited by the low frequency and exhausted phenotype of tumor-specific T cells in the final product. Here, we developed a personalized, neoantigen-specific TCR discovery platform that will enable engineering of multiple TCRs into autologous peripheral blood T cells. This allows for the generation of a fitter T cell product with a high frequency of tumor-reactive TCRs of defined specificity.

Methods Our platform first identifies tumor-specific mutations and TIL-derived TCR repertoires from non-viable tumor specimens using next-generation sequencing (NGS), which are subsequently recreated using synthetic biology technology. The synthesized TCR libraries are expressed in reporter T cells, whereas neoantigen libraries are engineered in autologous APCs. Following coculture of these cells, activated and non-activated T cells are separated, followed by neoantigen-specific TCR identification using NGS-based analysis.

Results We validated the high sensitivity and specificity of this platform by successfully identifying multiple TCRs and their cognate neoantigens from high tumor mutational burden (TMB) cancers including melanoma. Notably, we show that the platform is agnostic to the type of mutation and HLA class restriction. Importantly, neoantigen-specific TCRs can also be isolated from a panel of low TMB microsatellite-stable colorectal cancers, underscoring the pan-cancer potential of this approach.

Conclusions We commenced applying this approach in a clinical study in which patients will be treated with functional autologous T cells engineered with neoantigen-specific TCRs of defined specificity and composition.

242 DEVELOPMENT OF POOLED SCREENING PLATFORM FOR DISCOVERING THE NEXT GENERATION CHIMERIC ANTIGEN RECEPTORS

Taeyoon Kyung*, Nicole Wong, Andreas Rolfs, Lucas Hartsough, Joshua Mace, Jai Raman, Adam Scheidegger, Adam Meyer, Siqi Zhao, Lauren Baugh, Keith Robison, Narendra Maheshri, Shawdee Eshghi. *Ginkgo Bioworks, Cambridge, MA, USA*

Background Signaling cascades triggered by intracellular domains (ICDs) of Chimeric Antigen Receptor (CAR) in immune cells drive cell behaviors that correspond to different therapeutic outcomes. While canonical CAR-T ICD combinations 4-1BB-CD3z (BBz) and CD28-CD3z (28z) have achieved clinical success in a limited number of hematologic indications, CAR-based cell therapies have not yet been successful in more challenging indications. Systematic discovery of novel ICD combinations that drive more favorable T cell phenotypes has been onerous due to technical constraints in high-throughput screening and scaling.

Methods Here, we developed a versatile platform that allows parallel comparison of 10,000 different 2nd generation CAR ICD combinations in primary CD8+ T cells. We utilized combinatorial genetics en masse (CombiGEM) to assemble multiple DNA-barcoded lentiviral libraries of CAR ICDs distinguished by the affinity of extracellular binder and the length of hinge/spacer. We screened CAR ICD libraries for T cell persistence and fitness in a serial tumor rechallenge assay in a pooled manner.

Results Precisely tracking enriched barcodes over the course of 20 days allowed us to identify novel CAR clones with superior T cell proliferation and survival relative to conventional BBz and 28z CARs. Hits were validated in downstream arrayed studies with additional functional characterization including cytotoxicity, cytokine secretion, and T cell memory and exhaustion phenotypes in the serial tumor rechallenge assay.

Conclusions We believe our approach is readily applicable to diverse immune cell types, including T cell subsets, NK cells and macrophages, as well as different CAR domains including binders, structural components, and armoring components in addition to ICDs. Rapid and systematic generation and comparison of synthetic molecules at scale in pooled libraries via our platform will further elucidate design principles to guide next generation cell therapies engineering strategies.

243 NR4A3 GENE EDITING AND C-JUN OVEREXPRESSION SYNERGIZE TO LIMIT EXHAUSTION AND ENHANCE FUNCTIONAL ACTIVITY OF ROR1 CAR T CELLS *IN VITRO* AND *IN VIVO*

Viola Lam*, Jessica Barragan, Christina Cheung, Jia Lu, David Chian, Rowena Martinez, Candace Sims, Purnima Sundar, Hajime Hiraragi, Shobha Potluri, Rachel Lynn. *Lyell Immunopharma, Inc., South San Francisco, CA, USA*

Background Next-generation strategies to improve T-cell functional activity, persistence, and durability are needed for effective cellular immunotherapy against solid tumors. Overexpression of the activator protein 1 (AP-1) family transcription factor c-Jun reduces chimeric antigen receptor (CAR) T-cell exhaustion thereby improving functional activity in multiple preclinical models.[1] Nuclear receptor subfamily 4A (NR4A) transcription factors may contribute to exhaustion and limit T-cell function by restraining expression of AP-1 regulated genes.[2,3] Thus, we hypothesize that NR4A knockout (KO) and c-Jun overexpression may synergize to further limit exhaustion and enhance CAR T-cell function.

Methods Healthy donor T cells were transduced with a ROR1 CAR lentiviral vector with (+) or without (-) c-Jun overexpression. NR4A family genes (NR4A1, NR4A2, or NR4A3) were disrupted using CRISPR/Cas9 ribonucleoprotein delivery via electroporation (EP). CAR T-cell cytotoxicity and cytokine production were evaluated *in vitro* after primary and repeated antigen-stimulation assays designed to promote exhaustion. Cell phenotypes (flow cytometry) and transcriptional profiling (bulk and single-cell RNA-Seq) were also assessed. Finally, CAR T cells were evaluated *in vivo* using a ROR1-expressing H1975 lung cancer xenograft model in mice.

Results NR4A3 KO ROR1 CAR T cells consistently demonstrated superior cytotoxic activity and prolonged cytokine production upon repeated antigen stimulation compared to NR4A1 KO, NR4A2 KO, and EP control ROR1 CAR T cells. NR4A3 KO showed significant synergy in ROR1 CAR T cells overexpressing c-Jun (figure 1).

NR4A3 KO + c-Jun ROR1 CAR T cells were phenotypically and functionally indistinguishable at primary antigen stimulation. However, this combination resulted in the highest levels of cytokine production (IFN-γ, IL-2, and TNF-α), increased CAR T-cell persistence, and reduced surface expression of inhibitory receptors after repetitive antigen stimulation, suggesting a mechanism of resistance to exhaustion-induced dysfunction. Transcriptomic analysis indicated that NR4A3 KO + c-Jun increased effector and interferon response-associated T-cell subsets, yet reduced terminal exhaustion compared to control + c-Jun ROR1 CAR T cells following antigen restimulation.

NR4A3 KO + c-Jun ROR1 CAR T cells showed the most robust anti-tumor efficacy *in vivo* with activity at a 7-fold reduced CAR T-cell dose and demonstrated more than 20-fold greater CAR T-cell expansion in blood compared to control + c-Jun ROR1 CAR T cells (figure 2).

Conclusions These data suggest that reducing NR4A3 expression in combination with c-Jun overexpression has the potential to further limit exhaustion and provide durable ROR1 CAR T-cell functional activity compared to either strategy alone, which may improve cellular immunotherapy against ROR1-expressing solid tumors.

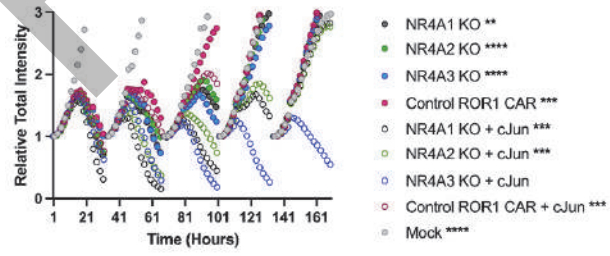
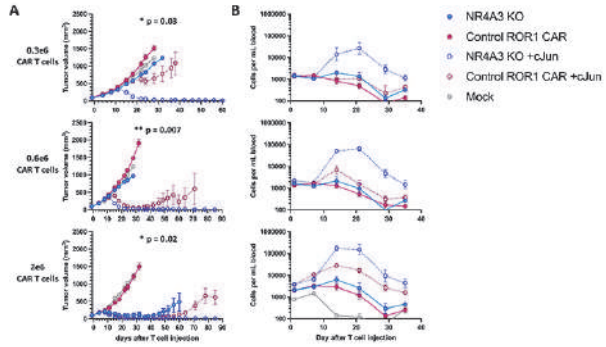
Ethics Approval Experiments presented in this abstract relied on human donor material that was obtained from commercial vendors. These vendors use their own IRB-approved protocol and consent process. In vivo experiments presented in this abstract were approved by Lyell Immunopharma's IACUC (EB17-010-117).



Abstract 243 Figure 1 Successive lysis of ROR1-expressing H1975-NucLight Red (NLR) target cells by NR4A1 KO, NR4A2 KO, NR4A3 KO, or control unedited ROR1 CAR T-cells with (+) or without (-) c-Jun overexpression, and mock untransduced T cells in one representative donor of four donors tested. Lysis of H1975-NLR target cells was quantified by measuring total NLR intensity. NLR intensity was normalized relative to the starting intensity after replating for each round of stimulation. NR4A3 KO + c-Jun showed significant synergy at the last timepoint of the fifth stimulation compared to other T-cells tested. Asterisks represent p-value significance of each condition compared to NR4A3 KO + c-Jun (unpaired t-test, ** $p < 0.005$, *** $p < 0.001$, **** $p < 0.0001$).



Abstract 243 Figure 2 Anti-tumor efficacy at three CAR T-cell doses (A) and CAR T-cell expansion (B) of NR4A3 KO or control edited ROR1 CAR T cells with (+) or without (-) c-Jun overexpression, and mock untransduced T cells in one representative experiment (n=3 healthy donors) tested in an in vivo H1975 xenograft model. NR4A3 KO + c-Jun CAR T cells significantly impaired tumor growth at all three CAR T cell doses tested compared to control + c-Jun (* $p < 0.05$, ** $p < 0.005$, Tukey one-way ANOVA). At the 0.6x106 CAR T-cell dose, NR4A3 KO + c-Jun CAR T cells demonstrated a significantly higher day 21-fold expansion compared to control + c-Jun (mean of 40.1 vs 1.7, ****$p <$ 0.0001, unpaired t-test, n=10 mice per group). Day 21-fold expansion was normalized relative to day 1.

244 AFNT-111, A SAFE AND EFFECTIVE TCR-ENGINEERED T CELL THERAPY TARGETING THE ONCOGENIC DRIVER KRAS G12V MUTATION

[1]Hubert Lam*, [1]Xingyue He, [1]Cheryl Black, [1]Michele Hoffmann, [1]Joshua Francis, [1]James Parsons, [1]Christian Roy, [1]Jinsheng Liang, [1]Hongjing Qu, [1]Martin Campbell, [1]Tomasz Sewastianik, [2]Jessica Webb, [2]Aude Chapuis, [2]Thomas Schmitt, [2]Philip Greenberg, [1]Damien Hallet, [1]Markus Vallaster, [1]Piotr Pierog, [1]Gary Shapiro, [1]Loic Vincent. *[1]Affini-T Therapeutics, Watertown, MA, USA; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, USA*

Background Mutations in the *RAS* family of genes are responsible for approximately 30% of all human cancers. Mutated RAS proteins are truncal oncogenic driver antigens essential for cancer development and progression making them optimal targets for cancer therapies by limiting tumor escape. The AFNT-111 cell therapy consists of autologous $CD8^+$ and $CD4^+$ T cells expressing a TCR specific for the highly prevalent $KRAS_{G12V}$ mutation presented by HLA-A*11:01, one of the most common HLA alleles worldwide. AFNT-111 is also engineered to express the CD8α/β coreceptor, enabling a coordinated $CD4^+/CD8^+$ tumor response that aims to promote increased T cell activity and persistence while minimizing T cell exhaustion.

Methods Lentiviral vector was used to transduce primary human $CD4^+$ and $CD8^+$ T cells with the $KRAS_{G12V}$-specific TCR and CD8α/β coreceptor. Engineered T cells were assessed against $KRAS_{G12V}$ peptide and a panel of $KRAS_{G12V}$-expressing tumor cell lines for *in vitro* activation, proliferation, and cytotoxicity. *In vitro* safety studies were performed to evaluate self-peptide cross-reactivity and alloreactivity and *in vivo* efficacy studies were conducted using human $KRAS_{G12V}$ xenografts in NSG mice.

Results AFNT-111 demonstrated potent functional avidity for $KRAS_{G12V}$ peptide with no reactivity to wildtype KRAS. Several naturally expressing $KRAS_{G12V}$ human tumor cell lines, derived from lung, colorectal, and pancreatic cancer, triggered significant AFNT-111 T cell activation and proliferation, and potent cytotoxicity towards tumor cells. *In vitro* killing by AFNT-111 was consistently observed even after repeated tumor cell challenge. Robust *in vivo* anti-tumor efficacy was also observed in two established mouse xenograft tumor models. XScan studies using amino acid substitutions of the reference $KRAS_{G12V}$ peptide revealed a restrictive TCR recognition motif limiting risk of promiscuous off-target activation. Further, potentially cross-reactive self-peptides in the human proteome matching this motif were tested and no cross-reactivities with significant avidity were identified. A large lymphoblastoid cell line library covering >95% of the most common HLA alleles was assessed with no alloreactive responses detected. For clinical studies, a robust manufacturing process has been developed in which $CD4^+/CD8^+$ T cell ratios are controlled, and the final AFNT-111 drug product preserves stem-like properties.

Conclusions AFNT-111 preclinical data demonstrate a highly potent and specific TCR-engineered T cell product that is cytotoxic to $KRAS_{G12V}$-expressing tumor cells both *in vitro* and *in vivo*. Cross-reactivity and alloreactivity assessments established a strong safety profile of AFNT-111, supporting clinical translation. First-in-human clinical studies will focus on advanced or metastatic pancreatic, colorectal, and lung cancer indications.

Ethics Approval These studies were approved by Affini-T Therapeutics and Fred Hutchinson Cancer Research Center Ethics Boards, approval number EB17-010-303 and PROTO000050898, respectively.

245 CORD BLOOD CD34+ STEM CELLS ARE EFFICIENTLY TRANSDUCED WITH ANTI-CD19-CAR AND EXPANDED AND DIFFERENTIATED INTO VIVENK™ NATURAL KILLER CELLS WHICH DISPLAY SELECTIVE CYTOTOXICITY AGAINST B-CELL LEUKEMIA

Monica Raimo*, Nina Lamers-Kok, Didem Özkazanc, Daniëlle Steenmans, Greis Shahini, Amanda van Vliet, Denise Panella, Arianna Micciché, Youri van Waardenburg, Anna-Maria Georgoudaki, Jan Spanholtz, Adil Duru. *Glycostem Therapeutics, Oss, Netherlands*

Background Chimeric antigen receptor (CAR)-engineered Natural Killer (NK) cells are a highly promising option for adoptive cancer immunotherapy. Glycostem Therapeutics has developed a closed, automated, and feeder-free system for ex vivo expansion and differentiation of umbilical cord blood-derived CD34+ stem cells into highly functional NK cells, currently evaluated in a Phase I/II clinical study (ClinicalTrials.gov ID: NCT04632316). The introduction of a genetic engineering step during early culture stages makes the system suitable for CAR-NK products, for the generation of billions of off-the-shelf viveNK™ cells for antigen-directed tumor targeting.

Methods To enhance the ability of NK therapies to kill resistant B-cell leukemia cells, we generated anti-CD19-CAR viveNK™ cells via lentiviral transduction with multiple second- and third-generation CARs carrying different hinge, transmembrane and intracellular domains. CAR cassettes were cloned into Glycostem's own clinically suitable lentiviral transfer plasmid; promoter analysis identified MNDU3 as the optimal transgene driver.

Results Engineered cells showed high expansion potential and fast differentiation into functional NK cells expressing specific surface markers. CAR surface expression increased up to 83% (n=8 donors) with higher Multiplicity of Infection (MOI) in a range of 1-20, but was sustained even at low (<5) MOI. CAR transgene genome integration (Vector Copy Number) and transcriptional efficiency was evaluated via quantitative Polymerase Chain Reaction (PCR). Exposure of CD19-viveNK™ cells to antigen-expressing B-cell leukemia cell lines resulted in increased degranulation and very potent antigen-specific cytotoxicity. Additionally, inherent innate NK cell phenotype and responses and the mechanism of action driving CD19-CAR viveNK™ cytotoxicity were investigated via flow cytometry-based analysis and single-cell RNA-sequencing (scRNA-Seq) of CAR-transduced vs non-transduced donors.

Conclusions Our data show how off-the-shelf, highly functional, and antigen-directed CAR-NK cells can be generated ex vivo, offering an option to target cancers which are often resistant or difficult to treat with standard immunotherapy.

ALLOGENEIC "OFF-THE-SHELF" γδ T CELLS MODIFIED WITH CD27-CONTAINING CAR FOR TARGETING CD70$^+$ CANCERS

Gauri Lamture, Alexander Teague, Morgan Smith-Boeck, Michael Salum, Ramandeep Kaur, Smitha Gundurao, Pannaga Parthasarathy, Yvan Chanthery, Marissa Herrman, Blake Aftab, Arun Bhat, Kevin Nishimoto*. *Adicet Bio, Inc., Redwood City, CA, USA*

Background CD70, a member of the TNF receptor ligand family, represents a compelling target for the development of CAR T cell therapies due to its high expression in multiple solid and hematologic malignancies. Although CAR T cells have shown remarkable clinical benefit in hematologic malignancies, efficacy in solid tumors has highlighted key challenges. Among the emerging strategies to improve clinical responses is the use of alternative cytotoxic effector cells with multifunctional tumoricidal activity. γδ T cells combine innate and adaptive immunity to recognize and kill malignant cells. In addition, the infiltration of γδ T cells into various cancer types, including those expressing CD70, significantly correlates with survival. Strategies for targeting CD70 have explored scFvs or engineering its natural receptor (CD27) as the antigen-recognition moiety of a CAR. Recent studies demonstrate improved preclinical antitumor activity using the CD27 ligand compared to scFv-based CAR, suggesting functional advantages associated with a CD27-based CAR approach.[1] Here we report on the functional characterization and manufacturability of γδ T cells expressing CD27-based CAR for targeting a set of CD70$^+$ cancers.

Methods Healthy donor PBMCs were used to activate, expand, and engineer cytotoxic Vδ1 T cells to express CD27-containing CAR. In vitro phenotype and antitumor functionality of Vδ1 CAR T cells were determined using flow cytometry and cell-based cytotoxicity assays against a panel of cell lines having a broad range of CD70 expression. Human tumor xenograft models in immunodeficient mice were used to evaluate in vivo efficacy after a single dose of CD27-containing CAR Vδ1 T cells.

Results Vδ1 T cells modified to express CD27-containing CAR were successfully generated and expanded, indicating product expansion was not hindered by putative risks for CD70-mediated fratricide. The resulting Vδ1 CAR T cells expressed a predominant naïve-like memory phenotype and were associated with potent in vitro cytotoxicity, production of proinflammatory cytokines, and proliferation against CD70+ tumor cell lines. To assess the potential impacts of soluble CD27 (sCD27) on cytotoxicity, exogenously added sCD27 resulted in no change in anti-tumor activity. Lastly, highly potent tumor growth inhibition was observed against tumor xenografts in immunodeficient mice (figure 1).

Conclusions In summary, these preclinical data support further development and clinical evaluation of an allogeneic γδ CAR T cell therapy utilizing the CD27 natural receptor CAR format for targeting CD70+ cancers.

247 **PRECLINICAL DISCOVERY AND EVALUATION OF ALLOGENEIC "OFF-THE-SHELF" γδ CAR T CELLS TARGETING B7-H6$^+$ TUMORS**

Gauri Lamture, Alexander Teague, Jonathan Wong, Morgan Smith-Boeck, Michael Salum, Erika Meaddough, Pannaga Parthasarathy, Atrish Bagchi, Matthew Hoopes, Elizabeth Speltz, Ramandeep Kaur, Smitha Gundurao, Nitya Ramadoss, Marissa Herrman, Blake Aftab, Arun Bhat, Kevin Nishimoto*. *Adicet Bio, Inc., Redwood City, CA, USA*

Background B7-Homolog 6 (B7-H6) is a B7 family member and the natural ligand for NK cell-activation receptor, NKp30. B7-H6 is expressed on multiple tumor types but has limited expression in normal tissues. Given this tumor specificity, B7-H6 represents an attractive target for CAR T therapy. CAR T cell therapy is associated with high clinical response rates in hematologic malignancies, but opportunities for improved efficacy in solid tumors remain. γδ T cells, whose solid tumor infiltration has demonstrated a significant correlation with survival, combine innate and adaptive mechanisms to recognize and kill tumors. In addition, γδ T cells engineered with CARs have shown enhanced tumoricidal activity and compelling clinical efficacy. Here, we evaluated the antitumor activity of γδ T cells modified with a set of novel scFv-based CARs targeting B7-H6, potentially applicable against multiple cancer indications for which natural tissue tropism of γδ T cells may offer advantages.

Methods Phage-display libraries were used to identify scFvs against B7-H6 epitopes. To confirm activation upon target engagement, scFvs formatted into CARs were evaluated in a Jurkat-Lucia™ NFAT reporter cell line. PBMCs from healthy donors were used to activate, expand, and engineer Vδ1 T cells to express libraries of CAR constructs representing permutated scFv arrangements. Vδ1 CAR T cells were assessed for phenotype and in vitro activity using flow cytometry and cell-based assays. Tumor xenograft models were further used to evaluate and assess CAR candidates for in vivo efficacy.

Results Phage-display derived scFvs showed a diverse range of affinities against multiple B7-H6 epitopes. Increased NFAT activity post-activation and minimal tonic signaling was observed in the majority of CAR-modified Jurkat-Lucia™ cells. Vδ1 CAR T cells manufactured from healthy PBMC donors demonstrated a predominant naïve-like phenotype with low levels of exhaustion-associated markers. Upon in vitro stimulation with B7-H6$^+$ cell lines, leading Vδ1 CAR T cells inhibited tumor cell growth, demonstrated antigen associated proliferation, and released proinflammatory cytokines. Robust tumor growth inhibition was also observed for a subset of active constructs against tumor xenografts in immunodeficient mice (figure 1).

Conclusions In summary, we present the preclinical discovery, optimization, and generation of allogeneic γδ CAR T cells targeting B7-H6 with potential applications across a broad set of cancer indications. Based on these data, continued preclinical development of a clinical lead candidate is ongoing for future evaluation in the clinic.

Ethics Approval All mouse experiments were performed in accordance with the Guide for the Care and Use of Laboratory Animals and followed all institutional and national guidelines with appropriate protocol review and approval.

248 **INTRATHECAL DELIVERY OF DENDRITIC CELL VACCINE ERADICATES TUMOR GROWTH AND PROTECTS AGAINST LEPTOMENINGEAL DISEASE RE-INOCULATION IN IMMUNOCOMPETENT HER2+ AND TRIPLE NEGATIVE BREAST CANCER LMD XENOGRAFT MODELS**

Vincent Law, Krithika Kodumudi, Colin Snyder, Brian Czerniecki, Peter Forsyth*. *H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, USA*

Background Leptomeningeal disease (LMD) occurs in approx. 5% of patients with breast cancer (BC) with median survival of 2-4 months. Here we investigated intrathecal (IT) delivery of HER2/HER3-dedritic cell vaccine (DCV) in BC-LMD murine model.

Methods HER2+ and triple negative breast cancer (TNBC) murine BC cells were injected into CSF of BALB/c mice ro render LMD. We developed an murine Ommaya device that mimics the Ommaya reservoir in patients for the IT administration of DCV into CSF.

Results HER2-/HER3-DCV was able to rescue disease mice (71% in HER2+ breast cancer-LMD and 28% in triple negative breast cancer-LMD) with complete tumor regression. Surviving mice also exhibited adaptive immunity against tumor rechallenge.

Conclusions Our preclinical data supported a clinical trial (submitted) of the IT delivery of DCV in breast cancer patients with LMD.

Ethics Approval For animal use, Institutional Animal Care and Use Committee (IACUC) approval was obtained from the University of South Florida (IS00010398) as well as been reviewed by the Department of Defense Animal Care and Use Review Office.

249 HETEROGENEITY AND CHANGES OF T-CELL SUBSET PROPORTION DURING THE EXPANSION OF TUMOR-INFILTRATING LYMPHOCYTES IN NON-SMALL CELL LUNG CANCER

[1]Hyun Lee*, [2]Gyungyub Gong, [1]Chae-Lyul Lim, [2]Hee Jin Lee. *[1]NeogenTC Corp, Gyeonggi-do, hanam-si, Republic of Korea; [2]Asan Medical Center, Seoul, Republic of Korea*

Background Adoptive cell therapy (ACT) using tumor-infiltrating lymphocytes (TILs) has emerged as an additional treatment option for non-small cell lung cancer (NSCLC). However, the absence of predictive factors for therapeutic efficacy and successful expansion and lack of knowledge of changes in TILs characteristics during expansion are hurdles to the clinical introduction of TIL therapy. Herein, we report the characteristics of TILs and their changes during manufacturing.

Methods 103 cases of NSCLC operational specimens were prospectively collected at the single institute. In the initial expansion (IE) step, lung cancer tissues were cut into 1 to 2-mm diameter fragments and expanded within 2 hours of surgery. In the rapid expansion (REP) step, post-IE TILs were cultured with allogeneic peripheral blood mononuclear cells, interleukin-2, and human anti-CD3 antibody. The memory subsets and PD-1 expression status of TILs were estimated via flow cytometry (CD3, CD4, CD8, CD45, CD45RA, CCR7, and PD-1). IFN-γ ELISA assay with TILs ($4.0\times10\hat{}5$) and autologous cancer cells ($1.0\times10\hat{}5$) was evaluated. We investigated clinicopathologic characteristics including the level of stromal TIL (sTIL) and tertiary lymphoid structures (TLS) in hematoxylin and eosin stained slides.

Results The median IE cells per fragment were $2.5\times10\hat{}5$ (range 0.02 ~ $30.8\times10\hat{}5$), and the success rate of IE is 81.6% (84 of 103 cases, cut-off value of $0.8\times10\hat{}5$). The sTIL and IE cells per fragment showed positive correlation (Pearson's r=0.215, p= 0.029). Increased TLS grades were associated with IE cells per fragment (Jonchheere-Terpstra test, p=0.008). Effector memory type was a major subset in both IE (n=39; CD8+, mean 72.4%; CD4+, mean 86.1%) and REP (n=29; CD8+, mean 85.6%; CD4+, mean 91.6%). Mean PD-1+ cells were 30.4% in IE (n=25) and 12.6% in REP (n=20). 75% (12 of 16) of the REP TIL cases showed a more than 2-fold increase of IFN-γ secretion against autologous cancer cells. Cases with less than 2-fold increased IFN-γ secretion showed higher PD-1+ cell proportion (n=2, 47.3%) in REP than cases with above 2-fold increase (n=6, 2.0%). Cases with higher IFN-γ fold change showed a decrease of PD-1+ cell proportion during IE to REP (n=3).

Conclusions We successfully manufactured expanded TILs from NSCLC specimens for TIL therapy. The TLS and sTIL may be potential markers for the prediction of successful TIL expansion in NSCLC. Effector memory cells were the main subset of therapeutic TIL products. PD-1 expression was decreased during REP and it was associated with higher IFN-γ secretion against autologous cancer cells.

250 **CHIMERIC ANTIGEN RECEPTORS CONTAINING CD30-DERIVED COSTIMULATORY DOMAIN ELICIT AUGMENTED T CELL EFFECTOR FUNCTIONS AND ANTI-TUMOR EFFICACY**

Hyun-Il Cho, Chung-Hyo Kang*, Sang-Eun Lee, In-Sil Song, Jung-Min Ha, Hyun-Jung Sohn, Tai-Gyu Kim. *VGeCell Inc., Seoul, Republic of Korea*

Background Adoptive cell therapy utilizing chimeric antigen receptor (CAR)-engineered T cells has demonstrated a feasible, attractive "off-the-shelf" approach against numerous types of cancers. Successful tumor eradication depends primarily on providing optimized costimulatory signals capable of achieving robust CAR-T cell proliferation, persistence, and antitumor reactivity. Here, we assessed the capability of a novel CD30-derived costimulatory domain, a known TNFR superfamily member involved in anti-apoptosis as well as cell activation and proliferation, to generate effective CAR-T cells.

Methods We designed CD19-redirecting second-generation CARs incorporating the intracellular signaling domain of CD30 and evaluated the immune-phenotype, cytokine secretion, and real-time cytolytic activity of CAR-transduced T cells against CD19-expressing cells in comparison with other CARs containing CD28 or 4-1BB costimulatory domains. Subsequentially, their therapeutic efficacy was assessed with a pre-clinical Nalm-6-bearing xenogeneic model. We also engineered third-generation CARs combining CD30 and either CD28 or 4-1BB and conducted multiple repeat in vitro experiments evaluating their proliferation and cytolytic functionality against CD19-expressing tumors. Further, we tested the efficacy of third-generation CAR signaling after alteration with glypican-3 or mesothelin-targeting single chain fragment variable (scFv) domains.

Results T cells activated by a CD30-ζ signaling-CAR displayed enhanced effector functions with similar levels of proliferation, cytolytic efficacies, and cytokine secretion in vitro against CD19-expressing cancer cells as those of other CARs with CD28 or 4-1BB costimulatory domain, which are currently in clinical use. Administration of CD30-containing CAR-T cells into tumor-bearing mice resulted in improved human T cell persistence and tumor regression in a xenogeneic allograft model, which was similar to those achieved with CD28- or 4-1BB–signaling CAR-T cells. Furthermore, third-generation CARs including CD30 with either CD28 or 4-1BB costimulatory domain retained potent antitumor efficacies independent of their position. More significantly, CAR-T cells containing CD30-signaling revealed effective cytolytic activities against several solid cancer cell lines based on its scFv fragments.

Conclusions Our results demonstrate that the CD30-derived costimulatory domain could be an alternative for developing CAR-engineered therapeutics which may be applicable for various design of CAR constructs, with an emphasis on effectiveness against solid tumors.

251 APPLICATION OF ANTIBODY-CELL CONJUGATION TECHNOLOGY IN A NOVEL OFF-THE-SHELF CD20-TARGETING GAMMA DELTA T CELL THERAPY ACE1831

Hao-Kang Li, Tai-Sheng Wu, Yi-Chiu Kuo, Ching-Wen Hsiao, Hsiu-Ping Yang, Chia-Yun Lee, Pei-Ju Leng, Zih-Fei Cheng, Sen-Han Yang, Yang-Liang Lin, Shih-Chia Hsiao, Sai-Wen Tang*. *Acepodia Biotech Inc., Alameda, CA, USA*

Background Chimeric antigen receptor T cells (CAR-T) therapy has been applied in the treatment of B cell lymphoma; however, CAR-T manufacturing requires virus or non-virus based genetic modification which causes high manufacturing cost and potential safety concerns. The novel antibody cell conjugation (ACC) technology has the advantage to direct innate immune cells, such as γδ T and NK cells, to find and erase cancer cells by linking cancer-targeting antibodies on cell surface proteins without genetic modification. In this study, ACC technology was applied to generate a novel off-the-shelf CD20-targeting γδ T cell therapy ACE1831, and the potential mechanism of ACC-mediated cytotoxicity was elucidated.

Methods PBMC-derived γδ T cells were expanded from healthy donors. DNA linker-1 and linker-2 were conjugated to γδ T cells and Rituximab, respectively. Linker-1 conjugated Rituximab was attached to linker-2 conjugated γδ T cells by DNA hybridization to generate off-the-shelf CD20-targeting γδ T cell product, ACE1831. *In vitro* and *in vivo* potency of ACE1831 against CD20-expressing cancer cells was evaluated in B cell lymphoma models. Mass spectrometry analysis was performed to identify Rituximab-linked surface proteins of γδ T cells. Jurkat T cells expressing a luciferase reporter driven by an NFAT-response element were used to examine the mechanism of ACC-mediated T cell activation.

Results ACE1831 exhibited CD20-specific binding activity and viability after recovery from cryopreservation. In vitro cytotoxicity analysis demonstrated the superior potency of ACE1831 against B cell lymphoma including Raji, Rituximab-resistant Raji and Daudi cells, while no significant off-target toxicity against CD20-negative cells or PBMCs was observed. The enhanced secretion of IFNγ and TNFα has been detected when ACE1831 encountered Raji cells, whereas IL-6 remained undetectable. Furthermore, ACE1831 showed excellent in vivo potency in B cell lymphoma xenograft model, and ACE1831-treated mice remained cancer-free to the end of the study. By mass spectrometry analysis, Rituximab-linked proteins were identified, and the protein functions were mainly related to cell activation and immune synapse. Additionally, NFAT signaling was significantly activated when Rituximab-linked Jurkat cells encountered CD20-expressing cancer cells. Blocking TCRγδ activation partially inhibited ACE1831-mediated cytotoxicity, indicating both TCRγδ and external ACC-linked Rituximab involved in ACE1831 potency against B cell lymphoma.

Conclusions This study provides the evidence for the efficacy and safety of ACE1831 to support the clinical application against CD20-expressing tumors and elucidates the potential mechanism of ACC-mediated activation and cytotoxicity. ACE1831 will be evaluated in clinical trials for relapsed/refractory B cell lymphomas.

Ethics Approval SCID-Beige mice were purchased and housed under the regulation of the Institutional Animal Care and Use Committee (IACUC) of the contract research organizations.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0251

252 **ENGINEERING POTENT CAR T-CELL THERAPIES BY CONTROLLING T-CELL ACTIVATION SIGNALING PARAMETERS USING THE STIM-R™ TECHNOLOGY, A PROGRAMMABLE SYNTHETIC CELL-SIGNALING PLATFORM**

Aileen Li*, Jessica Briones, Jia Lu, Candace Sims, Quinn Walker, Rowena Martinez, Stefan Siebert, Lora Zhao, Emily Fu-Sum, Sheila Lou, Andrew Jimena, Elizabeth Pedrosa, Purnima Sundar, Hajime Hiraragi, Shobha Potluri, Bijan Boldajipour, Omar Ali, Alexander Cheung. *Lyell Immunopharma, South San Francisco, CA, USA*

Background CART-cell therapy has shown clinical success in treating hematologic cancers. However, more effective CAR T-cell therapies are needed for the treatment of solid tumors. T-cell activation is a formative event that directs cell fate and function in mature T cells. In the context of cellular product derivation, these decisions critically impact the phenotypic and functional quality of the T-cell drug product. We hypothesized that optimization of signaling parameters during T-cell activation can generate more potent CAR T cells.

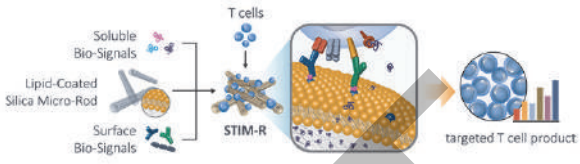
Methods To control signaling during T-cell activation, we employed our platform, the Stim-R technology, a synthetic cell mimic that mediates precise signal molecule presentation (figure 1). We designed and fabricated Stim-R technology formulations to present T-cell activating signals engaging CD3 and CD28 at different densities and stoichiometries. Utilizing these formulation variants, we generated arrays of diverse ROR1-targeted CAR T-cell products which we profiled phenotypically and functionally. Based on these metrics, we compared Stim-R-generated CAR T cells to CAR T cells generated using a conventional bead-based activator to identify lead formulations showing superior *in vitro* function. We interrogated the mechanisms underlying this improved function by performing transcriptomic analysis of Stim-R CAR T cells following multiple rounds of tumor cell stimulation in vitro and validated the Stim-R CAR T cells *in vivo* in an H1975 lung tumor xenograft model in mice.

Results *In vitro*, Stim-R CAR T cells exhibited increased polyfunctionality in response to ROR1$^+$ target-cell stimulation. Stim-R CAR T cells also demonstrated enhanced expansion and cytotoxicity in response to repeated ROR1$^+$ target-cell stimulation. Transcriptomic analysis revealed that Stim-R CAR T cells retained a unique subset of stem-like cells with effector-associated gene signatures and also displayed down-regulation of exhaustion-associated gene sets compared to conventional CAR T cells, following repeat antigen stimulation. *In vivo*, Stim-R-generated CAR T cells exhibited 10-40x greater peak T-cell numbers in the blood, prolonged persistence, and improved tumor control over two months.

Conclusions Potent CAR T-cell therapies may be engineered by optimizing signaling events during T-cell activation to direct the phenotypic and functional qualities of the resultant cell product. Stim-R technology formulations mediating optimized signal presentation enabled the production of ROR1-targeted CAR T cells with improved polyfunctionality, persistence, and anti-tumor activity that retained a stem-like subpopulation with effector-associated gene signatures and showed reduced exhaustion, following repeated antigen stimulation. Such enhanced T-cell products may result in improved therapeutic benefit against solid tumors.

Acknowledgements We acknowledge Brianna Parish, Carson Harms, and Melissa DeFrancesco for their help with Stim-R technology process development. We also acknowledge Blythe Sather, Suman Vodnala, Gary Lee, Stan Riddell, Stephen Hill, and Nick Restifo for their scientific input and strategic guidance.

Ethics Approval Animal studies were conducted in Explora BioLabs vivariums and are approved by Explora's IACUC under Core protocol amendment EB17-010.



Abstract 252 Figure 1 The Stim-R technology is a programmable cell-signaling platform. The technology comprises biodegradable lipid-coated silica micro-rods that can combinatorially present signals in precise densities and stoichiometries. Soluble signals are released in a controlled manner while surface-anchored signals are presented on a synthetic lipid membrane, mimicking physiologic presentation. By using the Stim-R technology to control cell-signaling parameters during T-cell activation, T-cell products with targeted phenotypic and functional profiles may be engineered.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0252

253 FULLY HUMAN CD123 CAR T CELLS IRRADICATE AML IN PRE-CLINICAL MODELS AND EXHIBIT A FAVORABLE SAFETY PROFILE

Genqing Liang*, Peirong Hu, Ngoc Tran, Hasan Mahmud, Pradyot Dash, Dina Schneider.
Lentigen Technology Inc, a Miltenyi Biotec Company, Gaithersburg, MD, USA

Background CD123, the interleukin-3 receptor alpha chain (IL-3Ra), is widely overexpressed in hematologic malignancies including acute myeloid leukemia (AML), at both the level of leukemic stem cells (LSCs) and leukemic blasts. This makes CD123 an attractive therapeutic target. Monoclonal antibodies directed against CD123, and CD123 chimeric antigen receptor (CAR)-modified T cells are explored for new immunotherapies for the treatment of AML. Here, we developed a second generation anti-CD123 CAR comprising a fully human CD123 targeting scFv domain, a 4-1BB (CD137) co-stimulatory domain, and CD3ζ activation domain, and investigated its potency against AML.

Methods Primary human T cells from healthy donors were enriched and transduced with lentiviral vector encoding the CD123 CAR, and CAR expression was detected by flow cytometry. CAR123 T cells or untransduced UTD control T cells co-cultured with the $CD123^+$ MOLM-14 and KG1a AML cells, or the $CD123^-$293T cells for 18h, were evaluated by luciferase assay, and cytokine production was measured by ELISA. Supernatants were collected from co-cultures of CAR T cells with $CD123^+$ MOLM-14 target cells, and the concentration of cytokines IL-2, IFN-γ, and TNF-a was determined. CAR123 T cell functionality *in vivo* was evaluated in a MOLM-14 acute myeloid leukemia NSG xenograft model exhibiting $CD123^+$ phenotype. In addition, myelotoxicity was investigated in colony-forming unit assays.

Results Lentiviral transduction resulted in robust expression of CD123 CAR in the transduced T cells. The CD123 CAR T cells showed potent *in vitro* killing of $CD123^+$ AML cell lines MOLM-14 and KG1a, but no killing of the $CD123^-$293T cells, indicating CD123-dependent efficacy. The TNF-α was modestly elevated in culture supernatants from CD123 CAR T cells co-incubated with target cells, however there was no significant induction of IL-2 or IFN-γ, suggesting low risk of cytokine release syndrome. Colony-forming unit assays utilizing peripheral blood CD34+ hematopoietic stem cells from healthy donors treated with CAR123 T cells overnight, yielded similar numbers of BFU-E erythroid and CFU-GM myeloid colonies to an untransduced T cell control, indicating an absence of CAR123-associated myelotoxicity. Moreover, CAR123 T cells showed efficient tumor clearance, expansion and persistence *in vivo*, and no apparent toxicity.

Conclusions In summary, the fully human CAR123 T cells are highly potent against AML *in vitro* and *in vivo*, manifest the desired safety attributes, and are a promising modality for AML therapy.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0253

254 THE CBL-B INHIBITOR, NX-0255, ENHANCES HUMAN DRUG ENHANCED TUMOR INFILTRATING LYMPHOCYTE (DETIL) EXPANSION AND T CELL FUNCTION IN FULL-SCALE RUNS

Xiaoyan Liang*, Xianzhu Wu, Jeevitha Jeevan, Samuel Butler, Pranav Murthy, Arthur Sands, Michael Lotze. *Nurix Therapeutics, San Francisco, CA, USA*

Background Ex-vivo expanded autologous tumor-infiltrating lymphocyte (TIL) therapy is one type of adoptive cellular therapy (ACT) which has demonstrated encouraging clinical responses in patients with melanoma or those with epithelial tumors. Effective methods to obtain sufficient TIL of suitable quality and diversity from tumor samples remains a challenge. The E3 ubiquitin ligase, Casitas B lineage lymphoma B (CBL-B) is expressed in T cells where it regulates signaling through the T Cell Receptor (TCR), limiting T cell activation and differentiation. Our previous studies (Whelan S., SITC; 2021) demonstrated that addition of NX-0255, our highly potent CBL-B inhibitor, during ex-vivo TIL expansion resulted in a favorable TIL phenotype and higher cell yields.

Methods Here we evaluated the comparative effects of the addition of the CBL-B inhibitor NX-0255 on expansion and phenotype of drug-enhanced TIL (DeTIL), in multiple full-scale processes. Six full-scale studies were conducted. All six runs were performed in parallel in TIL expanded either solely in the presence of 3,000-6000 IU/ml rHu IL-2 (TIL arm), or in the presence of rHu IL-2 and 1 μM NX-0255 (DeTIL-0255 arm). DeTIL-0255 and TIL harvested on day 22 were assessed for total cell number, viability, phenotype, and function.

Results Compared with the TIL arm, the addition of NX-0255 increased the total viable cell count on Day 22 in five out of six full-scale experiments. Significant increases in the total number of CD8+ T cells as well as those with a central memory phenotype were observed in all six runs. A significant increase in the proportion of $CD4^+$ central memory DeTIL-0255 was also demonstrated. No significant differences in effector memory populations were observed. DeTIL-0255 have a significantly ($p<0.05$) higher stem-like population of $CD39^-CD69^-$'double negative' $CD8^+$ cells as compared to TIL upon TCR and CD28 co-stimulation. $CD8^+$ T cells in DeTIL-0255 displayed higher intracellular expression of granzyme B as well as co-expression of granzyme B and the cell surface CD107α when compared to TIL. Furthermore, significant increases in intracellular IFN-γ expression were observed in activated DeTIL-0255 when compared to TIL using flow cytometric assessment.

Conclusions DeTIL-0255 demonstrates a superior phenotype and greater yield when compared with conventional TIL and is suitable for testing in clinical trials. We have initiated a clinical trial with DeTIL-0255 in patients with gynecologic malignancies. NCT05107739

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0254

255 EXPRESS™: AN ACCELERATED PROCESS FOR THE MANUFACTURE OF KSQ-001, A CRISPR/CAS9-EDITED ETIL™ PRODUCT

Sharon Lin, Leila Williams, Mitali Ghose, Hugh Gannon, Conor Calnan, Angelina Pizzo, Pei-Lun Kao, Mallory Brady, Katri Sofjan, Anne Dodson, Sol Shenker, Michael Schlabach, Fiona Sharp, Frank Stegmeier, Micah Benson*, Karrie Wong. *KSQ Therapeutics, Cambridge, MA, USA*

Background Adoptive cell therapy with ex vivo expanded tumor infiltrating lymphocytes (TIL) offers a potentially curative treatment for cancer. To improve the clinical durability of TIL, we have developed KSQ-001, a CRISPR/Cas9 engineered TIL (eTIL) product with inactivation of *SOCS1* gene. SOCS1 is a negative regulator of cytokine signaling in T cells that we previously identified as a top target restraining T cell in viv anti-tumor function and long-term persistence in genome-wide in vivo CRISPR screens. The clinical manufacture of TIL has historically required a complex multi-step baseline process involving a pre-Rapid Expansion Protocol (pre-REP) followed by a Rapid Expansion Protocol (REP) with feeder cells. To simplify and shorten the manufacture of KSQ-001, we developed a next-generation ExPRESS manufacturing process involving fewer steps and eliminating the use of feeder cells. We demonstrated that ExPRESS can robustly manufacture KSQ-001 with high functional potency at clinical scale from tumor starting material in 21 days or less across multiple solid tumor types.

Methods Viably-cryopreserved-tumor-fragments (VCTF) from different solid tumor indications were used as starting materials for eTIL manufacture. T cells in the tumor fragments are activated to propagate for 7-11 days, after which TIL were electroporated with ribonucleoprotein (RNP) complexes containing the *SOCS1*-targeting guide RNA (gRNA). Following electroporation, TIL were further expanded for an additional 7-11 days prior to cryopreservation. The editing level, phenotypic characteristics, and functionality of KSQ-001 was assessed by NGS, flow cytometry, and in vitro functional assays.

Results KSQ-001 was successfully manufactured from 10/11 VCTF starting materials from melanoma and NSCLC samples to clinically relevant doses, demonstrating robust viability at the time of cryopreservation and following thaw. KSQ-001 manufactured using ExPRESS showed >90% editing of the SOCS1 gene as well as complete knockdown of SOCS1 protein in all donors tested. Importantly, KSQ-001 manufactured using ExRPESS exhibited heightened anti-tumor function when compared to un-engineered TIL, including increased production of IFNγ and anti-tumor potency in an in vitro TIL/tumor co-culture system. KSQ-001 also retained high diversity of the TCR repertoire and specificity for autologous tumor. Lastly, adoptively transferred eTIL showed enhanced persistence and anti-tumor efficacy in immunodeficient mouse tumor models.

Conclusions We describe a shortened and streamlined process for the manufacture of CRISPR/Cas9-edited eTIL. KSQ-001 can be manufactured at clinically relevant doses in 21 days or less and displays enhanced functional potency. These data support evaluating KSQ-001 manufactured by the ExPRESS process in the treatment of patients with metastatic treatment-refractory solid tumors.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0255

256 ***IN VIVO* EXPANSION OF ENDOGENOUS ANTIGEN-SPECIFIC CD8+ T CELLS USING ARTIFICIAL T-CELL STIMULATING MICROPARTICLES**

Natalie Livingston*, John Hickey, Hajin Sim, Hai-Quan Mao, Jonathan Schneck. *Johns Hopkins University, Baltimore, MD, USA*

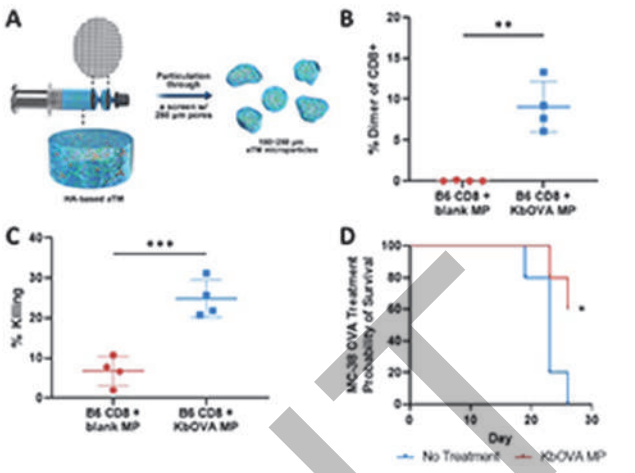
Background T cell-based immunotherapies such as chimeric antigen receptor T cell therapy (CAR T), have seen some clinical success; however, these therapies are still currently limited to a select few cancer types and have price tags that further limit accessibility for patients. Here, we create a novel biomaterials-based platform for the *in vivo* activation of naïve, antigen-specific T cells, removing the need for expensive and lengthy *ex vivo* expansion steps.

Methods Thiol-modified HA is cross-linked with PEDGA in the presence of thiol-modified signals 1 (here, KbOVA) and 2 (anti CD28).[1] The cross-linked gel is passed through a mesh to form microparticles (MPs) (figure 1A). MPs are mixed with naïve B6 CD8+ T cells and injected subcutaneously into mice. Eight days after injection, target cells expressing OVA antigen are injected i.v. On day 9, mice are sacrificed and analyzed for enrichment of antigen-specific cells and killing of target cells. MPs were also tested therapeutic tumor model, in which MC-38 OVA tumor cells were injected on day 0 and naïve OT I CD8s plus MPs were injected on day 6.

Results Nine days after co-injecting naïve B6 CD8+ T cells with KbOVA MPs, we can detect a significant enrichment of OVA-specific T cells via flow cytometry (figure 1B). Cells expanded *in vivo* showed significant and robust killing of target splenocytes (figure 1C). In the MC-38 OVA cancer treatment model, injection of naïve OT I CD8+ T cells with OVA MPs increased survival compared with naïve OT I CD8+ cells injected with blank MPs (figure 1D).

Conclusions We have developed an injectable, LN-mimicking MP platform that incorporates T-cell activation signals and critical ECM cues of the LN. These MPs are capable of expanding antigen-specific T cells from a fully endogenous B6 repertoire, and these cells are able to robustly kill target splenocytes as well as reduce tumor growth and extend survival in a therapeutic cancer model. Developing a system for the *in vivo* activation of antigen-specific T cells reduces both cost of T cell-based therapies as well as the time to treatment for patients.

Acknowledgements NKL is supported by the NSF GRFP and NIH F31 Fellowships.



Abstract 256 Figure 1 (A) Schematic of the preparation of T cell-stimulating MPs. (B) Enrichment of OVA-specific T cells within the biomaterial site 9 days after injection. (C) In vivo killing of OVA-pulsed splenocytes after 9 days of in vivo expansion of OVA-specific T cells. (D) Survival plot after mice are injected with MC-38 OVA tumor cells on day 0 and naïve OT I CD8s plus MPs on day 6.

257 AN OFF-THE-SHELF PERSONALIZED CELLULAR APPROACH TO IMMUNOTHERAPY FOR THE TREATMENT OF ADVANCED SOLID TUMORS

Miguel Lopez-Lago*, William Williams, Giuseppe del Priore, Sagarika Pachhal, Vikas Bhardwaj, Xiaoyi Zheng, Mingjin Chang, Charles Wiseman. *BriCell Therapeutics Corp., Philadelphia, PA, USA*

Background BriaCell is developing off-the-shelf personalized cellular immunotherapies based on our most advanced lead candidate—SV-BR-1-GM, which is in Phase I/IIa clinical trial in patients with metastatic or locally recurrent breast cancer. SV-BR-1-GM is a breast cancer cell line with features of an antigen presenting cell (APC) which has been stably transfected with the CSF2 gene encoding GM-CSF (SV-BR1-GM). We have recently reported favorable clinical outcomes in patient populations that match SV-BR-1-GM at one or more HLA alleles. This clinical observation, together with the fact that SV-BR-1-GM cells can directly activate CD4+ T-cells in an antigen-specific HLA-restricted manner, as demonstrated by an in vitro antigen presentation assay,[1] lead us to hypothesize that SV-BR-1-GM can function as an APC. We propose a therapeutic approach in which a patient will be treated with a cell line expressing HLA class I and II molecules matched to their genotype. Also, to further enhance direct antigen presentation to T-cells, the parent SV-BR-1 cells were genetically modified to express co-stimulatory molecules and additional immune-modulatory cytokines.

Methods Using CRISPR/Cas9 technology we have inactivated several endogenous *HLA-A* and *HLA-DRB* alleles present in five cancer cell lines (SV-BR-1, PC-3, LNCaP, SK-MEL-24, and NCI-H2228). Cells with inactivated HLA-A/DRB genes were transduced with lentiviral based vectors expressing selected cytokines and costimulatory molecules (GM-CSF, INFa, CD80, CD86, IL-12, IL-7, HLA-DRA, and 4-1BBL). Next, unique combinations of HLA-A and HLA-DRB3/4/5 alleles were transduced into the cells using lentiviral based vectors to generate a collection of cell lines that will match over 99% of the patient population for at least one HLA allele. Expression and functionality of the stimulatory molecules and transgenic HLA alleles was established using flow cytometry and cell-based assays.

Results Four cell lines (for each tumor type) that secreted GM-CSF, IFNa, IL12, IL7 and expressed CD80, CD86, 4-1BBL, and different combinations of both Class I and Class II HLA alleles were selected. Using cell-based assays – including mixed lymphocyte reaction assays -, we demonstrated that the generated cells stimulate naïve T-cells.

Conclusions We have successfully generated ''off the shelf'' personalized cell-based therapeutic cancer vaccines that induce potent T-cell responses. These modified cancer cell lines will be used in clinical studies designed to first evaluate the safety of intradermal inoculation with the irradiated cells and later combined with other agents to augment the immune response.

258 **INDUCTION OF TUMOR CELL AUTOSIS BY MYXOMA VIRUS-INFECTED CAR-T AND TCR-T CELLS TO OVERCOME PRIMARY AND ACQUIRED RESISTANCE IN SOLID TUMORS**

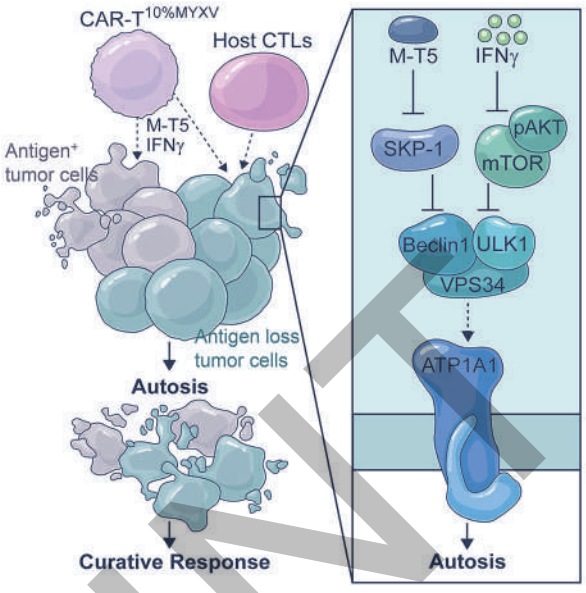
[1]Yong Lu, [2]Ningbo Zheng*. [1]*Houston Methodist Research Institute/Weill Cornell Medicine, Houston, TX, USA*; [2]*Wake Forest School of Medicine, Winston-Salem, NC, USA*

Background Cytotoxicity of tumor-specific T cells requires tumor cell-to-T cell contact-dependent induction of classic tumor cell apoptosis and pyroptosis. However, such canonical mechanisms may not trigger sufficient primary responses of solid tumors to adoptive cell therapy (ACT) and prevent tumor antigen escape-mediated acquired resistance.

Methods One of the candidate oncolytic viruses is myxoma virus (MYXV), a DNA virus, which has a highly restricted host range and is only pathogenic to European rabbits (Stanford et al., 2007). In this study, we investigated the potential to exploit CAR-T and TCR-T cells as myxoma virus (MYXV)-delivery carrier cells by pre-infecting the T cells with MYXV *ex vivo* by a spin-infection protocol (CAR-T^{MYXV} and TCR-T^{MYXV}).

Results Here, we demonstrate that myxoma virus (MYXV)-infected tumor-specific T (T^{MYXV}) cells, expressing chimeric-antigen-receptor (CAR) or T-cell-receptor (TCR), which systemically deliver MYXV into solid tumors to overcome primary resistance. In addition to T cell-induced apoptosis and pyroptosis, tumor eradication by CAR/TCR-T^{MYXV} cells is also attributed to tumor cell autosis induction, a special cell death unleashed by this unexpected novel T-cell-cytotoxic machinery. Mechanistically, T cell-derived IFN-γ/AKT signaling synergizes with MYXV-induced M-T5/SKP-1/VPS34 signaling to trigger robust tumor cell autosis. Moreover, CAR/TCR-T^{MYXV}-elicited autosis also functions as a potent bystander killing to restrain antigen escape.

Conclusions Collectively, our results highlight a pivotal role of CAR-$T^{10\%MYXV}$ cells in improving the efficacy of ACT by: (1) delivering MYXV into tumor beds; (2) recognizing and inducing classic tumor cell apoptosis and pyroptosis to antigen-positive tumor cells accompanied by IFNg secretion; (3) inducing autosis in antigen-positive and antigen-negative cancer cells; and (4) potentially eliminating ALV cells by autosis and adaptive antitumor immunity. Thus far, our data suggest the existence of a tumor cell autosis-triggering strategy dependent on both MYXV and antigen-programmed CAR-T cells, which strategically incorporates MYXV and tumor-specific T cells to overcome therapeutic resistance in solid tumors (figure 1).



Abstract 258 Figure 1 Graphical Abstract
• CAR-TMYXV cells systemically deliver MYXV into cognate antigen-expressing tumors
• T cell-derived IFNγ synergizes with MYXV-derived M-T5 to trigger tumor cell autosis
• Autosis is a potent bystander killing to eradicate antigen-negative tumor cells
• CAR/TCR-T10%MYXV induces autosis and adaptive immunity to restrain antigen escape

259 IPSC-DERIVED NK CELLS ENGINEERED WITH A NOVEL TGFβ SIGNAL REDIRECTOR RECEPTOR EXHIBIT ENHANCED PERFORMANCE AGAINST SOLID TUMORS

Eigen Peralta*, Dan Lu, Hui-Yi Chu, Justin Rahman, Diana Galvan, Amit Mehta, Eric Sung, Jeffrey Chen, Masanao Tsuda, Elena Demeester, Earl Avramis, Alec Witty, Tom Lee, Bob Valamehr. *Fate Therapeutics Inc., San Diego, CA, USA*

Background Transforming growth factor beta (TGFβ) is an immuno-suppressive cytokine commonly present in the tumor microenvironment (TME) that creates considerable challenges for the treatment of solid tumors. Here we describe a unique strategy where induced pluripotent stem cell (iPSC)-derived NK (iNK) and T (iT) cells engineered to express a chimeric TGFβ signal redirector receptor (TGFβ-SRR) block the TGFβ-mediated repressive signaling and redirect the signal to potentiate effector cell function and improve cell fitness.

Methods To identify iNK cell-specific pathways for TGFβ signal redirection, candidate cytokines were tested for their ability to mitigate suppression of iNK cell anti-tumor activity in the presence of recombinant TGFβ. Next, we developed TGFβ-SRR constructs where selected cytokine endodomains were fused to TGFBR2 ectodomain. TGFβ-SRR constructs were then engineered into iPSCs and differentiated into iNK cells. Phospho-flow for pSMAD2/3 was used to test for blockade of TGFβ signaling in recombinant TGFβ-treated cells. Antibody-dependent cellular cytotoxicity (ADCC) from TGFβ-SRR iNK cells was tested in co-cultures with SKOV-3, PC3, and MDA-MB-231 targets, then measured using xCELLigence readout. Innate killing mechanism was tested via serial restimulation assay with Raji targets and measured by flow cytometry. Co-cultures were performed in the presence of recombinant TGFβ.

Results Engineered iPSCs expressing candidate TGFβ-SRR constructs were successfully differentiated into iNK cells (>95% CD56+), uniformly expressing TGFβ-SRR transgene (TGFβ-SRR; >95% positive). Analysis for pSMAD2/3 in recombinant TGFβ-treated cells showed 95% reduction of SMAD2/3 phosphorylation in top performing TGFβ-SRR motif, indicating successful blockade of TGFβ signaling. Evaluation of ADCC toward multiple solid tumor lines and using various monoclonal antibodies (Herceptin, Cetuximab, and Avelumab) showed superiority of TGFβ-SRR iNK cells (>80% cytolysis) over parental iNK cell control (<40% cytolysis) in the presence of recombinant TGFβ. Innate killing mechanism was tested in the serial restimulation assay, where TGFβ-SRR iNK cells expanded 3.5-fold over parental iNK cells after the first round of co-culture. Notably, the TGFβ-SRR iNK cells exhibited enhanced functional persistence, completely controlling tumor growth through three rounds of co-culture despite the addition of suppressive quantities of recombinant TGFβ, unlike parental iNK cells which failed to control tumor growth after the first round.

Conclusions Collectively, the data illustrate that a customized TGFβ-SRR construct can redirect TGFβ-mediated suppression and potentiate effector cell function to enhance the anti-tumor activity of iNK cells. This novel synthetic receptor represents an innovative strategy to enable adoptively-transferred cell therapy to overcome the immunosuppressive TME for the successful treatment of bulky tumors.

260 INVESTIGATING CANCER CELL AUTONOMOUS CAR T CELL THERAPY RESISTANCE IN DLBCL *IN VITRO*

Fabiana Lueoend*, Youngchul Song, Beverly Nguyen, Xiaoyan Li, Andreas Raue, Jennifer Brogdon, Glenn Dranoff, Matthew Niederst, Louise Treanor. *Novartis Institutes for BiMedical Research, Cambridge, MA, USA*

Background CD19 CAR T cell therapy has greatly improved the outcome of r/r DLBCL patients, but durable responses are achieved in only 40% of cases. Relapses can be due to declining T cell fitness and/or cancer cells becoming inherently refractory. However, besides antigen loss, cancer cell autonomous resistance mechanisms are poorly understood.

Methods We generated DLBCL cell lines that are refractory to CD19 targeting CAR T cells by longterm co-culture *in vitro*. We assessed response to alternative CAR T cells targeting other antigens and performed RNAseq of resistant cancer cell lines to identify yet unknown resistance mechanisms.

Results Our *in vitro* longterm co-cultures recapitulate common resistance mechanisms observed in the clinics including CD19 loss. Interestingly, we do observe CD19 positive resistance and multiple of our CD19 CAR T cell resistant cell lines had become less sensitive also to alternative CAR T cells. Moreover, our RNAseq data indicate that the majority of transcriptional changes are associated with a common resistant phenotype rather than a specific resistance mechanism (e.g., antigen loss).

Conclusions Our results suggest that besides CD19 loss, DLBCL cells evolve mechanisms to overcome T cell killing which may render them cross-resistant to CAR T cells targeting other antigens. Analysis of our RNAseq data will allow us to characterize these mechanisms.

261 EVIDENCE FOR DURABLE ANTI-TUMOR RESPONSES BY TAC-T CELLS IN PRECLINICAL MODELS OF SOLID TUMORS

[1]Heather MacGregor*, [2]Duane Moogk, [1]Stacey Xu, [2]Joanne Hammill, [1]Philbert Ip, [1]Ling Wang, [1]Swati Shetty, [1]Kyle MacDonald, [1]Laura Shaver, [1]Sailaja Pirati, [1]Prabha Lal, [1]Christopher Helsen, [1,2]Jonathan Bramson, [1]Sadhak Sengupta, [1]Andreas Bader. [1]*Triumvira Immunologics Inc., Hamilton, ON, Canada*; [2]*McMaster University, Hamilton, ON, Canada*

Background T cell antigen coupler (TAC) is a chimeric receptor that redirects T cells (TAC-T) towards surface-expressed tumor antigens to create safe and durable anti-cancer immune responses. The TAC activates T cells by co-opting the endogenous T cell receptor machinery via a CD3ϵ-specific binding motif and a cytoplasmic co-receptor tail. TAC01-HER2, a first-in-class TAC-T product targeting HER2 (ERBB2), has entered a phase I/II clinical trial. Here, we have characterized the fate of TAC-T cells during anti-tumor responses *in vitro* and *in vivo*.

Methods *In vitro*, HER2-specific TAC-T products were challenged with HER2-expressing and HER2-negative tumors. Kinetics of proliferation, degranulation, activation, differentiation, and memory generation was assessed by flow cytometry. TAC-T products were subjected to multiple rounds of tumor cell exposure *in vitro* to test the durability of the T-cell-mediated immune response. Bioinformatic clustering analysis of flow cytometry data was performed to identify T cell populations and track them over time.

T cell expansion in blood, tumor, bone marrow, and spleen were evaluated *in vivo* after primary xenograft tumor treatment and secondary tumor rechallenge. Tumor- and spleen-infiltrating or circulating T cells were phenotyped by flow cytometry after treatment with TAC-T cells.

Results Co-culture studies revealed that TAC-T products become rapidly activated and degranulate upon contact with HER2-expressing, but not HER2-negative, cell lines. Activation coincided with rapid downregulation of the TAC receptor. A large proportion of the T cells expressed activation markers, and a majority of these also expressed degranulation markers, indicating ongoing cytotoxicity. *In vitro* and *in vivo* studies demonstrated a CD8-biased response characterized by a considerable expansion in the activated CD8 population enriched at the tumor site. Later, activation and differentiation markers returned to baseline concurrently with the re-emergence of surface TAC expression, initiating T cell proliferation. Importantly, central memory T cells were expanded, and stem-like cells were maintained, suggesting strong self-renewal potential. *In vitro* serial cytotoxicity assays showed that TAC-T products could repeatedly kill tumor cells up to several rounds. In tumor rechallenge experiments, a single dose of TAC-T cells expanded to clear solid tumor xenografts and protected mice from a second tumor challenge 30 days post initial tumor clearance, indicating long-lasting T cell persistence.

Conclusions The TAC-T product mounts an effective anti-tumor response in multiple preclinical models, comprising activated TAC-T cells that do not become terminally exhausted but are dominated by an activated CD8 response and supported by the expansion of a memory population, indicating robust self-renewal capacity.

Ethics Approval Animal studies were approved by McMaster University's Animal Research Ethics Board under AUP 20-10-37.

262 MULTIPLE TARGETING OF SOLID TUMORS WITH IPSC-DERIVED GAMMA DELTA CAR T CELLS IN COMBINATION WITH THERAPEUTIC ANTIBODIES

Hillary Millar Quinn*, Justin Bianchini, Liam Campion, Katherine Santostefano, Toshinobu Nishimura, Sydney Bucher, Buddha Gurung, Shelby Keating, Rebecca Genovese, Steven DeLuca, Bruno Bonanno, David Walker, Marilda Beqiri, Chris Dower, Kaitlin Idank, Tomas Aramburu, Michael Naso, Luis Borges, Mark Wallet. *Century Therapeutics, Philadelphia, PA, USA*

Background CAR-T cell therapies have proven safe and efficacious for hematologic malignancies, but there remains a significant unmet need for effective cell therapy options for solid tumors. CAR-engineered induced pluripotent stem cell (iPSC)-derived effector cells allow for the treatment of cancer as an off-the-shelf allogeneic cell therapy. Gamma delta (γδ) T cells exhibit the cytolytic features of conventional alpha beta (αβ) $CD8^+$ T cells with additional capabilities for innate recognition of tumors. For example, expression of CD16 on γδ T cells can mediate antibody-dependent cellular cytotoxicity (ADCC) against tumors. Here we describe development of an iPSC-derived CAR γδ T cell platform which can target solid tumors through both CAR-mediated recognition and ADCC when combined with a therapeutic antibody.

Methods Primary γδ T cells were enriched and expanded in culture to enable reprogramming to iPSCs by delivery of pluripotency genes. These T cell derived iPSCs (TiPSCs) were used to produce γδ T cells using a proprietary differentiation process. The TiPSC line was engineered with a CAR targeting EGFR and a membrane bound form of IL-15 to enhance T cell persistence. Tumor spheroids were generated from $EGFR^+Her\text{-}2^+$ SKOV-3 ovarian tumor cells. Cytolysis of spheroids was evaluated using CAR-T cells alone or in combination with anti-HER2 antibody (trastuzumab).

Results Batches of CAR-T cells were generated using a proprietary differentiation process yielding >90% pure CAR^+ γδ T cells. The TiPSCs contained the rearranged γδ TCR gene and upon differentiation to T cells, uniformly expressed a Vγ9Vδ2 TCR and expressed high levels of CD16. CAR γδ T cells were effective in killing SKOV-3 spheroids. When cultured with SKOV-3 spheroids in an ADCC assay, CAR γδ T cells exhibited enhanced cytotoxicity in the presence of trastuzumab but not isotype control antibody. Activity of the γδ T cells was not reliant on additional exogenous cytokine due to the engineered form of membrane-associated IL-15.

Conclusions We have demonstrated that iPSC-derived γδ T cells mediate anti-tumor activity in human solid tumor models through multiple pathways. The combination of two modes of tumor recognition (CAR and CD16/antibody) enabled more potent killing of solid tumor spheroids. The ability to manufacture large batches of iPSC derived CAR γδ T cells will enable a true off-the-shelf allogenic cell therapy for solid tumors.

263 A2B694, AN AUTOLOGOUS LOGIC-GATED CELL THERAPY TARGETING MESOTHELIN

[1]Julian Molina, [2]Talar Tokatlian*, [2]Jason Wang, [2]Shruti Sharma, [2]Diane Manry, [2]Martin Naradikian, [2]Grace Asuelime, [2]Breanna DiAndreth, [2]Aaron Winters, [2]Tisha San Miguel, [2]Armen Mardiros, [3]Sandip Patel, [4]Edward Garon, [5]Diane Simeone, [6]Scott Kopetz, [6]Maria Pia Morelli, [5]Theodore Welling, [7]Mitesh Borad, [8]Kedar Kirtane, [2]Eric Ng, [2]John Welch, [9]David Maloney, [2]William Go, [10]Alexander Kamb, [2]Agi Hamburger, [4]J Randolph Hecht. *[1]Mayo Clinic, Rochester, MN, USA; [2]A2 Biotherapeutics, Inc., Agoura Hills, CA, USA; [3]University of California San Diego, La Jolla, CA, USA; [4]University of California at Los Angeles, Los Angeles, CA, USA; [5]New York University Langone Health, New York, NY, USA; [6]University of Texas MD Anderson Cancer, Houston, TX, USA; [7]Mayo Clinic Cancer Center, Scottsdale, AZ, USA; [8]H. Lee Moffit Cancer Center, Tampa, FL, USA; [9]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [10]A2 Biotherapeutics, Inc., Westlake Village, CA, USA*

Background Mesothelin (MSLN) is expressed on a variety of solid tumors, including mesothelioma and ovarian, uterine, gastric, pancreatic, and lung cancers.[1] However, efforts to target MSLN using cellular therapies have been hampered by severe on-target, off-tumor toxicities associated with damage to normal tissues expressing MSLN.[2] To avoid these toxicities, we have developed a logic-gated engineered cell therapy, Tmod™, which is composed of two chimeric antigen receptors (CARs): an activator that targets a tumor-associated antigen and an inhibitory receptor (blocker) gated by an antigen expressed on normal tissue but lost in tumor cells due to loss of heterozygosity (LOH). A2B694 is an MSLN-specific Tmod construct combining a third-generation MSLN CAR with an LIR-1-based inhibitory receptor specific for human leukocyte antigen A*02 (HLA-A*02).

Methods Lentivirus encoding i) the CAR, ii) the blocker, and iii) an shRNA targeting β2M was used to transduce T cells from HLA-A*02 donors and generate MSLN Tmod cells. In vitro cytotoxicity measurements were performed using fluorescence-based imaging and luciferase readouts. In vivo assessments were performed in NSG mice subcutaneously implanted with "normal" cells (MSLN[+]A*02[+]), or tumor cells (MSLN[+]A*02[-]), in the left and right flanks, respectively. Following engraftment, mice were randomized and treated intravenously with MSLN Tmod cells or controls. Grafts were measured via caliper.

Results MSLN Tmod cells preferentially killed tumor cells (MSLN[+]A*02[-]) over "normal" cells (MSLN[+]A*02[+]) in vitro, unlike clinically active comparator M5 CAR T cells, which indiscriminately killed both target cell types (figure 1A). Soluble MSLN, tested across a 0-2 µg/mL range, did not impact MSLN Tmod function. Additionally, in mixed cell cultures where T cells and tumor and "normal" cells were simultaneously cultured (1:1:1 ratio), MSLN Tmod cells selectively killed tumor targets while sparing "normal" cells. Further, MSLN Tmod cells cycled between activated and blocked states in vitro when repeatedly challenged with tumor or "normal" target cells. Finally, while MSLN CAR T cells killed both "normal" and tumor grafts in vivo, MSLN Tmod cells selectively killed tumor grafts while sparing "normal" grafts (figure 1B, C).

Conclusions A2B694 is an autologous MSLN Tmod cell product that leverages LOH at the HLA locus in cancer cells, providing a mechanism to discriminate between normal and tumor cells. BASECAMP-1 (NCT04981119), an observational study that will identify patients with somatic HLA LOH, is currently recruiting. Eligible patients with metastatic colorectal, pancreatic, or non-small cell lung cancer will be apheresed for a future A2B694 interventional study (EVEREST-2).

Background The remarkable clinical responses of chimeric antigen receptor (CAR)-engineered immune cell therapies in hematological malignancies have not been replicated in solid tumors. Engineered, off-the-shelf, allogeneic natural killer (NK) cells are particularly attractive as a chassis for effective cell therapies for solid tumors given their clinical safety, efficacy, and ability to reduce tumor escape through inherent multimodal recognition of tumor cells.

We describe here preclinical efficacy and pharmacodynamics of CAT-179, a novel CAR-NK cell therapy, in multiple models of HER2-amplified ovarian and gastric cancer. CAT-179 cells are engineered to express three transgenes: a HER2-directed CAR to effectively target tumor cells, a transforming growth factor ß (TGFß) dominant negative receptor (DNR) for resistance to TGFß-mediated immune suppression in the tumor microenvironment, and interleukin-15 (IL15) to enhance NK cell persistence and activity for durable response.

Methods PBMC-derived NK cells were engineered with a tricistronic construct expressing HER2-directed CAR, TGFß DNR, and IL15 under the control of a MND promoter using TcBuster™ transposase. CAT-179 activity was assessed in vitro by quantifying cytotoxicity and cytokine production upon co-culture with HER2-expressing cell lines. TGFß DNR activity was assayed by quantifying TGFß-induced SMAD phosphorylation and DNAM1 receptor expression. In vivo persistence and anti-tumor efficacy was evaluated in NSG mice. Anti-tumor efficacy was tested against luciferase-engineered SKOV-3 ovarian cancer cells (SKOV-3-luc) and N87 gastric carcinoma xenografts.

Results CAT-179 demonstrates both CAR-dependent and innate NK receptor-dependent tumor cell killing in vitro, reducing the likelihood of tumor escape through antigen loss. CAT-179 demonstrated high CAR-dependent cytotoxicity as well as TNFa and IFNg production when co-incubated with multiple HER2-expressing cell lines. Engineered NK cells demonstrated 75% reduction (relative to control NK cells) in TGFß-induced SMAD2 phosphorylation, prevented TGFß-induced downregulation of NK cell activating receptors, and restored NK cell cytotoxic activity. Furthermore, TGFß DNR protected bystander cells from TGFß-induced phenotypic changes. After a single IV dose, CAT-179 cells persisted for more than two months and retained cytotoxic activity. CAT-179 effectively reduced SKOV-3-luc tumor burden in NSG mice (95% AUC, $p<0.0001$ for survival).

Conclusions CAT-179 is a promising demonstration of the Catamaran CAR-NK platform, as a novel off-the-shelf cell therapy to overcome the challenges associated with solid tumors.

265 EMPOWERING IPSC-DERIVED INK CELLS WITH MULTIPLE GENE EDITS TO IMPROVE PERSISTENCE AND ANTI-TUMOR EFFICACY

Buddha Gurung*, Annalise Jethon, Maisha Harris, Shelby Keating, Spencer Moros, Rebecca Genovese, Steven DeLuca, Arden Edgerton, Nicholas Alexander, Chiamin Bullaughey, Barry Morse, Liam Campion, Mark Mendonca, Kaitlin Idank, Hillary J, Millar Quinn, Diana Chin, Jill Carton, Michael Naso, Mark Wallet, Luis Borges. *Century Therapeutics, Chalfont, PA, United States*

Background A unique attribute of iPSCs is the ability to perform sequential gene edits thus enabling development of highly engineered cell therapies. Here, we describe our next generation platform for iPSC-derived NK cells (iNK cells) that include genetic enhancements for improved allo-evasion, cell fitness, tumor targeting, in vivo imaging, and safety. By adopting a common progenitor strategy, an engineered iPSC master cell bank will be used as the starting point for future therapies across diverse indications.

Methods Clinical grade iPSC lines were engineered using Mad7 CRISPR endonuclease. β2 microglobulin was disrupted and a bicistronic transgene encoding both HLA-E and HLA-G was inserted. The gene encoding CIITA was disrupted and a bicistronic transgene encoding HSV-TK and PSMA ectodomain was inserted. A transgene encoding IL-15/IL-15Ra was delivered into the NKG2A locus, and a bicistronic transgene encoding CD16 and NKG2D was delivered into the CD70 locus.

Results iNK cells exhibited uniform expression of each transgene. Functional studies demonstrated that HLA-E/G enabled evasion of allogenic NK cells; IL-15/IL-15RA enhanced persistence of iNK cells both in vitro and in vivo; PSMA expression on the cell surface was confirmed through binding of a PSMA-specific fluorescent tracer; HSV-TK enabled the elimination of iNK cells in culture in the presence of ganciclovir; NKG2D enhanced elimination of tumor lines expressing the stress ligands MICA/MICB; and high-affinity CD16 enabled ADCC-mediated killing of CD20-expressing target cells in the presence of rituximab. HLA-A/B/C, HLA-DR/DP/DQ, NKG2A, and CD70 were absent from iNK cells.

Conclusions A clonal iPSC line was derived with eleven total genetic modifications to improve allogeneic cell therapy for cancer. Future iNK cell therapies will be derived from the common progenitor by addition of a CAR(s) for indication-specific tumor targeting.

266 STING ACTIVATION IMPROVES T CELL ENGAGING IMMUNOTHERAPY OF ACUTE MYELOID LEUKEMIA

[1]Daniel Nixdorf*, [2]Andreas Linder, [2]Niklas Kuhl, [1]TengTeng Xu, [3]Roman Kischel, [1]Veit Bücklein, [2]Thomas Carell, [2]Veit Hornung, [1]Marion Subklewe med. *[1]University Hospital LMU, Munich, Germany; [2]LMU, Munich, Germany; [3]AMGEN Research Munich GmbH, Munich, Germany*

Background The treatment landscape for Acute myeloid leukemia (AML) patients has changed dramatically in recent years, however the majority of patients will eventually relapse. Allogeneic stem cell transplantation has proven the power of T-cells in eradicating residual leukemic cells, but alternative strategies based on T-cell recruiting bispecifics have failed to replicate these responses. Resistance is mediated by the immunosuppressive tumor-microenvironment and secretion of immune dampening metabolites by AML cells. We hypothesized that combining the CD33 BiTE construct AMG 330 with a cGAS-STING agonist has the potential to reverse immunosuppressive mechanisms and augment anti-leukemic activity.

Methods *In vitro* co-culture assays of human T-cells and AML cell lines were performed to study the effect of AMG 330 in combination with the STING-agonist cGAMP. Cytotoxicity, degranulation, and cytokine secretion were assessed by flow-cytometry. Transcriptomic analysis and systematic CRISPRCas9 knockout-studies were conducted.

Results We observed markedly increased target cell lysis upon simultaneous addition of cGAMP and AMG 330. Notably the cGAMP-dependent enhancement of AML cell lysis increased over time and was most pronounced at low effector-to-target ratio. Moreover, cGAMP improved AMG 330 mediated killing of primary AML cells. We noted increased T-cell degranulation, as well as increased T-cell intrinsic levels of Granzyme B and IFNy in the presence of cGAMP. In addition, we observed a strong increase in inflammatory cytokine (IFNy, TNFa, IL-4) secretion.

RNA-sequencing of AMG 330 and cGAMP stimulated target (HL-60) and effector cells revealed type-I-IFN signatures in both cell types, while HL-60 cells also displayed a signature of IFNy signaling. We observed a distinct activated T-cell phenotype with markedly increased TNFa, IFNy and GZMB expression induced by the co-treatment.

Knockout-studies revealed that the enhanced phenotype was fully dependent on target cell intrinsic STING/IRF3 signaling and functional IFNy/TNFa signaling. Increased T-cell mediated IFNy production upon combinatory treatment was also dependent on functional target cell STING and INFy/TNFa signaling, implying a crosstalk between effector and target cells. Most notably, the effector cytokines IFNy and TNFa in turn boosted the expression of ISGs, as well as the secretion of type-I-interferons (IFNa, IFNl) by HL-60 cells in the presence of cGAMP.

Conclusions We propose a novel mechanism by which AMG 330-activated T-cells prime and sensitize AML target cells in a forward feedback loop towards STING activation, leading to increased type-I-IFN production. This leads to pronounced expression of effector cytokines and an overall cytotoxic T-cell phenotype, contributing to the beneficial effect of cGAMP in enhancing BiTE construct-mediated lysis.

Ethics Approval Peripheral blood or bone marrow samples were collected from healthy donors and patients with acute myeloid leukemia at initial diagnosis, relapse, or complete remission after written informed consent was received in accordance with the Declaration of Helsinki and approval was granted by the Institutional Review Board of the Ludwig-Maximilian-Universität (Munich, Germany, reference number: 216-08).

267 MRNAS ENCODING IL-12 AND A DECOY-RESISTANT VARIANT OF IL-18 SYNERGIZE TO ENGINEER T CELLS FOR EFFICACIOUS INTRATUMORAL ADOPTIVE IMMUNOTHERAPY

[1]Irene Olivera*, [1]Elixabet Bolanos, [1]Jose González-Gomariz, [1]Sandra Hervas-Stubbs, [2]Karina V Mariño, [1]Carlos Luri-Rey, [1]Iñaki Etxeberria, [1]Assunta Cirella, [1]Josune Egea, [1]Javier Glez-Vaz, [1]Saray Garasa, [1]Maite Alvarez, [1]Iñaki Eguren-Santamaria, [3]Sonia Guedan, [1]Miguel F Sanmamed, [1]Pedro Berraondo, [2]Gabriel Rabinovich, [1]Alvaro Teijeira, [1]Ignacio Melero. *[1]Center for Applied Medical Research (CIMA), Pamplona, Spain; [2]IBYME, Buenos Aires, Argentina; [3]IDIBAPS, Barcelona, Spain*

Background Interleukin-12 (IL-12) is a potent immunotherapeutic cytokine in mouse models which application as a systemic agent in the clinical setting is hampered by IFNγ-dependent toxicity.[1] Engineering T cells with IL-12 is highly efficacious in mouse models[2] but has resulted in serious adverse events in clinical settings.[3] On the other hand, IL-18 is a myeloid-derived cytokine that elicits IFN-γ expression on T and NK lymphocytes.[4]

IL-12 and IL-18 are known to synergize in terms of eliciting massive IFNγ production.[5] For cancer immunotherapy, IL-18 has the caveat of being down-regulated in its function by a decoy receptor termed IL-18BP,[6] which is reportedly abundant in tumor tissues.[7,8] Recently, a mutant sequence of mouse IL-18 termed DRIL18 which preserves its bioactivity but lacks binding to IL-18BP has been reported to exert T-cell-dependent antitumor activity upon systemic delivery.[7]

We previously reported that transient engineering of tumor-specific CD8 T cells with IL-12 mRNA enhanced their systemic therapeutic efficacy when delivered intratumorally.[9] In this study, we sought to improve the therapeutic strategy of intratumoral delivery of T cells transiently engineered to express IL-12 with IL-18 mRNA electroporation.

Methods We mixed $CD8^+$ T cells (TCR transgenic, TILs and CAR-T) engineered with mRNAs to transiently express either single-chain IL-12 (scIL-12) or an IL-18 decoy-resistant variant (DRIL18) that is not functionally hampered by IL-18BP. $CD8^+$ T cells were injected repeatedly into mouse tumors for antitumor efficacy experiments. RNA-seq was performed to assess the functional changes induced after mRNA electroporation. Additionally, T-cell metabolic modifications and glycosylation profile functional changes were analyzed using seahorse and cell adhesion assays.

Results Pmel-1 TCR-transgenic T cells electroporated with scIL-12 or DRIL18 mRNAs exerted powerful therapeutic effects in local and distant melanoma lesions. These effects were associated with T-cell metabolic fitness, enhanced miR-155 control of immunosuppressive target genes, enhanced expression of various cytokines and unique changes in the glycosylation profile of surface proteins, enabling enhanced adhesiveness to E-selectin. Efficacy of this intratumoral immunotherapeutic strategy was recapitulated using other clinically relevant adoptive T cell therapies as tumor-infiltrating lymphocytes (TILs) and CAR T cells upon IL-12 and DRIL18 mRNA electroporation.

Conclusions We report on a substantial improvement of adoptive T-cell therapies strategy based on mRNA transient gene-transfer and repeated intratumoral delivery. The synergistic immunobiology of IL-12 and IL-18, best represented in the form of DRIL18, holds promise for efficacious outcomes in the treatment of metastatic cancer patients.

268 HARNESSING CD39 FOR THE TREATMENT OF COLORECTAL CANCER AND LIVER METASTASES BY ENGINEERED T CELLS

Alessia Potenza*, Chiara Bonini, Chiara Balestrieri, Luca Albarello, Federica Pedica, Martina Spiga, Francesco Manfredi, Beatrice Cianciotti, Claudia De Lalla, Lorena Stasi, Elena Tassi, Silvia Bonfiglio, Giulia Scotti, Miriam Redegalli, Donatella Biancolini, Danilo Abbati, Fabio Simeoni, Dejan Lazarevic, Ugo Elmore, Guido Fiorentini, Giulia Di Lullo, Giulia Casorati, Paolo Dellabona, Claudio Doglioni, Giovanni Tonon, Riccardo Rosati, Luca Aldrighetti, Eliana Ruggiero. *IRCCS San Raffaele Scientific Institute, Milan, Italy*

Background Colorectal cancer (CRC) is the 2nd cause of cancer-related death. Despite standard therapies, more than 50% of patients experience relapse, eventually with metastatic disease. Colorectal tumours are densely infiltrated by immune cells that have a role in surveillance and modulation of tumour progression, correlating with an improved overall survival. However, exhaustion mechanisms acting within the tumour microenvironment impede their functional capacity against tumour cells.

Methods We paired high-dimensional flow cytometry, RNA sequencing, immunohistochemistry and immunofluorescence to describe the T cell functional landscape in tumour and peritumoral tissues from primary colorectal cancers and liver metastases. By CRISPR/Cas9 genome engineering techniques, we redirected the specificity of T cells towards a tumor-specific antigen while disrupting inhibitory molecules, to counteract the immune-suppressive tumor microenviroment.

Results Analysis of the healthy, peritumoral and neoplastic tissues of treatment-naïve primary CRCs and of the peritumoral and tumoral tissues of CRC patients undergoing surgery for liver metastases revealed extensive transcriptional and spatial remodeling across tumors, being metabolic pathways among the major drivers of this variance. Regarding the immune infiltrate, we found that T cells are mainly localized at the front edge and that tumour-infiltrating T cells co-express multiple inhibitory receptors. Unsupervised analysis of flow cytometry data performed by an advanced pipeline of data handling by dimensionality reduction and clustering algorithms allowed the definition of a peculiar inhibitory receptors signature in TILs enriched both in primary CRCs and liver metastases. Among the highly co-expressed inhibitory receptors, CD39 was found to represent the major driver of exhaustion in both primary and metastatic colorectal tumours. CD39 is a diphosphohydrolase converting ATP into AMP that is emerging as exhaustion marker for tumor-specific T cells, thus highlighting its relevance as molecular target for T cells engineering. By CRISPR/Cas9 genome editing tools, we simultaneously redirected T cell specificity by disrupting the alpha and beta genes of the endogenous T cell receptor with >90% efficiency, and disrupted CD39 with 100% efficiency, generating triple-knockout engineered lymphocytes. By lentiviral transduction, we redirected the specificity of our engineered T cell product employing a novel T-cell receptor targeting the HER-2 antigen. Gene-edited, HER2-redirected T cells were challenged against HER2+ patient-derived organoids (PDOs) *in vitro* and *in vivo*: CD39-disrupted, HER2-redirected T cells displayed a functional advantage in recognizing and killing CRC PDOs and enhancing mice survival, compared to CD39-competent, HER2-redirected T cells.

Conclusions The CD39 axis is relevant for further exploitation in adoptive T-cell therapy to treat primary and metastatic colorectal cancer.

Ethics Approval The present study was approved by IRCCS San Raffaele Ethical Committee, protocols ACTxCRC and NCT04622423.

269 MITOCHONDRIAL APOPTOSIS MEDIATES CAR T CELL CYTOTOXICITY

[1]Alexandra Pourzia, [1]Michael Olson*, [2]Stefanie Bailey, [1]Aditi Aryal, [1]Jeremy Ryan, [2]Marcela Maus, [1]Anthony Letai MD. [1]*Dana-Farber Cancer Institute, Boston, MA, USA*; [2]*Massachusetts General Hospital, Charlestown, MA, USA*

Background CAR T cell therapy has greatly improved outcomes in relapsed hematologic malignancies, yet some patients do not respond to treatment. Dysregulation of apoptotic signaling pathways has been implicated in reduced sensitivity to chemotherapeutics in many hematologic malignancies, however, whether these pathways are also perturbed as a mechanism of resistance to CAR T cell therapy remains unclear. Here, we investigated the importance of mitochondrial apoptosis in CAR T cell anti-tumor cytotoxicity.

Methods Given that knockout of the pro-apoptotic proteins Bak and Bax is sufficient to significantly dampen mitochondrial apoptosis, we generated HeLa, HCT-116, JeKo-1 and NALM6 cells lacking Bak and Bax and cultured them with CAR T cells in order to determine the relevance of mitochondrial apoptosis to CAR T cell cytotoxicity. Cytoxicity was measured by Annexin V/Hoechst staining, impedance assays and colony formation assays.

Results HeLa cells expressing CD19 and lacking Bak and Bax (HeLa-19-DKO) exhibited significantly enhanced resistance to killing by CD19 CAR T cells when compared to cells expressing endogenous levels of Bak and Bax. Given the protection from CAR T cell cytoxicity conferred by loss of the pro-apoptotic proteins Bak and Bax, we next conversely sought to determine if overexpression of the anti-apoptotic proteins Bcl-2 and Bcl-XL would similarly confer protection. Consistent with our findings using DKO cells, HeLa-19 cells overexpressing Bcl-2 and Bcl-XL were more resistant to killing by CD19 CAR T cells, demonstrating that mitochondrial apoptosis is relevant to CAR T cell cytotoxicity.

We next sought to validate the importance of mitochondrial apoptosis in CAR T cell cytotoxicity by targeting an endogenously expressed CAR T cell target, namely EGFR. Coculture of EGFR CAR T cells with wild type and DKO HeLa and HCT-116 cells revealed significant resistance to CAR T cells by DKO target cells. Given the protective effect of dampening mitochondrial apoptosis in two solid cancer models, we finally sought to determine whether CAR T cells similarly utilize mitochondrial apoptosis to induce cell death in liquid cancers. In contrast with our solid cancer models, knockout of Bak and Bax in the liquid cell lines JeKo-1 and NALM6 did not result in enhanced resistance to CD19 CAR T cell cytotoxicity.

Conclusions Taken together, these data demonstrate that mitochondrial apoptosis plays a role in how CAR T cells kill solid but not liquid tumors, suggesting that cancer type may be an important factor in considering combinatorial treatments using CAR T cells and pro-apoptotic drugs.

270 DEVELOPING PLACENTAL CD34$^+$-DERIVED NATURAL KILLER CELLS WITH HIGH AFFINITY AND CLEAVAGE RESISTANT CD16 (CYNK-101) IN COMBINATION WITH AVELUMAB FOR ENHANCED THERAPY AGAINST PD-L1$^+$ SOLID TUMORS

Irene Raitman*, Gavin Foley, Eric He, Hemlata Rana, Niranjan Ghimire, Xuan Guo, Robert Hariri, Lin Kang. *Celularity Inc., Florham Park, NJ, USA*

Background Natural killer (NK) cells play a key role in antibody dependent cellular cytotoxicity (ADCC) via their CD16 Fc receptor. NK cell therapies can be targeted to tumors via tumor specific antibodies. Celularity Inc. is developing human placental CD34$^+$-derived, cryopreserved, off-the-shelf, allogenic NK cells (CYNK-101) with a high IgG binding affinity and proteinase cleavage resistant CD16 variant (CD16VP) for cancer treatment. We hypothesize that expression of CD16VP on CYNK-101 augments its anti-tumor ADCC activity.

Methods Here, we evaluated anti-tumor activity of CYNK-101 in combination with Avelumab, an anti-PD-L1 antibody, against PD-L1$^+$ lung, breast, and bladder cancer cell lines. Furthermore, the PI3-kinase inhibitor Wortmannin was used to investigate the molecular mechanism underlying CYNK-101-mediated cytotoxicity.

Results *In vitro* ADCC activity of CYNK-101 against PD-L1$^+$ targets was assessed in combination with Avelumab. At 4h, at an effector to target (E:T) ratio of 5:1, CYNK-101 displayed increased cytotoxicity against the lung cancer cell line NCI-H1975, 56.7 ± 19.3% with Avelumab vs. 37.3 ± 6.4% with IgG control (n=6 donors, $p<0.05$). For the breast cancer cell line MDA-MB-231, cytolysis with Avelumab at the 5:1 ratio was 64.4 ± 17.1% vs. 51.1 ± 15.7% with IgG control (n=6 donors, $p<0.005$). For the bladder cancer cell lines, the cytolysis with Avelumab compared to IgG control was 78.3 ± 16.9% vs. 10.4 ± 20.2% for 5637 ($p<0.005$), 57.8 ± 22.8% vs. 37.2 ± 19.4% for T-24 ($p<0.005$), and 38.1 ± 20.0% vs. 28.7 ± 14.3% for RT-112 ($p<0.05$), respectively (n=6 donors). CYNK-101 in the presence of Avelumab also secreted significantly higher levels of GM-CSF and IFN-gamma when co-cultured for 24h with NCI-H1975 and MDA-MB-231 compared to that of the IgG control (n=6 donors, $p<0.05$). The enhanced cytotoxicity of CYNK-101 was PI3-kinase pathway-dependent as Wortmannin (0.1 μM) significantly decreased the 24h cytotoxicity for NCI-H1975 with Avelumab from 92.4 ± 13.1% to 66.3 ± 16.7% at the E:T ratio of 5:1, such a decrease was also observed at E:T ratios from 2.5:1 to 0.6:1 (n=3 donors, $p<0.05$).

Conclusions Our results demonstrate that CYNK-101 has enhanced Avelumab-mediated ADCC activity against PD-L1$^+$ tumor cell lines, such as lung, breast, and bladder cancers. Further development of the combinational therapy for PD-L1$^+$ solid tumor indications is warranted.

271 **B CELL PRIMED CD8 T CELLS GENERATE SIMILAR PHENOTYPE, FUNCTION AND ANTI-TUMOR RESPONSES TO DC PRIMED CD8 T CELLS**

Ichwaku Rastogi*, Douglas McNeel. *University of Wisconsin-Madison, Madison, WI, USA*

Background Exogenous peptide-loaded antigen presenting cells (APCs) have been under investigation as a therapeutic approach for the treatment of cancer patients. However, in general APC vaccines have demonstrated limited efficacy in clinical trials. To date, only one APC based vaccine, Sipuleucel-T, has been approved by FDA for the treatment of cancer, in this case castrate-resistant metastatic prostate cancer. Dendritic cells (DCs), best known for their cross priming ability, have been the ultimate choice for APC based vaccine research. However, B cells, which also serve as professional APC and can function similarly to activate CD4 and CD8 T cells, remain largely understudied. We compared the phenotype and function of activated T cells that resulted from epitope-specific priming through either B cells or DCs.

Methods We isolated B cells and DCs from C57Bl/6 mice, which were either treated or not with LPS for maturation. These cells were then either loaded or not with SIINFEKL peptide (dominant ovalbumin epitope) for priming CD8 T cells isolated from OT-1 mice (transgenic for TCR specific for SIINFEKL). Resulting T cells were analyzed for their phenotype, function, and anti-tumor efficacy via flow cytometry, ELISA, and E.G7-OVA murine tumor model respectively.

Results We report that priming through peptide-pulsed immature B cells or immature DCs similarly activated antigen-specific CD8 T cells. However, priming through mature DCs resulted in generation of a stronger CD8 T cell activation profile when compared to priming through mature B cells. Similarly, we report that CD8 T cell priming through B cells or DCs resulted in comparable expression of exhaustion and checkpoint related markers on activated CD8 T cells, and similar expression of pro-inflammatory and cytotoxicity related cell surface proteins and intracellular cytokines. Lastly, we report that CD8 T cells primed through immature B cells, immature DCs or mature DCs, all generated a similar anti-tumor response upon adoptive transfer to tumor-bearing mice.

Conclusions Collectively, our data indicated that both B cells and DCs are equally capable of activating CD8 T cells and generating an anti-tumor response. Given that B cells are relatively easier to culture and expand when compared to DCs, our study warrants further investigation into the APC function of B cells and their potential use as APC-based vaccines.

Ethics Approval Al experiments involving animals were performed under IACUC approved protocol no. M005690.

272 PRE-CLINICAL EVALUATION AND FIRST-IN-DOG CLINICAL TRIALS OF INTRAVENOUS INFUSION OF PBMC-EXPANDED ADOPTIVE NK CELL THERAPY IN DOGS WITH CANCER

Aryana Razmara*, Lauren Farley, Rayna Harris, Sean Judge, Marshall Lammers, Cordelia Dunai, William Murphy, Robert Rebhun, Michael Kent, Robert Canter. *UC Davis, Davis, CA, USA*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0272

Background Natural killer (NK) cells are cytotoxic immune cells capable of recognizing heterogeneous cancer targets without prior sensitization, making them promising prospects for use in cellular immunotherapy. Previously, CD5 depletion of peripheral blood mononuclear cells (PBMCs) has been used in dogs to isolate and expand a $CD5^{dim}$-expressing NK subset prior to co-culture with an irradiated feeder line, but this can limit the yield of the final NK product. This study aimed to assess NK activation, expansion, and preliminary clinical activity in first-in-dog clinical trials using unmanipulated PBMCs without CD5 depletion to generate our NK cell product.

Methods Starting populations of CD5-depleted cells and PBMCs from 12 matched healthy beagle donors were co-cultured with irradiated K562-C9-mIL21 cells and 100IU/mL rhIL-2 for 14 days. Phenotype, cytotoxicity, and cytokine secretion were measured, and samples were sequenced using the 3'-Tag-RNA-Seq protocol for gene profiling. In addition, two first-in-dog feasibility clinical trials were performed in dogs with melanoma (MEL, N=5) and osteosarcoma (OSA, N=9) using autologous and allogeneic NK cells, respectively, expanded from unmanipulated PBMCs.

Results Calculated cell counts, overall fold change, and viability in NK expansions displayed higher means at day 14 using PBMCs versus CD5-depleted cells, reaching a peak mean of $677x10^6$ cells from 5 $x10^6$ starting cells (P=NS). Flow analysis showed similar upregulation of NKp46 and Granzyme B expression in both groups, reaching >90%. Killing assays against M5 (MEL) and OSCA78 (OSA) canine tumor targets demonstrated comparable percent killing >50% among both subsets of day 14 NK cells (P=NS). Median production of canonical NK cytokines, IFN-y and GM-CSF, at day 14 was over 5-fold greater in PBMC-expanded (IFN-y=316.7pg/mL, GM-CSF=267.0pg/mL) compared to CD5-depleted NK cells (IFN-y=59.6pg/mL, GM-CSF=48.7pg/mL) (P=NS). Sequencing data showed principal component sample variance based on time points and upregulation of NK pathways related to activation, crosstalk, and glycolytic function in both groups. PBMC-expanded NK cells for first-in-dog clinical trials showed sufficient expansion for multiple NK cell transfers at 7.5 x 10^6 cells/kg with no serious adverse events. We also observed preliminary data for efficacy, particularly in the allogeneic setting where peripheral blood gene expression significantly changed post-transfer and one dog survived 445 days post-treatment.

Conclusions Overall, the use of unmanipulated PBMCs appears safe and potentially effective for canine NK immunotherapy, with equivalent or superior results to CD5 depletion in NK expansion, activation, and cytotoxicity. Our pre-clinical and clinical data support further evaluation of this technique as a novel platform for optimizing NK immunotherapy in dogs.

Ethics Approval Clinical trials involving dog patients were IACUC and Clinical Trials Review Board-approved (Protocols #21620 and #22157). Dog owners gave informed consent before taking part.

273 GDA-501: ENGINEERED NAM-NK CELLS WITH HER2-CAR EXPRESSION DEMONSTRATE INCREASED CYTOTOXICITY AGAINST HER2-EXPRESSING SOLID TUMORS

Julia Rifman*. *Gamida Cell, Jerusalem, Israel*

Background Natural killer (NK) cells have generated considerable interest as potential adoptive cell immunotherapy. *Ex vivo* expansion of allogeneic NK cells using our proprietary nicotinamide (NAM) platform enhances NK cell functionality by preventing cell exhaustion, enhancing cytotoxic activity, generating a protective effect against oxidative stress, and exhibiting improved homing to lymphoid tissues. These attributes provide opportunities to enhance the therapeutic potential of NK cells in the clinic.

The success of immunotherapy in solid tumors has been limited due to several barriers, including immunosuppressive tumor microenvironment, inefficient trafficking, and heterogeneity of tumor antigens. A number of therapeutic approaches to overcome these limitations have emerged.

Gene modification strategies of NK cells may further enhance their functionality and provide a promising next-generation immunotherapeutic tool. The use of chimeric antigen receptors (CARs) can target specific antigens on tumors. Human epidermal growth factor receptor 2 (HER2)-CAR may be used to target $HER2^+$ solid tumors, such as breast, gastric, and ovarian carcinomas.

Methods HER2-CAR-NK cells were developed based on a single-chain variable fragment (scFv) of the widely used humanized monoclonal antibody trastuzumab. To construct our HER2-CAR-NK cells, we used the same binding domain present in trastuzumab, and designed different constructs in a modular way, optimized by modifying the hinge, transmembrane, and cytoplasmic domains with NK cell-related activating molecules to specifically enrich the cytotoxicity of NK cells.

Results Our engineered HER2-CAR NAM-NK cells (GDA-501) displayed significantly enhanced *in vitro* cytotoxicity when co-cultured with $HER2^+$ target cells such as ovarian adenocarcinoma cell line SKOV3. Elevated levels of the degranulation marker CD107a and proinflammatory cytokines including interferon (IFN)-γ and tumor necrosis factor (TNF)-α were observed, signifying increased potency of GDA-501 compared with control cells. Furthermore, increased cytotoxicity and potency persisted for up to 5 days post electroporation.

The specificity of the cytotoxic effect was evaluated. No significant elevation of HER2-CAR NK cell activation was detected when cultured with $HER2^-$ tumor cell lines or normal lymphocytes.

Conclusions GDA-501 is a genetically modified NAM-NK targeting HER2. By optimizing downstream signaling, we were able to directly enhance NK cell activity. *In vitro* data demonstrated potent cytotoxicity against HER2-expressing cells. These results suggest that GDA-501 represents a unique allogeneic cell therapy potentially targeting $HER2^+$ solid tumors.

Ethics Approval For the present study NK cells were collected from peripheral blood leukapheresis of individual donors. Ethics approval has been obtained from the local ethics committee (EC) at each of the sites (Hadassah Medical Center [0483-16-HMO], Rambam Medical Center [0641-18-RBM], Ichilov Sourasky Medical Center Tel-Aviv [0025-17-TLV]) prior to any study related activities.

The working procedures of the EC at the sites for conduct of clinical studies are in due compliance with local regulations (Israeli Ministry of Health) and provisions of Harmonized International Guidelines for Good Clinical Practice. Sites follow EC conditions & requirements in terms of submissions, notifications, and approval renewals. Participants gave informed consent (approved by the EC) before taking part in the study. Informed consent has been approved by the ECs. The Israeli template of informed consent is in used and it includes study specific information (e.g. study goal, design, method, duration, risks, etc.).

274 LCK KNOCKOUT CAR-T CELLS AS A NOVEL ALLOGENEIC PLATFORM

Previtha Dawn Sakthi Vale*, Ling Wu, Vivian Jia Yi Tan, Benson Chua, Liangzhe Wu, Jia Chi Tan, Clara Kai Ting Koh, June Ong, Nicholas Gascoigne. *National University of Singapore, Singapore, Singapore*

Background Chimeric antigen receptor (CAR) T therapy has shown remarkable success in treating liquid tumours but current approved therapies rely on autologous T cells which are expensive, difficult to manufacture and not readily available for patients whose disease progress rapidly. The production of safe and effective allogeneic CAR-T cells is needed to increase accessibility of CAR-T therapy and broaden its application. The main approach to generate allogeneic CAR-T therapy is by disrupting T cell receptor (TCR) expression to minimize Graft-versus-Host Disease (GVHD) mediated through the TCR of donor cells against the recipient's major histocompatibility complex (MHC). However, the TCR disruption approach has shown limited persistence *in vivo* [1] and in clinical trials [2] unlike the long term durability of autologous CAR-T cells. Here, we propose a novel platform for allogeneic CAR-T therapy that retains the TCR but inhibits TCR signalling by knocking out the Lymphocyte-specific protein tyrosine kinase (LCK) – a well-established kinase for proximal TCR activation. This builds on the discovery that our second generation CD28-CAR can be activated independently of LCK unlike the endogenous TCR.

Methods We utilise the CRISPR-Cas9 system to knockout LCK and TCR in both mouse and human primary T cells. We show how this difference in CAR and TCR signalling can be exploited to generate LCK knockout CAR-T cells that showed similar or enhanced *in vitro* and *in vivo* efficacy against tumour cells compared to conventional CAR-T cells of both human and mouse T cell origin.

Results LCK knockout T cells have reduced proliferation and intracellular cytokine staining against allogeneic PBMCs compared to T cells, suggesting comparable suppression of TCR-mediated alloreactivity to TCR knockout T cells. In the immunodeficient mouse model where human T cells cause xenogeneic GVHD, LCK knockout T cells showed reduced xenogeneic GVHD comparable to TCR knockout T cells. Murine LCK knockout T cells showed the same suppression of TCR signalling as TCR knockout T cells in vitro. In murine major mismatched allogeneic models, murine LCK knockout T cells showed a reduction in GVHD symptoms compared to wild-type T cells. Compared to TCR knockout T cells, the LCK knockout T cells showed superior persistence and higher engraftment in allogeneic recipient mice.

Conclusions Our study suggests LCK knockout CAR-T cells inhibits TCR-mediated alloreactivity and retains the TCR for improved persistence while maintaining CAR activation potential which results in a superior allogeneic CAR-T therapy compared to TCR knockout CAR-T cells.

275 **MANUFACTURE OF ALLOGENEIC, HLA-MATCHED, TCR-EDITED T-CELL THERAPY REACTIVE AGAINST MINOR HISTOCOMPATIBILITY ANTIGEN 1 TO TREAT ACUTE MYELOID LEUKEMIA IN COMBINATION WITH CD34 HSCT WITH THE POTENTIAL FOR HIGH POTENCY AND DURABILITY**

[1]Robert Keefe*, [1]Tim Mayall, [1]Egidio Cofano, [1]Marlyn Anguelov, [2]Constantinos Panousis, [1]Paola Sette. [1]*BlueSphere Bio, Walkersville, MD, USA*; [2]*BlueSphere Bio, Pittsburgh, PA, USA*

Background BlueSphere Bio (BSB) has developed a proprietary high-throughput T cell receptor (TCR) capture and screening platform to enable T-cell therapy for the treatment of cancer. Our TCX-101 program develops allogeneic TCR T-cells to enhance the beneficial alloreactive T cell response observed with allogeneic hematopoietic stem cell transplantation (alloSCT). The therapeutic goal is to promote a graft-versus-leukemia effect, whilst reducing the risk of graft versus host disease. The first product in the platform, BSB-1001, targets the hematopoietically-restricted minor HA-1 (HA-1 TCR). HA-1 is restricted by a common human HLA type A*02:01 and covers approximately 50% of the that population. BSB-1001 is currently in development for clinical testing in Acute Myeloid Leukemia (AML).

Methods BSB-1001 is generated by activation of healthy donor PBMCs from a mobilized apheresis, using anti-CD3 OKT3. Following the activation, CD8 T-cells are isolated, and the endogenous TCR knocked out with CRISPR edits, using formulated Cas9/guide RNA, RiboNuclear Particles (RNP). Cells are then transduced with the anti-miHA-1 TCR lentivector (Yposkesi). Cells are cultured and expanded and cryopreserved on harvest day using CryoStor10 in a controlled rate freezer. The product is co-administered with CD34 cells isolated from the same donor apheresis.

Results BSB-1001 was developed and generated at BSB. PBMCs derived from fresh APH are activated using OKT3, with T-cells over 90% by CD69 upregulation. CD8+ T-cells were isolated, and endogenous TCR knockout using RNP, and then transduced with anti-HA1 TCR lenti viral vector. Integrated vector copy number in these cells is under 5 copies/cell. After culture, day 12 harvest, and cryopreservation, cells are thawed and tested in QC. Phenotype of these cells demonstrates a generally stem-cell like phenotype (Tcm, Tem, Tscm), with Tscm cells predominating. BSB-1001 cells showed efficient killing of HA-1+ LCL222 cells, but not HA-1 -/- LCL224 cells. Log-scale plots shows strong IC50 points on the killing curve as low as 0.1:1 Effector:Target ratios. Continued culture of the cells after killing is measured, by the addition more LCL cells, shows that the cytolytic potency of the cells is maintained for at least an additional 20 days (32 days from initial activation).

Conclusions Taken together, the results indicate that BSB-1001 is an active, highly potent drug product candidate, with a potential to be effective in treating HA-1+ HLA-A*02:01 AML patients in the setting of alloSCT. The phenotype and high cytolytic bioactivity indicate that the clinical response has a potential to be very potent and durable.

276 ENGINEERING OF SYNTHETIC CHEMOKINE RECEPTORS INTO IPSC-DERIVED CAR-T CELLS TO INCREASE HOMING AND ENHANCE TRAFFICKING INTO SOLID TUMORS

[1]Soheila Shirinbak*, [1]Joy Grant, [2]Angela Gentile, [1]Bishwas Shrestha, [1]Philip Chu, [1]Amit Mehta, [1]Yijia Pan, [1]Bjoern Gaertner, [1]Mochtar Pribadi, [1]Joyee Yao, [1]Matthew Denholtz, [1]Alec Witty, [1]Layton Smith, [1]Tom Lee, [1]Eigen Peralta, [1]Martin Hosking, [1]Bob Valamehr. *[1]Fate Therapeutics Inc. (FHQ1), San Diego, CA, USA; [2]Fate Therapeutics, Inc. (FTP1), San Diego, CA, USA*

Background Despite the success of chimeric antigen receptor (CAR)-T cells in treating hematological malignancies, the efficacious treatment of solid tumors has been hampered by lack of CAR-T cell persistence, tumor-associated antigen heterogeneity, and the immuno-suppressive tumor microenvironment (TME). In addition, trafficking of CAR-T cells to solid tumors, potentially due to a chemokine-chemokine receptor mismatch between the tumor and the CAR-T cells, has proven ineffective. Early and sustained detection of T cells within a solid tumor has been associated with better outcomes across several clinical trials, suggesting that strategies focused on enabling CAR-T cell homing and trafficking can generate significant therapeutic benefit.

Methods IL8/CXCL8, a ligand for the chemokine receptor CXCR2, has been detected in many cancer types including ovarian, breast, prostate and renal and is often associated with poor prognosis and overall survival. We have previously shown high baseline expression and inducible upregulation of IL8 following chemo- or radiotherapy conditioning in multiple tumor lines. We therefore engineered CXCR2 into induced pluripotent stem cell (iPSC)-derived CAR-T (CAR iT) cells to express a synthetic CXCR2 transgene.

Results CXCR2-engineered iPSCs were differentiated to manufacture alpha-beta CAR iT cells expressing uniform and high levels of the chemokine receptor (>90% CXCR2 expression). Importantly, CXCR2 expression did not affect CAR-dependent effector function. CXCR2 engineered CAR iT cells demonstrated specific and functional *in vitro* chemotactic migration to recombinant IL8 and tumor preconditioned media (up to 3 fold increase compared to control CAR iT cells). In preclinical *in vivo* assessment with either (i) an aggressive ovarian xenograft model that produces high levels of CXCL8, or (ii) a triple negative breast cancer xenograft model that expresses CXCL8 following cyclophosphamide/fludarabine preconditioning, CXCR2-engineered CAR iT cells demonstrated enhanced infiltration (SKOV3 model; 6.01e6 cells/gr tumor vs 0.94e6 cells/gr tumor with CXCR2+ CAR iT cells vs control CAR iT cells, respectively) and increased retention specifically within the solid tumor microenvironment, resulting in improved tumor control (SKOV3 model; 81.3% TGI vs 60.9% TGI with CXCR2+ CAR iT cells vs control CAR iT cells, respectively).

Conclusions Preclinical data demonstrate that the engineering of synthetic chemokine receptors to further direct off-the-shelf CAR iT cells to the tumor site is an exciting strategy to improve anti-tumor activity, including as part of a multiplexed-engineering strategy for overcoming challenges in treating solid tumors.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0276

277 **DEVELOPMENT OF A ROBUST MANUFACTURING PROCESS FOR AB-1015, AN INTEGRATED CIRCUIT T CELL (ICT) PRODUCT, USING TARGETED, CRISPR INTEGRATION OF TRANSGENES BY ELECTROPORATION (CITE) EDITING**

Alice Chang*, Sophia Phillips, Max Lee, Elizabeth Huang, Navneet Anand, Hayden Ko, Stella Tran, Lindsay Rios, Rory Dai, Anton Nguyen, Anu Vasudevan, Rona Harari Steinfeld, Dina Polyak, Jessica Fuhriman, Hongruo Yun, Jun Feng, Haixia Wang, Ben Tran, Jenessa Smith, Tim Sirichoke. *ArsenaBio, South San Francisco, CA, USA*

Background AB-1015 is an autologous, integrated circuit T cell (ICT) product for the treatment of platinum-resistant ovarian cancer. AB-1015 includes a transgene cassette with two functional modules: an "AND" logic gate designed to limit off-tumor toxicity through dual tumor antigen recognition, and a dual shRNA-miR designed to resist TME suppression and to improve ICT cell function. ICT cells are generated via CRISPR integration of transgenes by electroporation (CITE), a non-viral and site-specific integration approach that provides enhanced safety, increased cargo capacity, and reduced cost. A scalable, semi-closed, and semi-automated manufacturing process was developed to support GMP manufacture of AB-1015 for Ph1 clinical evaluation.

Methods Clinical-scale, end-to-end runs were performed in healthy donors using ArsenalBio's manufacturing process for AB-1015. On Day 0, CD4 and CD8 positive cells were isolated from fresh apheresis from healthy donors. Cells were activated using CD3/CD28 stimulation, electroporated with Cas9 protein, sgRNA targeting a safe harbor site (GS94), and plasmid DNA encoding the transgene. Cells were expanded until harvest and formulated into drug product. Frozen cell drug product was thawed and characterized using flow cytometry, in vitro functional assays, and in vivo tumor efficacy models.

Results Processing of healthy donor apheresis from more than 20 donors using the AB-1015 manufacturing process resulted in average knock-in efficiencies of approximately 25% and total therapeutic yields exceeding 2.5e9 transgene positive cells. In addition to robust IFN-γ production and tumor cell killing in dual antigen-specific co-culture, AB-1015 ICT cells retained favorable memory phenotype (CCR7+) at harvest. Furthermore, AB-1015 ICT cells demonstrated potent anti-tumor responses in a xenograft in vivo model.

Conclusions A robust, 10-day manufacturing process was successfully developed for AB-1015 that enables high knock-in efficiencies of a large (> 6 kb) transgene using a site-specific, non-viral integration approach. Billions of ICT cells can be generated from a single healthy donor in a semi-closed, semi-automated fashion and these ICT cells display potent anti-tumor activity in vitro and in vivo with high specificity. AB-1015 will be evaluated in clinical trials for treatment of platinum-resistant ovarian cancer.

278 PHARMACOLOGICALLY-CONTROLLED EXPRESSION OF MEMBRANE-BOUND IL-12 RESULTS IN T-CELL THERAPY WITH ENHANCED POTENCY IN PRECLINICAL SOLID TUMOR MODELS

Sean Smith*, Benjamin Primack, Theresa Ross, Patricia Timpug, Dexue Sun, Dan Jun Li, Scott Lajoie, Violet Young, Meghan Langley, Jeremy Tchaicha, Dhruv Sethi, Jan ter Meulen, Michelle Ols. *Obsidian Therapeutics, Cambridge, MA, USA*

Background Solid tumors remain a challenging frontier for adoptive cellular therapies (ACT). Armoring T-cells with cytokines, such as interleukin 12 (IL-12), to remodel the tumor microenvironment (TME) has demonstrated preclinical efficacy against solid tumors. However, the clinical utility of IL-12 is limited by systemic toxicities, requiring tight control of expression. Herein, we show that T-cells armored with a small molecule-controlled membrane bound IL-12 (mbIL-12) drives regulation of pharmacodynamic markers and solid tumor efficacy in xenograft and syngeneic solid tumor models.

Methods We regulated mbIL-12 expression using Obsidian's cytoDRIVE® technology. In this system, a drug responsive domain (DRD) is fused to a protein of interest. In the "off-state" the fusion protein is rapidly degraded by the proteasome. Adding a small molecule ligand stabilizes the complex, enabling expression (the "on-state"). Here, we use a DRD derived from carbonic anhydrase 2 and the FDA-approved inhibitor acetazolamide (ACZ) as a stabilizing ligand. Unlike most other regulation systems, cytoDRiVE® is both fully human, reducing immunogenicity, and induced pharmacologically, allowing on-demand control. Adding oligomerization domains increases the local density of DRDs to form modulation-hubs that further increase the regulation of mbIL-12.

Cytokine levels were determined using flow cytometry and Meso Scale Discovery assays. Human mbIL-12 modulation hubs and CD19-CARs were transduced in peripheral blood T-cells and evaluated *in vivo* against subcutaneous Raji xenografts that form solid tumors in NSG mice after inoculation in Matrigel. Mouse constructs were evaluated in CD8 gp100 (PMEL) TCR transgenic cells against subcutaneous B16-F10 melanoma in C57BL6 mice.

Results In the xenograft setting, ACZ dosing resulted in 35-fold regulation of IL-12 in the plasma and showed remarkable ACZ-dependent anti-tumor efficacy against large, solid Raji tumors at a 10x lower cell dose than unarmored CAR-Ts. In the immunocompetent PMEL/B16 model, IL-12 modulation-hub PMEL cells slowed tumor growth over unarmored PMEL cells and showed improved tolerability over secreted IL-12. Animals receiving IL-12 modulation-hub cells showed ACZ-dependent regulation of IL-12 and IFNγ in the plasma with levels 100-fold and 20-fold less, respectively, than with constitutive secreted IL-12 cells. This regulation led to functional impacts at the cellular level, including an increase in circulating antigen presenting cells.

Conclusions The cytoDRiVE® platform enables enhanced regulation of IL-12 armored T-cells in multiple preclinical solid tumor models, potentiating an improved therapeutic window for IL12 in ACT.

Ethics Approval All animals studies were IACUC approved.

279 **PRECLINICAL *IN VIVO* MODEL DEVELOPMENT: HIGHLIGHTING SUCCESS AND DISCUSSING XENOGRAFT ADVANCEMENTS, A STEP CLOSER TO PREDICTING PATIENT OUTCOMES**

Thomas Dailey*, Angela Gentile, Lexe Linderhof, Layton Smith, Bob Valamehr. *Fate Therapeutics Inc., San Diego, CA, USA*

Background Immunotherapy, in particular chimeric-antigen receptor (CAR) T-cells, has been shown as an effective strategy for the treatment of cancer. However, the full therapeutic potential of these innovative therapies has not yet been fulfilled. This is particularly true of complex solid tumors. In comparison with hematologic tumors, solid tumors are more complex with unique three-dimensional structures, an immunosuppressive microenvironment and cellular heterogeneity that extends to the expression of tumor-associated antigens.[1] Therefore, robust preclinical models with a high degree of fidelity towards the clinical presentation of the tumor are required for the accurate evaluation and translation of next-generation immunotherapies, including advancement of *in vivo* xenograft mouse models that more closely recapitulate disease as it is observed in the clinical setting.

Methods We have developed an orthotopic, mammary fat pad #4 (MFP#4) xenograft model utilizing an engineered tumor cell line based on the MDA-MB-231 triple negative breast cancer (TNBC) to assess epithelial cancer progression. Using this anatomically implanted human tumor model, we evaluated tumor growth kinetics, body weight, metastases and control of tumor with bioluminescence imaging.

Results The established MFP#4 xenograft model yields consistent, uniform tumor growth that produces disease progression and secondary metastases in vivo. Importantly, the model produced secondary tumors in both the lung and liver, recapitulating human disease in distal sites where 31.4% and 26% of patients show metastases. Moreover, we observed metastases in the axillary lymph node, a hallmark sign for diagnosing and staging breast cancer in patients. In the initial proof of concept study, administration of induced pluripotent stem cell-derived CAR T (CAR iT) cells, which had been successful in demonstrating tumor growth inhibition in various other disseminated and subcutaneous in vivo tumor models, significantly reduced the size of the primary tumor burden and the secondary tumor nodes.

Conclusions This work demonstrates that our engineered TNBC cell line in the MFP#4 xenograft model recapitulates much of the human disease phenotype. Importantly, the model demonstrated metastatic disease consistent with clinical presentation. Furthermore, administration of CAR iT-cells resulted in a decrease in overall tumor burden, validating the use of the orthotopic tumor xenograft as a preclinical model of TNBC with a high degree of clinical translatability.

280 RAPID AND SIMPLIFIED PROCESS FOR MANUFACTURING MULTI-TUMOR-ASSOCIATED ANTIGEN SPECIFIC T CELLS

Anastasiya Smith*, Tara Shahim, Jeanette Crisostomo, Eric Smith, Jennifer Pickering, Anna Wilga-Savitski, Tsvetelina Hoang, Juan Vera. *Marker Therapeutics, Inc., Houston, TX, USA*

Background Marker Therapeutics, Inc. has developed MT-401, a multi-tumor-associated antigen (multiTAA)-specific allogeneic T cell product capable of recognizing multiple targets expressed on the tumor simultaneously, minimizing tumor escape. Currently, MT-401 is being used for treatment of AML patients following allogeneic stem-cell transplant in both the adjuvant and active disease settings. Although MT-401 has shown promising clinical results, the manufacturing process is time prohibitive for cancer patients with rapid disease progression. Here we demonstrate how additional process improvements streamlined the manufacturing process and resulted in products with superior T cell phenotype and potency, both of which have the potential to enhance clinical responses.

The original manufacturing process for multiTAA-specific T cell products is derived from Baylor College of Medicine studies and begins with the purification of PBMCs from leukapheresis material. Subsequently, dendritic cells (DCs) are matured and pulsed with a pool of exogenous peptides spanning the entire primary sequence of target antigens (Ags). The mature DCs expressing the antigens are co-cultured with T cells in a Gas Permeable Rapid Expansion Device (G-Rex®) to stimulate and expand antigen-specific T cells. For MT-401, the following four antigens are used: PRAME, NY-ESO-1, Survivin and WT1. This 36-day manufacturing process results in products containing an average of 83% CD3+ T cells with a predominantly effector memory T cell phenotype, and an average specificity for 4 tumor Ags of 179 spot-forming units (SFU) per 2e5 cells.

Methods We have now simplified the manufacture of multiTAA-specific T cells and eliminated the need to generate DCs in vitro prior to T cell stimulation.

Results The improved 9-day manufacturing process produces superior T cell products with an average%CD3+ purity of 96%, T cell phenotype showing a uniform distribution of naïve, central memory and effector memory T cells, increased Ag specificity (5-fold), Ag diversity and killing potential.

Conclusions These process improvements significantly reduced the number of interventions needed during manufacturing, thereby decreasing both the possibility of manufacturing failures and product manufacturing time, which translates to faster patient treatment. This sophisticated and rapid manufacturing approach has shown to be reproducible regardless of the tumor antigen combination, enabling the extension of this technology to other clinical indications.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0280

281 THE TWO SIDES OF THE COIN: PRO-INFLAMMATORY STIMULI LEAD TO UPREGULATION OF CD70 IN AML, BUT ALSO REDUCE NK-CELL-BASED IMMUNOTHERAPY EFFICACY

[1]Monika Sponheimer*, [1]Gerulf Hänel, [1]Lisa Rohrbacher, [1]Nora Philipp, [1]Daniel Nixdorf, [1]Anetta Marcinek, [1]Christian Wichmann, [1]Andreas Humpe Med, [2]Shyra Gardai, [2]Daniel Diolaiti, [1]Veit Leonhardt Bücklein, [1]Marion Subklewe. [1]*University Hospital LMU Munich, Munich, Germany*; [2]*Seagen, Bothell, WA, USA*

Background Novel immune cell-based treatment options are evolving for patients with acute myeloid leukemia (AML). The identification of a suitable target antigen with a restricted expression profile is still a major challenge and a prerequisite for success. CD70, which is transiently expressed in activated T-, B-, and NK cells, has been reported to be aberrantly expressed on AML and leukemic stem cells.[1-3] While the mechanism driving its expression in AML is not defined, its restricted profile in normal tissues makes it an ideal target for immunotherapeutic strategies.

Methods We evaluated CD70 expression by flow cytometry on primary AML cells from initial diagnosis (ID, n = 123) and relapse (RL, n = 14). NK cell-mediated antibody-dependent cellular cytotoxicity (ADCC) assays utilizing a sugar-engineered anti CD70 antibody with a nonfucosylated Fc backbone (SEA-CD70) were performed against AML cell lines with varying CD70 expression levels and primary AML cells (n=6). Modulation of CD70 and CD33 expression and susceptibility to ADCC were analyzed in a pro-inflammatory environment achieved by either supplementation of tumor necrosis factor alpha (TNF-alpha) and interferon gamma (IFN-gamma) or by the addition of conditioned media (CM) from a CD33xCD3 bispecific-based model system for T-cell activation.[4]

Results The percentage of $CD45^{dim}SSC^{lo}$ AML cells expressing CD70 ranged between 0.2 – 89.6% (mean = 15.2%) at ID and 0.3 – 90.3 (mean = 25.4%) at time of RL. SEA-CD70-mediated ADCC against AML cell lines was dependent on antigen expression level and antibody concentration (n= 4, $CD70^{bright}$93.1%, $CD70^{dim}$47.6%). Specific lysis of primary AML cells ranged from 9.5 to 33.2% (mean = 20.1%). Interestingly, pre-conditioning with TNF-alpha/IFN-gamma or CM from CD33xCD3-activated T cells resulted in a significant increase of CD70, but not CD33 expression on AML cell lines (fold change in MFI ratio: 2.7, n=5). However, CM or TNF-alpha//IFN-gamma treatment also reduces NK cell ADCC activity in a target-independent manner resulting in a reduction of CD70-mediated cell lysis from 74.8% to 36.5% (n=4), and CD33-mediated cell lysis from 81.8% to 30.5% (n=4).

Conclusions Our findings validate CD70 as a target antigen in the setting of AML and show that pro-inflammatory stimuli lead to an upregulation of CD70 expression on AML cells. However, these pro-inflammatory stimuli inhibit NK-mediated ADCC activity. This data warrant future studies to understand how modulation of the TME may be utilized as a strategy to enhance target expression without negatively impacting effector cell functions.

282 ANTI-FOLATE RECEPTOR ALPHA (FRα) COSTIMULATORY ANTIGEN RECEPTOR (COSTAR) IMPROVES T-CELL FUNCTION ACROSS PHYSIOLOGICALLY RELEVANT RANGES OF FRα EXPRESSION AND T-CELL RECEPTOR (TCR) AFFINITIES

Martina Sykorova*, Michelle Mojadidi, Leyuan Bao, Eric Gschweng, Milena Kalaitsidou, Gray Kueberuwa, Xingliang Zhou, Rubén Alvarez-Rodríguez, John Bridgeman. *Instil Bio, Inc., Dallas, TX, USA*

Background ITIL–306 is a genetically engineered autologous TIL cell therapy that amplifies TCR–specific antigen recognition (Signal 1) with an FRα-specific CoStimulatory Antigen Receptor (CoStAR; Signal 2).[1] T-cell activation through the endogenous TCR is dependent on the concentration of cognate peptide-MHC antigen. This study examined T-cell activation across a range of physiologically relevant FRα expression levels and characterized whether functional T-cell avidity (response to cognate antigen concentration) was impacted with CoStAR engagement.

Methods In vitro cocultures were used to determine T-cell response to variations in strength of Signal 1 and Signal 2. To evaluate the role of FRα on amplification of T-cell responses, stable cell lines expressing membrane-anchored OKT3 and different FRα levels were established. Healthy donor (HD) T cells transduced with anti–FRα CoStAR or non-transduced (control) were used as effector cells. Cytolytic activity and cytokine levels (IL-2, IFN-γ, TNF-α) were assessed.

To assess the effect of CoStAR on TCR functional avidity, HD T cells were non-transduced or transduced with a defined TCR recognizing HLA-A*02/MART-1 antigen, anti–FRα CoStAR, or both. Parental T2 or FRα-transduced T2 cells were used as targets. Target cells were pulsed with titrated concentrations of 4 different MART-1–altered peptide ligands of varying antigenicity. Cytokine secretion after coculture was measured, and antigen half-maximal effective concentration (EC_{50}) was calculated.

Results CoStAR amplified T-cell responses at all FRα expression levels. IL-2 secretion was significantly higher at any FRα expression level versus no FRα ($P<.0001$). CoStAR-transduced and non-transduced T cells were not activated in coculture with cells expressing any level of FRα alone. Kinetic activation studies demonstrated that engaging CoStAR (Signal 2) followed by TCR activation (Signal 1) at a later time resulted in amplified T-cell activity.

Cytokine secretion was increased from MART-1−TCR +CoStAR T cells versus MART-1−TCR T cells when cocultured with T2-FRα cells pulsed with titrated concentrations of all cognate peptides evaluated. EC_{50} was not impacted by CoStAR for cognate peptides with EC_{50} between 10^{-10} to 10^{-7} M.

Conclusions CoStAR augmented T-cell function across a range of physiologically relevant FRa expression levels and TCR/cognate peptide affinities. TCR/cognate antigen affinity (EC_{50}) was unchanged by CoStAR, suggesting that CoStAR TIL will have identical specificity as unmodified TIL. Further, CoStAR improved T-cell function at low FRa expression levels, supporting the evaluation of ITIL-306 activity across multiple tumors, including those with low FRα expression. These results are being explored in a first-in-human clinical study with ITIL-306 (NCT05397093).

283 GENOME-WIDE CRISPR SCREENS OF CYTOTOXIC T CELLS IDENTIFY A NOVEL REGULATOR THAT ENHANCES T CELL EFFECTOR FUNCTION

Vivian Jia Yi Tan*, Ling Wu, Clara Kai Ting Koh, Yen Leong Chua, Liangzhe Wu, June Xu Hui Ong, Nicholas Gascoigne. *NUS, Singapore, Singapore*

Background Despite the immense therapeutic potential of cytotoxic T lymphocytes (CTLs) in anti-tumor immune response, it remains under-exploited given the limited knowledge we have on genes that regulate its function. Current immunotherapies modulating CTL functions are promising anti-tumor treatment options, but they are severely underutilized due to the lack of druggable targets and potential side effects associated with the treatments. Moreover, the development of new immunotherapies is highly driven by our improved understanding of genetic programs that influences T cell function. Therefore, identifying new immunotherapeutic gene targets is crucial to open new avenues for immunotherapies.

Methods In this study, we first performed an *in vitro* CRISPR-based genome-wide screen for negative regulators of CD8 T cell effector function by sorting for transduced cells with an increased expression of CD107a and tumor necrosis factor (TNF) after gene editing. Using next-generation sequencing, enriched genes in the respective populations were identified and ranked using the available PinAPL-Py platform.[1] To validate and characterize hundreds of the top ranked hits from genome-wide screen at greater details, we created a custom sgRNA mini-pool with newly designed sgRNA sequences for the screened hits. We repeated the screens with the mini-pool against various cancer cell lines as antigen presenting cells to validate the gene targets as well as *in vivo* mice tumour models to examine its effect on tumour infiltration.

Results Our screens robustly identified a gene target which encodes for an actin-binding domain and signal-mediator scaffolding protein that is important in regulating CTL's cytotoxic function. Preliminary data suggests that knocking out the gene target in mouse CD8 T cells showed increased degranulation and production of effector cytokines. Gene-KO T cells also exhibited greater killing efficacy against mouse B16 melanoma cells at various effector to target ratios compared to the control group transduced with non-targeting sgRNA. Further mechanistic studies and validation in mouse tumor models are currently in progress to support the findings.

Conclusions Overall, our data demonstrate that genetic screens for immunotherapeutic gene target discovery is essential to identify new regulators of CTLs. We also showed that our identified gene target plays an important role in modulating the effector function of CTLs and suggests that manipulation of the gene would improve cancer immunotherapy.

284 EPSTEIN BARR VIRUS SPECIFIC T CELLS (EBVSTS) EXPRESSING B7-H3 TARGETING CHIMERIC ANTIGEN RECEPTORS (CAR) EXHIBIT GOOD PRE-CLINICAL ACTIVITY AND SAFETY AGAINST B7-H3 POSITIVE SOLID TUMORS

Kar Wai Tan*, Lionel Low, Xin Yu Koh, Lindsay Kua, Jin Wei Tan, Siok Ping Yeo, Joanna Kristyn Lim, May Delos Santos, Fiona Wong, Chek Meng Poh, Ivan David Horak, Angeline Goh. *Tessa Therapeutics, Singapore, Singapore*

Background The B7 homolog 3 protein (B7-H3, CD276) is an immune checkpoint member of the B7 and CD28 families that is minimally expressed in healthy tissues. In contrast, B7-H3 is found to be widely over-expressed in multiple types of human cancers, making it an excellent target for CAR T cell therapy.[1] Allogeneic EBVSTs have demonstrated good safety and efficacy in clinical trials and hold the promise to enable broad application of CAR-based T cell therapy in the allogeneic setting.

Methods With the goal of creating off-the shelf allogeneic CAR T cell therapy for solid tumors, we developed Epstein-Barr Virus Specific T cells (EBVSTs) expressing a nanobody-based CAR (B7-H3 CAR EBVSTs) to target B7-H3 positive solid tumors.

Results Our optimised cell manufacturing protocol produced good cell expansion with more than 80% of EBVSTs expressing B7-H3 targeting CAR. B7-H3 CAR EBVSTs demonstrated excellent killing of several B7-H3 expressing colorectal, gastric, non-small cell lung and triple negative breast cancer cell lines while cytolysis of B7-H3 knockout counterparts of these cell lines were attenuated. In addition, EBVSTs expressing a truncated B7-H3 CAR that did not contain any intracellular signalling domains was devoid of activity against these cell lines. B7-H3 CAR EBVSTs retained good specificity and reactivity to EBV antigens, evident by abundant production of Tumor Necrosis Factor α and/or Interferon-γ in response to EBV but not to irrelevant HIV pepmixes stimulation.

To assess *in vivo* anti-tumor efficacy, immunodeficient mice were randomized to receive no treatment or treatment with un-transduced or B7-H3 CAR EBVSTs following xenografting of colorectal (HT-29 and SW480) or gastric cancer cell lines (NCI-N87) or triple negative breast cancer (MDA-MB-468) cells. Treatment with B7-H3 CAR EBVSTs induced significant tumor regression in all models compared to the unabated growth in mice that received un-transduced EBVSTs. Further evaluation revealed significantly greater numbers of B7-H3 CAR EBVSTs in blood, liver, lung, spleen and tumors of mice compared to un-transduced EBVST. Body weight of mice from all treatment groups was stable in the days post treatment in all studies, indicating the absence of major tolerability issues.

Conclusions Altogether, our data provides first proof that we are able to generate B7-H3 CAR EBVSTs with good *in vitro* and *in vivo* activity against B7-H3 expressing solid tumors. Given the excellent activity and tolerable safety profile observed, we believe that B7-H3 CAR EBVSTs is a promising candidate for allogeneic CAR T cell therapy against solid tumors.

285 MULTIOMIC ANALYSIS OF TIL SUGGESTS THAT CD4+ POLARIZATION REPRESSES TIL EXPANSION AND CD8+ ACTIVATION AND IS ASSOCIATED WITH PROGRESSION OF DISEASE

[1]Brian Thompson*, [2]David Woods, [1]Ann Strange, [1]Carol Amato, [1]Jonathan Hester-McCullough, [3]Jeffrey Weber, [4]Amod Sarnaik. *[1]CU Anschutz, Aurora, CO, USA; [2]University of Colorado School of Medicine, Aurora, CO, USA; [3]NYU Langone, New York, NY, USA; [4]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, USA*

Background Tumor Infiltrating Lymphocyte (TIL) Adoptive Cell Transfer (ACT) is effective in treating malignant melanoma and other solid tumors. The success of TIL ACT relies on the adequate expansion of TIL, with previous studies showing a positive association between number of TIL infused and patient response. To identify characteristics important for TIL expansion, we performed a multiomic analysis of patients' TIL product.

Methods Expanded TIL products from metastatic melanoma patients enrolled in clinical trials at Moffitt Cancer Center were collected before infusion. CD4+ and CD8+ were isolated and analyzed by RNA-seq (n=13) and pan-acetyl histone 3 ChIP-seq (n=20). The number of TIL, percentage of CD4/CD8 infused, progression free survival (PFS), and overall survival (OS) were recorded. To more evenly divide both RNA-Seq and ChIP-seq samples between groups, patients were categorized into "TIL high" vs "TIL low" based on division at the geometric mean of the number of TIL infused (geometric mean= 4.6e10, range= 9.05e+09 – 1.13e+11). Log2 fold changes of ±0.5 and q-values of <0.1 were considered significant.

Results Individuals in the "TIL high" group had longer (PFS) (median=92 vs 4, p< 0.0001) and OS (OS median=92 vs 10 months , p<0.0001) than those in the "TIL low" group, and the percentage of CD4+ infused was negatively correlated with the number of TIL infused (R^2=-0.72, p=7.7e-05). RNA-seq revealed 30 differentially expressed genes (DEGs) in CD4+ between groups. The upregulated genes in the "TIL low" group included *TNFRSF4*, *PTGDR2*, *IL5*, and *CCL4*, which are associated with Th2 and T_{reg} phenotypes. Pathway analysis of the RNA-seq data further suggested increased Th2 and Th17 polarization in the "TIL low" group. ChIP-seq showed 18 differentially acetylated genes (DAGs) between "TIL high" and "TIL low" CD4+, including increased acetylation at known inducers of T_{regs} *CD200R1, IL12RB2*. RNA-seq revealed 3 DEGs between CD8+ in the "TIL high" and "TIL low" groups. ChIP-seq revealed 18 DAGs between "TIL high" and "TIL low" CD8+, with increased acetylation at genes known to be upregulated during CD8+ activation (e.g., *SLC4A10*, *TIGIT* and *P2RY1*).

Conclusions Our results and those of other groups have shown that increased number of TIL infused are associated with positive patient outcomes. Our results further indicate that CD4+ Th2, Th17 and T_{reg} phenotypes in the TIL product are associated with decreased numbers of TIL achieved during expansion. Consequently, we hypothesize that approaches to directing T-cell polarization during TIL expansion may increase patient response rates.

286 SYSTEMIC DISTRIBUTION OF GAMMA-DELTA PSCA-CAR T CELLS IN COMBINATION WITH ZOLEDRONATE IN A MODEL OF BONE METASTATIC PROSTATE CANCER

Leticia Tordesillas*Junior Cianne, Jeremy Frieling, Xiomar Bustos, Conor Lynch, Daniel Abate-Daga. *H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, USA*

Background Metastatic castrate resistant prostate cancer (mCRPC) frequently manifests in the bone, leading to increased morbidity and mortality. We have previously demonstrated that gd Chimeric Antigen Receptor (CAR) T cells targeting prostate stem cell antigen (PSCA) led to significant regression of established prostate cancer cells in the bone. Regression was further increased by combination with the bisphosphonate zoledronate (ZOL), usually administered to mCRPC patients to skeletal related events. To further optimize the use of gd CAR T cells for mCRPC, we aimed to determine the kinetics of gd CAR T cell accumulation and activation in a mouse model of bone metastatic prostate cancer, either as single treatment or in combination with ZOL.

Methods Male NSG mice were intratibial injected with C4-2B prostate cancer cells expressing PSCA and luciferase with the contralateral tibia receiving PBS. ZOL (25 ug/kg) was injected every other day subcutaneously in half of the mice and was discontinued one day prior to administering T cells. When tumors were established, mice received gd PSCA-CAR T cells, gd untransduced (UT) T cells or were left untreated. Bone marrow from tumor-bearing or naïve tibias, femur, spleen and blood were recovered at multiple time points, and the number of gd T cells and their activation status were analyzed by flow cytometry.

Results gd CAR T cells showed an accumulation in the bone marrow recovered from tumor-bearing tibias, with 3 times more gd T cells detected compared to mice treated with gd UT cells ($p=0.0002$). The number of gd T cells peaked at 5 days post infusion and could still be detected after 21 days. Increased gd CAR T cell accumulation was not observed in tumor naive bone marrows, spleen or blood, suggesting a preferential localization of gd CAR T cells at tumor sites. Moreover, gd CAR T cells presented increased expression of CD25, PD1 and CD56 in comparison with gd UT after only 5 days ($p<0.001$) suggesting their enhance activation. Treatment with ZOL did not significantly affect the number of gd T cells accumulated in bone.

Conclusions gd PSCA-CAR T cells quickly accumulate and become activated at tumor sites with limited distribution outside the bone. ZOL does not appear to impact gd PSCA-CAR T distribution kinetics. Taken together, our data further support the suitability for treatment of bone metastasis.

Ethics Approval The study was approved by University of South Florida IACUC, approval number R7429.

287 **NOVEL, BOOSTED, FULLY HUMAN ROR1-TARGETING CAR T CELLS EFFECTIVELY ELIMINATE HEMATOLOGIC AND SOLID TUMORS, AND RESIST TUMOR MICROENVIRONMENT**

Tri Tran*, Bal Krishna Chand Thakuri, Saule Nurmukhambetova, Brittany Steimle, Ngoc Tran, Darong Wu, Peirong Hu, Pradyot Dash, Dina Schneider. *Lentigen, Gaithersburg, MD, USA*

Background Receptor tyrosine kinase-like Orphan Receptor 1 (ROR1) is widely expressed in various hematologic and solid tumors. A clinical trial employing ROR1-CAR T-cells with scFv-R12 binder showed poor tumor infiltration and dysfunctionality of CAR T-cells in NSCLC & TNBC patients,[1] suggesting that further CAR-binder/construct optimization may be required to improve CAR T-cell persistence and control of T-cell inhibitory factors in the tumor microenvironment.

Methods We designed new ROR1-CAR constructs, either non-boosted (CAR-1), or boosted with TGFbRII Dominant Negative fragment (TGFbRIIDN), or membrane-bound IL-7 (mbIL7), to overcome the TGFb1 inhibitory effect in the tumor microenvironment, and to enhance T-cell persistence, respectively. We also designed ROR1-CAR with R12 binder[1] (CAR-2) as control. The ROR1-CARs were transduced into human primary T-cells using lentiviral vectors. *In vitro* cytotoxicity was assessed by co-culture with hematologic mantle cell lymphoma (MCL, Jeko-1), or solid ovarian (OVCAR-3), pancreatic (CAPAN-2) or lung (NCI-H226) tumor cell lines; TNF-a, IFN-γ and IL-2 cytokine release was assessed by ELISA. To simulate tumor microenvironment, CAR T-cells were challenged with TGFb1 or cultured without exogenous IL-2. *In vivo* xenograft studies were performed in NSG mice bearing Jeko-1 or OVCAR-3 xenografts; tumor progression was monitored, and CAR T cells expansion in mouse peripheral blood was analyzed by flow cytometry.

Results CAR-1-transduced T-cells showed enhanced activation and cytotoxicity against Jeko-1 MCL as compared to CAR-2 *in vitro*, and eliminated tumors in the Jeko-1 model *in vivo*. CAR-1 also mediated potent killing and enhanced cytokine release as compared to CAR-2 upon incubation with OVCAR-3, CAPAN-2, and NCI-H226 solid tumor cell lines *in vitro*. Surprisingly, in *in vivo* ovarian OVCAR-3 xenograft model, CAR-2 failed to reject tumors, whereas CAR-1 mediated remissions; analysis of CAR T-cells in peripheral blood revealed rapid expansion of CAR^{+}T-cell population and enrichment for the central memory phenotype in CAR-1 as compared to CAR-2. In addition, we successfully boosted CAR-1 with TGFßRIIDN, which attenuated the inhibitory effect of TGFß1 on CAR T-cell cytotoxic activity *in vitro*. We also equipped CAR-1 with mbIL7, which enhanced cytotoxic activity and mediated extended functionality of the CAR T-cells without exogeneous IL-2 for up to 18 days.

Conclusions The novel fully human ROR1-CAR1 T-cells effectively eliminated both hematologic and solid tumors *in vivo*, and were superior to ROR1-CAR-2 T cells. Furthermore, the boosting elements TGFßRIIDN and mbIL7 are promising tools to overcome the inhibitory effects of tumor microenvironment and sustain CAR T-cell persistence.

288 TARGETING COLD TUMORS USING IPSC-DERIVED CAR T CELLS DIRECTED TO THE IMMUNE CHECKPOINT MOLECULE AND TUMOR-ASSOCIATED ANTIGEN B7-H3

[1,3]Jon Tuncel*, [1]Bahram Valamehr, [1]Xu Yuan, [1]Francisco Martinez, [1]Nicholas Brookhouser, [1]Philip Chu, [1]Duygu Ozmadenci, [2]Zachary Davis, [1]Robert Blum, [1]Bryan Hancock, [1]Bjoern Gaertner, [2]Nicholas Zorko, [1]Shohreh Sikaroodi, [1]Miguel Meza, [1]Thomas Dailey, [2]Martin Felices, [2]Frank Cichocki, [1]Lauren Fong, [1]Tom Lee, [1]Raedun Clarke, [1]John Goulding, [1]Ryan Bjordahl, [2]Jeffrey Miller. *[1]Fate Therapeutics, Inc. (FHQ1), San Diego, CA, USA; [2]University of Minnesota, Minneapolis, USA; [3]Fate Therapeutics, Inc. (FTP1), San Diego, CA, USA*

Background B7 homolog 3 protein (B7-H3) is a cell-surface protein that is broadly expressed on tumors as well as tumor-associated stromal cells, where it provides inhibitory signals to T and NK cells. Inhibition of B7-H3 using antibody-based modalities has shown promising, albeit incomplete, suppression of tumor progression in clinical studies. Induced pluripotent stem cell (iPSC)-derived chimeric antigen receptor T (CAR-T) cells targeting B7-H3 antigen may offer a unique approach for the treatment of immunologically cold tumors, as treatment may provide an influx of CAR-T cells to tumors that are largely devoid of endogenous infiltrating lymphocytes.

Methods Here we used a unique iPSC engineering strategy to deliver a single tricistronic expression cassette encoding a highly tuned CAR construct consisting of a single-domain camelid antibody against B7-H3 fused to a (CD28-CD3z-1XX) signaling domain, an interleukin (IL)-7 receptor fusion protein, and a high affinity non-cleavable version of the CD16 Fc receptor (hnCD16) into the T-cell receptor α constant (TRAC) locus. These engineered iPSC-derived CAR-T cells demonstrate high potency and fitness and can, unlike naturally occurring T cells, mediate antibody-dependent cell-mediated cytotoxicity (ADCC) to enable combination with monoclonal antibody therapy for treatment of heterogenous tumors.

Results In preclinical studies, these multi-functional B7-H3 single-domain/1XX iPSC-derived CAR-T cells demonstrated improved tumor control compared to MGA271-scFv/1XX CAR-T cells. Additional preclinical studies confirmed antigen specificity and broad application in targeting various tumor lines. Furthermore, coactivation of hnCD16 markedly improved cytotoxicity against a variety of target cells both in vitro and in vivo, illustrating the potency of coordinated expression of these two pathways in CAR-T cells. Further preclinical studies are ongoing and will be discussed.

Conclusions Taken together, these results provide a tantalizing outlook for the effectiveness of multiplexed-engineered, iPSC-derived CAR-T cells targeting B7-H3, including in combination with therapeutic antibodies, for off-the-shelf treatment of solid tumors.

Ethics Approval All animal experiments were reviewed and approved by Fate Therapeutics Animal Care Committee (IACUC) under the protocol 2019-11-01 O'Rouke.

289 **CLINICAL EXPANSION AND PERSISTENCE OF CAR T-CELLS: AN ESSENTIAL BIOMARKER IN NEED OF STANDARDIZATION**

[1]David Turicek*, [1]Victoria Giordani, [1]Naomi Taylor, [2]Nirali Shah. *[1]National Cancer Institute, Bethesda, MD, USA; [2]National Institutes of Health, Bethesda, MD, USA*

Background *In vivo* CAR T-cell expansion and persistence are associated with response, toxicity, and long-term efficacy. As such, the tools used to detect CAR T-cells are fundamental for optimizing this therapeutic approach. Nevertheless, despite the critical value of this essential biomarker, there is significant variability in CAR T-cell detection methods and the frequency and intervals of testing. Furthermore, heterogeneity in the reporting of quantitative data adds layers of complexity that limit inter-trial and inter-construct comparisons.

Methods We sought to assess the heterogeneity of CAR T-cell expansion and persistence data in a scoping review using the PRISMA-ScR checklist. Based on 21 clinical trials from the United States featuring a Food and Drug Administration-approved CAR T-cell construct or one of its predecessors, 112 papers were screened and 60 were selected for analysis based on the inclusion of CAR T-cell expansion and persistence data (figure 1A). Paper identifiers, CAR construct and antigen targeted, detection technique(s), detection frequency, expansion data and persistence data were all captured in the analysis.

Results Across a wide array of CAR T-cell constructs (figure 1B) and based on the first/primary publication, flow cytometry and quantitative polymerase chain reaction (qPCR) were identified as the two primary techniques for detecting CAR T-cells (figure 1C). Despite apparent uniformity in detection techniques, the specific methods used were highly variable. Further, detection timepoints and the number of evaluated timepoints ranged broadly. Additionally, quantitative data for the parameters assessed were often not reported (figure 1D-R). To evaluate whether subsequent papers from a trial resolve this issue, we analyzed all remaining papers reporting on a clinical trial, recording all expansion and persistence data. Flow cytometry and qPCR remained the most common CAR T-cell detection techniques; however, additional methods included droplet digital PCR, NanoString, and single-cell RNA sequencing. Inconsistencies, however, with detection timepoints and frequency remained, and a significant amount of quantitative data was still not readily available (data not shown).

Conclusions Our findings highlight the critical need to establish a universal standard for reporting on CAR T-cell detection in patients on early phase studies. The current reporting of non-interconvertible metrics and limited provision of quantitative data make cross-trial and cross-CAR T-cell construct comparisons extremely challenging. While unique attributes of CAR T-cells may limit how they can be detected across various constructs, establishing a standardized approach for collecting and reporting data is urgently needed and would represent a substantial advancement in the ability to evaluate cross-trial outcomes.

290 A NOVEL IPSC-DERIVED CAR-INVARIANT NATURAL KILLER T (INKT) CELL THERAPY PLATFORM FOR HEMATOLOGIC MALIGNANCIES AND SOLID TUMORS

Akane Urakami, Tomokuni Shigeura, Makoto Kondo, Mari Isomi, Yuko Kokubu, Kenichi Suzuki*, Haruhiko Koseki. *BrightPath Biotherapeutics Co., Ltd., Kawasaki-Ku, Kawasaki-Shi, Japan*; *[2]Riken, Yokohama, Japan*

Background Following a success of autologous chimeric antigen receptor (CAR)-T cells in hematologic malignancies, allogeneic CAR-transduced cells have been developed with various immune cells including induced pluripotent stem cell (iPSC)-derived NK cells and T cells. We have developed a novel platform of first-in-class iPSC-derived CAR-invariant natural killer T (iNKT) cells. iNKT cells are a rare subset of innate lymphocytes that bridge innate and adaptive immune response. iNKT cells can recognize and kill tumor cells, and further enhance antitumor activities of host endogenous immune cells by; cross-talking with dendritic cells; cross-priming tumor-specific $CD8^+$T cells; transactivating NK cells; and reprograming protumor myeloid cells. These intrinsic functions of iNKT cells possibly lead to high persistence and durability of allogeneic CAR-T cell therapy especially for solid tumors in the immunosuppressive tumor microenvironment. Usage of iPSC derived from iNKT cells is an ideal strategy to realize clinical scale production of functional iNKT cells from such a rare cell population. A Phase 1 study of the iPSC-derived non-transduced iNKT cells is currently ongoing in patients with head and neck squamous cell carcinoma. To demonstrate that CAR-transduced iPSC-derived iNKT cells provide a novel platform for effective cancer immunotherapy, the killing activities of CD19-CAR or HER2-CAR-transduced iPSC-derived iNKT cells were investigated in this first set of study.

sMethods iNKT-derived iPSCs were engineered to express CD19-CAR or HER2-CAR by targeting the adeno-associated virus integration site-1 locus using genome editing method. CAR-iNKT cells were obtained by differentiation from CAR-introduced iPSCs under feeder cells free culture condition. The expressions of CAR and iNKT cell surface markers were examined by flow cytometry analysis. *In vitro* cytotoxicity of CAR-iNKT cells against cancer cell lines was examined by xCELLigence® real-time cell analyzer.

Results CD19-CAR or HER2-CAR molecules were continuously expressed on engineered CAR-iPSCs. Both CAR-iPSCs were successfully differentiated into iNKT cells in feeder cell-free culture system without losing CAR expression. CAR-iNKT cells showed similar phenotypic properties to iPSC-derived non-transduced iNKT cells. Cytotoxic assay revealed that CAR-iNKT cells possessed enhanced antigen-specific killing activities against target molecule expressing cancer cell lines, such as CD19 positive NALM6 (B cell leukemia) or HER2 positive U-2 OS (Osteosarcoma), compared with iPSC-derived non-transduced iNKT cells.

Conclusions This study showed the first successful delivery of a CAR construct into iPS cells that differentiate precisely into iNKT cells with enhanced cytotoxicity. iPSC-derived CAR-iNKT cells is demonstrated to become a novel allogeneic cell therapy platform.

291 CAR T CELLS AS A SURGICAL ADJUVANT FOR UNRESECTABLE ADENOCARCINOMA

Ugur Uslu*, Tong Da, Charles-Antoine Assenmacher, John Scholler, Regina Young, Julia Tchou, Carl June. *University of Pennsylvania, Philadelphia, PA, USA*

Background Unresectable tumor or incomplete surgical excision of solid tumors are risk factors for primary treatment failure. For those patients, treatment options to clear residual tumor cells following incomplete surgical excision which could be administered promptly and safely in an intraoperative setting would be beneficial. Approaches that could simultaneously clear positive margins without raising safety concerns and interfering with wound healing would be ideal. Here we have tested the hypothesis that the local, intraoperative use of chimeric antigen receptor (CAR) T cell therapy might be an effective surgical adjuvant, based on their emergence as an effective systemic immunotherapy for several hematological malignancies.

Methods We have optimized the use of tissue adhesives as a CAR T cell carrier, which could be applied intraoperatively on the wound surface without the need for intratumoral injection and have evaluated fibrin glue, a biologic tissue adhesive which was found to be an effective sealant and topical hemostatic agent. We then tested the feasibility of this approach in partial resection xenograft models of pancreatic adenocarcinoma and triple negative breast cancer using mesothelin-specific CAR T cells. In addition, we developed a novel in vivo toxicity model to evaluate safety of this approach and effects on wound healing in immunocompetent C57BL/6 mice.

Results We found that the local delivery of CAR T cells in a fibrin-glue based carrier (fibrin gel) applied within the resection cavity was effective in clearing residual cancer cells following incomplete surgical excision of subcutaneous tumors. This resulted in significantly longer overall survival when compared to mice treated with surgery and direct intracavitary CAR T cell injection without fibrin gel. Importantly, on-target off-tumor toxicity was diminished compared to mice treated with systemically administered CAR T cells. In addition, wound healing complications were not seen in any of the immunocompromised or immunocompetent mice.

Conclusions In summary, CAR T cells can be effectively and safely used as a surgical adjuvant in adenocarcinomas that cannot be completely excised. Based on these promising observations, a clinical trial in patients with locally advanced breast cancer is planned.

292 DISCOVERY AND DEVELOPMENT OF T CELL RECEPTORS FOR ADOPTIVE T CELL THERAPY AGAINST SOLID TUMORS

Juliana Velez Lujan*, Hannah Fields, Kan Xing Wu, Natalie Epstein, Florence Chioh, Nicholas Tan, Daniel Carbajo, Neeraja Kulkarni, Lorenz Gerber, Yovita Purwanti, Alessandra Nardin, Michael Fehlings, Katja Fink, Dan Macleod. *Immunoscape, San Diego, CA, USA*

Background T cell receptors (TCRs) have the potential to recognize epitopes derived from both intracellular and cell surface antigens. This facilitates targeting a wide range of tumor antigen classes including overexpressed, differentiation and cancer-testis antigens as well as antigens derived from driver mutations, frameshift mutations, splice variants and human endogenous retroviral elements (HERV). Despite this array of potentially targetable shared antigens, TCR-based anti-tumor therapies have to date only focused on a very limited number of target epitopes. The discovery of clinically relevant TCRs has been challenging due to the limitations in novel tumor antigen discovery and low throughput TCR screening approaches in addition to the inherently low frequency of tumor-reactive T cells in tumor samples and in peripheral blood.

Methods We employ our sensitive and high-throughput Deep Immunomics platform using a mass-cytometry-based multiplexed tetramer staining approach to screen and characterize CD8+ T cells in peripheral blood mononuclear cells (PBMC) for reactivity against >500 potential T cell targets per sample. Downstream single cell sequencing of identified tumor antigen-specific T cells enables a combined analysis of T cell phenotype, transcriptome, TCR specificity and TCR sequence. TCRs identified using this approach are transduced for expression in engineered Jurkat reporter cells and primary T cells and evaluated for activation and effector function, respectively.

Results We have utilized this approach to discover novel TCRs targeting a diverse list of potential tumor epitopes. We identified a TCR recognizing an HLA-A*02-restricted epitope derived from an HERV that is reported to be expressed across many cancer types. In Jurkat reporter cells, this TCR is activated specifically in the presence of the same epitope initially used to identify this TCR, but also through a related epitope variant from the same HERV subfamily. Furthermore, we have identified multiple TCRs that recognize an epitope resulting from alternative splicing of the target antigen in multiple cancers with mutations in a specific splicing factor. Primary T cells expressing these transgenic tumor specific TCR candidates demonstrated killing activity when exposed to target cells presenting the specific cognate peptide.

Conclusions Our Deep Immunomics platform allows us to identify, characterize, and confirm the activity of TCR candidates against novel and therapeutically relevant shared cancer antigens. These findings validate our discovery workflow leading to a portfolio of potential clinical candidates that are currently under preclinical development.

293 THE EFFECTS OF NEGATIVE ISOLATION AND AGGREGATE STRAINERS ON EXPANDED GAMMA/DELTA T CELLS AND THEIR CANCER CELL CYTOTOXICITY

[1]Georg von Massow*, [1]Kenth Gustafsson, [1]Jack Firth, [2]Steve Oh, [3]Alan Lam. *[1]UCL, London, UK; [2]BTI A-Star, Singapore, Singapore; [3]A-Star, Singapore, Singapore*

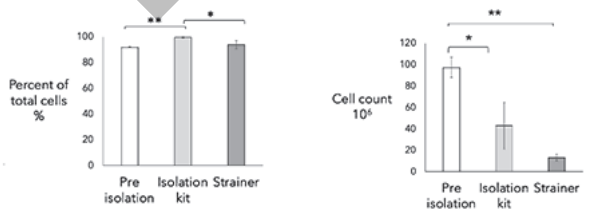
Background One of the most effective ways to purify gd T cells after their expansion, is through negative selection isolation kits. However, even though the target gd T cells are not stained themselves, they appear to suffer stress during the process. An alternative method is to use aggregate strainers which filter cell aggregates through a membrane. This is based on the concept that expanding activated gd T cells, aggregate together. In the context of gd T cells ability to kill cancer cells, the potential stress caused by these methods could affect their functionality.

To shed light on this topic we here analysed the viability, purity, and the functionality of 14 days expanded gd T cells with 24h killing assays on HER2 positive SKBR3 breast cancer cells.

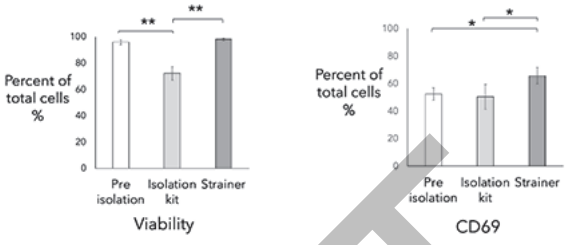
Methods Gd T cells were expanded for 14 days with Zoledronate added on day 0 and IL-2 added every 3 days. Negative isolation was performed using EasySep™ Human Gamma/Delta T Cell Isolation Kit from StemCell Technologies. StemCell Technologies 37mm Reversible Strainers were used for the aggregate isolation. An MTS assay with 1:1 target to effector, with 24h incubation was performed to analyse the killing capacity.

Results The negative isolation showed the highest reliability in generating a near 100% purity of gd T cells (figure 1). The aggregate strainer increased the purity significantly with donors with low gd T cells yield before isolation from 40% to 70%, but could not purify donors with high purity before isolation over 92%. While not statistically significant, the CD69 expression was elevated on the aggregate strainer isolated gd T cells compared to the negative selection isolated gd T cells (figure 2). The viability was significantly reduced after negative selection isolation but was not affected by the aggregate strainer isolation. The killing capacity of gd T cells was significantly reduced for 2 donors after isolation via the negative selection isolation, compared to the gd T cells isolated via aggregate strainers (figure 3). The absolute number of cells isolated was significantly reduced in the aggregate strainer isolation.

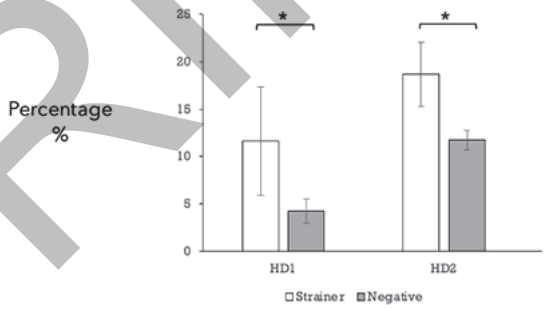
Conclusions This indicates that negative selection isolation, while generating a high purity, has a negative impact on the functionality of gd T cells. Aggregate strainers on the other hand can purify gd T cells not to the same purity as negative selection isolation, however retain a high viability in the cell population and show higher killing capacity against SKBR3 cancer cells.



Abstract 293 Figure 1 Purity and absolute cell count
The left graph shows the percent of gd T cells before and after isolation with negative isolation kit and aggregate strainers. The right shows the absolute cell count before and after isolation with the methods mentioned above.



Abstract 293 Figure 2 The Viability and CD69 expression of gd T cells
The left graph shows the viability before isolation as well as after negative isolation and aggregate strainer isolation in percentage. The right graph shows the expression of CD69 on the same three conditions as the left graph. (* $p<0.05$; ** $p<0.005$; n=3)



Abstract 293 Figure 3 Percentage of killing of SKBR3 cells by gd T cells
The killing of SKBR3 cancer cells after 24h with a target to effector ratio of 1:1 is shown for two donors. The killing was analysed via MTS assay.

294 PRECLINICAL STUDIES OF TAC01-CLDN18.2, AN AUTOLOGOUS CLAUDIN 18.2-DIRECTED TAC T CELL THERAPY, IN THE TREATMENT OF GASTRIC CANCER

Ling Wang*, Stacey Xu, Tania Benatar, Suzanna Prosser, Laura Shaver, Ritu Randhawa, Philbert Ip, Prabha Lal, Thanyashanthi Nitya-Nootan, Heather MacGregor, Sadhak Sengupta, Christopher Helsen, Andreas Bader. *Triumvira Immunologics Inc, Hamilton, ON, Canada*

Background The T cell antigen coupler (TAC) is a novel, proprietary chimeric receptor that facilitates the re-direction of T cells to tumor cells and activates T cells by co-opting the endogenous T cell receptor complex with the goal to elicit safe and durable anti-tumor responses. TAC01-HER2, a first-in-class TAC T product targeting HER2 (ERBB2), has entered a phase I/II clinical trial in patients with HER2-positive solid tumors. The subject of this presentation is a new TAC T product, TAC01-CLDN18.2 targeting Claudin 18.2 (CLDN18.2) to treat gastric cancer. CLDN18.2 belongs to a family of Claudin tight junction proteins and is naturally restricted to epithelia of normal stomach. In gastric cancer cells, CLDN18.2 expression can go awry, is no longer confined to tight junctions and, thus, targetable by CLDN18.2-TAC T cells.

Methods CLDN18.2-TAC T cells were evaluated using a variety of *in vitro* and *in vivo* assays. *In vitro* assays were based on flow cytometric analysis of T cell proliferation and surface activation marker expression. Cytotoxicity was assessed via a real-time microscopy-based co-culture assay. *In vivo* studies examined the anti-tumor effect of CLDN18.2-TAC T cells against established solid CLDN18.2-expressing tumors.

Results CLDN18.2-TAC T cells showed a specific anti-CLDN18.2 response as no cytotoxicity, increase in proliferation or activation was observed when they were co-cultured with CLDN18.2-negative target cells. While CLDN18.2-TAC T cells showed cross-reactivity *in vitro* towards target cells expressing murine CLDN18.2, mice showed no signs of toxicity, suggesting that CLDN18.2-TAC T cells do not induce off-tumor effects.

The *in vitro* repeat killing assay demonstrated strong and persistent anti-tumor activity of CLDN18.2-TAC T cells against CLDN18.2 expressing target cells. Lastly, treatment with CLDN18.2-TAC T cells in MHC DKO mice bearing CLDN18.2-positive tumors led to complete and sustained tumor clearance, even after a secondary tumor re-challenge, indicating long-term persistence of TAC cells up to 56 days after initial dosing.

Conclusions The *in vitro* and *in vivo* data confirm strong and specific activity of CLDN18.2-targeted TAC T cells against CLDN18.2-expressing solid tumor models and highlight the versatility of the TAC platform for therapeutic applications in solid tumors.

Ethics Approval The animal study was approved by McMaster University's Animal Research Ethics Board (AUP 20-10-37).

295 AFFINITY FINE-TUNING ANTI-CAIX CAR-T CELLS MITIGATE ON-TARGET OFF-TUMOR SIDE EFFECTS

[1]Yufei Wang*, [1]Alicia Buck, [2]Michael Lynch, [1]Gabriella Kastrunes, [3]Jae-Won Cho, [1]Marion Grimaud, [4]David Braun, [1]Cecile Razimbaud, [1]Matthew Chang, [1]Atef Fayed, [1]Audrey Apollon, [1]Ze-Hua Li, [1]Luann Zerefa, [1]Brandon Piel, [1]Elena Ivanova, [1]Dennis Bonal, [1]Kristen Jones, [1]Quang-De Nguyen, [3]Zhu Zhu, [3]Kevin Wei, [1]Rebecca Jennings, [1]Miriam Ficial, [1]Maura Aliezah Sticco-Ivins, [3]Sabina Signoretti, [1]Catherine Wu, [1]Toni Choueiri, [3]Jon Wee, [1]Cloud Paweletz, [3]Martin Hemberg, [2]Aedin Culhane, [1]David Barbie, [1]Gordon Freeman, [1]Wayne Marasco. *[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]University of Limerick, Limerick, Ireland; [3]Brigham and Women's Hospital, Boston, MA, USA; [4]Yale University, New Haven, CT, USA*

Background Chimeric Antigen Receptor (CAR) T cell therapy is a new type of "living drug" that has proven to be a powerful immunotherapy for hematologic malignancies. To date, there are six CAR-T products approved by FDA, four CD19 targeted CAR-T cells, and two targeting B-cell maturation antigen (BCMA).[1-8] However, this success has not yet been transferred to solid tumors. A major hurdle is the on-target off-tumor toxicities due to the shared expression of target antigen on healthy tissues.

Methods Here, we assessed the *in vitro* cytotoxicity of carbonic anhydrase IX (CAIX) targeted CAR-T cells generated from a series of single chain fragment variables (scFvs) that have various affinities against CAIX. In addition, we studied the avidity of CAR-T cells using a cell avidity analyzer. We established a tetracycline (Tet)-On inducible CAIX expressing system that provides different CAIX levels on the cell surface covering the range from the density on CAIX-high skrc-59 cells to the one on CAIX-low MMNK-1 cholangiocytes. To assess the therapeutic effect of CAR-T on patient samples, we generated patient derived organotypic spheroids (PDOTS) *ex vivo* cultures and tested CAR-T cell migration and cytokine release using these miniature tumors.

Results We identified a low affinity, high avidity anti-CAIX CAR G9, which only kills CAIX high tumor cells but not CAIX-low normal tissues *in vitro*. G9 demonstrates a CAIX density dependent response on Tet-On inducible CAIX expressing cell lines. G9 CAR has a wider therapeutic window compared to G250 that caused serious adverse events in the first anti-CAIX CAR-T clinal trial.[9-11] G9 exhibits superior efficacy *ex vivo* on ccRCC PDOTS 3D cultures which recapitulates ccRCC patient tumor microenvironment (TME), as well as mitigating toxicity on cholangiectasis spheroids.

Conclusions In summary, affinity fine-tuned CAR-T cell therapy holds the promise to achieve cures of ccRCC by killing ccRCC tumor cells and mitigating on-target off-tumor toxicity on normal tissues.

296 TARGETING B-CELL MALIGNANCIES WITH ANTI-ROR1 CAR T-CELL THERAPY

Jinsheng Weng*, Owhofasa Agbedia, Jingjing Cao, Xiaoyun Cheng, Shao Qing Kuang, Fuliang Chu, Sridevi Patchv, Yongfu Tang, Divyam Bansal, Jingwei Liu, Neeraj Saini, Sattva Neelapu. *The University of Texas MD Anderson Cancer Center, Houston, TX, USA*

Background Anti-CD19 chimeric antigen receptor (CAR) T cell therapy has been shown to induce high complete response rates in the majority of B-cell lymphoma patients. However, over 50% of patients relapse within one year. A major cause of failure appears to be due to loss of CD19 expression on the tumor cell surface. This indicates that novel therapeutic strategies are still needed in clinic. Receptor tyrosine kinase like orphan receptor 1(ROR1) is an oncofetal receptor for Wnt5α that is expressed in multiple embryotic tissues but absent in virtually all adult tissues. However, ROR1 is expressed at high levels in chronic lymphocytic leukemia (CLL), mantle cell lymphoma (MCL), diffuse Large B-Cell Lymphoma (DLBCL), and several solid tumors. The high expression level of ROR1 in tumor cells is associated with adverse clinical prognosis. In addition, a small percentage of cancer cells with characteristics of undifferentiated leukemia cells or cancer stem cells were found to overexpress ROR1.

Methods Using hybridoma technology, we generated an anti-ROR1 monoclonal antibody that specifically recognized ROR1 protein. The antibody bound to ROR1-expressing MCL cell lines but not to normal donor T cells, B cells, or monocytes, indicating the specificity of the antibody. Lentiviral transduction of a CAR molecule derived from the anti-ROR1 antibody into primary human T cells redirected their specificity against B-cell lymphoma cell lines.

Results We found the anti-ROR1 CAR T cells specifically lysed B-cell lymphoma tumor cells at high efficiency but not normal B cells. At an effector: target ratio of 1:1, the anti-ROR1 CAR T cells lysed over 95% of B-cell lymphoma tumor cells during 3-days of coculture. To determine the optimal CAR construct, we evaluated various hinge, transmembrane, and costimulatory domains in the CAR molecule. We found that incorporation of the CD28 hinge and transmembrane domain in the CAR construct dramatically enhanced the in vitro lysis efficiency of anti-ROR1 CAR-T cells.

Conclusions In conclusion, we developed a novel and potent anti-ROR1 CAR T-cell therapy product that may be used for treatment of various B-cell malignancies and ROR1-expressing solid tumors.

297 MANUFACTURE OF KSQ-001, A CRISPR/CAS9-ENGINEERED TIL (ETIL) THERAPY, FOR THE TREATMENT OF HEAD AND NECK SQUAMOUS CELL CARCINOMA

[1]Karrie Wong*, [1]Leila Williams, [1]Nick Constant, [1]Mitali Ghose, [1]Sharon Lin, [1]Frank Thompson, [1]Conor Calnan, [1]Fiona Sharp, [2]Sean Donnelly, [2]Charles Quinn, [2]Glenn Hanna, [1]Frank Stegmeier, [1]Micah Benson. *[1]KSQ Therapeutics, Cambridge, MA, USA; [2]Dana-Farber Cancer Institute, Boston, USA*

Background Head and neck squamous cell carcinoma (HNSCC) is characterized by frequent immune infiltration and an immunosuppressive tumor microenvironment. In recent years, adoptive cell therapy with ex vivo expanded tumor infiltrating lymphocytes (TIL) has shown clinical efficacy among HNSCC patients (pts), although the durability of responses to TIL therapy remains limited. To address this issue, we developed KSQ-001, a novel engineered TIL (eTIL) product with CRISPR/Cas9 mediated inactivation of *SOCS1* gene. This gene was identified as a top target for enhancing T cell anti-tumor potency and persistence in vivo from our genome-wide CRISPRomics screens.

Methods Viably cryopreserved primary tumors and/or metastatic lymph nodes (mLN) from HNSCC pts were processed into small fragments and cultured in the presence of IL-2 through the pre-Rapid Expansion Protocol (pre-REP). TILs were then electroporated with ribonucleoprotein (RNP) complex containing the SOCS1-targeting guide RNA (gRNA). Following electroporation, engineered TIL (KSQ-001), and an unengineered control TIL were expanded under the REP. Both KSQ-001 and control TIL were harvested on day 27 and cryopreserved. SOCS1 editing in KSQ-001 was assessed by Next Generation Sequencing (NGS). The phenotypic characteristics and functionality of thawed KSQ-001 drug product from HNSCC tumors were assessed by flow cytometry, TCR sequencing, *in vitro* functional assays, and in *in vivo* models.

Results KSQ-001 was successfully manufactured from 7/8 (88%) of HNSCC tumors with an average of 2000-fold post-electroporation expansion at the REP phase and an average of 95.2% editing at the SOCS1 locus as assessed by NGS. KSQ-001 from all donors showed levels of TCR diversity similar to those of the matched unedited TIL, and displayed hypersensitivity to IL-12 with elevated pSTAT4 levels upon stimulation. In comparison to donor-matched TIL, KSQ-001 showed greater cytotoxicity and enhanced IFNγ production against 3D tumor spheroids *in vitro*. Further, after infusion into immunocompromised mice, KSQ-001 was detected in circulation at a significantly higher level than control TIL at 7-days post infusion, suggesting hyperresponsiveness to IL-2 and greater persistence *in vivo*.

Conclusions We demonstrated feasibility and robust manufacture of KSQ-001, a SOCS1-edited eTIL product, from HNSCC tumors at clinical scale. KSQ-001 from HNSCC tumors consistently displayed enhanced functional potency while retaining a highly diverse TCR repertoire. These data provide a compelling rationale for evaluating KSQ-001 as a therapeutic strategy for patients with HNSCC.

298 ONCOMETABOLITES IN THE TUMOR MICROENVIRONMENT DRIVE ALTERED NATURAL KILLER CELL FUNCTIONAL CAPACITY

Xinyu Wu*, Sandro Matosevic, Xinyu Wu. *Purdue University, West Lafayette, IN, USA*

Background Natural killer (NK) cells are part of innate immunity with high cytolytic activity against tumor cells, along with the ability to secrete cytokines and chemokines. However, solid tumors have been largely resistant to treatment, owing to unfavorable interactions between immune cells and tumors driven by an immunosuppressive tumor microenvironment (TME). Among tumor-driving metabolites, we have found that adenosine (ADO), has the ability to alter the phenotypic profile of NK cells in solid tumors and enhance their cytotoxicity via inhibiting LAG-3 expression. At the same time, targeting these in the TME of solid tumors with CAR-engineered NK cells enables tumor control and the identification of drivers of resistance to CAR-NK cell killing.

Methods NK cells from lung cancer patients were isolated from blood samples. To study the effect and role of oncometabolites, we treated NK cells with various concentrations of ADO for 24 hours before either removing or leaving them in the medium. NK cell phenotyping, including LAG-3 expression, was measured using flow cytometry. Subsequently, we generated dual-specific CAR-NK cells and identified drivers of resistance to CAR-NK-mediated killing via a genome-based CRISPR screen involving patient-derived GBM.

Using the same conditions as above, NK cells from both groups were then co-cultured with wild type and CD73 knockout (KO) lung carcinoma cell line A549 (A549 WT and A549 CD73KO).

Results Our results showed that NK cell phenotype is altered in response to ADO, including increasing cytotoxicity and aberrant expression of LAG-3, which was downregulated upon ADO treatment, and could be partially recovered upon removal of ADO from the culture medium.

Finally, genome-based CRISPR screening of dual-specific CAR-NK cells co-targeting CD73 identified metabolic drivers of GBM response to NK attack and could represent new targets for adoptive cell therapy with NK cells.

Conclusions Our data showed that metabolites affect NK cell killing capacity. Interestingly, we found that ADO heterogeneously modulates the killing ability of NK cells , suggesting that context- and receptor-specific activation – such as the continued presence of cytokines and metabolites – drives NK cell responses to metabolic factors in the TME. We corroborated these findings with the phenotypic characterization of NK cells isolated from tumors of lung cancer patients and revealed a dysfunctional state linked with an inability of NK cells to support proliferative or cytolytic functions. This dysfunction could be repaired by targeting new transcriptional drivers of GBM resistance to NK cell attack.

299 3D *IN VITRO* TUMOR MICROENVIRONMENT MODELS FOR SCREENING CAR-T CELL THERAPY EFFICACY

[1]Bin Xue, [2]Sophie Vermond, [2]Ulrike Herbrand, [2]David Harris, [2]Gemma Moiset, [1]Kolin Hribar*, [2]Julia Schuler. *[1]Cypre Inc., San Francisco, CA, USA; [2]Charles River Laboratories International Inc., Leiden, Netherlands*

Background T cells that are genetically modified to express chimeric antigen receptors (CARs) show promising results for treating hematological tumors, however CAR-T cell therapy have thus far demonstrated limited anti-tumor activity in solid tumors.[1] The immunosuppressive tumor microenvironment (TME)[2] and T cell dysfunction, driven by chronic antigen exposure in solid tumor, likely contribute to the CAR-T resistance. In order to advance the CAR-T therapy into patients with solid tumors, we need models which accurately represent the TME to evaluate CAR-T efficacy at the discovery, preclinical and translational stages of R&D.

Methods Using a proprietary 3D hydrogel patterning technology,[3] a 3D in vitro tumor model was generated in 96-well plates utilizing breast cancer cells and human dermal fibroblasts to reflect the tumor and stromal compartments, respectively, of the tumor microenvironment. Specifically, the commercially available HER2-positive breast cancer cell line, JIMT-1, and the triple-negative patient-derived xenograft (PDX) cell line MAXFTN 401, were utilized in these 3D TME models and subsequently interrogated with HER2-specific CAR-T cells as well as untransduced T cells. 5,000, 10,000, or 25,000 T cells were added to each well of the 3D in vitro models and apoptosis via Caspase 3/7 staining was analyzed at day 4 endpoint using high content imaging.

Results T cell-mediated killing in the respective models was highly dependent on their HER2 status – HER2-positive JIMT-1 demonstrated a dose dependent effect in apoptosis (Caspase 3/7 marker) and up to 42% of JIMT-1 cells underwent apoptosis in response to HER2-specific CAR-T cells, while less than 5% of HER2-negative MAXFTN 401 showed a response to any therapeutic dose of the CAR-T cells. Moreover, inclusion of fibroblasts in the 3D TME model enhanced the CAR-T mediated tumor killing in JIMT-1 model. Finally, the untransduced T cells demonstrated negligible effects (<2% in the JIMT-1 model), highlighting the specificity of the HER2-targeting CAR-T cells.

Conclusions A novel 3D in vitro tumor model platform has been described for assaying CAR-T efficacy. In this case, the platform demonstrated the highly specific nature of the CAR-T cells in targeting HER2-positive tumors cells in a translationally relevant 3D in vitro TME model.

300 **TRI-MODAL CAR$^+$TCR$^+$HNCD16$^+$ IPSC-DERIVED T CELLS CO-TARGETING SURFACE AND INTRACELLULAR/ NEOANTIGENS DEMONSTRATE ADDITIVE EFFECT ON OVERCOMING TUMOR HETEROGENEITY AND CANCER ESCAPE**

Bi-Huei Yang*, Soheila Shirinbak, Wen-I Yeh, Alma Gutierrez, Mochtar Pribadi, Bjoern Gaertner, Hui-Yi Chu, David Gonzalez, Angela Liao, Tom Lee, Eigen Peralta, Ryan Bjordahl, Martin Hosking, Chia-Wei Chang, Bob Valamehr. *Fate Therapeutics Inc., San Diego, CA, USA*

Background Antigen escape and tumor heterogeneity remain significant hurdles to the development of curative treatments in many cancers. To address tumor heterogeneity, the introduction of pairs of chimeric antigen receptors (CARs) in donor T cells has been demonstrated, however, this adds complexity to a manufacturing process already challenged by cellular product consistency. To tackle tumor heterogeneity while maintaining product purity, we applied our induced pluripotent stem cell (iPSC)-derived T cell (iT) platform to design an off-the-shelf cell therapy capable of targeting multiple tumor antigens through complementary activation pathways, including targeting of both cell-surface antigens as well as intracellular/ neoantigens.

Methods A CAR construct targeting BCMA or MICA/B, a T-cell receptor (TCR)αβ targeting NYESO1 (1G4) or tumor-associated metabolite presented by MR1 (MC.7.G5), and a high-affinity non-cleavable (hnCD16) to promote antibody-dependent cellular cytotoxicity (ADCC) were engineered into iPSCs for use as a renewable starting source in deriving uniformly-engineered T cells. Resulting multiplexed-engineered CAR$^+$TCR$^+$hnCD16$^+$ (tri-modal) iPSCs were differentiated into T cells and the function of each individual edit was evaluated by preclinical models designed to represent tumor heterogeneity. In addition to *in vitro* mix-culture assays, a mixed cell disseminated *in vivo* model was used to mimic cancer heterogeneity and to evaluate the *in vivo* potency of tri-modal iT cells at mitigating tumor heterogeneity and antigen escape.

Results Assessment of individual edits in tri-modal iT cells demonstrated independent functionality by exhibiting increased antigen-mediated IFNγ and TNFα production, and degranulation compared to the control group ($p<0.0001$). Using 9-day daily restimulation assay, each edit produced significant tumor reduction compared to tumor only control ($p<0.0001$). By stimulating tri-modal iT cells with multiple antigens simultaneously using various solid tumor lines (A549, Caski and MDA-MB-231), we found that co-activation by two or three targeting edits significantly enhanced tumor killing ($p<0.0001$). Furthermore, when challenged with *in vivo* heterogenous tumor models, we found that the co-activation of all three targeting moieties in tri-modal iT cells achieved nearly complete tumor clearance ($p<0.0001$). *Ex vivo* bone marrow analysis further confirmed antigen-specific target elimination, reenforcing the specificity and potency of the tri-modal iT cells.

Conclusions Our data highlight the potency and broad applicability of tri-modal iT cell expressing CAR, TCR, and hnCD16. This consistent and scalable approach to multiplex-engineered T-cell therapy is an ideal strategy to mitigate antigen escape and combat difficult to treat heterogeneous solid tumors.

301 SINGLE-CELL RNA STUDY OF TRANSCRIPTIONAL ACTIVITIES ASSOCIATED WITH ANAKINRA PROPHYLAXIS AND AXICABTAGENE CILOLEUCEL IN PATIENTS WITH RELAPSED OR REFRACTORY LARGE B-CELL LYMPHOMA

[1,2,3]Ning Yao*, [4]Matthew Frigault, [4]Marc Wehrli, [4]Kathleen Gallagher, [4]Charlotte Graham, [5]Caron Jacobson, [6]Rhine Shen, [6]Simone Filosto, [6]Justin Budka, [6]Sao-Mai Nyugen-Mau, [6]Jenny Nater, [6]Mike Mattie, [3,4,7]Gad Getz, [3]Nicholas Haradhvala, [3,4,7]Marcela Maus. *[1]Harvard T.H. Chan School of Public Health, New York, NY, USA; [2]Tri-Institutional PhD Training Program, New York, NY, USA; [3]The Broad Institute, New York, NY, USA; [4]Massachusetts General Hospital Cancer Center, Boston, MA, USA; [5]Dana Farber Cancer Institute, Boston, MA, USA; [6]Kite, a Gilead Company, Santa Monica, CA, USA; [7]Harvard Medical School, Boston, MA, USA*

Background Chimeric antigen receptor T-cell (CAR-T) therapy has shown unprecedented treatment outcomes for B-cell malignancies. The wider utilization of CAR-T, however, is limited by CAR-T-induced adverse events including cytokine release syndrome (CRS). Tocilizumab, a monoclonal antibody blocking Interleukin (IL)-6 receptor, is the only approved treatment for CRS. Recent animal studies suggest that anakinra, a recombinant form of IL-1 receptor antagonist, could have potential benefit in managing toxicity, with or without tocilizumab. We have opened a clinical trial (NCT04150913) testing the use of prophylactic anakinra in patients with relapsed or refractory large B-cell lymphoma eligible to receive axicabtagene ciloleucel (axi-cel) as per the registration study ZUMA-1. Here, we used single-cell RNA sequencing (scRNA-seq) on clinical samples of the first ten subjects on the study[1] to probe the molecular pathways altered by anakinra and to discover potential mediators of breakthrough cases of CRS.

Methods We conducted scRNA-seq on the peripheral blood mononuclear cells (PBMCs) of 10 patients 7 days post infusion (D7) and the infusion products (IP). We compared data from the trial subjects to 4 control samples from the same institution along with our previously generated scRNA-seq IPs and D7 PBMCs from 19 subjects that were treated with axi-cel without prophylaxis for toxicity.[2] We utilized pseudo-bulk differential expression analysis of major immune cell types to reveal transcriptional signals associated with CRS and anakinra treatment.

Results Our study revealed that IL-4 and IL-10 anti-inflammatory pathways in IPs of both anakinra and non-anakinra cohorts were negatively associated with breakthrough CRS. We further observed that the same pathways were enriched at D7 in anakinra-treated CAR+ CD4+ T cells populations. Anakinra prophylaxis had little effect on the overall CAR+ T-cell compositions from IPs to D7, but was associated with an increased proportion of CAR+ regulatory T cells (Tregs). Expression of interferon gamma (IFN□) pathways, cytokine levels of IFNγ and IFNγ-induced protein 10 (CXCL10) in CD14+ monocytes were significantly enriched in patients with breakthrough CRS treated with tocilizumab in the anakinra cohort. Differential cell–cell interaction analysis further showed the association of IFNγ ligand receptor activities with breakthrough toxicity uniquely among anakinra- and tocilizumab-treated patients.

Conclusions We identified key molecular pathways and immune cell populations that were possibly modulated by anakinra, including the upregulation of IL-10 signaling pathway in CAR+ CD4+ T cells and increased abundance of Tregs. IFNγ enrichment in patients with breakthrough CRS further suggests that this pathway is also targetable and not inhibited by anakinra alone.

Acknowledgements The clinical trial is funded by Kite Pharma and the correlative studies are funded by R01CA252940.

302 ALLOGENIC ADOPTIVE NK CELLS AND IRRADIATION JOIN FORCE TO CONTROL TRIPLE NEGATIVE BREAST CANCER STEM CELLS

Meesun Yoon*. *Chonnam National University Medical School, Hwasun-gun, Korea, Republic of Korea*

Background Previously, our group has shown the long-term synergistic effects of allogeneic expanded natural Killer (NK) cells and Irradiation in a human triple-negative breast cancer (TNBC) model. Primary tumor irradiation enhanced the migration and infiltration of adoptive NK cells into tumor microenvironment (TME), hence increasing the NK cell's ability to lyse tumor cells. Although RT alone successfully controlled primary tumor, however, the primary tumor bioluminescence intensity was significantly reduced only in the RT+NK group compared to the RT alone. To clarify this phenomenon, we investigated cancer stem cells (CSC) population correlated with radioresistance and metastatic propensity.

Methods We analyzed CSC phenotype in human TNBC after irradiation in a time- and dose-dependent manner by using multiparameter flow cytometry. Ex vivo expansion of NK cells from human peripheral blood mononuclear cells was performed by co-culture with conventional K562 cells. NK cell cytotoxicity against CSCs were evaluated under irradiated TME. Mammosphere was generated to investigate the efficacy of combination therapy against CSC. Allogenic NK cells were i.v injected twice after local tumor irradiation in human TNBC xenograft model. Single cells suspension of tumors was prepared on day 14 after treatment and analyzed with flow cytometry

Results We identified ALDH+CD44+CD24- CSC phenotype showing increased absolute number of MDA-MB-231 CSCs population after fractionated RT compared to single-dose RT. Interestingly, NK cells effectively killed CD44+CD24- CSC population in response to an increased effector to target ratio. Combined NK cells with RT significantly decreased CD44+CD24- population of tumors both single-dose and fractionated RT ($p=0.0104$ and $p=0.0188$). We observed a significantly increase NK cells' lysis ability against TNBC mommosphere both single-dose RT ($p=0.0011$) and fractionated RT ($p=0.0145$) compared to non-irradiated group. However, there was no synergistic effect of NK cells and irradiation against parental TNBC cells. Moreover, allogeneic NK cells prefer to lyse mammosphere but not parental cells when co-cultured sphere and parental cells together. NK cells combined with single-dose irradiation more effectively killed TNBC mammosphere than fractionated irradiation ($p=0.0212$).

Conclusions Allogenic NK cells effectively killed breast-stem like cells. Combination therapy enhances NK cells antitumor response against breast cancer stem-like cells, suggesting that elimination of stem like cells by NK cells is closely correlated to long-term primary tumor control under irradiated TME. For RT dose scheme when combined with NK therapy, single-dose irradiation improved antitumor response against breast cancer stem-like cells.

303 TARGETING EWING SARCOMA WITH ANTI-IL1RAP CHIMERIC ANTIGEN RECEPTOR MODIFIED NATURAL KILLER CELLS

[1]Wen Luo*, [2]Poul Sorensen, [1]Mitchell Cairo, [1]Hai Hoang, [1]Yaya Chu, [1]Janet Ayello, [3]Wei Li, [2]Michael Lizardo, [2]Renata Ribeiro, [2]Melanie Rouleau, [3]Dimiter Dimitrov, [4]Dean Lee, [2]Hai-Feng Zhang. *[1]New York Medical College, Valhalla, NY, USA; [2]BC Cancer Research Centre, Horsholm, Denmark; [3]University of Pittsburgh, Pittsburgh, PA, USA; [4]Nationwide Children's Hospital, Columbus, OH, USA*

Background Metastatic and recurrent/refractory Ewing sarcoma (ES) has a dismal prognosis,[1] largely secondary to therapy resistance within the tumor microenvironment.[2] ES have heightened natural killer (NK) cell sensitivity,[3] and increased abundance of activated NK cells in ES patient tumors are correlated with extended survival.[4] Solid tumors are resistant to NK in large part due to the small number of active NK cells and lack of specific tumor targeting of NK cells.[2] Our group has developed a genetically engineered feeder cell to expand peripheral blood mononuclear cells (PBMCs) into NK cells,[5] and demonstrated that expanded NK cells engineered to express chimeric antigen receptor (CAR) against various targets including CD20, GD2, ROR1 and MCAM had significantly enhanced cytotoxicity against lymphoma and sarcomas[6,7] compared to mock NK. IL-1 receptor accessory protein (IL1RAP) is highly expressed on ES cells and minimally expressed in normal tissues as we previously reported.[8]

Methods Here we developed an anti-IL1RAP CAR NK cell and investigated its efficacy in promoting NK cell cytotoxicity against ES. PBMCs were expanded into NK cells using K562-mbIL21-41BBL artificial antigen presenting cells. The IL1RAP antibody VH domain DNA was codon optimized and synthesized to create the anti-IL1RAP CAR. CAR NK cells were generated by non-viral electroporation of CAR mRNA into expanded NK cells. CAR expression was analyzed by flow cytometry using biotinylated IL1RAP protein. Anti-IL1RAP CAR NK cytotoxicity was evaluated in vitro by luciferase based cytotoxicity assay. CRISPR-Cas9 mediated IL1RAP knockout (KO) in ES cells was utilized to evaluate the specificity of CAR NK targeting.

Results Electroporation resulted in CAR expression in 70% of expanded NK cells and the CAR expression lasted for at least 6 days (figure 1). We found a significantly increased cytotoxicity of anti-IL1RAP CAR NK cells compared to mock NK cells against ES A673 and SKNMC cells at various effector to target ratios after co-culturing for 4 hours (**p<0.01 and *p<0.05) (figure 2). In the IL1RAP KO A673 cells, we did not observe the significant increase in cytotoxicity with IL1RAP CAR NK compared to mock NK as we did in the wildtype (WT) A673 cells (figure 3), demonstrating the enhanced cytotoxic activity of CAR NK cells is due to specific targeting of IL1RAP.

Conclusions These findings demonstrate enhanced efficacy of anti-IL1RAP CAR NK cells compared to mock NK cells against ES and support a preclinical evaluation of anti-IL1RAP CAR NK in limiting ES xenograft tumor growth and/or metastasis and prolonging animal survival in vivo.

304 OFF-THE-SHELF IPSC-DERIVED CAR-T CELLS CONTAINING SEVEN FUNCTIONAL EDITS OVERCOME ANTIGEN HETEROGENEITY, IMPROVE TRAFFICKING, AND WITHSTAND IMMUNOSUPPRESSION ASSOCIATED WITH FAILED TUMOR TREATMENT

Martin Hosking*, Soheila Shirinbak, Bishwas Shrestha, Joy Grant, Kyla Omilusik, Hannah Keegan, Demetrio Cardenas, Angela Gentile, Shilpi Chandra, Lorraine Loter, Lexe Linderhof, Nicholas Brookhouser, Stephanie Kennedy, Francisco Martinez, Loraine Campanati, Chris Ecker, Xu Yuan, Karina Palomares, Yi-Shin Lai, Lauren Fong, Yijia Pan, Shohreh Sikaroodi, Mark Jelcic, Philip Chu, Amit Mehta, Layton Smith, Eigen Peralta, Tom Lee, Ramzey Abujarour, Raedun Clarke, Bob Valamehr. *Fate Therapeutics, Inc, San Diego, CA, USA*

Background Although chimeric antigen receptor (CAR) T-cell therapy has shown remarkable efficacy in liquid tumors, its wider application to solid tumors has been hampered by tumor-associated antigen (TAA) heterogeneity, inefficient CAR-T cell trafficking to the tumor, and immunosuppression inherent to the tumor microenvironment. Moreover, the often-dysfunctional and heterogenous yield of highly-edited (*e.g.* >2 transgenes) CAR-T cells necessary to address these obstacles has limited their efficacy and wider clinical investigation.

Methods T-cell derived induced pluripotent stem cells (TiPSCs) were engineered to express a CAR targeting a novel TAA domain and an interleukin-7 receptor fusion protein (IL7RF) under the regulation of the T-cell receptor alpha chain constant locus. Additionally, these TiPSCs were engineered to express TGFβ-signal redirection receptor (TGFβ-SRR), high-affinity non-cleavable CD16A (hnCD16), and CXCR2 within the CD38 locus enabling TGFβ resistance, secondary TAA targeting via antibody-dependent cell cytotoxicity (ADCC), and solid tumor specific trafficking, respectively. Engineered TiPSCs were differentiated into alpha-beta T (iT) cells, uniformly expressing all engineered transgenes and completely lacking both CD38 and T-cell receptor expression, avoiding the potential risk of graft-versus-host disease in an allogeneic setting.

Results Functional evaluation of these multiplexed-engineered CAR iT cells demonstrated broad, potent, and specific CAR based efficacy across multiple solid tumor indications. Importantly, hnCD16 activation with multiple therapeutic antibodies further augmented anti-tumor efficacy across target cell lines with heterogenous CAR antigen expression, underscoring the broad efficacy, applicability, and multi-antigen targeting capability of these CAR iT cells. Additionally, engineered CAR iT cells maintained high levels of anti-tumor efficacy over multiple rounds of tumor challenge, even in the presence of high and suppressive levels of TGFβ (Round 3 challenge with TGFβ: 90% cytolysis with TGFβ-SRR expressing CAR iT cells vs. 10% cytolysis with control CAR iT cells), demonstrating potent resistance to TGFβ-mediated effector suppression. CXCR2 expression enabled specific and potent migration to the CXCR2 ligand IL-8 (2-fold specific migration, 10ng/ml) that has been associated with, along with other CXCR2 ligands, poor outcomes in diverse tumor indications. Furthermore, we demonstrate robust anti-tumor efficacy in an aggressive ovarian cancer xenograft model which, when coupled with the activation of hnCD16 via therapeutic antibody, reached complete tumor clearance.

Conclusions Together these results demonstrate that a multiplexed-engineered CAR-iT cell product tailored for solid tumors can promote trafficking, overcome tumor microenvironment resistance, and elicit enhanced anti-tumor activity.

Ethics Approval These studies were approved by Fate Therapeutics Institutional Animal Care and Use Committee and were carried out in accordance with the National Institutes of Health's Guide for the Care and Use of Laboratory Animals.

305 COMBINATION IMMUNOTHERAPY USING A NOVEL CHIMERIC ONCOLYTIC VIRUS TO REDIRECT CD19 BISPECIFIC T CELL ENGAGERS TO TARGET SOLID TUMORS

[1]Anthony Park*, [1]Saul Priceman, [2]Leslie Chong, [1]Yuman Fong, [1]Isabel Monroy, [1]Colin Cook, [2]Monil Shah. *[1]City of Hope, Duarte, CA, USA; [2]Imugene, Sydney, Australia*

Background Bispecific T cell engager (BiTE) monoclonal antibodies have emerged as a promising immunotherapy strategy for the treatment of hematological malignancies. Blinatumomab, an FDA approved BiTE carrying CD19 and CD3 epitopes has shown durable clinical responses for the treatment of B-cell acute lymphoblastic leukemia (B-ALL) and non-Hodgkins lymphomas. Despite a wide array of research in hematological malignancies, BiTE therapies for the treatment of solid tumors have remained a significant challenge in demonstrating comparable efficacy. Solid tumors often lack amenable and targetable tumor antigens, and in many solid tumors the tumor microenvironment (TME) is largely known to be immunologically "cold" and a barrier to immunotherapy responses. Oncolytic viruses have recently gained traction in the field for the treatment of solid tumors because of their ability to target tumor-intrinsic properties and reshape the immunosuppressive TME. We have previously described the use of a chimeric oncolytic vaccinia virus (CF33) for the treatment of a variety of tumor cell types, including triple-negative breast cancer, lung cancer, and liver cancer. Building on this, we generated an OV that expresses a non-signaling, truncated CD19 antigen (CF33-CD19t or onCARlytics, in collaboration with Imugene Limited), onto the surface of infected tumor cells prior to virus mediated tumor lysis, which redirected CD19-targeting chimeric antigen receptor (CAR) T cell activity against solid tumors (Park *et al*. STM 2020). Using this combination, we have created a universal system that is agnostic to solid tumor type and can be provided with a targetable and well-characterized antigen. We now show that blinatumomab can be redirected to solid tumors with CF33-CD19t, enabling an off-the-shelf combinatorial immunotherapy strategy.

Methods For preclinical testing, we utilized *in vitro* co-culture assays using human healthy donor-derived T cells and human triple-negative breast cancer cells treated with CF33-CD19t and blinatumomab. We evaluated tumor cell killing and T cell activation using flow cytometry and cytokine assays. Humanized NSG mice were used to evaluate anti-tumor activity of the combination *in vivo*.

Results Tumors infected with CF33-CD19t along with blinatumomab show specific tumor cell killing *in vitro* and robust anti-tumor efficacy using *in vivo* human triple-negative breast cancer xenograft models.

Conclusions Using this approach, we show that a clinically-approved CD19-directed BiTE can be combined with oncolytic viruses to activate and redirect endogenous anti-tumor immunity against solid tumors.

306 **EVALUATION OF AB-101, AN ALLOGENEIC CORD BLOOD-DERIVED NATURAL KILLER (NK) CELL THERAPY, AS AN ADCC ENHANCER IN HEMATOLOGIC AND SOLID TUMORS**

[1]Paul Rogers, [2]Bitna Yang, [2]Hyojin Kim, [2]Yusun Kim, [2]Sunglim Cho, [1]Bret Morin, [1]Amanda Conerty, [3]Lavakumar Karyampudi, [1]Lisa Guerrettaz, [1]Peter Flynn, [2]Bokyung Min, [1]Heather Raymon*. *[1]Artiva Biotherapeutics, San Diego, CA, USA*; *[2]GC Cell, Seoul, Republic of Korea*; *[3]Moffitt Cancer Center, Tampa, FL, USA*

Background AB-101 is a non-engineered, allogeneic, off-the-shelf, cryopreserved cord blood-derived natural killer (NK)-cell therapy in development as a cancer therapeutic. A highly scaled manufacturing process enables production of 1000s of doses from a single donor cord blood unit (CBU). AB-101 has been optimized for combination with monoclonal antibodies (mAbs) to enhance antibody-dependent cellular cytotoxicity (ADCC) and anti-tumor responses through selection of key attributes in the CBU. These include a KIR-B haplotype and natural high-affinity variant of CD16 (158V/V polymorphism), which are associated with improved anti-tumor activity and ADCC enhancement. Administration of AB-101 to patients in combination with mAbs has the potential to enhance the ADCC response thereby increasing anti-tumor activity. Here we present preclinical data to support development of AB-101 in combination with mAbs as an ADCC enhancer in hematologic malignancies and solid tumor indications.

Methods AB-101 was expanded utilizing a proprietary engineered feeder-cell line. In vitro characterization of AB-101 included evaluation of the purity and expression of cell surface markers by flow cytometry. In vitro ADCC assays were performed at various effector to target ratios against hematologic (Raji, ARH-77) and solid tumor (MDA-MB-468) cell lines in the presence of approved therapeutic antibodies. In addition, AB-101 efficacy was assessed in vivo in established hematologic (Raji) and ovarian (SKOV-3) xenograft models.

Results AB-101 was ≥95% CD3-CD56+ with ≥80% CD56+CD16+ and high expression of NK activating receptors such as NKG2D, NKp30, NKp44 and DNAM-1 was observed. Cytotoxicity assays were used to demonstrate the ADCC mechanism of activity in combination with approved therapeutic antibodies. In the Raji cell line, when AB-101 was combined with rituximab, ~ 90% of target cell lysis was observed vs ~ 79% with AB-101 alone. Similar cell killing activity was observed against ARH-77 and MDA-MB-468 cell lines in combination with obinutuzumab and cetuximab, respectively. In addition, in vivo efficacy of AB-101 and AB-101 in combination with rituximab demonstrated enhanced median survival in the Raji xenograft model and AB-101 in combination with trastuzumab led to enhanced survival in the SKOV-3 xenograft model.

Conclusions Data presented suggests that AB-101 is a pure and readily expandable NK cell product that has the potential to be effective in combination with mAbs to treat both hematologic and solid tumors without the need for engineering. AB-101 is currently in a Ph1 clinical trial to evaluate the safety and anti-tumor activity alone and in combination with rituximab in patients with relapsed or refractory NHL (ClinicalTrials.gov: NCT04673617).

Ethics Approval All animal work was conducted under reviewed IACUC protocol and with approval of an IACUC committee at each center where the studies took place.

307 IL12 GENETICALLY ENGINEERED MYELOID CELLS EFFECTIVELY TARGET THE MYELOID-ENRICHED TUMOR AND METASTATIC MICROENVIRONMENT IN AN IMMUNE-COMPETENT MURINE MODEL OF OSTEOSARCOMA

Kristin Wessel*, Miranda Clements, Wei Ju, Sabina Kaczanowska, Rosandra Kaplan. *National Institutes of Health, Bethesda, MD, USA*

Background Osteosarcoma is the most common bone tumor in children and adolescents. Outcomes for patients presenting with metastatic and recurrent disease are poor and have not improved over the past forty years; therefore, novel therapies are urgently needed. Immunotherapy has shown promise for some solid malignancies, however, durable responses are often rare and several challenges, including an immune-suppressive microenvironment, limit efficacy. We hypothesized that Genetically Engineered Myeloid cells (GEMys) could be used as a platform to locally deliver the anti-tumor cytokine IL12 to primary tumor and metastatic sites. We aimed to profile the tumor and pre-metastatic immune microenvironments in a syngeneic murine model of osteosarcoma and to evaluate the effect of IL12-GEMys on tumor microenvironment dynamics and survival.

Methods We utilized a syngeneic orthotopic OS model (F40210 gifted by Dr. Yustein, Baylor College of Medicine) derived from a spontaneous tumor arising in Col2.3-Cre/p53$^{fl/+}$ mice. C57BL/6 mice were inoculated with tumor cells via orthotopic intratibial injection. Immune populations in the primary tumor and pre-metastatic lung were profiled at various timepoints during tumor progression utilizing flow cytometry, immunofluorescence and RNAseq. We engineered myeloid cells with a lentiviral vector to express IL-12, a potent anti-tumor cytokine, and administered IL12-GEMys intravenously to mice inoculated with osteosarcoma tumors.

Results Our characterization of the tumor and pre-metastatic microenvironment revealed a dense vascular and stromal matrix with steady enrichment of myeloid cells during cancer progression. Analysis of the immune microenvironment revealed an abundance of tumor-associated macrophages that develop an increasingly immune-suppressive phenotype during tumor progression. CD8+ T cells in the tumor were relatively rare and showed increased expression of activation markers PD-1 and CD44 during tumor progression. The presence of F42010 orthotopic tumors was associated with pre-metastatic niche formation in lungs of tumor-bearing mice, as evidenced by increased macrophage infiltration and upregulation of a myeloid-mediated immune suppressive gene signature. In the pre-metastatic lung, IL12-GEMy treatment increased T and NK cell activation and increased myeloid MHCII expression. IL12-GEMy administration resulted in enhanced T and NK cell infiltration into the primary tumor microenvironment. Finally, IL12-GEMy monotherapy reduced tumor growth and prolonged survival compared to vector control GEMy cell therapy.

Conclusions These data provide insight into immune population dynamics and pre-metastatic niche formation in immune-competent murine model of osteosarcoma and show that IL12-GEMys represent a promising strategy to reverse or limit the immune-suppressive microenvironment in osteosarcoma.

Acknowledgements We would like to acknowledge the Children's Cancer Foundation for supporting this work.

Ethics Approval All animal studies were approved by the NCI Animal Care and Use Committee (Protocol PB-054) and were conducted in specific pathogen-free conditions at the NIH animal facility.

308 HARNESSING TUMOR LOCALIZED IL-12 TO ENHANCE STEAP1 CAR T CELL THERAPY FOR PROSTATE CANCER

[1]Vipul Bhatia*, [2]Nikhil Kamat, [1]Tiffany Pariva, [1]Li-Ting Wu, [1]Annabelle Tsao, [3]Koichi Sasaki, [1]Lauren Wiest, [1]Ailin Zhang, [1]Dmytro Rudoy, [2]Lawrence True, [1]Radhika Patel, [2]Martine Roudier, [1]Roman Gulati, [1]Michael Haffner, [1]Peter Nelson, [4]Saul Priceman, [3]Jun Ishihara, [1]John Lee. *[1]Fred Hutchinson Cancer Center, Seattle, WA, USA; [2]University of Washington, Seattle, WA, USA; [3]Imperial College London, London, UK; [4]City of Hope, Duarte, CA, USA*

Background Surfaceome profiling of prostate cancer identified six transmembrane epithelial antigen of the prostate 1 (STEAP1) as a compelling prostate cancer-associated antigen. Adoptive transfer of chimeric antigen receptor (CAR) T cells has shown limited success in solid tumors, like prostate cancer due to the immunosuppressive tumor microenvironment (TME). Combining CAR T cell therapy with strategies that augment host immune responses and remodel immunologically "cold" TMEs may represent a promising treatment strategy for metastatic castration-resistant prostate cancer (mCRPC).

Methods We evaluated differences in the patterns of STEAP1 and prostate-specific membrane antigen (PSMA) expression using lethal mCRPC tissue microarrays. Second-generation STEAP1 CAR T cell therapy was developed and tested for its antitumor potency in various human prostate cancer disseminated mice models. We also generated a humanized STEAP1 knock-in (hSTEAP1-KI) mouse model and tested the potency and safety of murine STEAP1 CAR T cells. Systemic administration of a collagen binding domain-IL-12 (CBD-IL-12) fusion cytokine in combination with STEAP1 CAR T cells was assessed as a strategy to potentiate anti-tumor responses.

Results STEAP1 was found to be broadly expressed in ~87% of lethal mCRPC tissues compared to PSMA in 60%. CAR T cells targeting STEAP1 showed anti-tumor efficacy in various disseminated models tested with complete responses in the C4-2B model and substantial tumor growth inhibition in the 22Rv1 model with evidence of antigen loss in residual tumors. Mouse-in-mouse studies in hSTEAP1-KI mice bearing RM9-hSTEAP1 tumors treated with murine STEAP1 CAR T cell therapy showed preliminary safety without gross toxicity or architectural disruption and increased T cell infiltration at sites of systemic hSTEAP1 expression. Transient anti-tumor responses and a modest survival benefit were observed with progressive tumors demonstrating loss of STEAP1 expression. Concomitant treatment with STEAP1 CAR T cells and CBD-IL-12 showed enhanced anti-tumor effects by engaging host immune cells and increased epitope spreading.

Conclusions We generated STEAP1 CAR T cell therapy with promising potency in preclinical prostate cancer models and preliminary evidence of safety. We highlight antigen heterogeneity and escape as a major mechanism of resistance to effective STEAP1 CAR T cell therapy in prostate cancer. A strategy of combining CBD-IL-12 together with STEAP1 CAR T cell therapy enhances anti-tumor responses by remodeling the TME and engaging host immunity.

Ethics Approval All mouse studies were performed in accordance with protocols approved by the Fred Hutchinson Cancer Center Institutional Animal Care and Use Committee and regulations of Comparative Medicine.

309 DETERMINING THE HISTOCOMPATIBILITY BARRIERS BETWEEN UNIVERSAL CAR T (UCART) CELLS AND NK CELLS

Kimberly Apodaca*, Chong Xu, Kelsey Stanton, Beatriz Carreno, Gerald Linette. *University of Pennsylvania, Philadelphia, PA, USA*

Background Chimeric antigen receptor (CAR) T cell adoptive therapies have proven efficacy in the treatment of hematological malignancies. However, there are challenges to the current CAR T cell manufacturing process, one being manufacturing failure due to dysfunctional, patient-derived T cells.[1] A proposed solution to overcoming this limitation is the development of universal CAR T (UCART) cells engineered from healthy, normal donor-derived T cells. Histocompatibility barriers must be addressed when creating the UCART cell. Ablation of the alpha/beta T cell receptor surface expression will prevent graft-versus-host disease while host-versus-graft responses will be mitigated by ablating the surface expression of the major histocompatibility complex (MHC) class I and II molecules.[2,3] These triple knockout (TKO) T cells could serve as universal recipients for development of the UCART cell. Importantly, a consequence of MHC class I ablation is NK cell activation due to the "missing-self" response.[4] HLA-E, a non-classical MHC class I molecule, is known to interact with the NK cell inhibitory receptor NKG2A and we propose its overexpression on UCART cells will mitigate NK cell activation.

Methods Because the HLA-E/NKG2A interaction is dependent upon the peptide presented by HLA-E, 10 HLA-E single-chain trimer (SCT) constructs expressing various peptide sequences were created to determine which HLA-E/peptide complex would result in significant NK cell inhibition.[5] K562 cells transduced to express these HLA-E/peptide complexes were used as a model for UCART cells in preliminary experiments.

Results An HLA-E SCT presenting an HLA-C leader peptide (HLA-E/C) resulted in significant inhibition of NK cells as determined by flow cytometry-based NK cell degranulation (CD107a) assays. Decreased lysis of K562 HLA-E/C -expressing target cells in ^{51}Cr release assays further validated the inhibitory effect of HLA-E/C complexes on NK cell activation. Finally, HLA-E/C complex expression on TKO T cells lead to protection against NK lytic activity.

Conclusions Altogether these data demonstrate the effectiveness of selected HLA-E/peptide complexes to inhibit NK cell activation due to the "missing-self" response. Modifications such as the one described here may prevent UCART cell clearance due to host recognition (NK cell activation) and may ultimately lead to a more potent, safe, and long-term persistent UCART cell therapy.

310 ENGINEERING OPTIMAL CAR T CELLS TO OVERCOME PANCREATIC TUMORS WITH SECRETED ANTAGONISTIC PEPTIDES

Heather Lin*, Ruby Freeman, Alysa Evans, Tenzin Passang Fnu, Tongrui Liu, Elyse Christensen, Raymond Fei, Tanisha Sinha, Sruthi Ravindranathan, Lily Yang, Edmund Waller, Sarwish Rafiq. *Emory University, Atlanta, GA, USA*

Background Chimeric antigen receptor (CAR) T cell therapies have shown remarkable clinical efficacy in hematological cancers, but still face significant obstacles in the treatment of solid tumors such as pancreatic ductal adenocarcinoma (PDAC). Two hurdles in developing effective CAR T therapies for PDAC are the identification of ideal tumor-associated antigens (TAA) to target and overcoming a complex tumor microenvironment (TME). We hypothesize that the optimal CAR T cell to treat PDAC both recognizes an ideal TAA and is protected from immune suppression from the TME. Here, we propose the ectodomain of Muc16 (Muc16CD) as a viable TAA expressed in PDAC tumors (figure 1) and antagonizing vasoactive intestinal peptide (VIP), an immunosuppressive neuropeptide,[1,2] to overcome the PDAC TME.

Methods CAR T cells were generated to specifically target Muc16CD and express a novel, potent VIP receptor (VIPR) antagonist (antVIPR) peptide.[3] CAR T cells were assayed in vitro and in vivo against human VIP-expressing PDAC cell lines (Panc1) and PDX cell lines.

Results We first assayed patient-derived xenograft (PDX) PDAC cell lines for Muc16CD and VIP expression to establish the clinical relevance of these targets (figure 1). Interestingly, despite modest Muc16CD expression on PDX lines, anti-Muc16CD CAR T cells had cytotoxic function *in vitro* (figure 1) and reduced tumor burden in mice engrafted with orthotopic PDX PDAC tumors. Next, we investigated whether VIP is immunosuppressive for CAR T cell function. VIP limits the proliferative capacity of CAR T cells, which can be reversed by treatment with VIPR antagonist peptides. We therefore engineered novel antVIPR-secreting CAR T cells that provide continuous and localized delivery of antVIPR peptides within the TME. AntVIPR expression by CAR T cells impacts their phenotype as these cells have improved cell viability and express less VIP and VIPRs at baseline. Functionally, antVIPR CAR T cells have a proliferative advantage after antigen-stimulation and enhanced activation compared to parental CAR T cells. Finally, treatment with antVIPR CAR T cells reduces tumor burden and improve overall survival in mice bearing human VIP-expressing PDAC tumors (figure 2).

Conclusions Collectively, this data demonstrates that the combination of targeting Muc16CD and VIP with a novel CAR T cell can improve anti-tumor efficacy against PDAC. Ongoing experiments are determining the mechanisms by which locally secreted VIPR antagonists can modulate the PDAC TME using an orthotopic syngeneic PDAC mouse model with the long-term goal of translating antVIPR-secreting CAR T cells for the treatment of PDAC.

311 **PD-1 BLOCKADE PROTEIN COUPLED IN 4TH GENERATION ARMORED CAR-T CELLS ENHANCES CYTOTOXICITY EFFECT WITH *IN VITRO* RE-CHALLENGE SYSTEM**

Zhifeng Zhao*, Jinyan Ma, Tiantian Wang, Ka Fung Noi, Jie Xu, Qingyang Gu. *WXi ApTec, Nantong, China*

Background Chimeric antigen receptor (CAR)-T cells are genetically engineered T cells expressing a receptor on their surface to recognize tumor-associated antigens (TAA). CAR-T cell therapy has been coined as a 'living drug' and have demonstrated remarkable success with hematological malignancies. However, limited headway has been made with solid tumors due to various challenges, including recognition of tumor-specific antigens, trafficking and penetration, and survival within an immunosuppressive tumor microenvironment (TME). Some overexpression of immunosuppressive cytokines/proteins, such as TGF-β and PD-L1, downregulates cytotoxic CD8+ T cells and reduces the efficacy of CAR-T cell therapy. Immune checkpoint inhibitors (ICIs), such as anti-PD-1/PD-L1 and anti-CTLA-4 antibodies have gathered immense attention due to their efficacy across multiple solid malignancies. Therefore, a combination of CAR-T and ICIs could be a viable strategy to overcome the unfavorable TME. Here, we have established a 4th generation, armored CAR-T coupled with a PD-1 blockade protein to enhance the anti-exhaustion effect of CAR-T cells.
Methods CAR-T cells were generated from primary human T cells which were isolated from human PBMC using a pan T cell isolation kit. Lentiviral particles containing the MSLN CAR gene with/without PD-1 transgene were generated in 293T cells. T cells were stimulated by CD3/CD28 beads for 2 days, followed by the addition of CAR lentiviral particles for an additional 24 hours, then further proliferated for 6 days. Cells were collected for surface marker analysis after the second stimulation or co-cultured with luciferase-transduced HCT-116 cells for re-challenge cytotoxicity assay.
Results • 4th generation CAR-T cells have reduced surface PD-1 available for binding, compared to 3rd generation CAR-T cells and untransduced T cells.

• CAR-negative 4th generation T cells also have reduced available PD-1 binding sites.

• 4th generation CAR-T cell retains >70% cytotoxicity effect, while 3rd and 2nd generation CAR-T cells have markedly reduced cytotoxicity effect after two re-challenges with HCT-116-luc cells.
Conclusions PD-1 immune checkpoint blockade enhances and prolongs CAR-T cells cytotoxic effect in an *in vitro* re-challenge assay. This research indicates the possibility of adding an immune checkpoint inhibitor transgene to the existing CAR gene to enhance CAR-T cytotoxicity.

312 IDENTIFICATION OF NOVEL NSC LUNG CANCER DARK ANTIGENS™ WITH EXPRESSION IN MULTIPLE TUMOR TYPES, AS PROMISING TARGETS FOR IMMUNOTHERAPIES

[1]Rachel Abbott*, [1]Okba Alassadi, [1]Matthew Davies, [1]Magdalena Von Essen, [1]Verónica Freire-Benéitez, [1]Vicki Jefferson, [1]Samit Kundu, [1]Prathiba Kurupati, [2]Ralf Leonhardt, [2]Samuel Lukowski, [1]Fabio Marino, [1]Giulia Masi, [1]Rayner Queiroz, [1]Hayden Selvadurai, [1]Joana Senra, [1]Emily Tye, [1]Joseph Dukes. [1]*Enara Bio Ltd, Oxford, UK*; [2]*Boehringer Ingelheim RCV, Vienna, Austria*

Background Recent advances in immunotherapy have led to the development of multiple therapeutic modalities that harness T cells to recognize and eliminate cancer cells, bringing benefit to cancer patients with unmet need. However, targeted immunotherapies have utilized traditional tumor-associated antigens, which lack cancer specificity and broad expression across patient populations.

We utilized Enara Bio's EDAPT™ (Enara Dark Antigen Platform Technology) platform to probe the genomic dark matter (genomic regions previously thought to be non-coding) and discover novel, cancer-specific antigens with validated presentation on Class I HLA of primary tumors.

Methods We created a *de novo* pan-cancer transcriptome assembly with RNA-seq reads from The Cancer Genome Atlas (TCGA) non-small cell (NSC) lung cancer projects. Transcript sequences were subject to differential expression analysis selecting those with enriched expression in tumors compared to a comprehensive panel of healthy tissues.

To discover *bona fide* Dark Antigens™ encoded by tumor-specific transcripts, we translated all possible open reading frames (ORFs) and interrogated these against mass spectrometry-based immunopeptidomics data, from primary NSC lung cancer samples, to identify peptides solely mapping to putative ORF sequences. Subsequent filtering was performed to extract those antigens with robust immunopeptidomic support, transcript expression prevalence, and cancer specificity.

Confirmation of tumor-specific expression of antigen-encoding transcripts was carried out using RNA *in situ* hybridization (ISH) and RT-qPCR. The immunogenicity of detected epitopes was assessed by characterization of antigen-specific T cell responses from healthy donors.

Results Our *de novo* assemblies identified >1,000 transcripts encoding >15,000 ORFs. Interrogation of these ORFs against MS immunopeptidomic datasets mapped HLA-bound peptides to hundreds of ORFs, demonstrating presentation of these novel antigens in multiple patient tumor samples. Many candidate antigens displayed promising expression across additional tumor types, supporting potential for broader clinical utility.

RNA ISH revealed tumor-specificity and intra-tumoral homogeneity at the transcript level, with little to no transcript expression identified across healthy tissues. Assessment of immunogenicity in healthy subject peripheral blood cells revealed reactive T cells, indicating a lack of central-tolerance deletion of T cells specific for these antigen-derived peptides.

Conclusions We identified a suite of candidate Dark Antigens™ that are expressed in a cancer-specific manner with evidence of processing and HLA presentation on the surface of tumor cells. T cells with specificity for these antigens can be detected in healthy subjects, and thus these antigens show promise as candidates for the development of targeted immunotherapies such as cancer vaccines, TCR-T cell and bi-specific T cell engager therapies.

313 **EDIT-202, A MULTIPLEXED ASCAS12A EDITED IPSC DIFFERENTIATED INK, DISPLAYS A MATURE PHENOTYPE, HIGH KIR EXPRESSION, AND ADCC TOWARDS MULTIPLE SOLID TUMOR LINES**

Alex Allen*, Kaitlyn Izzo, Mrunali Jagdale, Scott Mordecai, Jared Getgano, Laura Blaha, Abhijit Dandapat, Mark Shearman, Kai-Hsin Chang. *Editas Medicine, Cambridge, MA, USA*

Background Chimeric antigen receptor (CAR)-T cells have demonstrated that cell therapy can achieve durable remissions in hematologic malignancies. CAR-T cell therapies have limited efficacy in solid tumors, however, and are often associated with severe toxicity, highlighting the need for safer, more efficacious cell therapies. Natural killer (NK) cells with high-affinity CD16 represent an attractive alternative therapy option to CAR-T cells due to their natural cytotoxic ability and low toxicity.

Methods Using our proprietary engineered AsCas12a, we generated a multiplexed edited iPSC clone(s) that includes four edits: high affinity, cleavable, CD16 KI (knock-in), membrane-bound IL-15 (mbIL-15) KI, TGFBRII KO, and a CISH KO. The two gene knock-ins were enabled with our proprietary **Se**l**e**ction by **E**ssential **E**xon **K**nock-in (SLEEK™) technology which enables high levels of KI, while expressing the cargo transgene consistently over time. Subsequently, we differentiated the iPSC clone(s) into iNK cells, termed EDIT-202, using a feeder-free differentiation process. We have previously demonstrated that this unique combination of edits in EDIT-202 results in an enhanced ability to overcome TGF-β-mediated immunosuppression, persist long-term without exogenous cytokine support, and control ovarian tumors in vitro and in vivo via natural and antibody-dependent cellular cytotoxicity.

Results The phenotype of EDIT-202 and its effector function against multiple solid tumor cell lines were further characterized. EDIT-202 expressed high levels of CD16 and KIR, which are commonly used markers for maturation. In addition, EDIT-202 expressed high levels of perforin, granzyme b, and T-bet, a critical transcription factor that helps control maturation in NK cells. Higher expression of KIR correlated to potent NK cell killing with an R^2 of 0.78 in a 3D tumor spheroid killing assay. Tumor cells from head and neck squamous cell carcinoma (HNSCC), gastric cancer, and non-small cell lung cancer (NSCLC) were screened against cryopreserved EDIT-202 cells. When combined with cetuximab (anti-EGFR antibody) against HNSCC and NSCLC, or with trastuzumab (anti-HER-2 antibody) against gastric cancer cells, EDIT-202 showed an approximately 10-fold increase in IFN-γ secretion compared with an EDIT-202 alone control. Moreover, there were significant increases in ADCC at multiple effectors to target ratios (E:T) when EDIT-202 cells were screened against the aforementioned solid tumor types.

Conclusions In conclusion, iPSC derived NK cells (iNK) have the unique advantage of being an off-the-shelf, and fully characterizable cell therapy amenable to multiplexed gene editing to enhance anti-tumor activity. EDIT-202 demonstrates a mature phenotype which translates to a highly potent and persistent iNK cell for potential treatment of multiple solid tumor types.

314 CELL THERAPY DEVELOPMENT IN ONCOLOGY REQUIRES A COLLABORATION BETWEEN SPONSORS AND CELL THERAPY EXPERIENCED CROS

Jaikrishna Balkissoon*. *PPD, Piedmont, CA, USA*

Background From 2017 to 2022 the oncology community has seen a significant increase in the number of cell therapy clinical trials in both hematologic malignancies and solid tumors. With breakthrough designations, priority reviews and orphan drug status, cell therapy regulatory approvals in hematologic malignancies have also significantly increased during this time based on acceptable safety/tolerability and positive clinical efficacy data from single-arm studies with relatively small sample sizes. As a global CRO, PPD has gained a wealth of experience in the management of these complex cell therapy trials in hematologic malignancies and solid tumors. Project teams managing these complex trials are supported by our Immuno-Oncology Cell and Gene Therapy Center of Exellence which provides a platform for sharing of knowledge and best practices as well as comprehensive cell therapy training. Through these cross-functional monthly meetings we review safety/tolerability between the different genetically modified cell therapies as well as those that are not genetically modified. We can also identify gaps in the management of cell therapy trials that could impact study timelines and create enrollment challenges. We demonstrate our comprehensive analysis of factors that could impact enrollment into our cell therapy trials and describe proposed solutions.

Methods We reviewed cell therapy approvals in relapsed/refractory DLBCL from 2017 to 2022 and the changing treatment options that could impact enrollment into current and future clinical trials using the IPSOS prescribing database. The Citeline-Trialtrove study database was then used to assess the number of studies competing for the same patient population.

Results From this evaluation we identified multiple factors that could impact enrollment requiring mitigation strategies to be implemented to prevent delays to study timelines (figure 8,9).

Conclusions By using a combination of experiential metrics and publicly available data, it is possible to identify remediable factors which could negatively impact enrollment. Rapid implementation of targeted measures can improve enrollment and keep study timelines on track (figure 9).

315 **CHARACTERIZATION OF CT-0508, AN ANTI-HER2 CHIMERIC ANTIGEN RECEPTOR MACROPHAGE (CAR-M), MANUFACTURED FROM PATIENTS ENROLLED IN THE PHASE 1, FIRST IN HUMAN, CLINICAL TRIAL OF CT-0508**

Michael Ball*, Madison Kremp, Rehman Qureshi, Poonam Sonawane, Maggie Schmierer, Josh VanDuzer, Michael Lynch, Adam Pfendt, Melissa Christiano, Ken Locke, Ramona Swaby, Daniel Cushing, Michael Klichinsky, Thomas Condamine. *Carisma Therapeutics, Philadelphia, PA, USA*

Background Adoptive T cell therapies have led to remarkable advances among patients with hematologic malignancies but have had less success in those with solid tumors. Macrophages are actively recruited and abundantly present in the solid tumor microenvironment (sTME). Tumor associated macrophages are predominantly immunosuppressive and support tumor growth (M2), while a subset of proinflammatory macrophages enhance anti-tumor immunogenicity (M1). M1 macrophage function can be augmented by CAR expression to selectively recognize and phagocytose antigen overexpressing cancer cells. Moreover, CAR macrophages can reprogram the sTME and present neoantigens to T cells, leading to epitope spreading and anti-tumor immune memory. Human Epidermal Growth Factor Receptor 2 (HER2) overexpression promotes tumorigenesis in many solid tumors. CT-0508 is a cell product comprised of autologous monocyte-derived proinflammatory macrophages expressing an anti-HER2 CAR and is being investigated in a currently ongoing first in human clinical trial (NCT04660929).

Methods Using the chimeric adenoviral vector Ad5f35, we manufactured CT-0508 product from apheresis material collected from patients enrolled in group 1 of the CT-0508 phase 1 clinical trial. To assess the activity of pre-infusion CT-0508 products, *in vitro* cell based assays were utilized including killing, phagocytosis, cytokine secretion, and transcriptomics analysis. Donor-matched untransduced (UTD) macrophages served as controls. Additionally, healthy donor derived products were used in some experiments.

Results CT-0508 was successfully manufactured with high viability, purity and CAR expression for patients enrolled in group 1. CT-0508 products demonstrated enhanced killing and phagocytosis of HER2-expressing tumor cells over autologous UTD macrophages. CITE-Seq analysis of CT-0508 confirmed an M1 macrophage transcriptional signature compared with pre-manufacturing monocyte and apheresis populations. Using healthy donor derived CT-0508 products, cell product activation was demonstrated by ex vivo CAR engagement and led to an increase in secreted immunostimulatory cytokines and chemokines, consistent with pro-inflammatory macrophage activation including TNF, IL-6, MIP-1α, and MIP-1β. Secreted factor analysis also showed HER2 responsive changes in extracellular matrix remodeling factors and growth factors. Additionally, transcriptomic and proteomic analysis revealed that CAR engagement further enhanced CAR-M M1 polarization. CAR engagement mediated effects are also being investigated in patient derived products.

Conclusions Together, these results demonstrate that functional CT-0508 CAR-M were successfully manufactured with an M1 phenotype and that CAR-antigen interaction drives cell product activation and amplifies the M1 polarization status of CT-0508 CAR-M.

316 NEXT GENERATION CAR-T INCORPORATING AN INHIBITORY CAR (ICAR) FOR INCREASED SAFETY IN SOLID TUMORS

David Bassan*, Michael Weist, Leehee Weinberger, Jason Yi, Gregor Adams, Tanya Kim, Caitlin Schnair, Kristina Vucci, Sarit Tabak, Neta Chaim, Nir Bujanover, Yael Lopesco, Limor Levy-Kanfo, Orit Foord, Jim Johnston, Frank Calzone, Rick Kendell, Adi Sharbi-Yunger.
ImPACT-Bio, Rehovot, Israel

Background Chimeric antigen receptor (CAR)-T cell therapy has shown incredible clinical success for hematopoietic malignancies, but for solid tumors is limited by "on-target off-tumor" toxicity to vital organs due to lack of target specificity. We have developed dual CAR-T cells consisting of a canonical activating CAR (aCAR), intended to elicit efficacy in solid tumors, and an inhibitory CAR (iCAR) designed to effectively suppress aCAR activation in normal tissues. The iCAR and aCAR bind distinct cell-surface antigens that are widely co-expressed in normal tissues. The iCAR is allele specific, and targets an antigen that is commonly lost in cancer due to chromosomal loss-of heterozygosity (LOH). Therefore, whereas healthy cells express the iCAR antigen and are protected, tumors have irreversibly lost iCAR antigen expression via LOH and are killed.

Methods In this study we developed dual CARs with an aCAR targeting Her2 and iCAR targeting HLA-A2. We screened bicistronic dual CARs in human PBMCs following lentiviral transduction against target cell lines that express normal levels of both antigens paired with targets following CRISPR KO of the HLA-A2 to mimic LOH. *In-vitro* assays included Luciferase-based killing assays, live-imaging killing assays, and cytokine secretion. *In-vivo* studies were performed in NSG-mice inoculated with either the HLA-A2+ or HLA-A2 KO targets.

Results We optimized the iCAR scFv, hinge, signaling domain, and bicistronic linker to generate dual CARs with high potency and tumor-specificity. These dual CARs were highly active against HLA-A2 KO targets ("tumor") and inhibited against HLA-A2+ targets ("normal tissue").

Conclusions These results show that the iCAR enables the tremendous therapeutic potential of CAR-T therapy to transition to solid tumors while maintaining safety and tumor specificity.

317 **ALK CHIMERIC ANTIGEN RECEPTOR T CELLS COOPERATE WITH ALK INHIBITORS TO TARGET NEUROBLASTOMA CELLS WITH LOW TARGET DENSITY**

[1]Elisa Bergaggio*, [1]Wei-Tien Tai, [1]Andrea Aroldi, [2]Elisa Landoni, [1]Manuel Nuesch, [1]Ines Mota, [3]Jasna Metovic, [4]Leyuan Ma, [5]Diego Alvarado, [3]Chiara Ambrogio, [3]Claudia Voena, [1]Rafael Blasco, [6]Tongqing Li, [6]Daryl Klein, [4]Darrell Irvine, [3]Mauro Papotti, [2]Barbara Savoldo, [2]Gianpietro Dotti, [1]Roberto Chiarle. *[1]Boston Children's Hospital and Harvard Medical School, Cambridge, MA, USA; [2]University of North Carolina Chapel Hill, Chapel Hill, NC, USA; [3]University of Torino, Torino, Italy; [4]Koch Institute and Massachusetts Institute of Technology, Cambridge, MA, USA; [5]Celldex Therapeutics, New Haven, CT, USA; [6]Yale University School of Medicine, New Haven, USA*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0317

Background Neuroblastoma is the most common extracranial solid tumor of childhood[1] and accounts for 12-15% of cancer-related deaths in children.[2] The survival of patients with refractory or relapsed neuroblastoma remains dismal.[3] In neuroblastoma, chimeric antigen receptor (CAR) T cells against GD2 have shown encouraging clinical results, but relapses are associated with loss of antigen expression. The selection of the best target is critical for the therapeutic success of CAR-T cells in hematologic malignancies and solid tumors. The Anaplastic Lymphoma Kinase (ALK) receptor is expressed by most neuroblastoma while virtually absent in the majority of normal tissues. It is an oncogenic driver in neuroblastoma and ALK inhibitors show promising clinical activity. All these features render ALK a great candidate for CAR-T therapy.

Methods We generated seven ALK.CAR constructs using the single-chain variable fragment derived from different anti-ALK monoclonal antibodies that recognize the ALK extracellular domain into a CAR construct that included the CD28 costimulatory endodomain. Their ability to target and kill was tested in vitro and in vivo against neuroblastoma cells expressing different intensities of ALK. The activity of ALK.CAR-T cells was compared to GD2.CAR-T cells.

Results

ALK CAR-T cells showed potent activity without on-target or off-target toxicity against neuroblastoma with high ALK expression. Combination with ALK inhibitors specifically potentiated the activity of ALK.CAR-T cells, but not GD2. CAR-T cell, against neuroblastoma with low ALK expression in cell lines and in a patient-derived xenograft (PDX), where the combination of ALK inhibitors with ALK.CAR-Ts significantly reduced tumor growth and extended mice survival. Mechanistically, ALK inhibitors impaired tumor growth and upregulated the expression of ALK, thereby improving the targeting of neuroblastoma tumors by ALK.CAR-T cells.

Conclusions These data indicate that ALK.

CAR-T cells are effective and safe as monotherapy against neuroblastoma with high ALK expression. Furthermore, treatment with ALK inhibitors increases the efficacy of ALK.CAR-T cells by enhancing ALK targeting.

318 PRE-CLINICAL DEVELOPMENT OF A CAR MONOCYTE PLATFORM FOR CANCER IMMUNOTHERAPY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0318

Linara Gabitova*, Brett Menchel, Silvia Beghi, Larissa Ishikawa, Rehman Qureshi, Andrew Best, Sabrina DeLong, Sascha Abramson, Thomas Condamine, Daniel Blumenthal, Michael Klichinsky. *Carisma Therapeutics, Philadelphia, PA, USA*

Background Engineered cell therapies have demonstrated significant clinical activity against hematologic malignancies, but responses against solid tumors remain rare. Our previously developed human chimeric antigen receptor macrophage (CAR-M) platform has shown potent anti-tumor activity in pre-clinical solid tumor models,[1] and an anti-HER2 CAR-M product (CT-0508) is currently being evaluated in a Phase I trial. Use of myeloid cells for immunotherapy has the potential to overcome the main challenges presented by solid tumors – tumor infiltration, immunosuppression within the tumor microenvironment (TME), lymphocyte exclusion, and target antigen heterogeneity. Currently, CAR-M are generated in a week-long *ex-vivo* process in which peripheral blood monocytes are differentiated into macrophages prior to genetic manipulation. Here, we demonstrate the feasibility, phenotype, pharmacokinetics, durable CAR expression, cellular fate, specificity, and anti-tumor activity of human CD14+ CAR monocytes.

Methods Using the chimeric adenoviral vector Ad5f35, we engineered primary human CD14+ monocytes to durably express an anti-HER2 CAR (CAR-mono). Using a partially automated approach, we established a process that allowed for same day manufacturing (from Leukopak to cryopreserved CAR-mono cell product).

Results CAR-mono showed high CAR expression and viability (>90%), and efficiently differentiated into CAR-expressing macrophages. The production process was designed to precondition CAR-mono to differentiate into M1-like CAR macrophages with strong pro-inflammatory effector functions. CAR-mono derived CAR-M (cmdCAR-M) demonstrated potent anti-tumor activity regardless of exposure to GM-CSF or M-CSF, and were protected against M2 switching by immunosuppressive factors. Treating CAR-mono with GM-CSF and IL-4 resulted in their differentiation to monocyte-derived CAR-DCs with an activated phenotype, indicating that these cells retained their myeloid differentiation potential. *In vivo*, intravenous administrated CAR-mono demonstrated the ability to traffic to tumors and showed remarkable long-term CAR expression and persistence (>180 days) in both NSG and NSG-S mouse models, demonstrating lasting persistence and CAR expression irrespective of human cytokine support. CAR-mono differentiated into strong pro-inflammatory CAR-M even when injected directly into well-established tumors. Finally, CAR-mono induced anti-tumor activity in various HER2+ solid tumor xenograft models.

Conclusions The CAR-mono platform allows for a rapid, same-day manufacturing process while maintaining the key characteristics of CAR-M therapy. Ad5f35 engineered human CAR monocytes are primed toward M1 macrophage differentiation, demonstrate durable CAR expression and persistence, and produce a cell population highly similar to our established CT-0508 product. These data provide strong pre-clinical support to advance the CAR-mono platform into clinical testing.

319 IMMUNOMETABOLIC MODULATION OF ENGINEERED IPSC-NK CELLS FOR IMMUNOTHERAPY OF SOLID TUMORS

[1]Shambhavi Borde*, [1]Sandro Matosevic, [2]Kyle Lupo. *[1]Purdue University, West Lafayette, IN, USA; [2]Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background Natural killer (NK) cells have efficient intrinsic recognition capabilities towards abnormal cells. This fact makes them particularly attractive as safe effector cells for cancer immunotherapy. Despite being innately tumor-killing cells, sourcing them from human donors is a tedious and highly donor-specific process.[1] As an alternative, induced pluripotent stem cells (iPSCs) represent a universal source of NK cells. iPSC-NK cells can be prepared with homogenous quality and can be easily genetically modified to modulate their specificity and activity.[2] Despite their demonstrated potential, differentiation processes to generate NK cells from iPSCs require improvements in terms of NK cell yield. Our group has reported that chemically defined and serum- and feeder-free differentiation generates NK cells that are predominantly CD56+/CD16+/CD3- and which express NK activation markers NKG2D, NKp30, NKp44, NKp46, and DNAM-1. We also recently engineered these cells to express multi-specific CAR constructs and showed that they mediate strong anti-tumor activity and lead to improved survival in mouse xenografts of glioblastoma.[3]

Methods However, we also found that modulating the differentiation and genetic engineering processes can yield further improvements in terms of NK cell quality, yield, and activity. Here, we report our recent work on evaluating iPSC-NK protocol advancements to improve reproducibility and yield, as well as the generation of more efficient immunometabolically-reprogrammed CAR-iPSC-NK cells. These involve the addition of Interleukin-15 in the second stage of differentiation, where differentiating embryoid bodies transitions to the generation of NK cells. We are also modulating the activity of multi-specific CAR-iPSC-NK cells with small molecule inhibitors of metabolic activity, by targeting mitochondrial dysfunction.

Results The involvement of interlukin-15 and inhibition/silencing of metabolic acitivity with small molecule inhibitors generated metabolically resilient and functionally robust CAR-NK cells. In addition, these cells showed robust cell-mediated effector functions including cytotoxicity, degranulation, and IFN-γ production against patient-derived cancer cells.

Conclusions These advancements lead to improved NK cell quality and activity and represent a significant step toward off-the-shelf immunotherapies for solid tumors.

Background In the United States, the HPV16 strain is responsible for nearly 60% of newly diagnosed HPV-driven cancers. HPV16 drives oncogenesis through persistent expression of the E6 and E7 oncoproteins.[1] The viral antigens E6 and E7 are absent from healthy tissues, making them attractive targets for TCR T-cell therapy. Both oncoproteins are validated targets for TCR T-cell therapies based on clinical trials with objective clinical responses in 50% (6 of 12) of patients for an E7-directed TCR, however, durability of response and coverage of the patient population were limited.[2,3] Both issues can be addressed by a larger TCR library that allows treatment of patients of all ethnicities with a multi-TCR product. Here we describe a suite of TCR discovery and validation platforms for the rapid generation of an off-the-shelf TCR library targeting the HPV16 E6 and E7 oncoproteins presented by the 16 most prevalent HLA alleles across all ethnicities in the US. This library of TCRs provides social equity for patients with HPV16-driven cancer, since it will enable more than 80% of the US population to receive a multi-TCR T-cell therapy product with the potential to mitigate tumor escape mechanisms, such as HLA mutation or loss of heterozygosity, for durable anti-tumor responses.

Methods E6- and E7-specific TCRs were identified using the rapid and highly sensitive imPACT Isolation Technology® (capable of capturing T cells at a frequency of 1 in 300,000 CD8+ T cells) and barcoded libraries of peptide-HLA proteins predicted to derive from the HPV16 E6 or E7 oncoproteins. Every identified TCR undergoes functional validation as well as safety and specificity testing using primary human T cells non-virally edited to express the TCR of interest.

Results We have identified potent TCRs specific for HPV16 E6 or E7 from both HPV+ cancer patients and healthy donors (+/- HPV infection). In one example, circulating T cells from an HPV+ cancer patient yielded three novel TCRs against related E6 peptides restricted by A*11:01 that exhibit clinically relevant T-cell functionality. Interestingly, in this patient, the A*11:01 allele in the tumor had a deleterious mutation allowing the tumor to escape killing by these TCRs further validating their biological relevance. However, as part of an off-the-shelf HPV library for use in a multi-TCR T-cell therapy product, these TCRs have the potential to be highly effective in patients with intact A*11:01 expression.

321 SINGLE MRNA CONSTRUCTS ENCODING MULTIPLE LINKED ANTIGENS ALLOW FOR A MULTIANTIGEN-SPECIFIC CD8+ T CELL RESPONSE DRIVEN BY SQZ® EAPCS

Ashley Brate*, Michael Maloney, Carolyne Smith, Katarina Blagovic, Andrea Silva, Amber Martin, Jodie Wong, Scott Loughhead. *SQZ Biotechnologies, Watertown, MA, USA*

Background During cancer progression, genomic mutations develop that can generate immunogenic neoepitopes, which are potential targets for immunotherapies. In contrast to microbial and other exogenous antigens where most of the protein is immunogenic, neoepitopes are immunogenic in a narrow region of the protein due to self-tolerance for the flanking regions. Previously, we demonstrated that SQZ® eAPCs, produced from human peripheral blood mononuclear cells (PBMCs) with mRNA encoding for full-length viral antigens (98-561 aa in length), can elicit robust $CD8^+$ T cell responses. To understand whether the smaller immunogenic regions of multiple neoepitopes (~25 aa) could be linked together in a single mRNA construct, we delivered various mRNA constructs encoding 5-10 model antigen fragments (*e.g.*, HPV16 E6, HPV16 E7, mutant KRAS, and Influenza M1) linked together into PBMCs to generate SQZ® eAPCs.

Methods Model antigen fragments with known $CD8^+$ T cell epitopes were linked together to form a single mRNA. Cell Squeeze® technology was used to deliver the linked antigen mRNAs directly into the cytosol of all major cell subsets of PBMCs. Western blots were used to confirm the delivery and translation of the linked antigen mRNA constructs. The MHC-I presentation of epitopes on the SQZ® eAPCs was assessed *in vitro* by culturing SQZ® eAPCs with antigen-specific responder T cells or TCR-transduced Jurkat-Lucia NFAT reporter cells overnight before measuring the activation response of these T cells via luciferase or IFNγ ELISA.

Results We demonstrate simultaneous antigen presentation on MHC-I by SQZ® eAPCs with a single mRNA encoding for 5 or 10 linked antigen fragments. Multiple antigen-specific responder cells are activated after co-culture with PBMCs squeezed with linked antigen mRNA, as measured by an increase in the secretion of luciferase or IFNγ.

Conclusions SQZ® eAPCs with mRNA encoding for up to 10 linked antigen fragments allows for simultaneous antigen presentation and robust $CD8^+$ T cell responses. These findings further enhance the versatility of the Cell Squeeze® technology to potentially target multiple tumor-associated neoantigens (*e.g.*, mutated KRAS) in a single mRNA construct.

322 MINK-413: A NEXT GENERATION ARMORED ALLOGENIC BCMA CAR INKT PRODUCT

Eleni Chantzoura*, Efrat Altman Sharoni, Reed Masakayan, Martyna Popis, Darrian Moskowitz, Paul Ibbett, Sapana Kadel, Moira Pinzan Rossi, Deborah Wright, Burcu Yigit, Olivier Le Tonqueze, Xavier Michelet, Marc Van Dijk. *MNK Therapeutics, Cambridge, MA, UK*

Background We are developing MiNK-413; a novel allogeneic CAR-iNKT product targeting BCMA and secreting soluble IL-15 for treatment of relapsed/refractory Multiple Myeloma (rrMM). Chimeric Antigen Receptor (CAR)-T cell therapy has revolutionized treatment of rrMM with two autologous products already approved by the FDA. However, current treatments come with significant toxicity, cost, and logistical challenge and many patients relapse, with 60% of relapsed patients still expressing BCMA. To address these, we propose the use of invariant Natural Killer T (iNKT) cells as a platform for BCMA-targeted allogenic cell therapy for rrMM. iNKT cells have potent immunostimulatory activity and intrinsic CD1d- and NK receptor ligand targeted cytotoxicity, and do not cause Graft *versus* Host Disease due to their invariant T cell receptor. In our native iNKT cell (agenT-797) clinical trials for COVID, solid tumors and Multiple Myeloma we observe excellent tolerability to up to 1 billion cell dosing with minimal treatment-related adverse events, absence of signs of CRS or peripheral neuropathy, and early signs of biological activity. AgenT-797 is administered without prior lymphodepletion, which is an approach we intend to pursue with MiNK-413.

Methods Our proprietary CARDIS^{TM} platform consists of highly diverse ($>10^{10}$) scFv library screening followed by library-based direct functional selection in CAR format using mammalian display. Candidates can be further optimized using affinity tuning to ensure optimal and highly selective on-target/on-tumor activity. We developed a manufacturing approach to engineer and specifically expand CAR and soluble IL-15-expressing allogeneic iNKT cells. Lead candidates are assessed *in vitro* and *in vivo* for cytotoxicity, cytokine secretion, exhaustion, tumor homing and persistence.

Results Discovery using our CARDIS^{TM} platform generated a fully human, potent, and specific anti-BCMA CAR which forms the basis for MiNK-413. Xenograft *in vivo* studies demonstrate effective bone marrow homing, and potent cytotoxic activity, with soluble IL-15 prolonging persistence. *In vitro* data show potent immunomodulatory activity and lack of exhaustion against BCMA+ human hematologic tumor cell lines *in vitro* and *in vivo*.

Conclusions Combination of our proprietary CARDIS^{TM} and iNKT platforms enabled rapid discovery and development of MiNK-413, a next generation armored allogeneic BCMA-targeting CAR therapies. MiNK-413 is eligible to target a broader rrMM patient population due to intrinsic iNKT cell properties such as effective bone-marrow homing, high BCMA specific activity augmented by natural CD1d and NK receptor-ligand mediated activity. We believe MiNK-413 will provide additional benefits to rrMM patients beyond currently available treatments.

323 TALEN®-BASED GENE EDITED IPSC-DERIVED NK (INK) CELLS DEMONSTRATE ENHANCED ANTITUMOR ACTIVITY

[1]An-Ping Chen*, [1]Peng Gao, [1]Preeti Ashok, [1]Marshall Chao Ma, [1]David Zou, [1]Andrea Chambers, [1]Liang Lin, [1]Hao-Ming Chang, [1]Antonio Arulanandam, [2]Justin Eyquem, [1]Elisabetta Burchi, [1]Armin Rath, [1]Stanley Frankel, [3]Alex Boyne, [3]Alexandre Juillerat, [4]Philippe Duchateau, [1]Daniel Teper, [1]Nejmi Dilmac, [1]Wei Li. *[1]Cytovia Therapeutics, Natick, MA, USA; [2]University of California San Francisco, San Francisco, CA, USA; [3]Cellectis Inc., New York, NY, USA; [4]Cellectis Inc., Paris, France*

Background Natural killer (NK) cell therapies have shown a great promise for solid and liquid tumors in initial clinical trials. NK cells are innate immune cells with distinct potential safety and efficacy advantages compared to adoptive T-cell therapies. However, there are limitations with the persistence and immunosuppression of these cells in the tumor microenvironment. Furthermore, multiple sources of NK cells have been used in clinical trials and there are challenges with manufacturing homogeneous and high doses of these cells. Induced Pluripotent Stem Cell (iPSC)-derived NK cells offer an opportunity to generate unlimited and homogenous NK cells for allogeneic off-the-shelf therapies. We combined Cytovia's iNK cell platform with Cellectis TALEN® gene editing technology to improve potency and the manufacturing process. Clonally edited iPSC lines were generated by knocking in IL-15 and knocking out TGFβR2 to improve the persistence and antitumor activity, respectively. Edited iPSCs were differentiated into iNK cells with high efficiency using Cytovia's proprietary platform.

Methods iPSCs were edited at the B2M locus with TALEN® pairs along with a template to knock in IL-15 by electroporation. Another TALEN® pair was sequentially used to knock out TGFβR2. Edited single cell iPSCs were printed, expanded, and screened for clone selection. Selected clones were sequence verified by NGS and samples were submitted for off-target assessment by GUIDE-seq. Expression of IL-15 and TGFβR2 was measured by ELISA and western blot, respectively. iPSCs were differentiated into iNK cells and analyzed by surface staining and flow cytometry. Cytotoxicity assay was performed against K562 tumor cells.

Results Several single and double gene edited iPSC lines were generated with high efficiency to produce NK cells: iPSC-IL-15 (+/+), iPSC-TGFβR2 (-/-) and iPSC-IL-15 (+/+)-TGFβR2 (-/-). These TALEN®-edited iPSCs kept their pluripotency, exhibited normal morphology and karyotype with no detected off-target effect. Edited iPSCs were differentiated into NK cells with high efficiency (CD56+/CD45+>95%) and enhanced cytotoxicity against K562 tumor cells compared to unedited iNK cells. Moreover, TGFβR2 protein was not detected, while the expression of secreted IL-15 was observed in the edited iNK cells confirming the phenotype of these cells.

Conclusions Cytovia's iPSC-NK platform combined with TALEN® gene editing robustly and reliably generated single cell edited iPSC clones, which were expanded and differentiated into functionally improved iNK cells. The data indicated iNK cells edited with an IL-15 knock in and TGFβR2 knock out resulted in enhanced antitumor activity. The editing and manufacturing process will enable clinical evaluation of these product candidates.

324 SENSITIZING POORLY DIFFERENTIATED THYROID CANCERS TO TSHR-CART CELL THERAPY WITH MEK INHIBITORS

John Copland, Kendall Schick, Justyna Gleba, Truc Huynh, James Miller, Erin MIller, Aylin Alasonyalilar Demirer, Erin Tapper, Reona Sakemura, Elizabeth Siegler, Michelle Cox, Carli Stewart, Ismail Can, Ekene Ogbodo, Claudia Manriquez Roman*, Bezerra Evandro, Cui Gaofeng, Mer Georges, Olivier Gloria, Yushi Qui, Robert Smallridge, Abba Zubair, Han Tun, Saad Kenderian. *Mayo Clinic, Jacksonville, FL, USA*

Background Thyroid cancer incidence is rising,[1] and most thyroid cancer deaths are attributed to a subset of de-differentiated, treatment-refractory, metastatic tumors. Thyroid stimulating hormone receptor (TSHR),[2,3] making TSHR a compelling target for advanced thyroid cancer diagnostics and therapeutics. We therefore developed a novel TSHR-targeted chimeric antigen receptor (CAR) T cell therapy to treat these aggressive thyroid cancers.

Methods TSHR-CAR constructs were synthesized using a single chain variable fragment derived from thyroid auto-antibody clone KI-70 and cloned into a lentiviral CAR construct containing 4-1BB and CD3ζ. We then generated TSHR-CART by transducing T cells derived from normal donors. TSHR-CART demonstrated potent antigen-specific in vitro and in vivo antitumor activity. NOD-SCID-γ-/- (NSG) mice were inoculated subcutaneously with a TSHR-overexpressing thyroid cancer cell line, THJ529, and were randomized by tumor volume to treatment with TSHR-CART cells or control untransduced T cells (UTD). Treatment with TSHR-CART cells resulted in dose-dependent antitumor activity and prolonged survival (figure 1).

Results Anaplastic thyroid cancers (ATC) are reported to downregulate TSHR. Our TSHR immunohistochemistry results corroborated these findings and displayed attenuated or no TSHR protein expression, precluding successful TSHR-CART treatment (figure 2). We therefore sought to sensitize these tumors with mitogen-activated protein kinase (MEK) inhibitors, which have been shown to upregulate TSHR expression in patients with metastatic thyroid cancer.[4,5] We verified that TSHR expression was upregulated in patient-derived xenograft (PDX) ATC models after one week of daily administration of the MEK inhibitors trametinib and R05126766 (figure 3). After confirming that MEK inhibition does not dampen TSHR-CART effector functions (not shown), we tested combination therapy of TSHR-CART with MEK and BRAF inhibition in vivo. NSG mice were engrafted with ATC BRAF-mutant PDX tumors and were randomized by tumor volume to daily oral treatment with placebo or trametinib (MEK inhibitor) plus dabrafenib (BRAF inhibitor). One week later, mice received either UTD or TSHR-CART. Because MEK/BRAF inhibitors alone inhibit tumor growth, treatment groups receiving placebo were implanted one week later than groups receiving MEK/BRAF inhibitors to achieve similar tumor volumes at the time of TSHR-CART treatment. Mice conditioned with trametinib plus dabrafenib and subsequently treated with TSHR-CART showed superior antitumor activity (figure 4).

Conclusions Collectively, our findings indicate that MEK/BRAF inhibition of de-differentiated thyroid cancers upregulated TSHR expression and enhanced TSHR-CART antitumor activity. This work represents a viable strategy to improve outcomes of patients with aggressive, metastatic thyroid cancers.

325 TALEN-EDITED SMART CAR T-CELLS LEVERAGE SOLID TUMOR MICROENVIRONMENT FOR SPECIFIC AND EFFECTIVE IMMUNOTHERAPY

[1]Shipra Das*, [1]Sonal Dharani, [2]Julien Valton, [2]Philippe Duchateau, [2]Laurent Poirot. [1]*Cellectis Inc, New York, NY, USA*; [2]*Cellectis, Paris, France*

Background Adoptive cell therapy based on chimeric antigen receptor-engineered T (CAR-T) cells has proven to be life-saving for many cancer patients. However, its therapeutic efficacy has so far been restricted to only a few malignancies, with solid tumors proving to be especially recalcitrant to efficient therapy. Poor intra-tumor infiltration by T cells and T cell dysfunction due to an immunosuppressive microenvironment are key barriers against CAR-T cell success against solid tumors. Furthermore, low level expression of CAR-directed tumor-associated antigens (TAA) in normal tissues can result in "on-target off-tumor" cytotoxicity, raising potential safety concerns.
Methods Using our TALEN®-based gene editing platform, we present here innovative T cell engineering strategies that can combat some of the challenges posed by CAR-T cell development for solid tumors. These allogeneic 'Smart CAR-T' cells are designed to integrate locus-specific synthetic genes that can either respond to or take advantage of the unique cues localized to the solid tumor microenvironment (TME).
Results Inducible expression of a tumor-antigen directed CAR by a constitutive CAR specific to TME cues greatly enhanced anti-tumor activity, while limiting 'on target, off-tumor' cytotoxicity. Additionally, CAR induced gene expression could boost anti-tumor CAR-T only within the TME. Thus, our gene editing strategies could increase CAR-T cell persistence and anti-tumor activity while staying restricted to the tumor milieu.
Conclusions Our proof-of-concept study demonstrates the feasibility of developing CAR-T cell engineering strategies that can improve solid tumor targeting while mitigating potential safety risks, paving the way for clinical development.
Ethics Approval All procedures involving animals were performed in accordance with regulations and established guidelines and were reviewed and approved by the Cellectis Institutional Animal Care and Use Committee (IACUC), as well as by the Animal Ethical Committee at Mispro-Biotech (New York, NY)

326 OFF-THE-SHELF IPSC-DERIVED CAR-T CELLS TARGETING KLK2 DEMONSTRATE PROLONGED TUMOR CONTROL AND SURVIVAL IN XENOGRAFT MODELS OF PROSTATE CANCER

[1]Charles Drake*, [2]Alex Garcia, [2]Chia-Wei Chang, [2]Bi-Huei Yang, [2]Samad Ibitokou, [2]Cameron Pride, [2]Spas Markov, [2]Angela Liao, [2]Mochtar Pribadi, [2]Yijia Pan, [2]Thomas Dailey, [2]Tom Lee, [1]Szeman (Ruby) Chan, [1]Michael Ports, [2]Jode Goodridge, [2]Ryan Bjordahl, [1]Joseph Erhardt, [2]Bahram Valamehr. *[1]Janssen, USA, Spring House, PA, USA*; *[2]Fate Therapeutics, Inc., San Diego, CA, USA*

Background Human kallikrein-related peptidase 2 (KLK2) is an antigen with prostate-restricted expression which is maintained during prostate cancer progression – making it an attractive therapeutic target for chimeric antigen receptor (CAR) T cells. While CAR-T cell therapies have shown remarkable success in hematologic malignancies, application to solid tumors has been broadly unsuccessful. Cost of treatment, manufacturing consistency, and scalability remain significant hurdles to broader patient access. To overcome these challenges, we are developing a KLK2 targeted off-the-shelf CAR-T cell product using our induced pluripotent stem cell (iPSC)-derived immunotherapy platform.

Methods A clonal master iPSC line was derived by knock-in of a CAR construct targeting KLK2 into the T-cell receptor alpha constant chain (TRAC) locus in a bi-allelic manner. Specificity of the engineering strategy and testing for random donor vector integration and transgene copy number were confirmed by PCR and DNA sequencing. A clonal master iPSC line containing the TRAC-edits was differentiated into T cells (CAR-KLK2 iT cells) and subsequently expanded using a stage-specific protocol.

Results iPSC-derived CAR-KLK2 iT cells expressed a cell-surface profile consistent with a pure population of T lymphocytes; no TCRαβ cell-surface expression was detected, cells showed homogenous expression of CD45/CD7 (>99%), and uniform CAR expression driven by TRAC (>99%). Notably, the complete loss of T-cell receptor expression by genetic knock-out eliminates the potential of graft-versus-host disease in an allogeneic setting. Preclinical *in vitro* analyses of these CAR-KLK2 iT cells demonstrated potent and specific cytotoxicity against multiple prostate cancer cell lines, including VCap cells which naturally express KLK2, PC3 cells engineered to express KLK2, and DU-145 cells engineered to express KLK2. *In vivo*, a multi-dose regimen of CAR-KLK2 iT cells controlled established (>100 mm3) VCap and PC3-KLK2 subcutaneous xenograft models with greater than 90% tumor growth inhibition and associated increased survival. Follow-up dose titration studies demonstrated that a single dose of CAR-KLK2 iT cells was sufficient to mediate approximately 70% tumor growth inhibition.

Conclusions These early preclinical *in vitro* and *in vivo* data suggest that CAR-KLK2 iT cells may have the potential to selectively eliminate prostate cancer cells. Since the behavior of engineered iT cells and additional edits in this novel platform are both currently not predictable, significant additional work is ongoing to generate an appropriate clinical candidate

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0326

327 CLONAL EXPANSION OF CD22 CAR T-CELLS FOLLOWING LENTIVIRAL VECTOR INTEGRATION IN THE PWWP3A GENE

[1]Alka Dwivedi*, [2]Ling Su, [1]Justin Mirazee, [1]Mehdi Benzaoui, [1]Christopher Chien, [1]Nirali Shah, [2]Xiaolin Wu, [1]Naomi Taylor. [1]*National Cancer Institute, Rockville, MD, USA*; [2]*Frederick National Laboratory for Cancer Research, Frederick, MD, USA*

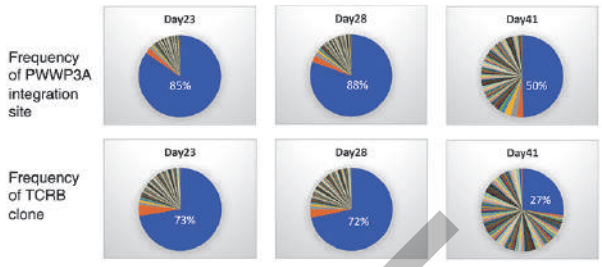
Background A 17-year-old female with multiply relapsed B-cell ALL following CD19 CAR T-cells and blinatumomab was treated with CD22 CAR T-cells (NCT02315612) for marrow and extramedullary disease (EMD). Following development of grade 2 cytokine release syndrome (on day +10) and resolution, she experienced a rapidly rising lymphocyte count at day 21 that was further evaluated.

Methods Following parental permission and minor assent, the patient was treated on a National Cancer Institute IRB approved protocol for a phase 1 trial of CD22 CAR T-cells. To evaluate for clonal expansion, TCR sequencing and integration site analysis were performed by ImmunoSEQ hsTCRB sequencing and a ddPCR assay, respectively. Evaluation of the mutant CAR and the novel endogenous protein generated by integration of the lentiviral vector was performed following their introduction into a lentiviral vector. Functional assays included cytotoxicity analyses, expansion analyses, and high throughput cytokine analyses.

Results The patient experienced full resolution of her clonal expansion and achieved a minimal residual disease negative CR in the bone marrow, with partial response at sites of EMD. TCR sequencing and integration site analyses revealed a single dominant T cell clone with lentivector integration in the PWWP domain-containing DNA repair factor 3A (PWWP3A) gene on chromosome 19 (figure 1) resulting in a fusion transcript, generated by a read-through from the EF-1a-driven CAR transcript. Additionally, a single glycine to serine mutation at position 51 (G51S) of the single chain variable fragment of CD22 CAR was detected. T cells engineered to express the mutant G51S CD22 CAR efficiently killed leukemic cells overexpressing CD22 but exhibited lower cytotoxicity against CD22+ leukemic cells. Furthermore, a high throughput dynamic evaluation of cytokine secretion revealed a significantly reduced secretion of IFN-g, IL-2, IL-10, IL-4, IL-8 and TNF-a of G51S CD22 CAR T-cells in response to CD22 antigen. Notably though, T cells engineered to express the G51S CD22 CAR exhibited an augmented cytokine-driven proliferation as compared to WT CD22 CAR T-cells.

Conclusions This is the second report of clonal expansion in the context of the CD22-CAR trial. Interestingly, in both this case and the previous one (PMID: 31387880), clonal expansion occurred in the setting of extramedullary disease and spontaneously resolved. In this patient, clonal expansion occurred secondary to a G51S CAR mutation and generation of a PWWP3A fusion transcript. The relative impact of these two events in promoting clonal T cell expansion in this CD22 CAR T-cell treated patient will be discussed.

Ethics Approval All human samples were obtained with informed consent and following institutional guidelines under protocols approved by the National Cancer Institute institutional review board and the National Institutes of Health Recombinant DNA Advisory Committee. The subject was also enrolled on an institutional review board-approved genomics protocol, which allowed for additional testing of blood samples. This trial was registered at clinicaltrials.gov as NCT02315612.



Abstract 327 Figure 1 Frequency of T cells wherein the CAR is integrated in the PWWP3A gene and frequency of the TCRB clone post CD22 CAR T-cell infusion.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0327

328 PROMOTING NK SURVIVAL AND FUNCTION WITHIN THE TUMOR MICROENVIRONMENT

Matthew Dysthe*, Ishwar Navin, Corrine Baumgartner, Stephanie Fetzko, Cliona Rooney, Robin Parihar. *Baylor College of Medicine, Houston, TX, USA*

Background The efficacy of CAR-NK cellular therapies in solid tumors is limited by insufficient survival and expansion within the suppressive tumor microenvironment (TME). To augment CAR-NK survival and anti-tumor function, CAR-NK cells are typically administered with exogenous cytokines or other signal modifiers that converge on signal transducer and activator of transcription-5 (STAT5) activation, an essential signaling node for NK survival and function.[1] However, systemic administration of these cytokines or signal modifiers is associated with toxicity,[2] unintended bolstering of TME components,[3] and CAR-NK rejection.[4] Thus, novel strategies to enhance CAR-NK function within the TME are needed. To promote CAR-NK survival and function in the TME while bypassing the need for exogenous signal dependency, we genetically modified GD2-specific CAR-NK cells to express a constitutively active IL-7 receptor complex, termed C7R (C7R.GD2-NK), that intrinsically confers persistent STAT5 activity within NK cells.

Methods To mimic challenges of the TME, we created an *in vitro* TME model by preconditioning $CD14^+$ monocytes with CHLA255 neuroblastoma cells for 72 hours, converting them to an inhibitory M2-TAM phenotype expressing suppressive cytokines and ligands. 4 days after the addition of the C7R.GD2-NK cells to this immunosuppressive milieu, we assessed NK survival, expansion, cytokine secretion, and anti-tumor function.

Results Resting C7R.GD2-NK cells exhibited 3.4-fold (± 0.7; n=4 donors, $p<0.005$) higher phosphorylated STAT5 (pSTAT5) compared to resting GD2-NK cells. C7R.GD2-NK cells alone in long-term culture expanded for 14 days without exogenous cytokine support but not indefinitely. In short-term co-cultures with $GD2^+$ CHLA255 cells, C7R.GD2-NK demonstrated similar IFNγ levels as GD2-NK stimulated with exogenous IL-2 or IL-15 (mean% GD2-NK $IFN\gamma^+$ of 26.1, 21.2, and 22.4, respectively). In the *in vitro* TME model, C7R.GD2-NK cells expanded less than IL-15- or IL-2-stimulated GD2-NK cells (mean fold expansions of 2.8-, 4.5-, and 4.3-fold, respectively) but demonstrated similar anti-tumor activity. Furthermore, cell culture supernatants from C7R.GD2-NK treated conditions exhibited similar levels of NK effector cytokines IFNγ, TNF-α, and GM-CSF to exogenous cytokine-stimulated GD2-NK cells. Ongoing experiments in an *in vivo* TME xenograft model will assess the benefit of C7R in CAR-NK activity.

Conclusions C7R drives STAT5 activity in GD2 CAR-NK cells within TME conditions without the need for exogenous cytokines. The NK-intrinsic STAT5 signal is sufficient to promote NK survival, expansion, and function within the TME, potentially without the side effects of exogenous cytokines or cytokine modulators. Thus, C7R may be a viable alternative therapeutic strategy to augment CAR-NK efficacy in solid tumors.

329 SUPERKINE IL-2 AND IL-33 ARMORED CAR T CELLS RESHAPE THE TUMOR MICROENVIRONMENT TO UNIVERSALLY REDUCE SOLID TUMORS

Shannon Ferry, Rachel Brog, Courtney Shiebout, Cameron Messier, W Cook, Charles Sentman, H Frost, Yina Huang*. *Dartmouth College, Lebanon, NH, USA*

Background CAR T cell efficacy against solid tumors is challenged by key obstacles present within the tumor microenvironment (TME). These include tumor-intrinsic expression of inhibitory ligands that induce T cell exhaustion, the heterogenous expression of tumor antigens that contribute to immune evasion, the absence of essential nutrients required for T cell survival, and the presence of tumor associated immunosuppressive cells.

Methods To increase CAR T cell resistance to immunosuppression and broaden tumor recognition, we armored CAR T cells with a combination of the IL-2 superkine (Super2) and the alarmin IL-33. Super2+33 armored CAR T cells were transferred to mice with established primary or metastatic B16F10 melanoma or intradermal MC38 colon cell carcinoma without preconditioning regimens. Tumor growth, overall survival, and changes to tumor infiltrating leukocytes were assessed.

Results We show that a single dose of CAR T cells armored with Super2 and IL-33 promoted the control of solid tumors in immune competent mice without lymphodepletion or preconditioning regimens. Super2 and IL-33 synergized to expand adoptively transferred CAR T cells and shifted leukocyte proportions in the TME by recruiting and activating a broad repertoire of endogenous innate and adaptive immune cells. Tumors treated with Super2 and IL33 CAR T cells had significantly increased infiltration of endogenous CD8 T cells, including an effector subset with low expression levels of PD-1 and TIM-3. Super2 and IL33 synergy also resulted in reduced proportion of regulatory T cells and a phenotypic switch from M2-like to M1-like macrophages that expressed increased MHC class II. However, depletion of endogenous CD8 T cells or NK cells did not disrupt tumor control, suggesting that broad immune activation compensates for loss of individual subsets. Additionally, IFNg, perforin, and CAR expression by transferred T cells were dispensable for the observed therapeutic effect of Super2 and IL33 expressing T cells, underscoring the contribution of endogenous immune cells in mediating tumor control.

Conclusions Super2 and IL-33 CAR T cells promoted antitumor immunity in multiple solid tumor models and was impervious to antigen loss, highlighting its potential as a universal CAR T cell platform for treatment of solid tumors. CAR T cells harnessing Super2 and IL33 synergy represent a novel strategy for improving the efficacy of CAR T cells in solid tumors by promoting the activation of endogenous immune cells.

330 REDIRECTING GLUCOSE USAGE DURING IN VITRO EXPANSION IMPROVES THE IN VIVO PERSISTENCE AND FUNCTION OF ADOPTIVE T CELL THERAPIES FOR CANCER

[1]Andrew Frisch*, [2]Yiyang Wang, [1]Yupeng Wang, [3]Konstantinos Lontos, [1]Greg Delgoffe. *[1]University of Pittsburgh, Pittsburgh, PA, USA; [2]Tsinghua University, Beijing, China; [3]The University of Texas MD Anderson Cancer Center, Houston, TX, USA*

Background While adoptive T cell therapies have shown impressive results in cancer therapy, persistence of cells remains a key feature of therapeutic efficacy. In all forms of cellular therapies, large numbers of cells are transferred to the patient, yet comparatively few can be detected within the body. We hypothesize this lack of survival and persistence is in part due to the hypermetabolic conditions, especially hyperglycemia, used to generate large numbers of T cells in vitro. Within this study, we aim to preserve a more in vivo-like metabolic state during T cell expansion so that upon transfer they may more easily re-enter the immune system and persist as a living drug.

Methods T cells were activated in culture with cognate peptide or *in vivo* with cognate antigen. The pyruvate dehydrogenase kinase (PDHK1) inhibitor dichloroacetate (DCA) was used to redirect glucose flux in vitro. Mouse tumor experiments were performed with gp100-specific pmel-1 TCR-Tg T cells transferred into B16-F10 -bearing mice. Mouse co-transfer experiments were performed with pmel-1 T cells on a congenically mismatched background. Human CAR-T experiments were performed using anti-hCD19 CAR-T cells transferred into immunodeficient mice bearing hCD19-A549 lung cancer cells.

Results Identical T cells stimulated in vitro or in vivo do not differ in effector function but differ heavily in their glycolytic metabolism. As direct inhibition of glycolysis severely hinders T cell expansion, the PDHK1 inhibitor DCA redirects glucose away from lactate production into mitochondrial metabolism, maintaining a robust expansion rate. Expansion under DCA improves cytokine production and promotes features of stemness. However, the most striking effect of expansion under DCA is evident after cells are transferred: improved immediate and long term survival of the transferred T cell product. These immediate changes in survival result in striking therapeutic efficacy, including increased tumor clearance, immunologic memory, and long-term cellular persistence in both mouse and human tumor models.

Conclusions We demonstrate that by redirecting glucose into mitochondria using DCA, T cells experience vastly reduced metabolic stress during expansion. This relatively simple energetic shift in vitro drastically improves the immediate survival and engraftment of T cells after infusion, resulting in enhanced anti-tumor efficacy and long-term memory. Our study not only suggests the current manufacturing process for cell therapies, utilizing hypermetabolic media, may hinder their ultimate therapeutic success, but provides potential solutions to bring the promise of cellular therapies to additional patients.

331 A NOVEL SMALL MOLECULE INHIBITOR OF CBL-B SHOWS POTENT ANTITUMOR ACTIVITY IN COMBINATION WITH PMEL-1 ADOPTIVE CELL TRANSFER IN AN AGGRESSIVE MOUSE MELANOMA MODEL

Marilena Gallotta*, Jose Gomez Romo, Serena Ranucci, Austin Tenn-McClellan, Frederick Cohen, Gwenn Hansen, Arthur Sands, Ryan Rountree, Cristiana Guiducci. *Nurix Therapeutics, San Francisco, CA, USA*

Background Adoptive cell transfer (ACT) involving engineered T cells (CAR-T) or autologous tumor-specific lymphocytes (TIL) induces effective antitumor response in advanced cancer patients. However, tumors frequently relapse after an initial response due to suboptimal T-cell activation and expansion within the tumor microenvironment. Moreover, current ACT treatment paradigms require application of high dose bolus infusions of IL-2 which are associated with acute toxicities restricting the use of ACT in the clinic. The E3 ubiquitin ligase Casitas B-lineage lymphoma B (CBL-B) is highly expressed in T cells, where it functions as an intracellular checkpoint that constrains T-cell activation following T cell receptor (TCR) engagement, therefore limiting T cell-mediated antitumor responses.

Methods We have developed two highly potent small molecule inhibitors of CBL-B to increase T-cell antitumor function both *in vitro* (NX-0255) and *in vivo* (NX-1607).

Results We previously reported that addition of NX-0255 during *in vitro* treatment of tumor-specific T cells increases the frequency and absolute numbers of less exhausted CD8+ memory T cells, profoundly improving their functionality and ability to control tumor growth following ACT in tumor-bearing mice. Here, we hypothesized that CBL-B inhibition could reduce the requirement for IL-2 bolus and utilized the Pmel-1 ACT/B16 melanoma tumor model to compare the antitumor effect of post infusion *in vivo* treatments with NX-1607 to high dose IL-2. C57BL/6 mice were implanted with B16-OVA and received Pmel-1 CD8+ T cells activated *in vitro* using anti-CD3 stimulation and NX-0255 combined with IL-2, followed by systemic treatment with either IL-2 (IP, 150000 IU for three days, BID) or oral NX-1607 (30 mg/kg, QD). We found that ACT supported by *in vivo* treatment with NX-1607 increased the antitumor activity of Pmel-1 cells when compared to ACT alone. Importantly, the increased antitumor activity of NX-1607-supported ACT was comparable to IL-2. Spectral cytometry analysis performed at 7 and 14 days after ACT showed that following NX-1607, a larger fraction of circulating Pmel-1 cells had a central-memory phenotype and expressed high levels of Granzyme B. Interestingly, both *in vivo* treatments induced increased 4-1BB/CD137 expression that significantly correlates with antitumor response.

Conclusions These findings demonstrated that oral dosing of NX-1607 in combination with ACT can support the functionality of transferred cells providing a robust antitumor response in the aggressive B16-OVA model. Treatment with NX-1607 induces a more favorable T cell phenotype compared to IL-2 treatment and is well tolerated. The observed antitumor effects of NX-1607 support its potential use in combination with cell-based therapeutics.

332 CRISPR/CAS9-BASED INTEGRATION OF A LARGE AND MODULAR CASSETTE INTO A SAFE HARBOR SITE TO IMPROVE CAR T CELL THERAPY EFFICACY AND SAFETY

Brendan Galvin*, Grace Zheng, Robby Moot, Michelle Nguyen, Michelle Tan, Rene Sit, Lionel Berthoin, David DeTomaso, Sofia Kyriazopoulou Panagiotopoulou, Shan Sabri, Jun Feng, Manching Ku, Anzhi Yao, Andrea Liu, Jennifer McDevitt, Matt Drever, Stephen Santoro, Aaron Cooper, Susie Jun, W Nicholas Haining, Tarjei Mikkelsen. *Arsenal Biosciences, South San Francisco, CA, USA*

Background Chimeric antigen receptor (CAR) T cell therapy has emerged as an important new tool in the treatment of cancers. However, the complexity of the enhancements used is limited by the amount of genetic information that can be integrated into the genome. Our approach utilizes Integrated Circuit T (ICT) cells, which are engineered to include a large DNA cassette that includes: receptor strategies to target multiple tumor antigens; transcriptional modifications that alter cell state; engineered cytokines and chemokines and variations in the CAR binding and signaling domains.

Our first ICT clinical program, AB-1015, is an autologous cell product for the treatment of ovarian cancer. The AB-1015 transgene cassette consists of a logic gate directed against ALPG/P and MSLN and an shRNA-miR module targeting FAS and PTPN2 that enhance potency and confer resistance to the tumor microenvironment. This transgene is delivered into primary T cells via non-viral, site-specific editing into a safe-harbor locus via CRISPR integration of transgenes by electroporation (CITE). CITE has many advantages over viral and other non-viral random integration methods, including more predictable transgene expression and function, reduced risk of unsafe insertional mutagenesis, and efficient integration of large cassettes.

Methods To identify candidate genomic loci for CITE-directed gene insertion we used epigenetic analysis, transcriptional profiling, and high-throughput gene-editing of primary T cells. Loci were further characterized using T cell functional assays. Knock-in efficiency and transgene expression stability in primary human T cells were evaluated for all loci. Lead candidate loci were tested for compatibility with complex T cell programs embodied by our integrated circuits, containing a priming receptor (PrimeR, ALPG/P) that triggers the expression of a CAR (MSLN) in response to a priming antigen. The top insertion site, GS94, was further characterized using in silico and empirical approaches.

Results GS94 was identified as an optimal locus for CITE-directed gene insertion based upon: 1) stable and high PrimeR expression; 2) high and inducible CAR expression; and 3) a superior T cell cytotoxic and cytokine secretion profile. We were unable to identify any off-target events generated by CITE at GS94, including off-target editing, knock-in and translocations, using a suite of molecular assays including iGUIDE, rhAMPseq, deep whole genome sequencing, and anchored-PCR.

Conclusions CITE editing at GS94 is specific and generates highly functional ICT cells. This novel approach to engineering tumor-specific T cells enables the generation of exceptional clinical candidates that both target new cancer types and improve efficacy.

333 **NOVEL PHYTOCHEMICALS-BASED CELL CULTURE MEDIUM MITIGATES NATURAL KILLER (NK) CELLULAR EXHAUSTION AND ENHANCES MATURE SUBPOPULATIONS, LEADING TO HIGHER ANTICANCER CYTOTOXIC ACTIVITY**

Marc Gillig*, Rafet Amoor, Nicholas Ingala, Borom Chean, Rachit Ohri. *Enable Life Sciences LLC, Farmington, CT, USA*

Background The biological significance of the mitigation of NK cell dysfunction (exhaustion and/or anergy and/or senescence) is increased potential for solid tumor infiltration by NK cells, as well as decreased dysfunction of NK cells in the tumor microenvironment.[1,2] Enable-NK, a novel phytochemicals-based culture medium that increases the cytotoxic activity of NK cells, has been previously demonstrated to mitigate cellular exhaustion in the NK cell line KHYG-1, as illustrated by the consistent downregulation of several exhaustion biomarkers (e.g. Tim-3, TIGIT, NKG2A). We evaluated the mitigation of exhaustion in human primary NK cells by culturing them in Enable-NK.

Methods Peripheral Blood Mononuclear Cells (PBMCs) were isolated from fresh buffy coats using density gradient centrifugation, and NK cells were enriched to ~90% purity using magnetic separation. Media conditions used were Enable-NK (DMEM/F12 supplemented with proprietary ingredients) or control (DMEM/F12). Cocultures were set up with K562-GFP target cells, undisturbed for several days using a 24-well G-Rex plate. Propidium iodide (PI) staining was used for cytotoxicity determination, and a panel of 12 antibodies for cellular exhaustion and subpopulation determination using surface biomarkers.

Results Several endpoints illustrate mitigation of cellular exhaustion when NK cells are cultured in Enable-NK media. Cell surface exhaustion markers (e.g. Tim-3, TIGIT, NKG2A) are consistently lower, and cytotoxicity-activating receptors (e.g. NKp46) trend higher with the use of Enable-NK media (figure 1). The CD56dimCD16+CD57+ subpopulation is doubled in Enable-NK monocultures compared to control monocultures (figure 2), and also greatly expanded in cocultures. Finally, increased cytotoxic performance of Enable-NK-cultured NK cells, predicted based on the phenotypic differences and enrichment of the highly cytotoxic subpopulation, was confirmed by assessing the death of target cells in the cocultures by staining with propidium iodide (figure 3). Cytotoxic activity was initially equivalent to the control on Day 1, but it was boosted by over 40% in the Enable-NK group by Day 4 while remaining at the same level in the control group. Greatly enhanced cytotoxic activity was maintained through Day 7.

Conclusions The phenotypic and functional data indicate that cellular exhaustion in NK cells is significantly mitigated by culturing NK cells in the phytochemicals-based Enable-NK medium. By inducing downregulation of several inhibitory cell surface molecules, simultaneously inducing upregulation of cytotoxicity-activating receptors, and expanding cytotoxic subpopulations such as CD56dimCD16+CD57+, Enable-NK-cultured NK cells are better equipped to kill cancer cells.

334 FUNCTIONAL VALIDATION OF SINGLE DOMAIN ANTIBODY-DERIVED CD33 SPECIFIC CAR-T CELLS FOR THE TREATMENT OF ACUTE MYELOID LEUKEMIA

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0334

Brikena Gjeci*, Salar Khan, Julian Scherer, Tirtha Chakraborty. *Vor Biopharma, Cambridge, MA, USA*

Background Acute myeloid leukemia (AML) is an aggressive bone marrow malignancy with relapse rates >50% in treatment-responsive patients.[1] One promising new class of AML treatment is chimeric antigen receptor (CAR) T cell therapy, which has demonstrated success for certain leukemias, lymphomas, and myelomas. Conventional CAR-T cells are generated using single-chain variable fragments (scFv) derived from two domains (V_L and V_H) of monoclonal murine antibodies, potentially leading to misfolding and anti-CAR immunogenicity. In contrast, camelid-derived single domain antibodies (sdAbs) have high thermal stability and refolding capacity due to their reduced size. Single domain antibodies can access novel epitopes and exhibit reduced immunogenic potential,[2] suggesting their suitability as binders in CARs. Focusing on CARs targeting the AML-relevant antigen CD33, we here validate novel sdAb-derived CARs (sdCD33CAR) in a semi-automated multi-step process including cell-cell avidity and compare them to traditional scFv-derived CARs.

Methods A phage-display library containing ~10^{11} vicuña sdAbs was panned against soluble and cell-associated CD33 to identify distinct sdAb binders by ELISA and FACS. Ten binders were selected, expressed as soluble human Fc tagged molecules, and screened for affinity by Octet. Five binders were used for sdCARs with 4-1BB costimulatory domains. Lentiviral vector (LVV) was generated with a liquid handler to express CARs in an IL-2 Reporter System (CAR-IRS cells). CAR-IRS cells enable functional CAR validation by activation-dependent induction of a fluorescent reporter. CAR-IRS activation was assessed by flow cytometry or continuous IncuCyte live cell imaging. CAR-IRS cells were also tested for cell-cell avidity against CD33-expressing target cells using the Z-Movi platform.

Results Octet analysis of sdAbs indicated affinity values (K_D range 2-13 nM) and binding kinetics favorable for CAR development. In the CAR-IRS assay, sdCD33CARs exhibited higher surface expression (up to 3-fold) and normalized activity (up to 70-fold) compared to scFv-based CD33CARs. Fluorescent reporter results were supported by CD69 staining (up to 15-fold increase). CAR-IRS flow cytometry was validated by IncuCyte imaging. Z-Movi analysis showed comparable avidity between the sdAb and scFv CARs, suggesting that sdCD33CARs represent a promising therapeutic approach.

Conclusions We have undertaken extensive *in vitro* validation of sdCD33CARs in an objective CAR-IRS background. Automated liquid handling allows for high-throughput LVV transduction to generate CAR-IRS cells, which enables reliable, fast, and economical comparisons across CAR constructs. We have identified one sdCD33CAR construct, which out-performs the traditional scFv-derived CD33CARs in our initial *in vitro* screens. These results provide promising *in vivo* screening candidates for future CAR-T cell therapies against AML.

335 ANALYSES OF SEVERE IMMUNE-MEDIATED TOXICITY IN PATIENTS WITH ADVANCED MCRPC TREATED WITH A PSMA-TARGETED ARMORED CAR T-CELLS

[1]Whitney Gladney*, [1]Adina Vultur, [2]Michael Schweizer, [3]Joseph Fraietta, [3]Andrew Rech, [3]Carl June, [1]Matthew O'Rourke, [1]Amy Roberts, [1]Hinel Patel, [1]Jamie Rosen, [1]Pam Hufner, [1]Yanping Luo, [1]David Barrett, [1]Thomas Fountaine, [1]Karen Chagin. *[1]Tmunity Therapeutics, Philadelphia, PA, USA; [2]University of Washington, Seattle, WA, USA; [3]University of Pennsylvania, Philadelphia, PA, USA*

Background We previously reported preliminary safety and efficacy results from a multi-center Phase 1 trial of CART-PSMA-TGFβRDN T-cells (TmPSMA-01; NCT04227275) in patients (pts) with metastatic castration resistant prostate cancer (mCRPC). Nine pts were dosed with TmPSMA-01 across three doses ranging from $1x10^7$-$3x10^8$ CAR+ cells. Evidence of clinical activity was observed, however, two pts developed severe immune-mediated toxicity and experienced Grade (Gr) 5 events. These pts had no known clinically relevant risk-factors and demonstrated disparate pre- and post-infusion clinical courses. Translational research efforts to evaluate the mechanisms of immune-mediated toxicity to TmPSMA-01 were undertaken. Results are summarized herein.

Methods Pt samples collected per clinical protocol were subjected to correlative analysis platforms. Longitudinal serum and peripheral blood specimens were evaluated for soluble factors by immunoassays and TmPSMA-01 kinetics by molecular techniques, respectively. Biomarker comparisons between patients with Gr5 events and those without were made. As available, pt tissues (tumor and autopsy samples) were evaluated for TmPSMA-01 infiltration by RNA-ISH. Additionally, an *in vitro* model of immune toxicity was applied to evaluate TmPSMA-01 product potency and new CAR candidates.

Results Serum cytokines from all pts showed patterns consistent with an immune-effector response but pts with Gr5 events demonstrated an elevated inflammatory signature with higher levels of IL2, IL6, GM-CSF and IL-18, among others. Peripheral expansion of TmPSMA-01 was observed and kinetics correlated with cytokine response. Autopsy evaluation from one pt with a Gr5 event showed TmPSMA-01 lymph node tumor infiltration but no presence in the sampled brain, despite clinical presentation of immune effector cell associated neurotoxicity. Finally, *in vitro* modeling of immune-toxicity demonstrated higher cytokine levels in TmPSMA-01 cell products from Gr5 pts. Using the same assay, substituting CD2 for 41BB showed a reduction in cytokine levels without impacting efficacy.

Conclusions Correlative studies from pts who demonstrated severe immune-mediated toxicity following TmPSMA-01 revealed trends toward patient-intrinsic hyperinflammation. Biomarker findings suggest a contribution of IL-18 to TmPSMA-01-associated cytokine response which can be further explored for toxicity management. Moreover, we found no evidence of on-target, off-tumor involvement in the examined tissues. While a clear mechanism explaining the excessive immune-mediated response in 2 pts following TmPSMA-01 is not fully elucidated, our preclinical data demonstrate potential risk mitigation by replacing the 41BB co-stimulatory domain with CD2. Knowledge gained from these studies supported the development of a next-generation PSMA-targeting CAR, TmPSMA-02, to improve safety while maintaining anti-tumor activity and will be explored in a multi-center, Ph1/2 trial for pts with mCRPC.

Ethics Approval Patients were enrolled on a WCG Institutional Review Board (IRB) approved protocol, IRB#20191909, titled "A Phase 1 Open-Label, Multi-Center Study of PSMA Targeted Genetically Modified Chimeric Antigen Receptor T Cells in Patients with Metastatic Castration Resistant Prostate Cancer." This clinical study was designed and implemented, and the results of the trial reported in accordance with the International Conference on Harmonization (ICH) Harmonized Tripartite Guidelines for Good Clinical Practice with applicable local regulations and international guidances, including the 21 CFR and all ethical principles written in the Declaration of Helsinki. The clinical study protocol and the informed consent form (ICF) were both reviewed and approved by the properly chartered IRBs and Independent Ethics Committee before the study commenced. Patients enrolled in the study underwent the appropriate Screening procedures only after providing the appropriate written consent using the approved ICF for this study.

A NOVEL METHOD FOR EFFICIENT CGMP PRODUCTION OF NATURAL KILLER CELLS FROM CLONAL MASTER INDUCED PLURIPOTENT STEM CELLS FOR NEXT GENERATION, OFF-THE-SHELF CANCER IMMUNOTHERAPY

[1]Davide Bernareggi*, [1]Caryn Gonsalves, [1]Max Schabla, [1]Alejandra Gárate-Carrillo, [1]Mohammad El-Kalay, [2]Dan Kaufman, [1]Robert Hollingsworth, [1]Huang Zhu. *[1]Shoreline Bioscience, San Diego, CA, USA; [2]University of California-San Diego, La Jolla, CA, USA*

Background Natural killer (NK) cells are innate immune cells that play a key role in in tumor immune surveillance. Recent advances allow for the derivation of immune cells, including NK cells, from human induced pluripotent stem cells that can be utilized for cancer immunotherapy. High doses of NK cells and multiple doses are both safe and likely necessary for clinical efficacy. Manufacturing large number of NK cells from a clonal master iPSC line provides a promising strategy to enable next generation, off-the-shelf, cancer immunotherapies.

Methods We have developed a novel process to produce high purity, clinical scale NK cells efficiently and consistently. Briefly, hematopoietic progenitor cells are derived using an improved spin embryoid body (EB) method using defined cytokines including bone morphogenic protein-4 (BMP-4), stem cell factor (SCF), vascular endothelial growth factor (VEGF), fms-like tyrosine kinase 3 (FLT-3) etc. The hematopoietic progenitor cells are subsequently differentiated into mature NK cells using a second set of defined cytokines such as IL-3, IL-7, IL-15, SCF etc.

Results Using this novel method, fully functioning NK cells could be expanded more than 8,000-fold to enable us to produce 1 x 10^{12} NK cells starting from 1 x 10^{6} undifferentiated iPSCs.This cell production scale can supply >200 clinical doses from one cGMP manufacturing campaign. NK cells produced using this method are CD56-positive and display the typical phenotype of NK cell activating receptors including NKG2D, NKp44, NKp46, DNAM-1. Importantly, these NK cells demonstrate better anti-tumor activities and produce higher levels of IFNγ and TNFα compared to peripheral blood-derived NK cells isolated from healthy donors. Moreover, this protocol has been adapted and optimized for clinical scale manufacturing of NK cells from a genetically engineered iPSC cell line bearing a knock-out of *CISH*, a key intracellular checkpoint of NK cell activation.[1] *CISH* KO NK cells produced using this optimized method show significantly better anti-tumor activities against multiple liquid and solid tumor cell lines (figure 1), including K562, Raji (B cell lymphoma), Daudi (B cell lymphoma), SUP-B15 (B cell lymphoma), MOLT-4 (T cell lymphoma), SKOV-3 (ovarian cancer), OVCAR-4 (ovarian cancer), HCC-827 (lung cancer), ZR-75 (breast cancer), and BT-474 (breast cancer), in standard cytotoxicity assays compared with unmodified NK cells.

Conclusions Overall, this novel cell production strategy paves the way for clinical trials using higher doses of iPSC-derived NK cells with increased potency, thus enabling next-generation CAR-NK cell-based immunotherapies.

337 DEVELOPMENT OF POTENT IPSC-DERIVED MACROPHAGES (IMACS) FOR OFF-THE-SHELF CANCER IMMUNOTHERAPY – A NEW CELL TYPE IN THE EVO*CELLS* PLATFORM

[1]Kathrin Haake, [2]Michela Mirenda, [2]Julien Bousquet, [1]Philine Scheinpflug, [2]Michael Esquerré, [1]Audrey Holtzinger, [1]Stefanie Pfaender, [2]Michael Paillasse, [1]Daniel Sommermeyer, [2]Oriane Bombarde, [3]Loïc Ysebaert, [3]Fabien Despas, [1]Matthias Austen, [1]Andreas Scheel, [1]Markus Dangl, [1]Monika Braun, [1]Nadja Wagner*. *[1]Evotec International GmbH, Göttingen, Germany; [2]Evotec France SAS, Toulouse, France; [3]Oncopole (IUCT-O), Toulouse, France*

Background Cellular immunotherapy has transformed the oncology landscape and provided promising treatment options for patients suffering from hematological malignancies in the form of chimeric antigen receptor (CAR)-T therapies, which involve the adoptive transfer of autologous patient-derived ab T cells equipped with a CAR for enhanced tumor cell targeting. However, the manufacturing complexity and logistical hurdles associated with such autologous products have shifted the focus to the development of allogenic therapies including off-the-shelf immune cells derived from induced pluripotent stem cells (iPSCs). Whilst CAR-Ts have been effective in treating a range of different blood cancers, they have demonstrated limited efficacy to date in solid tumors, which represent approximately 90% of all adult human cancers. Recently, CAR-directed autologous macrophages have emerged as a new potential treatment for solid tumors, as they carry many inherent characteristics beneficial for the penetration into and reprogramming of an immunosuppressive tumor microenvironment (TME). We aim to generate genetically modified iPSC-derived macrophages (iMACs) as an innovative, off-the-shelf cell source for cancer immunotherapy.

Methods Using a validated GMP iPSC line as starting material, we have established a proprietary feeder- and cell sorting-free 3D differentiation protocol that enables robust and large-scale production of iMACs. To ensure reproducible high quality and safety of our cells, we perform stringent monitoring of all process stages using flow cytometry, transcriptome analysis (scRNAseq), as well as an array of analytical methods to ensure genetic integrity of the cells. iMACs were polarized towards an M1-like phenotype and compared to blood-derived counterparts in functional assays, including antibody-dependent cellular phagocytosis (ADCP) and cytokine release.

Results Our iMACs exhibited the typical cell morphology and marker expression of fully differentiated macrophages at a homogeneous level. Transcriptome analysis confirmed the complete switch of iPSCs to cells with a macrophage-specific gene profile. The iMACs responded to M1 polarization by inducing expression of classic pro-inflammatory macrophage markers, showed a cytokine profile comparable to blood-derived macrophages and exhibited high phagocytic activity. In combination with clinically well-validated monoclonal antibodies, iMACs could be directed to target tumor cell lines as well as primary patient samples *in vitro*.

Conclusions Using our proprietary EVO*cells* iMAC differentiation process we were able to generate highly pure iMACs that can be polarized to M1-like macrophages with a pro-inflammatory phenotype and a high phagocytic capacity against cancer cell lines and primary tumor samples, indicating their great potential as a cell source for cancer immunotherapies.

338 ANALYSIS OF CHEMOKINE EXPRESSION PROFILE OF NORMAL AND TUMOR TISSUE FOR EFFECTIVE ADOPTIVE CELL THERAPY

[1]Do Yeon Han*, [1,2]Jung Han Seo, [2]Cho Rong Hong, [2]Hyeon Jin Lee, [1]Gyung Yub Gong, [1,2]Hee Jin Lee. [1]*University of Ulsan College of Medicine, Seoul, Republic of Korea*; [2]*NeogenTC Corp, Seoul, Republic of Korea*

Background Adoptive cell therapy (ACT) is transfer of ex vivo expanded immune cells to treat cancers. In solid tumors, ACT is less effective because injected immune cells need to infiltrate to the tissue. To improve the ACT, engineering of chemokine receptors on immune cells has been developed. Since tumors secret different chemokines, it is important to analyze frequently secreted chemokines and modulate their corresponding receptors. We analyzed and compared the chemokine expression in the normal and tumor tissues and proposed useful chemokine receptors for ACT.

Methods RNA sequencing data for tumor and normal tissues were obtained from the TCGA (n=9,807, pan-cancer) and GTEx (n=7,862, normal tissues from whole body). To identify chemokines expressed more in tumor tissues than normal tissues, we compared chemokine expression between TCGA and GTEx data. To identify chemokine receptors which are already expressed in activated T cells, we analyzed gene expression of expanded tumor-infiltrating lymphocytes (TILs) from 14 breast cancer patients.

Results Twenty-nine chemokines were expressed more than twice in tumors than normal tissues in pan-cancer analysis. Total 16 chemokine receptors are matched with these 29 chemokines. We checked expression of corresponding chemokines of 16 chemokine receptors. According to average expression in the normal and tumor tissues, 9 chemokine receptors that covered more than 80% of pan-cancer cases were considered to be useful for engineering of ACT. In RNA sequencing data of the TILs, 3 out of 9 chemokine receptors were highly expressed. About 98.1% of pan-cancer cases showed high expression of chemokines corresponding to these 6 chemokine receptors.

Conclusions Six chemokine receptors (CCR3, CCR4, CCR8, CXCR5, CXCR6, and XCR1) could be useful to modulate for ACT by enhancing cell trafficking.

Ethics Approval This study was approved by the Institutional Review Board of Asan Medical Center, approval number IRB#2015-0438.

339 QUANTITATIVE ASSESSMENT OF CAR-T CELL THERAPY TARGETS USING COMPUTATIONAL PATHOLOGY

Nathalie Harder*, Markus Schick, Pallavi Sontakke, Alma Andoni, Karma DaCosta, Ruppen Nalbandian, Philipp Wortmann, Ansh Kapil, Gordon Moody, Maria Letizia Giardino Torchia, Martin Philip Lloyd, Nicholas Durham, Eric Tu. *AstrZeneca, Munich, Germany*

Background CAR-T cell-based therapies have improved the treatment of some advanced lymphomas and leukemias. While loss of CAR-T target expression is an established resistance mechanism, a large fraction of target-negative patients responded well to CAR-T cell therapy in early phase clinical trials revealing the urgent need for precise quantification of cell therapy targets as biomarkers. Typically, biomarkers are assessed by standard pathologist scoring of immunohistochemically stained tissue. However, this process is subjective, semi-quantitative and does not assess expression heterogeneity.

Methods To tackle this challenge, we used an automatic image analysis approach for Quantitative Continuous Scoring (QCS) of GPC3 and TGF-b expression in Hepatocellular carcinoma (HCC) patient-derived xenograft (PDX) samples. Our approach is based on supervised Deep Learning (DL) to precisely quantify GPC3 membrane expression and TGF-b membrane and cytoplasmic expression in tumor epithelium on digitized IHC whole slide images (WSI).[1] QCS consists of two supervised DL models which (1) identify epithelium versus non-epithelium regions and (2) segment tumor cells into cell nucleus, cytoplasm, and membrane compartments (figure 1). Based on this segmentation, GPC3 and TGF-b expression is computed as the mean optical density (OD) as a measure of brown staining intensity for each subcellular compartment. All WSIs used in this study have been scored by pathologists for validation.

Results We validated our approach on a set of 23 WSIs by correlating the automatically computed mean GPC3 expression on membranes with pathologist's H-scores (Pearson correlation 0.93, 95% CI [0.85, 0.97]), as well as the computed TGF-b percentage positive cells (based on mean OD on membrane and cytoplasm, OD threshold=25) with the pathologist scoring of TGF-b percentage positive cells (Pearson correlation 0.95, 95% CI [0.89, 0.98]). Our automatic scoring provides continuous measurements of expression levels which allows us to reproduce the pathologist scoring, and provides additional resolution and enables analysis of expression heterogeneity.

Conclusions We adjusted QCS to precisely quantify GPC3 and TGF-b expression in HCC PDX samples and validated our approach based on pathologist´s scoring and our automatic GPC3 scoring enables detailed and precise studies of CAR-T cell targets.

340 THE EPI-R™ TECHNOLOGY PRODUCES A POLYCLONAL TIL PRODUCT (LYL845) WITH DIVERSE TUMOR-REACTIVE CLONES THAT HAVE STEM-LIKE QUALITIES AND ANTI-TUMOR FUNCTION

Benjamin Harris*, Yogin Patel, Ngoc-Han Ha, Lora Zhao, Sheila Lou, Stefan Siebert, Emily Fu-Sum, Rigel Kishton, Purnima Sundar, Suman Kumar Vodnala, Shobha Potluri. *Lyell Immunopharma, South San Francisco, CA, USA*

Background Adoptive cell therapy using tumor-infiltrating lymphocytes (TIL) is a promising method for cancer treatment. Unlike other cell therapies that engineer the tumor-targeting receptor into the T cells, TIL therapy preserves and expands tumor-reactive T-cell clones from surgically resected tumors. TIL products that are highly enriched with tumor-reactive T-cell clones have been shown to mediate responses to treatment.[1-3] Additionally, stem-like qualities of T cells have been associated with improved outcomes in patients treated with cellular therapies, including TIL.[4] Therefore, a polyclonal TIL product containing diverse, potent tumor-targeting clones with stem-like qualities is vital for improving clinical outcomes in TIL therapy. LYL845 is an autologous TIL product produced with our proprietary Epi-RÔ epigenetic reprogramming protocol, which was developed to preserve polyclonality and tumor-reactive clones with enhanced stem-like qualities and anti-tumor function.

Methods LYL845 was generated using Epi-R technology and compared with TIL product generated by a standard protocol (as control). To identify tumor-reactive clones, we primarily rely on surrogate measures of clonal frequency and clonal phenotype,[5-7] but also used tumor co-culture assays to directly measure tumor-reactivity. Using bulk TCR sequencing and CITE-seq + scTCR-seq, LYL845 was assessed for retainment of tumor-reactive clones.

Results We observed that both the research and large-scale TIL products expanded from multiple tumor types (melanoma, lung, colon) using Epi-R technology were highly polyclonal. Furthermore, putative tumor-reactive clones identified from initial tumor samples were preserved in LYL845, both at research (n=13) and large-scale (n=3). Using tumor co-culture assays, we confirmed that our approach for identifying putative-tumor reactive clones is a good surrogate for true tumor reactivity. The cells from putative tumor-reactive clones (and true tumor-reactive clones defined from co-culture assays) in LYL845 demonstrate more stem-like and effector function and less exhaustion than the putative tumor-reactive clones in the control products. In tumor co-culture assays, LYL845 demonstrates potent antitumor function, including dose-dependent cytolytic activities and cytokine secretion (figure 1).

Conclusions Pre-clinical data show that LYL845 is an expanded TIL product that preserves tumor-reactive clones with stem-like qualities. Based on these promising preclinical data, we plan to evaluate LYL845 for safety, tolerability, and anti-tumor activity in an upcoming first-in-human Phase 1 clinical trial.

NOVEL IMMUNE RECONSTITUTION MODEL HIGHLIGHTS THE IMPORTANCE OF STEALTH STRATEGIES THAT POTENTIATE EFFECTOR CELL FUNCTION AND PROMOTE FUNCTIONAL PERSISTENCE OF NEXT-GENERATION ADOPTIVE CELL THERAPIES

[1]Ken Hayama*, [1]Alan Williams*, [1]Yijia Pan, [1]Brian Groff, [1]Rina Mbofung, [1]Lauren Fong, [1]Nicholas Brookhouser, [1]Ramzey Abujarour, [1]Tom Lee, [1]Peter Szabo, [1]Lilly Wong, [2]Maksim Mamonkin, [3]Karl-Johan Malmberg, [1]Ryan Bjordahl, [1]Jode Goodridge, [1]Bob Valamehr. *[1]Fate Therapeutics, San Diego, CA, USA; [2]Baylor College of Medicine, Houston, TX, USA; [3]University of Oslo, Oslo, Norway*

Background Cyclophosphamide and Fludarabine (Cy/Flu)-based lymphodepletion conditioning (LDC) regimens are recognized as critical steps toward creating greater access to homeostatic cytokines and immune system modulation favorable for adoptively transferred, cell-based cancer therapy. However, protracted LDC has been associated with poor immune reconstitution and increased susceptibility to opportunistic infections. Therefore, the next-generation of cancer cell therapies should prioritize reducing the requirement for LDC regimens. Using a novel immune reconstitution in vitro assay, we provide promising evidence for unique stealth strategies designed to potentiate effector cell function without the need for Cy/Flu-based LDC; including, (1) engineering an alloimmune defense receptor (ADR)[1] which targets 4-1BB expressed on alloreactive immune cells and provides a CD3ζ signaling boost to potentiate ADR-edited iPSC-derived NK (iNK) and T (iT) cells; (2) knockout of two costimulatory ligands to prevent immunological synapse formation; and (3) a combinatorial therapeutic strategy including CD38-null iNK and iT cells with the addition of anti-CD38 monoclonal antibody (mAb) to deplete alloreactive effector cells.

Methods By adjusting the dosage and temporal administration of Cy/Flu *in vitro*, we established a novel lymphodepletion model with a range of phosphoramide mustard (the active metabolite of cyclophosphamide) and fludarabine-treated PBMCs to mimic the kinetics alloreactive immune depletion and reconstitution post-Cy/Flu LDC. Using high-resolution and mixed lineage- and source-detection flow cytometry panels, different sources and compartments of input cells were analyzed for persistence and activity.

Results Using our reconstitution model, preliminary data show that ADR potentiates iNK cells and extends functional persistence by selective targeting of 4-1BB-positive control or Cy/Flu-treated alloreactive immune cells. Double knockout of costimulatory ligands or supplementing PBMC and iNK cell cocultures with anti-CD38 mAb protected costimulatory ligands-null and CD38-null iNK cells, respectively, and extended functional persistence by stagnating proliferation of alloreactive immune cells. Furthermore, we highlight translational data depicting the addition of anti-CD38 mAb to an LDC regimen further delays immune reconstitution in patients and may provide a prolonged window for therapeutic efficacy.

Conclusions Collectively, the data demonstrate that unique stealth strategies that potentiate effector cell function and promote functional persistence have the potential to eliminate the need for Cy/Flu mediated LDC. Notably, arming iNK cells with ADR extends functional persistence in the presence of an intact endogenous immune compartment. As exhibited by the immune reconstitution model, we show the first evidence of promising stealth strategies for allogeneic cell therapies that reduce or overcome the requirement of LDC while maintaining robust cytotoxic tumor responses.

KRAS G12V T CELL RECEPTOR-ENGINEERED T CELLS EXPRESSING THE DURABILITY FAS-41BB SWITCH RECEPTOR EXHIBIT A POTENT, PERSISTENT, COORDINATED CD4/CD8 ANTI-TUMOR RESPONSE *IN VITRO* AND *IN VIVO*

[1]Xingyue He, [1]Michelle Hoffmann, [1]Jinsheng Liang, [1]Hongjing Qu, [1]Allison Drain, [1]Hubert Lam, [2]Shannon Oda, [3]Thomas Schmitt, [3]Aude Chapuis, [3]Philip Greenberg, [1]Gary Shapiro*, [1]Loic Vincent. *[1]Affini-T Therapeutics, Watertown, MA, USA; [2]Seattle Children's Medical Research Institute, Seattle, WA, USA; [3]Fred Hutchinson Cancer Research Center, Seattle, WA, USA*

Background Adoptive cell therapy with genetically modified T cells has shown promising efficacy in solid tumors but has been limited by immunosuppressive mechanisms that interfere with sustained activity including FAS ligand-induced apoptosis of tumor-infiltrating, FAS receptor-positive lymphocytes.[1] As previously reported, T Cell Receptor (TCR)-engineered T cells expressing a FAS-41BB switch receptor, consisting of FAS extracellular and 41BB intracellular domains, demonstrated improved anti-tumor efficacy.[2] KRAS is a frequently mutated oncogene in cancers[3] and recent clinical evidence suggests that it is immunogenic and targetable via TCR-engineered T cells.[4] Targeting a mutated oncogenic driver such as KRAS G12V offers many advantages, including tumor dependence driving homogenous expression and decreasing risk of therapeutic escape. We are now reporting an optimized construct that achieves high functional co-expression of the KRAS TCR, CD8ab, and FAS-41BB switch receptor in a single viral vector.

Methods Human T cells isolated from healthy volunteers were lentivirally transduced with constructs encoding the KRAS TCR, CD8ab chains, and FAS-41BB. Preclinical studies included peptide titrations with the index peptide and ones in which one residue was individually substituted to all possible amino acids (XScan), co-cultures with tumors or B-LCL, and in vivo subcutaneous xenografts.

Results Co-expression of CD8ab with the KRAS G12V-specific TCR allowed for efficient stimulation of $CD4^+$ T cells, and further engineering with the FAS-41BB switch receptor increased sensitivity to low peptide concentrations. In tumor co-culture assays, the inclusion of FAS-41BB allowed for tumor control, even after re-challenge with fresh addition of tumor cells. In a repetitive T cell transfer/tumor exposure assay, continued proliferation and tumor control required both expression of FAS-41BB and inclusion of engineered CD4 and CD8 T cells, suggesting that CD8ab exogenous expression in CD4 T cells allowed for a coordinated T cell response able to resist exhaustion. Intravenous administration of engineered T cells prevented tumor outgrowth *in vivo*. Using the XScan assay, no off-target liabilities were identified upon co-incubation of A11-KRAS G12V/CD8ab/FAS-41BB switch receptor engineered T cells with all possible peptides in the human proteome matching the recognition motif, demonstrating the specificity of our TCR. No alloreactivity to the most prevalent HLA alleles was detected in B-LCL co-cultures.

Conclusions Preclinical development of the KRAS G12V-specific TCR with co-expression of CD8ab and the durability FAS-41BB switch receptor supports the clinical development of this first-in-class product for solid tumor patients with high unmet medical needs.

343 IDENTIFICATION OF TUMOR-REACTIVE T CELLS TARGETING MELANOMA DARK ANTIGENS™ VALIDATES THIS NOVEL CLASS OF TARGETS FOR DEVELOPMENT OF IMMUNOTHERAPIES

[1]Rachel Abbott*, [2]Tom Hofland, [3]Thomas Hulen, [4]Elizabeth (Els) Verdegaal, [5]Michael Crowther, [1]Joseph Dukes, [3]Shawez Khan, [4]Pita de Kok, [1]Giulia Masi, [3]Özcan Met, [3]Aimilia Schina, [1]Hayden Selvadurai, [4]Marten Visser, [1]Katarzyna Ward, [1]Rachel Abbott, [4]Sjoerd van der Burg, [2]George Kassiotis, [3]Inge Svane. *[1]Enara Bio Ltd, Oxford, UK*; *[2]The Francis Crick Institute, London, UK*; *[3]Center for Cancer Immune Therapy, Herlev, Denmark*; *[4]Leiden University Medical Centre, Leiden, Netherlands*; *[5]National Center for Cancer Immune Therapy, Herlev, Denmark*

Background Better solid tumor targets are needed to help realise the potential for TCR-directed immunotherapy. Dark Antigens™, encoded by regions of the genome previously thought to be non-coding, are promising targets for immunotherapy due to their cancer-specific expression and broad patient coverage.

Using our EDAPT™ (Enara Dark Antigen Platform Technology) platform, we have previously identified a number of melanoma-specific antigens, demonstrated their presentation on Class I HLA molecules of primary tumors using mass spectrometry-based immunopeptidomics data, validated their cancer-specificity and demonstrated homogenous tumor expression using RNA-Scope.[1-2]

We sought to demonstrate that antigen-reactive T cells can be found in both the periphery of healthy donors and melanoma patient tumor material, and to further characterize these T cell responses.

Methods Tumor-infiltrating lymphocytes (TILs) expanded from twenty-one melanoma patients were screened by IFNγ ELISpot for reactivity against peptides from four different melanoma-specific antigens.

Healthy donor PBMCs were assessed for the presence of antigen-specific T cells using peptide-HLA tetramers, either directly *ex vivo* or following a period of peptide-specific stimulation and expansion.

T cell receptors (TCR) sequences were obtained from antigen-reactive isolated T cells using either iRepertoire or 10x Genomics, and are being screened for function against patient-derived tumor lines with endogenous expression of the cognate antigen.

Results We have shown that TILs expanded from two melanoma patients are reactive to a common epitope within EVA003, a melanoma-specific antigen. The autologous tumor lines derived from both patients were shown to be EVA003-positive.

Furthermore, we have identified T cells specific for two melanoma-specific antigens, EVA001 and EVA003, from PBMCs of several healthy donors.

TCRs have been sequenced, for further functional characterization, from T cells reactive to HLA-A3 and HLA-B7-restricted peptides from EVA003 and to an HLA-A2-restricted peptide from EVA001.

Conclusions We have identified T cells that are reactive against epitopes derived from melanoma-specific antigens in both patient TILs and peripheral blood of healthy subjects, supporting their relevance as cancer-specific antigens. TCRs isolated from these T cells are currently being assessed for reactivity against antigen-positive patient-derived melanoma tumor lines. This work highlights the promise of Dark Antigens™ as a novel class of targets for the development of targeted immunotherapies such as cancer vaccines, TCR-T cell and bi-specific T cell engager therapies, and our EDAPT™ platform is now being employed to identify Dark Antigen™ targets in a range of other tumor types.

344 COMPARATIVE ASSESSMENT OF PRODUCT QUALITY ATTRIBUTES ASSOCIATED WITH PRODUCTION OF CHIMERIC ANTIGEN RECEPTOR T CELLS EXPRESSING SCFV CD-19 AND SCFV IL-13RA2 BY TWO MANUFACTURING PLATFORMS

Sujin Hwang*, Heba Degheidy, Mondona McCann, Steven Bauer, Raj Puri, Bharat Joshi.
Food and Drug Administration, Silver Spring, MD, USA

Background The recent advances in adoptive immunotherapy of cancer have led to the FDA approval of chimeric antigen receptor modified T (CAR-T) cells targeting CD19 antigen on advanced hematological malignancies, which has resulted in dramatic responses in large numbers of patients. Because of several challenges and complexities in manufacturing for characterizing CAR-T cell products, it is important to optimize their manufacturing and critical quality attributes (CQAs). Herein, we performed a comparative assessment of scFv-CD-19-CAR-T and IL-13Ra2-CAR-T cells and manufactured using conventional and G-REX platforms.

Methods We manufactured lentiviral vectors (LVV) by employing common molecular biology techniques using HEK 293T as a producer cell line, transfected with scFVIL-13Ra2 or CD19 transgene plasmids along with three helper plasmids. The LVVs were used for transducing PBMCs from normal human blood donors after their activation and were expanded in T cell growth medium supplemented with cytokines including IL-2 or IL-2 + IL-15, IL-7 + IL-15 for specified durations. A battery of activation and exhaustion phenotype markers was studied at the end of expansion along with their potency to lyse the target cells and secrete Interferon-gamma in a co-culture assay.

Results Our results showed that the T cell activation was efficient by commercially available reagents such as anti-CD3/CD28 coated magnetic beads or nanoparticles and transduction either by retronection or Vectofusin. The CAR-T cell yields were at least two logs higher in the G-REX platform. Analysis of phenotype markers for T cells (CD3, CD4, CD8), T cell activation (CD25, CD45, CD69)/exhaustion markers (PD-1, LAG-3, TIM-3) and Central memory T cells, {CD45RA low, CD62L (CCR7 high} revealed better health and yield of CAR-T cell products manufactured in G-REX platform.

Conclusions We conclude that G-REX platform was superior to conventional methods for manufacturing both types of CAR-T cells. The data also suggest that better activation and transduction by specific reagents and expansion in combination with selected cytokines are key issues associated in manufacturing healthy and potent CAR-T cell products.

Acknowledgements We thank Pamela Leland, former lab member in the Center for Biologics Evaluation and Research, FDA, Silver Spring, for her performance of the experiment.

345 CRS ASSESSMENT POST FAST-TRACK – CAR T CELLS APPLICATION IN NSG-SGM3 MOUSE MODEL

Arezoo Jamali*, Naphang Ho, Angela Braun, Elham Adabi, Frederic Thalheimer, Christian Buchholz. *Paul Ehrlich Institut, Langen (Hessen), Germany*

Background CRS (Cytokine Release Syndrome) is considered as a recurrent side effect of CAR (Chimeric Antigen Receptor) T cell therapy. An experimental animal model for better investigating different aspects of CRS is still in demand. Besides CAR T cells` astonishing achievements, numerous efforts are determined on manufacturing hindrance, notably shortening production procedures. Here, we introduce a novel CRS mouse model employing the NSG-SGM3 strain to address adverse effects of FT- CAR T cells (Fast-Track CAR T).

Methods CD19-specific FT- CAR T cells were produced from 48 hours activated human PBMC plus 24h incubation with lentiviral vectors (LV). Cytotoxic activity of FT- CAR T cells was determined against Nalm-6 cells +/- same donor-derived monocyte supplementation allowed *in vitro* CRS assessment. Next, to launch a CRS mouse model, FT-CAR T cells were administered into NSG-SGM3 mice engrafted with Nalm-6 cells. Mice received $1x10^7$ FT-CAR or activated T cells intravenously. Health condition assessment and body index calculation were regularly monitored using weight, and body temperature measurements. Human cytokines in plasma were determined by the LEGENDplex kit.

Results Flow cytometric analysis revealed that the majority of FT-CAR T cells were positive for the VSV-glycoprotein. Upon reactivation and further cultivation, 65% of all T cells converted into CAR-positive T cells by day 6. The FT-CAR T cells indicated significant cytotoxic activity against tumor cells compared to T cell control, without any contraction in presence of monocytes. The co-culture supernatant displayed significantly elevated amounts of pro-inflammatory cytokines, including IL-6, INF-γ, TNF-α, and IL-10. Next, we appointed the NSG-SGM3 mice to refine FT-CAR T cell competence in CRS induction. While all control mice were in good condition, detrimental side effects came up rapidly within 24h for all FT-CAR T-treated mice. Tremendous temperature change over 2°C and more than 10% weight loss led to termination of this group. Highly elevated cytokine levels were observed, notably enhanced for IFN-γ, TNF-α, IL-2, IL-10 (all $P<0.0001$), and IL-6 ($P<0.0121$).

Conclusions Our study introduces an appropriate CRS mouse model to substantiate the acute side effects of FT-CAR T cells. The key feature of this model is innate myeloid cells releasing cytokines upon interaction with CAR T cells. Our results suggest that FT-CAR T cells carry residual LV components and can induce at least as severe CRS as conventional CAR T cells.

346 ENHANCED ANTI-TUMOR ACTIVITY OF HBSAG SPECIFIC TCR-T (SCG101) IN HEPATITIS B VIRUS (HBV) RELATED HEPATOCELLULAR CARCINOMA (HCC) BY PREVENTING T CELL EXHAUSTION THROUGH PD-1/PD-L1 AXIS BLOCKADE

[1]Pin Xie, [1]Yanzhou Huang, [1]Lu Yang, [1]Karin Wisskirchen, [2]Ulrike Protzer, [1]Ke Zhang, [1]Tao Jin*. *[1]SCG Cell Therapy , Shanghai, China; [2]Technical University of Munich, Munich, Germany*

Background Checkpoint inhibitors as standard of care for hepatocellular carcinoma have limited tumor response, highlighting the importance of the tumor-reactive T cell abundance for effective treatment and the potential synergy with adoptive T cell therapy. SCG101 is a first-in-class, autologous TCR-T encoding a high-avidity TCR directed towards HLA-A*02-restricted HBsAg, with preliminary clinical benefits demonstrated in HBV related HCC patients. Given the profound immune-suppressive microenvironment of HCC, combining TCR-T cell therapy with PD-1/PD-L1 inhibition may have a synergistic effect by TCR-T cells potentially infiltrating immunogenically cold tumors, and checkpoint inhibitors reversing TCR-T cell exhaustion. Herein, we report results from preclinical combination therapy of SCG101 and checkpoint inhibition.

Methods SCG101 $CD4^+$/$CD8^+$ T cells were isolated via magnetic bead enrichment. T cell functionality was performed using Real Time Cellular Analysis (RTCA) and Cytometric Bead Array (CBA). Expression of PD-1 was analyzed on SCG101 cells after co-culturing with $HBsAg^+$ HepG2 cells. For in vitro tumor rechallenge assay, the cytokine secretion and target cell lysis were performed to evaluate the functional impact of combining SCG101 cells and PD-1/PD-L1 inhibitors. In vivo, anti-tumor activities were evaluated in $HBsAg^+$ PD-$L1^+$ HepG2 cell xenograft mice by i.v. infusing pre-exhausted PD-1^+ SCG101 with and without PD-1 (Pembrolizumab) or PD-L1 (Atezolizumab) inhibitors.

Results Both $CD8^+$ and $CD4^+$ SCG101 T cells exert profound anti-tumor activities via target cell lysis and cytokine secretion, while $CD8^+$ SCG101 T cells confer stronger effects. The expression level of PD-1 was significantly and specifically elevated in TCR transduced SCG101 cells co-cultured with either $HBsAg^+$ HepG2 cells or $HBsAg^+$ $PDL1^+$ HepG2 cells, comparing to the HepG2 cell control. The elevation was observed preferably in SCG101 $CD8^+$ T cells. In tumor rechallenge assay, serial antigen stimulation led to dramatic decrease of the cytokine secretion and cytotoxic activity due to PD-1 induced T cell exhaustion, which could be restored by Pembrolizumab (anti-PD-1) or Atezolizumab (anti-PD-L1). This finding was confirmed in $HBsAg^+$ PD-$L1^+$ HepG2 CDX model, where a more prolonged antitumor effect was achieved when pre-exhausted SCG101 were co-administered with anti-PD1 or anti-PD-L1 inhibitors.

Conclusions Continuous antigen exposure under tumor microenvironment results in activation-induced cell death of T cells with hallmark features of exhaustion including reduced proliferation capacity and cytotoxicity, and severe defects in cytokine production. The benefit of PD-1/PD-L1 axis blockade on adoptively transferred T cells was demonstrated in vitro and in vivo xenograft models. Combination studies with PD-1/PD-L1 inhibitors is planned to augment SCG101 functionality and persistence in HBV related HCC patients.

347 DEVELOPMENT OF OPTIMIZED CAR T CELLS FOR THERAPY OF GLIOBLASTOMA

[1]Jonathan Khan*, [1]Winson Cai, [1]Yanhong Yang, [1]Lauren Dong, [1]Kelsey Hopland, [1]Kenny Kwok-Hei Yu, [1]Ruby Freeman, [2]Terence Purdon, [1]Viviane Tabar, [1]Taha Merghoub, [1]Jedd Wolchok, [2]Renier Brentjens. *[1]Memorial Sloan Kettering Cancer Center, Floral Park, NY, USA; [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA*

Background Glioblastoma (GBM) is the most lethal form of primary brain tumor in adults, with a 95% five-year mortality rate. Current therapy consists of surgical resection, chemotherapy, and radiotherapy. However, there remains an urgent need for novel therapies as recent trials have failed to improve overall survival.[1] A new approach to target GBM is the administration of Chimeric Antigen Receptor (CAR) T cells to treat relapsed/refractory disease.[2] To date, multiple clinical trials employing CAR T cells targeting disparate antigens in the context of GBM have been completed; and analysis of data accrued from these trials identified antigen loss and the upregulation of T cell inhibitory pathways to be major limitations of CAR T cell antitumor efficacy.[3,4] Accordingly, we have identified B7-H3 as a potential target antigen for CAR T cell therapy of GBM, and the Programmed Death-1/Programmed Death Ligand-1 (PD-1/PD-L1) axis as an inhibitory pathway suitable for combinatorial immunotherapy with CAR T cell therapy of GBM.

Methods B7-H3 expression on U251, U87, and 4 primary GBM cells lines was evaluated by flow cytometry, while patient tumor samples were analyzed by immunofluorescence. B7-H3 targeting CAR T cells were engineered by transducing primary human T cells with a retroviral vector encoding either a CD28-based CAR, or a CD28-based CAR containing a PD-1 blocking scFv. *In vitro* luciferase-based killing assays, and Luminex-based quantification of cytokine release were used to characterize CAR function. NSG mice were engrafted with U251 GBM cell line and treated with a single peripheral infusion of CAR T cells. Tumors were harvested at various time points following CAR T cell treatment and characterized for T cell infiltrate, T cell phenotype, and expression of checkpoint pathways.

Results We demonstrate that B7-H3 is a suitable antigen for CAR T cell therapy of GBM, and that B7-H3-targeting CAR T cells are able to safely, and efficiently control disease progression in a disease-relevant xenograft model. We also show that GBM tumor cells upregulate PD-L1 in direct response to CAR T cell activity, and that CAR T cells upregulate PD-1 following activation through the CAR. We subsequently demonstrate that concomitant PD-1 blockade augments the antitumor capabilities of B7-H3-targeting CAR T cells through increased T cell engraftment and improved effector function to confer durable, long-term remissions in a disease-relevant preclinical model.

Conclusions These data demonstrate the concomitant PD-1 blockade is safe and efficient method for improving the antitumor capabilities of B7-H3 targeting CAR T cells in the context of GBM.

348 DEFINING T CELL RECOGNITION OF A HIGHLY CONSERVED FUSION NEOANTIGEN IN FIBROLAMELLAR CARCINOMA

[1]Allison Kirk*, [1]Jeremy Crawford, [1]Ching-Heng Chou, [1]Phuong Nguyen, [1]Walid Awad, [1]E Kaitlynn Allen, [2]Xiaoyu Zhang, [3]Anthony Zamora, [1]Christopher DeRenzo, [4]Scott Strome, [1]Paul Thomas. *[1]St. Jude Children's Research Hospital, Memphis, TN, USA; [2]University of Maryland School of Medicine, Baltimore, MD, USA; [3]Medical College of Wisconsin, Milwaukee, WI, USA; [4]University of Tennessee Health Science Center, Memphis, TN, USA*

Background Fibrolamellar carcinoma (FLC) is a rare and fatal liver malignancy that primarily affects otherwise-healthy adolescents and young adults. No curative therapies are currently available, so novel treatments are needed to improve patient outcomes. In 2014, Honeyman et al.[1] identified the key genetic event in FLC tumorigenesis: a recurrent deletion in chromosome 19 that fuses *DNAJB1* to *PRKACA*. The resulting fusion protein, now known to be the essential driver mutation in FLC, is present in all cases and has an identical amino acid sequence in more than 90% of patients. We believe this highly conserved fusion protein is a potentially-ideal neoantigen target for T cell-based immunotherapy, and therefore sought to define fusion-specific T cell responses in FLC patients.

Methods To identify functional T cell responses to the *DNAJB1-PRKACA* fusion, tumor infiltrating lymphocytes (TILs) from an FLC patient tumor were expanded *ex vivo*, then stimulated with fusion peptides predicted to be presented by the patient's class I HLA alleles. We then used single cell gene expression profiling and T cell receptor (TCR) sequencing of patient TILs, and antigen-specific expansion[2] and peptide-HLA tetramer staining of patient peripheral blood T cells, to identify two fusion-specific TCRs. Both TCRs were reconstructed and expressed in cells, and their specificity and functionality were validated *in vitro* using peptide-HLA tetramer staining, intracellular cytokine staining, and killing assays. Finally, using a xenograft model in immunodeficient mice, we tested the ability of these TCRs to control the growth of fusion-expressing tumors *in vivo*.

Results We observed a small but robust T cell response to fusion peptide EIFDRYGEEV among patient TILs, and subsequently identified two TCRs in the patient that recognize this fusion peptide presented on HLA-A*68:02. These TCRs specifically bind their cognate tetramer and mediate both cytokine production and killing of fusion-expressing target cells *in vitro*, while sparing wild-type-expressing controls. Treating mice bearing fusion-expressing tumors with TCR-engineered T cells resulted in transient tumor clearance and significantly extended survival compared to mice treated with vehicle or mock-transduced T cells.

Conclusions We have identified, to our knowledge, the first reported endogenous T cell response to the *DNAJB1-PRKACA* fusion in an FLC patient. Further, we have defined two fusion-specific T cell receptors that hold promise for development in novel cell-based immunotherapies for FLC.

349 HIGHLY POTENT TUMOR-TARGETING OPTIMALLY PRIMED NATURAL KILLER CELLS PRODUCED UNDER A FEEDER-CELL FREE CONDITION IN A 50L-SCALE BIOREACTOR WITH CYTOKINE-FUSION PROTEINS ELICITS ROBUST ANTI-TUMOR RESPONSE IN PRECLINICAL STUDY

[1]Dongwoo Ko, [1]Jae Chan Park*, [1]Min-Kyong Hyon, [1]Young Hyun Park, [1]Gil-Jung Kim, [1]Jong Beom Ku, [1]Iseul Eom, [1]Su Bin Lee, [1]Jeong Mi Yun, [1]Dan Bee Park, [1]Do Yeon Kim, [1]HyeHyeon Jang, [1]Sora Lim, [1]Do Soo Jang, [1]Sung Yoo Cho, [1]Chun Pyo Hong, [2]Myung Ho Jang. *[1]GI Cell, Seongnam-si, Republic of Korea*; *[2]GI Innovation, Seoul, Republic of Korea*

Background The use of allogeneic natural killer (NK) cell as an adoptive immunotherapeutic is a promising strategy for a large pool of cancer patients, ensuring greater time- and cost-efficiency than autologous NK or T cell-based immunotherapies. However, large-scale production of clinical-grade NK cells is challenging with often use of genetically modified feeder cells, and the impairment of cytotoxic function in vivo due to exhaustion or senescence is a significant concern.

Methods We produced highly potent NK cells called Tumor-targeting Optimally Primed NK cell (T.O.P. NK), which are CD3-CD56+ cells directly derived from human PBMCs. These cells are expanded in a 50L bioreactor without feeder cells or genetic modification.

Results The T.O.P. NK demonstrates an increased expression of chemokine receptors, CCR5 and CXCR4, and NK activation markers, such as NKG2D, NKp46, and DNAM-1; the NK inhibitory and exhaustion markers such as CD57, PD-1, and TIM-3 maintained low expression levels after the harvest. The elevated expression of CCR5 and CXCR4 on T.O.P. NK elucidates its active migration in response to CCL5/RANTES and CXCL12/SDF-1 ligands, respectively, with high sensitivity. Furthermore, T.O.P. NK showed robust cytotoxicity in vitro and in vivo against various solid cancer cell lines even after recovery from cryopreservation. We observed strong anti-tumor activity of T.O.P. NK in short-term and long-term in vitro killing assays against solid cancer cell lines, including colorectal, breast, and head and neck cancers. Moreover, T.O.P. NK elicited strong anti-tumor effects in immunodeficient NOG mouse grafted with various human cancer cell lines.

Conclusions Collectively, we report T.O.P. NK, which are generated at clinical grade, with high productivity and purity while maintaining active phenotype and anti-tumor cytotoxicity. These findings suggest that the feeder-free expansion platform of T.O.P. NK proficiently generates allogeneic adoptive NK cells for the treatment of solid cancers.

Ethics Approval The study was approved by EWHA Womans University Medical Center's Ethics Board, approval number SEUMC 2021-04-026

350 HARNESSING ARGININE METABOLISM TO OVERCOME HYPERTHERMIA-INDUCED METABOLIC DYSFUNCTION OF CAR T-CELLS

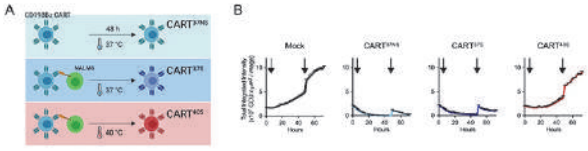
[1]Taisuke Kondo*, [1]Justyn DuSold, [1]Sooraj Achar, [1]Serifat Adebola, [2]Pedro Gonzalez-Menendes, [2]Julie Perrault, [1]Bonnie Yates, [3]Hannah Song, [1]Stephen Fox, [1]Xia Xu, [1]King Chan, [1]Abdalla Abdelmaksoud, [1]Christopher Chien, [1]Marie Pouzolles, [1]Haiying Qin, [3]Steven Highfill, [1]Thorkell Andresson, [1]Nirali Shah, [2]Valérie Dardalhon, [1]Grégoire Altan-Bonnet, [1]Naomi Taylor. *[1]National Cancer Institute, Bethesda, MD, USA; [2]Université de Montpellier, Montpellier, France; [3]National Institutes of Health Clinical Center, Bethesda, MD, USA*

Background Chimeric antigen receptor (CAR) T-cells have shown remarkable success in the treatment of hematological malignancies, but many patients still relapse. One common adverse on-target effect of CAR T-cells is cytokine release syndrome (CRS), due to the triggering of a systemic inflammatory response. Importantly though, the impact of CRS, and especially the fever that is a hallmark of this syndrome, on CAR T-cell function is not known.

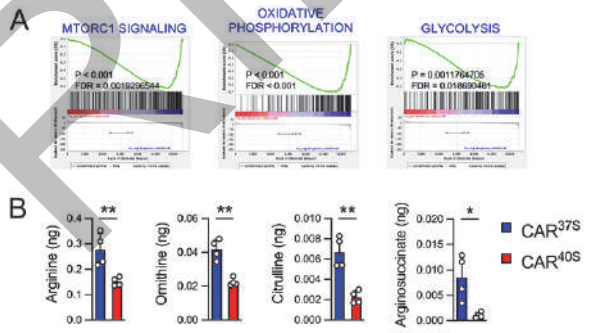
Methods T cells were generated to express an anti-CD19 (FMC63) CAR construct harboring the 4-1BB costimulatory domain. CD19CAR T-cells were exposed to hyperthermia (40°C) and their cytotoxic activity against $CD19^{+}$ NALM6 leukemic cells was evaluated in both *ex-vivo* (Incucyte) and *in-vivo* (NSG mouse) models. Hyperthermia-induced changes in CAR T-cells were evaluated by cytokine secretion profiles, CyTOF, RNASeq, and metabolomic analyses. Arginine supplementation was performed as described.

Results Exposure of CD19CAR T-cells to hyperthermia significantly decreased their subsequent cytotoxicity against $CD19^{+}$ leukemic cells at 37°C, both *ex-vivo* and *in-vivo* (figure 1). This was associated with reduced secretion of IL-2, IFNg, and IL-8 by CD19CAR T-cells and high dimensional analyses revealed the induction of a terminally differentiated $CD25^{Hi}CD39^{Hi}CD44^{Hi}TIM3^{Hi}$ CAR T cell. Mechanistically, gene profiling assays highlighted a negative enrichment of mTORC1, glycolysis, and oxidative phosphorylation gene sets in CAR T-cells subjected to hyperthermia (figure 2A), and these data were confirmed by functional metabolic assays. Furthermore, the metabolome of hyperthermia-exposed CAR T-cells unveiled significant reductions in arginine and urea cycle metabolites (figure 2B). Notably, pharmacological supplementation of arginine markedly enhanced the *ex-vivo* and *in-vivo* cytotoxicity of hyperthermia-exposed CAR T-cells. Moreover, in the absence of hyperthermia, short-term arginine supplementation to CAR T-cells during the expansion process enhanced metabolic fitness, promoting the potential of these CAR T-cells to respond to repetitive *ex-vivo* NALM6 stimulations (E/T=0.1) and enhancing *in-vivo* anti-leukemic activity under stress conditions (figure 3).

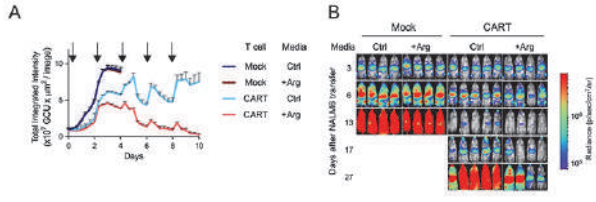
Conclusions Exposure of CAR T-cells to hyperthermia results in a metabolic reprogramming associated with attenuated cytotoxic function and the induction of a terminally differentiated state. We identify arginine metabolism as a critical pathway in CAR T-cells rendered dysfunctional by exposure to hyperthermia. On the basis of these data, we assessed the impact of short-term arginine supplementation on long-term CAR T-cell function, and our data highlight a significantly augmented CAR T persistence and cytotoxicity in stress conditions. Pharmacological arginine support will inform future iterations of CAR T-cell interventions.



Abstract 350 Figure 1 Hyperthermia-exposed CAR T-cells exhibit attenuated anti-leukemic cytotoxicity
(A) Schema of the experimental strategy used to expose CAR T-cells to hyperthermia. Human peripheral T cells were transduced with a CD19-41BB-CAR lentiviral construct and the resulting CAR T-cells were stimulated (S) by co-culture with CD19+ NALM6 leukemic cells (GFP +Luc+) at an effector/target ratio of 1 in physiological (37°C, CART37S) or hyperthermic (40°C, CART40S) conditions. Non-stimulated (NS) CAR T-cells (CART37NS) were maintained at 37°C as a control.
(B) The cytotoxic potential of pre-stimulated CART37S and CART40S was evaluated by Incucyte technology at a 1:1 effector/target ratio at 37 °C and non-transduced (Mock) T cells and non-stimulated CART (CART37NS) were used as positive and negative controls, respectively. NALM6 cells were added at the indicated time points (arrows) and cytotoxicity is presented as a function of GFP intensity over time (n?=?3 technical replicates).



Abstract 350 Figure 2 Hyperthermia-exposed CAR T-cells exhibit a dysregulated metabolic state.
(A) Hyperthermia-exposed CAR T-cells were stimulated with CD19+ NALM6 cells as shown in Fig. 1A and transcriptional changes were evaluated by RNASeq. Gene Set Enrichment Analysis (GSEA) plots of significantly altered metabolic pathways in CART40S relative to CART37S are presented (n = 3 biological replicates).
(B) The metabolomes of CAR T-cells pre-exposed to 37°C (CART37S, blue) and 40°C (CART40S, red) were evaluated by mass spectrometry following a 48h stimulation by NALM6 cells at 37°C as shown in Fig. 1A. The abundance of urea cycle metabolites in CART37S and CART40S are presented (n = 4 biological replicates, statistical difference assessed by a two-tailed unpaired Student's t-test).



Abstract 350 Figure 3 Short-term arginine supplementation enhances CAR T-cell function under stress conditions.
(A) Human peripheral T cells were transduced with CD19-41BB-CAR lentivirus and expanded from days 4-8 in either control media (blue) or in arginine-supplemented media (10mM, red). CD19CAR T-cells were then harvested and ex-vivo cytotoxicity against NALM6 was evaluated

in stress conditions, at a 1:10 effector/target (E: T) ratio in control media. Cytotoxicity was evaluated as a function of GFP intensity and NALM6 cells were added every 48h as indicated (arrows). Non-transduced (Mock) T cells, expanded in control (dark blue) or arginine-supplemented (dark red) conditions, were used as controls.
(B) To evaluate in-vivo cytotoxicity of CD19CAR T-cells under stress conditions, suboptimal numbers of CAR T-cells (0.5x106), prepared as in panel A, were injected into NALM6 (GFP+Luc+)-bearing NSG mice at day 3 following engraftment. Tumor growth was monitored by bioluminescent imaging (BLI) using the Xenogen IVIS Lumina at the indicated time points and data were quantified by radiance (photons/s/cm2/sr).

351 VITAMIN C TREATMENT PREVENTS CAR T CELL EXHAUSTION, MAINTAINS STEM CELL PHENOTYPE AND ENHANCES ANTITUMOR FUNCTION

Leonce Kouakanou*, Hanmin Wang, Grace Sun, Tristan Chan, Jennifer Shepphird, Darya Alizadeh, Christine Brown, Leo Wang. *City of Hope, Duarte, CA, USA*

Background Chimeric antigen receptor (CAR) T cells have emerged as an effective therapy for B cell malignancies. However, major limitations to efficacy are lack of T cell persistence and T cell exhaustion, which result from epigenetic repression. Previous reports demonstrated that epigenetic remodeling can prevent T cell exhaustion and enhance CAR T antitumor activity.[1,2,3]Vitamin C (VC) was previously described to modulate immune cell function through epigenetic modification.[4,5]

Methods Here we sought to determine the effect of VC on CD19-CAR T cell functional differentiation. CD3+ T cells were activated and transduced with lentiviral supernatant in the presence of IL-2, low IL-15, and VC. The effect of VC on T cell differentiation was determined using flow cytometry, and on proliferation by direct cell count. To analyze functional differences between control (without VC) and VC-manufactured CD19-CAR T cells (VC-CD19-CAR T), we used a repeat challenge assay in which CAR T cells were cocultured with tumor cells, with fresh tumor cells reintroduced each week for four weeks in total. CAR T cell expansion, differentiation, and exhaustion were determined using flow cytometry and cell count. Cytotoxicity was assessed by measuring lactate dehydrogenase release. Whole-genome bisulfite sequencing was performed to analyze cell-intrinsic changes in CAR T cell DNA methylation as a result of VC treatment. Xenograft tumor mouse models were used to evaluate the long-term *in vivo* function of VC-CD19-CAR T cells.

Results Our data showed that addition of VC during CD19-CAR T cell production enforces a stem cell memory–like phenotype, characterized by increased expression of $CD45RA^{+}CD62L^{+}$ and $CD27^{+}CD62L^{+}$. VC-CD19-CAR T cells expanded more during manufacturing than controls, and their higher rate of expansion was preserved during the extended *in vitro* challenge. Interestingly, VC-CD19-CAR T cells were better at killing target cells in the first exposure to target cells, and retained their killing ability after subsequent stimulations while control CAR T cells did not. The improved function was mirrored by phenotypic analysis showing that stimulated VC-CD19-CAR T cells retained a stem cell memory–like phenotype with a lower expression of exhaustion markers after the last stimulation compared to control. *In vivo*, VC-CD19-CAR T cells efficiently delayed tumor growth resulting in superior overall survival compared with control.

Conclusions Our studies demonstrate that the addition of VC to CD19-CAR T production increased their expansion and prevented their exhaustion, resulting in enhanced antitumor function. Studies are ongoing to determine whether this occurs via epigenetic reprogramming.

352 **STASH SELECT, A SIMPLE AND ROBUST METHOD OF PURIFYING CELLS ENGINEERED WITH MULTIPLE VECTORS USING A SINGLE SELECTION MARKER**

Louai Labanieh*, Kaithlen Zen Pacheco, Robbie Majzner, Chris Fisher, Elena Sotillo, Peng Xu, Jennifer Cochran, Crystal Mackall. *Stanford University, Stanford, CA, USA*

Background CAR-T cell therapies have demonstrated remarkable clinical benefit in liquid tumors, but significant obstacles such as antigen loss, tumor heterogeneity, T cell exhaustion, and poor persistence limit the frequency and durability of complete responses. To overcome these challenges and expand this class of therapeutics to solid tumors, T cells will need to be multi-specific, resistant to exhaustion, and maintain their fitness in the tumor microenvironment. Engineering NextGen therapies with these enhanced capabilities will require the introduction of additional genetic modules that often do not fit within the payload capacity of a single vector, necessitating the use of multiple vectors. However, engineering cells with multiple vectors results in a heterogeneous cell product that requires purification for each vector, which is not currently possible in the clinical setting. Here, we present STASH Select, a simple method for enriching cells containing multiple genetic modifications using a single selection marker.

Methods Human CAR-T cells were generated from healthy donors and characterized by flow cytometry, ELISA, tumor killing assays, bulk RNAseq, and MACS.

Results The core principle of STASH-Select is the conditional cellular localization of a selectable marker. We integrate a protease cleavage site and an ER-Tag onto the C-terminus of the EGFRt selection marker, which "STASHes" it inside the cell. Co-expression of the cognate TEV protease results in cleavage of the ER Tag, which releases the EGFRt from the ER and allows it to translocate to the cell surface. Encoding the STASHed EGFRt on one vector and the protease on a second vector creates an AND gate system, where only cells transduced with both vectors express high levels of surface EGFRt that can be used as a selection handle for isolating double+ cells. We screened 22 ER retention domains and identified four novel, compact (<45aa) human ER tags that yield high performance STASH-Select systems. We tested the two-vector STASH-select in primary human T cells and were able to enrich an initial double+ population of 12.3% to 96.3% purity via EGFRt MACS. We expanded this approach to a three-vector STASH-Select using Split TEV protease. Configuring the STASHed EGFRt and the two TEV fragments onto three separate vectors produces a 3-vector AND gate which allowed for purification of three clinically relevant cargos with a single-step MACS selection, enriching an initial population of cells from 16.7% to >90% triple+.

Conclusions STASH-Select is a novel selection platform designed to propel NextGen smart therapies containing multiple enhancing modules into the clinic.

353 ARTIFICIAL IMMUNE MODULATION ADOPTIVE CELL THERAPIES FOR VIRALLY DRIVEN MALIGNANCIES

David Langan*, Keshanti Tidwell, Alison Farrell, Selome Mitiku, Catrina Johnson, Pratima Kunwar, Ruipeng Wang, Sojung Kim, Mathias Oelke. *Neximmune, Gaithersburg, MD, USA*

Background NexImmune is developing novel, antigen-specific immunotherapies to meet serious unmet clinical needs. Here we report on the development of adoptive cell therapies (ACT) for virally driven malignancies. The proprietary Artificial Immune Modulation (AIM™) platform mimics natural T cell biology to target, activate and expand antigen-specific $CD8^+$ T cells. EBV, HPV, and HTLV are estimated to contribute to 6-7% of global cancer cases. The targeted antigens are implicated in multiple malignancies including B cell lymphomas (EBV), adult T cell leukemia/lymphoma (HLTV1) as well as multiple HPV related malignancies such as oropharyngeal, cervical, and anal cancers.

Methods Using the paramagnetic AIM nanoparticle as an artificial antigen presenting cell (aAPC), in two-weeks T cells were enriched and expanded from HLA-A*02:01 donor apheresis material against immunodominant antigens of EBV, HTLV, and HPV. The memory phenotype of these cells was determined by CD45RA, CD62L, and CD95 expression. Antigen specific killing was observed on HLA-A2+ cell lines and polyfunctional activity characterized by an intracellular cytokine staining assay.

Results Greater than 90% of the total resulting $CD8^+$ T cells display a phenotype of effector, central, or long-lived stem-like memory. From 8 independent healthy donor clinical scale manufacturing runs of NEXI-003, a pentavalent specific AIM ACT against the E6 and E7 antigens of both HPV-16 and HPV-18, as well as the tumor-associated antigen Survivin, 0.28E9 to 3.79E9 cells were generated. These cells showed dual HPV-16^+ and HPV-18^+ cancer antigen specificity and cytotoxic activity against HLA-$A2^+$ cell lines, without significant cytotoxic activity against autologous PBMCs. With respect to EBV, using HLA-$A2^+$ cell lines we further show antigen specific killing directed at LMP2, BRLF1, BMLF1, EBNA3, and LMP1 from a single healthy donor AIM ACT selected on 6 EBV antigens. In addition, these expanded memory T cells demonstrate a high degree of polyfunctional activity upon stimulation.

Conclusions NEXI-003 is an immunotherapy for HPV cancers in HLA*A02:01 patients that recently received IND clearance and it is anticipated to begin clinical trials in 2022. In addition to B cell lymphomas, B cells that are present in the plaques of multiple sclerosis patients have been found to express EBV antigens. Therefore, by directing a multivalent EBV T cell response there is the potential to treat other EBV-associated diseases using one AIM ACT product. Results reported here, will support the expansion of the AIM platform modalities for use in the treatment of virally driven malignancies, as well as potential virally associated autoimmune and infection diseases.

354 **PULLING THE LEVER ON ALL FRONTS: ICT01, A G9D2 T CELL-ACTIVATING MONOCLONAL ANTIBODY, IN COMBINATION WITH VENETOCLAX AND 5-AZACYTIDINE AS A NOVEL COMBINATION THERAPY FOR AML**

[1]Elisabeth Wieduwild*, [2]Anne-Charlotte Le Floch, [1]Céline Garulli, [1]Sarah Bourass, [2]Caroline Imbert, [1]Paul Frohna, [3]Norbert Vey, [2]Daniel Olive, [1]Aude de Gassart, [1]Loui Madakamutil. [1]*Imcheck Therapeutics SAS, Marseille, FL, France*; [2]*Inserm, Marseille, France*; [3]*Institut Paoli-Calmettes, Marseille, France*

Background Combination of Venetoclax, a BCL-2 inhibitor, and 5-Azacytidine, a hypomethylating agent, is the standard of care for patients with newly diagnosed acute myeloid leukemia (AML) who are not candidates for intensive chemotherapy.[1] In addition to their anti-leukemic activity, 5-Azacytidine was shown to improve cancer cell recognition by immune effector cells through induction of stress ligand expression,[2,3] and Venetoclax was described to enhance T-cell and NK-cell–mediated cytotoxicity against AML blasts [3,4]. Among attractive mediators of anti-tumor immunity, g9d2 T-cells are emerging as effector cells that harbor strong cytolytic and pro-inflammatory activities and are associated with good prognosis in cancer patients.[5,6] ICT01 is a first-in-class anti-BTN3A mAb activating g9d2 T-cells and is being evaluated in a Phase 1/2a clinical study in solid tumors and hematologic malignancies (NCT04243499).[7,8]

Here, we explore the potential of combining ICT01 with Venetoclax and 5-Azacytidine to increase the anti-leukemic activity of g9d2 T-cells.

Methods Flow cytometry was used to assess the effects of Venetoclax and 5-Azacytidine on ICT01-mediated g9d2 T-cell activation after *in vitro* culture of healthy donor (HD) or patient derived PBMCs. AML cell lines' and primary AML blasts' sensitivity to ICT01-activated g9d2 T-cell killing was monitored after 4 or 24 hours of target:effector co-culture. Targets and/or effectors were pre-treated with Venetoclax, 5-Azacytidine or the combination. Expression of specific stress ligands upon treatment with Venetoclax, 5-Azacytidine or the combination was analyzed by flow cytometry.

Results First, we show that activation of g9d2 T-cells by ICT01 is unaltered in HD-PBMCs treated *in vitro* with Venetoclax or 5-Azacytidine, in naïve AML patients' PBMCs or in PBMCs from AML patients under respective treatment. In addition, ICT01-mediated activation of g9d2 T-cells improved resistance to Venetoclax-induced cell death, which is otherwise pronounced in resting g9d2 T-cells. Next, we identified several stress ligands to be upregulated on AML cell lines and primary AML blasts upon treatment with Venetoclax, 5-Azacytidine or the combination. Consequently, pre-treatment of AML (cell lines and primary) with Venetoclax, 5-Azacytidine or the combination improved g9d2 T-cell killing capacities, which confirms previous findings on NK- and T-cells and adds further mechanistic insights. Finally, activation of g9d2 T-cells with ICT01 in combination with Venetoclax and 5-Azacytidine treatment further increased apoptosis of AML cells.

Conclusions These results demonstrate the ability of Venetoclax and 5-Azacytidine to potentiate ICT01-mediated killing of AML cells by γ9δ2 T-cells and support clinical evaluation of this combination as a novel therapeutic approach for AML patients.

355 TCR γδ+ TIL FROM PATIENTS WITH PANCREATIC CANCER RECOGNIZE AUTOLOGOUS TUMOR CELLS RESTRICTED BY CD1D

[1]Joana Lerias*, [1]Patrícia António, [1]Jéssica Kamiki, [1]Rodrigo Eduardo, [1]Sara Cascais, [1]Bernardo Marinheiro, [1]Eric De Sousa, [1]Carolina Gorgulho, [1]Andreia Maia, [1]Mireia Castillo-Martin, [1]Markus Buechler, [1]Carlos Carvalho, [1]Antonio Beltran, [2]Sam Jeong, [2]Ridong Chen, [1]Markus Maeurer. *[1]Champalimaud Center for the Unknown, Lisbon, Portugal; [2]Human Cell Inc, Naperville, IL, USA*

Background Pancreatic cancer is the 7th leading cause of cancer-related deaths worldwide. Treatment options are still limited; immunotherapeutic approaches using tumor infiltrating lymphocytes (TIL) represent a viable option for PDAC patients. TILs from PDAC lesions will include αβ+ and γδ+ T-cells, that recognize tumor cells restricted by non-classical MHC I molecules.[1,2] γδ+ TILs are generally associated with a more favorable prognosis[3] and present promising candidates for adoptive cellular therapy as cellular products, or by cloning the molecular blueprint of cancer-specific TCRs that could be transferred into recipient immune cells. The study focused on the expansion of TIL containing TCR γδ+, molecular analysis of TCR γδ+ cells, and testing anti-tumor directed TIL specificity defined by IFN-gamma production upon NRLP3 pathway stimulation.

Methods Freshly harvested tumor tissue was used to propagate TIL using cytokines in combination with an NRLP3 pathway activator for 2-3 weeks. γδ+ T-cell expansion and T-cell activation/exhaustion were tested by flow cytometry and autologous tumor recognition assays were performed using blocking mAbs and IFN-gamma as the biological readout; molecular recognition analysis was performed using synthetic peptides derived from tumor exome sequencing. TCR deep sequencing was performed in sorted TCR γδ+ TIL. Tumor infiltration by TCR γδ+ was gauged by immunohistochemistry and spatial transcriptomics.

Results NRLP3 stimulation results in increased TCR γδ+ cells which – after sorting (>90% purity) – recognized autologous and allogeneic pancreatic cancer cells in a CD1d-restricted fashion defined by IFN-gamma production. TCR sequencing revealed a focused TCR repertoire with unusual Vgamma3 and Vgamma8 usage. NRLP3 stimulation increased the frequency of αβ+ T-cells against autologous tumor cells and mutant target epitopes defined by IFN-gamma production, abrogated with an NRLP3 inhibitor. Spatial transcriptomics revealed co-localization of CD1d and perforin+granzymeA +granzymeB γδ+ T-cells; TCR-sequencing of PDAC tissue and corresponding TIL exhibited an oligoclonal TCR repertoire. NRLP3 stimulation increased mRNA and protein expression of CXCL9 and CXCL10, which facilitates tissue invasion and favored CD1d restricted recognition of damaged mitochondria by γδ+ T-cells.

Conclusions NRLP3 pathway stimulation increased tumor-reactive and mutant epitope specific TILs, increased expression of chemokines facilitating tissue invasion and expansion of γδ+ TIL engaged in surveillance of damaged mitochondria. This allows a clinically relevant expansion of TIL for patients with PDAC that recognized tumor associated antigens restricted by classical and non-classical MHC molecules. CD1d restricted and tumor-reactive γδ TCRs can be used as blueprints for anti-cancer directed receptors that could be transferred into recipient cells for active cellular immunotherapy for patients with PDAC.

356 GENERATION OF GD2-CAR NEUTROPHILS FROM HPSCS FOR TARGETED CANCER IMMUNOTHERAPY OF SOLID TUMORS

[1]Asiri Majumder*, [1]Ho Sun Jung, [2]Jue Zhang, [1]Kran Suknuntha, [2]James Thomson, [1]Igor Slukvin. *[1]University of Wisconsin, Madison, WI, USA; [2]Morgridge Institute for Research, Madison, WI, USA*

Background Chimeric antigen receptor (CAR) T cell and NK cell therapies already been successful in the eradication of lymphoid malignancies. However, many challenges remain in the applying CAR therapies for solid tumors, and responses with CAR-T cells have been limited to isolated exceptional cases. Thus, opportunities exist for new immunotherapies for specific targeting of solid tumors using CAR-weaponized neutrophils which are capable of cytotoxicity and migration into solid tumors. Human pluripotent stem cells (hPSCs) are a logical alternative for large-scale production of CAR neutrophils due to their renewability and uniform quality. In this study we explored a feasibility of generation GD2-CAR neutrophils from hPSCs with superior cytotoxic activities against GD2-expressing tumors *in vitro* and *in vivo*.

Methods We used CRISPR-Cas9 gene editing method to integrate a third generation GD2-CAR (anti-GD2-14g2A-CD28-OX40-CD3z) into AAVS1 locus of IISH2i-BM9 hiPSCs. GD2-CAR-hiPSCs differentiated into neutrophils in defined serum- and feeder-free conditions using ETV2 modified mRNA. The in vitro antitumor activity of CAR-M was evaluated by co-culture with GD2-expressing CHLA-20 neuroblastoma and WM266-4 melanoma and GD2-negative SKOV3 ovarian carcinoma and SK-BR3 breast carcinoma. To assess *in vivo* potential of GD2 CAR neutrophils, NSG mice were inoculated intraperitoneally (IP) with $3x10^5$ Luc2-eGFP$^+$ WM266-4 melanoma cells and engraftment was assessed by IVIS bioluminescent imaging. On day 4 post WM266-4 injection, mice were either treated with 10^7 WT or GD2-CAR neutrophils via IP injection every 7 days.

Results GD2-CAR hiPSCs differentiated into CAR-neutrophils with the same efficiency as unmodified hiPSCs. CAR-neutrophils demonstrated typical neutrophil morphology and phenotype, including expression CD15, lactoferrin and MPO. Neutrophils generated from GD2-CAR hiPSCs, as compared to unmodified neutrophils, demonstrated superior cytotoxicity *in vitro* against GD2$^+$ WM266-4 melanoma and CHLA20 neuroblastoma, while minimal differences were observed in cytotoxicity against GD2-negative SKOV3 ovarian and SK-BR3 breast cancer cells between unmodified and CAR-neutrophils. Upon assessment of anti-tumor activities of GD2-CAR neutrophils in mice engrafted with WM266-4 melanoma over 30 days (figure 1), CAR neutrophil-treated mice showed significantly reduced tumor burden (figure 2) and prolonged survival (figure 3) compared to untreated mice or mice treated with unmodified iPSC-derived neutrophils.

Conclusions Our studies demonstrate that hiPSCs can be used to efficiently generate CAR-neutrophils with potent activity against solid tumors. Thus, hiPSCs provide a novel approach for generation CAR-neutrophil off-the-shelf product for targeted immunotherapy of solid tumors.

357 PHOSPHORYLATION OF CD28-Y218 MODULATES IL-2 SECRETION AND ANTITUMOR EFFECT OF CAR-T CELLS, IN A PRECLINICAL MODEL OF PANCREATIC CANCER

Elena Martinez Planes*, Miguel Fontela, Cecilia Ramello, Daniel Abate-Daga. *H. Lee Moffitt Cancer Center, Tampa, FL, USA*

Background CD28-derived co-stimulation modules are frequently used as part of the signaling domain of chimeric antigen receptors (CAR). These modules contain well characterized tyrosine-containing moieties (YMNM and PYAP) that become phosphorylated upon CAR activation, resulting in IL-2 secretion and T cell expansion.[1,2] Previous work by our group has shown that an additional tyrosine residue, located in the C-terminus of CD28 (Y218), was also phosphorylated upon CAR activation.[3] In this work we sought to evaluate the functional relevance and molecular mechanism of CD28-Y218 phosphorylation in CAR-T cells.

Methods We first analyzed the kinetics of Y218 phosphorylation. To that end, prostate stem cell antigen (PSCA) specific CAR-T cells were stimulated through co-culture with HPAC pancreatic cancer cells for 0, 1, 10, 30 and 60 minutes. Phosphorylation of Y218 was analyzed by Western blotting using a phospho-specific antibody. To determine the functional relevance of this phosphorylation event, we generated mutant CARs where the tyrosine residue was replaced with a non-phosphorylatable amino acid (Y218F) and evaluated its effects *in vivo* and *in vitro*. CAR-T cell cytotoxicity was monitored using the xCELLigence Real Time Cytotoxicity Assay (RTCA). A CD19-specific CAR was used as an alternative model, where NALM6 cells expressing firefly luciferase served as target cells. Luciferase activity was used as surrogate for target cell viability. In both models, we monitored cytokine production following overnight co-culture with target cells using the ELLA system (Biotechne, CA, USA). To evaluate *in vivo* antitumor effect of PSCA-specific CAR-T cells, NSG mice were injected (s.c.) with 1 HPAC cells and infused 14 days later with 5 CAR-T cells (i.v.). Tumor growth was monitored for 35 days.

Results We observed an antigen-dependent phosphorylation of Y218 which reached maximum levels approximately 10 min post-stimulation. Mutation of the CD28-Y218 residue did not affect CAR expression, cytotoxicity *in vitro*, or INFγ production. However, this mutation was associated with reduced IL-2 and TNFα secretion. *In vivo*, this mutation completely abrogated the therapeutic effect of these cells in the pancreatic cancer model.

Conclusions These results show that CD28-Y218 plays a role in CAR-T cell function, with direct impact on IL-2 secretion and antitumor efficacy. Future experiments will determine the specific signaling events that are triggered by Y218 phosphorylation.

358 DEVELOPMENT OF AN ALLOGENIC FAP CAR INKT PRODUCT TO TARGET TUMOR STROMA AND MODULATE THE TUMOR MICROENVIRONMENT

[1]Xavier Michelet*, [1]Martyna Popis, [1]Shannon Boi, [1]Magda Niedzielska, [1]Reed Masakayan, [1]Efrat Altman Sharoni, [1]Paul Ibbett, [1]Deborah Wright, [2]Barbara Barbara Kalinowska, [2]Justin Keith, [2]Bishnu Joshi, [1]Moira Pinzan Rossi, [1]Rachel Smith, [1]Burcu Yigit, [1]Olivier Le Tonqueze, [1]Eleni Chantzoura, [3]Marc Van Dijk. *[1]MiNK Therapeutics, Lexington, MA, USA; [2]Agenus, Lexington, MA, USA; [3]MiNK Therapeutics, Cambridge, UK*

Background The emergence of antibodies targeting checkpoint modulators such as PD-1 and CTLA-4 has revolutionized solid tumor treatment and highlighted the importance of effectively engaging the immune system to drive durable responses. However, well over 50% of solid tumor patients do not respond adequately to checkpoint modulators; due to generally ascribed active immune suppression in the tumor microenvironment (TME). To overcome suppression and increase tumor control, we developed a highly selective and precisely tuned Chimeric Antigen Receptor (CAR), which targets Fibroblast Activating Protein (FAP)) expressed on both tumor cells and immune-suppressive Cancer Associated Fibroblasts (CAFs). This novel allogeneic CAR-iNKT cell (invariant natural killer T cell) product is IL-15 secreting, in addition to being FAP binding, and is intended for treatment of solid tumors. iNKT cells were selected as hosts due to their natural resistance to exhaustion, tissue homing properties, selective cytotoxicity towards M2 macrophages and stimulation of dendritic cell maturation properties which are essential for effective solid tumor directed therapies. In addition, iNKT cells have intrinsic CD1d- and NK receptor ligand targeted cytotoxicity, while not causing Graft *versus* Host Disease due to the presence of invariant T cell receptors.

Methods Our proprietary CARDIS™ platform combines screening of highly diverse ($>10^{10}$) fully human scFv libraries with library-based direct functional selection in CAR format using mammalian display. Candidates can be further optimized using affinity tuning to ensure optimal and highly selective on-target/on-tumor activity and full mouse cross-reactivity. We developed a scalable manufacturing approach to engineer and specifically expand CAR and soluble IL-15-expressing allogeneic iNKT cells.

Results Using our CARDIS™ platform, we generated a panel of fully human, potent, and highly selective anti-human FAP CARs with equivalent cross-reactivity towards mouse FAP. In xenograft mouse models our FAP-CAR-IL-15 iNKT cells effectively control FAP-expressing tumors, as well as FAP negative tumors with immune-suppressive stroma mediated by FAP+ CAFs, while soluble IL-15 prolongs persistence in immunocompromised mice. In addition, we show that FAP-CAR-IL-15 iNKT cells mediate the infiltration of tumor-specific T-cells and enhance their anti-tumor activity.

Conclusions We have used our CARDIS™ and iNKT platforms to develop a CAR-iNKT therapy effectively and selectively targeting FAP positive tumor cells and suppressive CAF subsets in the TME. We believe that combining the activity of our FAP-CAR with the potent natural activity of iNKT cells will enable a level of tumor control and immune engagement to solid tumor patients beyond currently available treatments.

359 **HYALURONIC ACID NANOGEL BASED CANCER VACCINE, IN COMBINATION WITH ADOPTIVE T CELL THERAPY TOTALLY SUPPRESSES ICI RESISTANT-TUMORS**

[1]Hiroshi Shiku*, [1]Fumiyasu Momose, [2]Takashi Nakai, [2]Kohei Yabuuchi, [2]Toru Katsumata, [2]Tsuyoshi Shimoboji. *[1]Mie University Graduate School of Medicine, Tsu, Japan*; *[2]Asahi Kasei Corporation, Fuji, Japan*

Background In this study, we questioned efficacy of combination therapy of newly developed cancer vaccines for tumors refractory to immune checkpoint inhibitors (ICIs) and adoptive therapy of TCR-T cells. We have developed a nano-sized hydrogel particles (nanogels) to create novel nanomaterials for biomedical applications. In particular, HANG; Hyaluronic Acid partially hydrophobized by a chemical modification with cholesteryl groups forms physically cross-linked NanoGel particles with a diameter of 30~100 nm via self-assembly in water. HANG efficiently forms a stable complex with antigenic polypeptides (HANG-V) through hydrophobic interactions. Two murine tumor models, B16F10 melanoma and CMS5a sarcoma, both of which are known to be refractory to ICI therapy and adoptive T cell therapy of TCR engineered T cells were studied.

Methods The peptides, gp100 or CMS5a neoantigens, in DMSO were added to the HANG aqueous solution and the mixture was incubated for 24 h at room temperature. After 0.22 μm filtration, the antigen peptide concentration was quantified by reverse phase chromatography analysis.

Results HANG-V cancer vaccine (HANG and gp100 long peptides) with TLR agonist were subcutaneously injected to B16F10-bearing C57BL/6 mice on days 7, 11, 15 and subsequently administered with $CD8^+$ T cells obtained from Pmel-1 transgenic mice. B16F10 tumors more than 100 mm^2 became complete regression. This effect persisted for a long period without recurrence, by changing hair color of mice into white. Control non-vaccinated mice were all dead by day 25. The gp100-specific CTLs with effector phenotype and IFN-γ secretion, were observed with high frequency in LNs, spleen, PBMCs and TILs. Two months after last treatment of HANG-V, Ag-specific adoptive T cells were detected in circulating blood, which show effector memory/central memory phenotype. Furthermore, booster vaccination induces explosive expansion of these memory T cells. In similar experimental settings, BALB/c CMS5a tumor were treated with the HANG-V (HANG and mERK2 long peptides) plus TLR agonist with adoptive transfer of T cells from TCR transgenic DUC18, for CMS5a-specific mERK2 neoantigen, resulted in total suppression of tumor growth.

Conclusions HANG cancer vaccine (HANG-V) strongly enhances efficacy of adoptive TCR engineered T cell therapy against ICI refractory tumors leading to total tumor suppression. In addition, HANG-V induces potent and sustainable antigen-specific CTL systemically and intratumorally. Our studies may propose crucial insights for clinical application of HANG-V with adoptive T cell therapy for ICI-resistant and metastatic tumors with poor prognosis.

360 NOVEL IMMUNOTHERAPY FOR PROSTATE CANCER COMBINING CAR T CELLS AND MYELOID CELL STAT3 INHIBITION

John Murad*, Saul Priceman. *City of Hope, Duarte, CA, USA*

Background Poor prognosis for patients with metastatic castration resistant prostate cancer (mCRPC) has inspired efforts to develop effective treatments for advanced disease. Our lab has developed a chimeric antigen receptor (CAR)-engineered T cell targeting prostate stem cell antigen (PSCA), which is overexpressed in a majority of primary and metastatic prostate cancers. We believe PSCA-CAR T cells will provide a safe and effective strategy for improving clinical outcomes for mCRPC patients. While encouraged by clinical activity in our phase 1 trial (NCT03873805), the immunosuppressive tumor microenvironment (TME) will limit therapeutic potential. Central to tumor/immune cell interactions is the transcription factor, signal transduction and activation of transcription-3 (STAT3), recognized for its critical role in regulating multiple tumor-associated myeloid cell-related genes known to suppress anti-tumor immunity, including type-I IFNs, IL-10, IL-12, TGFβ, and PD-L1. Thus, we hypothesized that TME modulation with a TLR9-guided STAT3 anti-sense oligonucleotide CpG-STAT3ASO (CSI3) would provide myeloid cell-selective STAT3 inhibition, which combined with PSCA-CAR T cells will improve responses in mCRPC.

Methods Using a PSCA knock-in (hPSCA-KI) immunocompetent mouse model of prostate cancer *(Murad et.al., 2021 Mol Ther)*, we describe cyclophosphamide (Cy) preconditioning as crucial for unleashing the therapeutic potential of PSCA-CAR T cells, yet still achieving approximately 50% curative responses. Here, we interrogated synergy of Cy and PSCA-CAR T cells combined with targeted STAT3 inhibition with CSI3. Following dosing optimization, tumor reduction and survival kinetics in subcutaneous or intratibial prostate tumors were assessed. Modulation to tumor and systemic immune landscapes using CSI3 treatment was assessed via flow cytometry, Nanostring digital spatial profiling, and immunohistochemistry.

Results In an intratibial bone metastatic prostate cancer model, Cy and CAR T cell treatment was effective in curing 50% of mice. Impressively, we demonstrated 88% curative response rate when combined with CSI3 treatment. The benefit in survival via CSI3 necessitated Cy preconditioning, as only 25% of mice were cured when treated with the CAR T cell/CSI3 combination alone. Lastly, no cures were seen in single treated mice. Analysis is on-going to determine changes in the immune landscape when treated with Cy, PSCA-CAR T cells, and CSI3 combinations.

Conclusions Alone, PSCA-CAR T cell or CSI3 targeted approaches are insufficient in producing a robust immune response without dose limiting toxicities. Our data suggests that myeloid cell-selective STAT3 inhibition in combination with our PSCA-CAR T cells may synergize to improve overall responses and boost endogenous anti-tumor immunity. In sum, this approach presents an exciting avenue for clinical development in mCRPC.

361 UNIVERSAL EXPANSION OF CBL-B-INHIBITED TUMOR INFILTRATING LYMPHOCYTES, DETIL-0255, FROM WOMEN WITH OVARIAN CANCER: PROCESS VALIDATION

[1]Pranav Murthy*, [1]Nell Namitha Narasappa, [1]Xiaoyan Liang, [1]Xianzhu Wu, [1]Irene Luu, [1]Jeevitha Jeevan, [1]Sagar Sharma, [1]Alison Ross, [1]Caleb Lampenfeld, [1]Sam Zahn, [1]Thomas Musial, [1]Jennifer Bone, [2]John Nakayama, [2]David Bartlett, [3]Jocelyn Chapman, [1]Greta Garrido, [1]Nicholas Shinners, [1]Arthur Sands, [1]Michael Blackton, [1]Ena Wang, [1]Michael Lotze. *[1]Nurix Therapeutics, San Francisco, CA, USA; [2]Allegheny Health Network, Pittsburgh, PA, USA; [3]UCSF Medical Center, San Francisco, CA, USA*

Background Despite objective responses to immune checkpoint blockade in patients with ovarian cancer (OC), therapies providing durable clinical benefit are lacking.[1] An increased density of OC tumor infiltrating lymphocytes (TIL), specifically memory T cells with enhanced CD28 signaling, are associated with improved survival[2] and immunotherapy response.[3]Adoptive cell therapy (ACT) utilizing *ex vivo* expanded TIL has demonstrated durable complete responses in several epithelial malignancies, but has shown limited clinical benefit in OC.[4,5] This is due in part to extended manufacturing times and use of TIL products with a differentiated and exhausted phenotype.[4,5] Casitas B lineage lymphoma-B (CBL-B) is an E3 ubiquitin ligase that limits T cell activation in the absence of CD28 co-stimulation following T cell receptor engagement. *Ex vivo* inhibition of CBL-B with the small molecule inhibitor NX-0255 increases the expansion of stem-like TIL with enhanced *in vivo* tumor cytotoxicity and persistence compared to conventional TIL expanded in IL-2 alone.[6,7] Here we present our pre-clinical and early manufacturing experience of drug enhanced TIL therapy (DeTIL-0255) in OC.

Methods Tumor tissue from N=21 consenting patients undergoing resection for OC across multiple US clinical sites was fragmented and cultured with IL-2 and NX-0255 under research (N=20) or clinical scale (N=1) manufacturing conditions. Following 22 days of culture, DeTIL-0255 cell products were characterized by multiparameter spectral flow cytometry.

Results Even with as low as five input 2x2 mm^3 tumor fragments, DeTIL-0255 was reproducibly expanded from primary and metastatic OC lesions with an average fold increase of 184±179 (mean ± SD) following the rapid expansion protocol and Day 22 total viable cell count of $8.0x10^8 \pm 5.3x10^8$ cells (research scale) and $2.5x10^{10}$ cells (clinical scale). OC DeTIL-0255 was comprised of T (81.4±10.1%) and NKT (10.5±10.4%) cells with < 4% monocytes, NK, or B cells. OC DeTIL-0255 showed a balanced mixture of CD4 (53.4 ±28.9%) and CD8 (38.8±27.8%) T cells with heightened expression of the co-stimulatory marker CD226 (CD4: 87.4 ±12.6%; CD8: 86.0±16.4%), previously shown to predict immunotherapy response [8]. In contrast to prior OC TIL products, OC DeTIL-0255 were primarily effector memory (CD4: 59.7±30.6%; CD8: 55.6±29.8%) and central memory cells (CD4: 21.0±23.7%; CD8: 12.4±16.9%) displaying limited T cell exhaustion (CD4: PD-1 26.2±22.8%, LAG-3 15.1 ±13.5%, CD57 4.4±4.3%; CD8: PD-1 17.7±19.6%, LAG-3 45.4±28.4%, CD57 2.9±2.5%).

Conclusions OC DeTIL-0255 demonstrate a favorable phenotype amenable for ACT. A Phase 1 clinical study of DeTIL-0255 in women with recurrent/platinum resistant OC is ongoing (NCT05107739).

362 DEFINING T CELL EXHAUSTION AND MEMORY CORRELATES OF GD2 CAR T CELL EXPANSION IN PEDIATRIC PATIENTS WITH SOLID TUMOR MALIGNANCIES

[1]Tara Murty*, [1]Sneha Ramakrishna, [2]Sabina Kaczanowska, [2]Cristina Contreras, [1]Caroline Duault, [1]Priyanka Balasubrahmanyam, [1]Warren Reynolds, [1]Reema Baskar, [3]Aashna Jhaveri, [3]Yang Liu, [3]Jennifer Altreuter, [3]Franziska Michor, [1]Mina Pichavant, [1]Bita Sahaf, [1]Sean Bendall, [1]Holden Maecker, [4]Melinda Merchant, [1]Crystal Mackall, [2]Rosandra Kaplan. *[1]Stanford University School of Medicine, Stanford, CA, USA; [2]National Cancer Institute, Bethesda, MD, USA; [3]Dana-Farber Cancer Institute, Boston, MA, USA; [4]Black Diamond Therapeutics, Cambridge, MA, USA*

Background Chimeric antigen receptor T cells (CAR-Ts) hold promising therapeutic potential for solid tumors but have yet to produce consistent durable responses in patients. A major limitation to response in solid tumors remains the lack of CAR-T expansion, persistence, and anti-tumor cytotoxicity. Identifying molecular markers that correlate with CAR-T activity could elucidate key biological pathways and T cell populations central to the success of CAR-Ts in patients.

Methods A phase I trial (NCT02107963) was conducted to determine the feasibility of producing and safety of administering escalating doses of a third generation GD2 CAR-T (GD2-CAR.OX40.28.z.ICD9) in children and young adults with GD2+ solid tumors, including neuroblastoma and osteosarcoma. To understand biological differences correlating with CAR-T cell activity in patients, patient apheresis, CAR-T product, and post-treatment peripheral blood samples were analyzed for immune phenotype by mass cytometry (CyTOF), transcriptomic profile by RNA-sequencing (RNA-seq), and epigenetic landscape with Assay for Transposase-Accessible Chromatin using sequencing (ATAC-seq).

Results Across 4 dose levels, 15 patients (8-28 years old) were enrolled, of which 13 patients were infused. At Day 28 following GD2 CAR-T infusion, 23.1% (3/13) of evaluable patients had progressive disease and 76.9% (10/13) had stable disease (SD), but all patients eventually progressed. Despite limited GD2-CAR-T persistence, half of the patients had expansion similar to that seen in clinically active CD19 and CD22 CAR-Ts. Since a major barrier to CAR-T efficacy is inadequate CAR-T expansion, we comprehensively evaluated patient immune profiles to identify determinants of CAR-T expansion. Good CAR-T expansion was found to be associated with increased abundance of naïve CD8+ T cells in apheresis by CyTOF. Similarly, RNAseq demonstrated enrichment of naïve memory T cell pathways in the apheresis samples of good expanders. ATACseq identified epigenetic differences in apheresis that may predict good CAR-T expansion in patients. CAR-T products across all patients, regardless of CAR-T expansion, expressed activation/exhaustion markers by CyTOF. RNAseq of CAR-T products revealed an enhanced exhaustion signature in poor compared to good expanders. At post-treatment timepoints, poor expanders demonstrated increased expression of T cell exhaustion markers.

Conclusions Comprehensive analyses of patients' apheresis, product, and post-treatment timepoints enable characterization of the T cell immune compartment before CAR-T treatment, after CAR-T manufacturing, and after CAR-T infusion. We identified phenotypic, transcriptomic, and epigenetic T cell signatures correlating with CAR-T expansion. These data suggest key mechanisms of underlying T cell biology that may contribute to CAR-T activity in pediatric solid tumors.

363 **LOCALIZED INTERLEUKIN-2 CYTOKINE FACTORIES ERADICATE MESOTHELIOMA TUMORS VIA ACTIVATION OF ADAPTIVE AND INNATE IMMUNE CELLS**

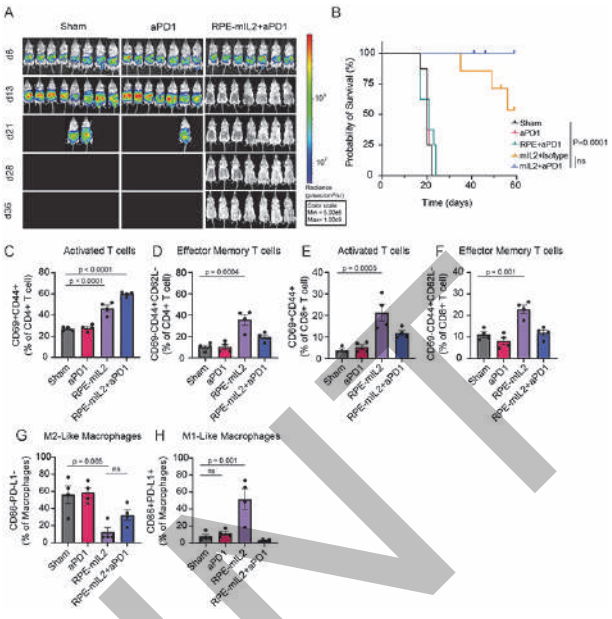
[1]Samira Aghlara-Fotovat*, [1]Amanda Nash, [1]Bertha Castillo, [1]Andrea Hernandez, [2]Aarthi Pugazenthi, [2]Hyun-Sung Lee, [2]Hee-Jin Jang, [1]Annie Nguyen, [1]Alexander Lu, [2]Bryan Burt, [2]Ravi Ghanta, [1]Omid Veiseh. *[1]Rice University, Houston, TX, USA; [2]Baylor College of Medicine, Houston, TX, USA*

Background High-dose interleukin-2 (IL-2) immunotherapy has previously demonstrated effective tumor lysis via activation of effector immune cells;[1] however, clinical utility is limited due to pharmacokinetic challenges and life-threatening toxicities experienced by patients.[2] To overcome these challenges, we developed a safe and clinically translatable localized IL-2 delivery system to boost the potency of therapy while minimizing systemic cytokine exposure.[3]

Methods We evaluated the therapeutic efficacy of hydrogel encapsulated, cell-based IL-2 cytokine factories in a mouse model of malignant mesothelioma. An effective and well tolerated dose was determined by tracking tumor burden in response to increasing doses of our cytokine factories. Therapeutic efficacy of the optimal dose was subsequently evaluated in combination with anti-PD1 checkpoint inhibitor. Changes in immune populations across groups were analyzed using time-of-flight mass cytometry (CyTOF). Finally, safety and translatability of the platform were evaluated following pleural implant in rats, using complete blood counts and serum chemistry analysis.

Results IL-2 cytokine factories enabled 150x higher IL-2 concentrations in the local compartment with limited leakage into systemic circulation. Additionally, AB1 tumor burden was reduced by 80% after one week of monotherapy treatment, and 7/7 animals exhibited tumor eradication when IL-2 cytokine factories were combined with aPD1 therapy (figure 1A). Resultantly, IL-2+aPD1 combination therapy led to significant improvements in tumor-free survival compared to controls (figure 1B). Further, CyTOF analysis showed an increase in CD69+CD44+ and CD69-CD44+CD62L- T cells (figure 1C-F), reduction of CD86-PD-L1- M2-like macrophages, and a corresponding increase in CD86+PD-L1+ M1-like macrophages (figure 1G and H) and MHC II+ dendritic cells after treatment. Finally, healthy blood chemistry ranges in rodents demonstrated the safety of cytokine factory treatment and reinforced its potential for clinical use.

Conclusions IL-2 cytokine factories led to eradication of aggressive mouse malignant mesothelioma tumors, protection from tumor recurrence, and increased the therapeutic efficacy of anti-PD1 checkpoint therapy. The results of this study provide support for clinical evaluation of our IL-2-based delivery system.



Abstract 363 Figure 1 IL-2 Cytokine factories eradicate MM tumors. (A) Luminescent images tracking tumor burden over time. (B) Survival curves plotted as percent survival over time beginning after tumor injection (n=7-8). C-F) Comparison of activated, and effector memory CD4+ and CD8+ T cells across treatment groups. 364 ANTIGEN ABUNDANCE AND TCR AVIDITY IMPACT T CELL-MEDIATED TUMOR RECOGNITION IN NOVEL B16F10 ACT MODEL

[1]Jenna Newman*, [1]John Finnigan, [2]Andrew Ishizuka, [2]Geoffrey Lynn, [3]Alexander Rubinsteyn, [1]Timothy O'Donnell, [4]Jeffrey Hammerbacher, [1]Nina Bhardwaj. *[1]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [2]Avidea Technologies, Washington, USA; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, USA; [4]Medical University of South Carolina, Charleston, SC, USA*

Background Adoptive cell transfer (ACT) of neoantigen-reactive $CD8^+$ T cells has had some success in the clinic; however, mouse models recapitulating neoantigen-reactive $CD8^+$ T cell ACT have been limited, especially in poorly immunogenic models such as the murine melanoma model B16F10. Further, direct comparison of neoantigen-reactive $CD8^+$ T cell ACT versus ACT utilizing T cells reactive against overexpressed-self or heteroclitic tumor-associated antigen (TAA) peptides has been lacking. To address these gaps, we developed a model system to study neoantigen- and TAA-reactive $CD8^+$ T cell ACT in parallel.

Methods Whole exome sequencing and RNA sequencing were employed to predict neoantigens present in B16F10. C57BL/6 mice were then administered charge-modified TLR7/8 conjugate vaccines targeting neoantigenic peptides predicted to elicit T cell responses. Vaccination against neoepitopes and previously characterized TAA epitopes elicited neoantigen- or TAA-reactive $CD8^+$ T cells and modest tumor growth control; T cell receptors were isolated from neoantigen- and TAA-reactive $CD8^+$ T cell clones. To develop an ACT model, we conducted CRISPR/Cas9-mediated knockdown of endogenous TCR and subsequent transduction (g-retrovirus encoding neoantigen- or TAA-reactive TCRs) in murine $CD8^+$ T cells. T cells were expanded *in vitro* for use in downstream *in vitro* and *in vivo* applications.

Results Peptide stimulation *in vitro* of neoantigen- and TAA-reactive T cells revealed wide ranges of 1) specificity (vs. cross-reactivity to wild type peptide), and 2) avidity for cognate peptide. Neoantigen- and TAA-reactive T cells were able to recognize B16F10 cells *in vitro*, with the most robust recognition (readout:% T cells $IFNg^+$) when target antigen is highly expressed by tumor cells. Ability of neoantigen- or TAA-reactive T cells to kill B16F10 *in vitro* was strongly dependent upon both tumor antigen expression and T cells' TCR avidity. Similarly, reduction of tumor growth *in vivo* required both high tumor antigen expression and transfer of high avidity neoantigen- or TAA-reactive $CD8^+$ T cells.

Conclusions To conclude, we have created a novel model of neoantigen- and TAA-reactive ACT in immunotherapy-refractory B16F10 melanoma. Our data suggest that antigen abundance and TCR avidity are parameters that influence ACT efficacy; future research will be conducted to dissect the individual and summative contributions of these parameters and translate this knowledge towards improving ACT design in the clinic.

365 COMPARISON OF VIRAL VECTOR TRANSDUCTION METHODS FOR TUMOR-INFILTRATING LYMPHOCYTES

[1]Seung Eon Oh*, [2]Won Seon Bang, [2]Hee Jae Lee, [3]Hee Jin Lee, [2]Chae Lyul Lim. *[1]University of Ulsan College of Medicine, Geoje-si, Republic of Korea; [2]Neogen TC, Hanam, Republic of Korea; [3]Asan Medical Center, Seoul, Republic of Korea*

Background Tumor-infiltrating lymphocytes (TIL) therapy has been developed and its efficacy has been proven mainly for malignant melanoma. TILs are composed of various T cell clones with T cell receptors (TCRs) that can target tumor antigens. However, TILs are highly differentiated and exhausted. To improve the efficacy of TIL therapy, engineering various genes that are associated with immune activation and persistency is necessary. We tried to find methods to increase the gene transfer efficiency using lentiviral vectors.

Methods TILs were cultured in 2 steps; initial expansion and rapid expansion (REP). For initial expansion, tumor tissue from colorectal cancer patients was minced into fragments (1-2 mm) and cultured in a 24-well plate with IL-2 for 2 weeks. Gene transfer was conducted with initially expanded TILs with a lentiviral vector with Zsgreen. IL-2 and CD3/28 beads were used and compared for stimulation. Transduction efficiency was compared between protamine and retronectin during viral transduction. We compared three conditions with protamine according to the timing of viral transduction during REP (before, in the middle of, and after). We analyzed the fluorescence expression level of Zsgreen using a flow cytometer.

Results On post-transduction day 6, transduction efficiency for IL-2 stimulation was 4.3%, while CD3/28 beads achieved 13%. The doses of CD3/28 beads were compared and set as 1:1. Transduction efficiency was higher for protamine (17%) than retronectin (1.4%). For the timing of viral transduction, transduction in the middle of REP (17%) and before REP (16.8%) showed higher transduction efficiency than transduction after REP (5.6%).

Conclusions We showed different lentiviral transduction efficiency for TILs according to culture methods. Further studies with larger sample size and optimization of the culture protocol are necessary for better application of TIL therapy.

366 SYNTHETIC RECEPTOR ENABLED DIFFERENTIATION (SHRED), A NOVEL PLATFORM FOR MANUFACTURING OF IPSC-DERIVED CYTOTOXIC INNATE LYMPHOCYTES FOR "OFF-THE-SHELF" CANCER IMMUNOTHERAPIES

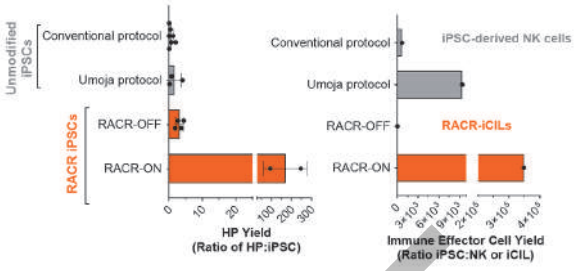
Sam O'Hara*, David Vereide, Teisha Rowland, Ashley Yingst, Dillon Jarrell, Ryan Koning, Cassidy Arnold, Susana Hernandez, Way Wu, Kristen Mittelsteadt, Chris Nicolai, Wai-Hang Leung, Shon Green, Laurie Beitz, Byoung Ryu, Christopher Garbe, Ryan Crisman, Andrew Scharenberg, Ryan Larson. *Umoja BiPharma, Boulder, CO, USA*

Background Induced pluripotent stem cells (iPSCs) are a renewable, modifiable, and scalable starting material for manufacturing cell-based therapies. However, current approaches for differentiating iPSCs into therapeutic immune effector cells, such as natural killer (NK) cells, require complex growth factors and feeder cells to achieve sufficient yields. Here, we present **S**ynt**h**etic **R**eceptor **E**nabled **D**ifferentiation (ShRED), a directed differentiation and expansion process controlled by the **R**apamycin-**A**ctivated **C**ytokine **R**eceptor (RACR^{TM}). RACR is activated via the addition of its synthetic ligand rapamycin, which induces a JAK/STAT signal that drives differentiation and expansion of cells into hematopoietic progenitors (HPs) and then into immune effector cells, termed RACR-**i**nduced **C**ytotoxic **I**nnate **L**ymphocytes (RACR-iCILs). Furthermore, because rapamycin is a safe, effective, and approved therapeutic for immune suppression, we beleive RACR can also be engaged *in vivo* through rapamycin dosing to increase the persistence of RACR-iCILs, while simultaneously protecting these cells from allogeneic rejection.

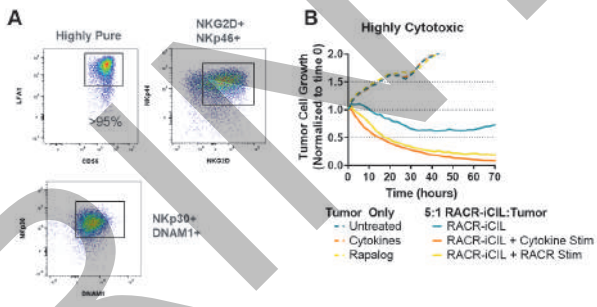
Methods RACR was introduced into iPSCs through CRISPR/Cas9 editing, enabling consistent expression of RACR throughout differentiation and expansion. Next, RACR was activated at the start of the manufacturing process, and the resulting differentiated cells were phenotyped by flow cytometry and assessed functionally in cytotoxicity assays.

Results Activating RACR in our engineered iPSCs resulted in enhanced HP differentiation, consistently producing a 300x yield of HPs (CD43+/CD45+/CD34+ cells) from iPSCs, two orders of magnitude greater than conventional protocols (figure 1). Continued engagement of RACR during differentiation resulted in >300,000x yield of RACR-iCILs (CD45+/CD56+/LFA1+ cells) from iPSCs in a completely feeder-free process (figure 1). These cells were highly pure and expressed receptors associated with NK cytotoxicity (figure 2A). Functionally, RACR-iCILs demonstrated potent cytotoxicity against solid tumors, and activation of RACR enhanced the cells' ability to clear tumor cells in a manner similar to potency-enhancing cytokines (figure 2B). Lastly, in a preclinical tumor xenograft model, RACR-NK cells demonstrated robust rapamycin-mediated expansion and clearance of breast adenocarcinoma tumors, highlighting RACR's ability to replace cytokine support and potentially increase cell persistence *in vivo*.

Conclusions These data demonstrate the potential of RACR to solve both the manufacturing and *in vivo* persistence challenges of iPSC-derived cell therapies. ShRED improves the manufacturing of iPSC-derived cells, producing unprecedented yields of immune effector cells (RACR-iCILs) and eliminating the need for complex cytokines and feeder expansions. *In vivo*, RACR activation increases the proliferation of RACR-expressing NK cells, potentially enhancing the persistence of cell immunotherapies and eliminating the need for cytokine dosing and lymphodepletion.



Abstract 366 Figure 1 Synthetic Receptor Enabled Differentiation (ShRED) enhances HP and effector cell generation to unprecedented yields.



Abstract 366 Figure 2 ShRED-generated RACR-iCILs are pure and cytotoxic against breast adenocarcinoma cells.

367 CRISPR/CAS9 GENE-EDITED, ALLOGENEIC ANTI-CD83 CAR-T CELLS DEMONSTRATE POTENT ACTIVITY IN GVHD AND AML TUMOR MODELS

Ismael Oumzil*, Valerie Guerrero, Pooja Smruthi Keerthipati, Jaqlyn Colangelo, Brendan Lawler, Victoria Singson, Aditya Khedkar, Shweta Singh, Jonathan Terrett, Daniel Hostetter. *CRISPR Therapeutics, San Francisco, CA, USA*

Background CD83 is expressed on blood cancer cells, including acute myeloid leukemia (AML) blasts, and on allo-activated immune cells that are implicated in graft-versus-host disease (GvHD).[1] Targeting CD83 thus has the potential to improve outcomes in AML, as well as to reduce the risk of GvHD, which is a significant cause of mortality and morbidity in patients who undergo allogeneic hematopoietic cell transplant. The potential benefit of targeting CD83 is supported by literature showing that depletion of CD83+ cells in preclinical models of GvHD and AML is an effective therapeutic strategy.[1,2]

Methods We assessed the effectiveness of CRISPR/Cas9 gene-edited, allogeneic anti-CD83 CAR-T cells against animal models of GvHD and AML, and whether additional gene edits could enhance CAR-T potency in these settings. Anti-CD83 CAR-T cells were made with *TRAC* disruption to reduce the risk of GvHD, *B2M* disruption to reduce allogeneic host rejection, and insertion of an anti-CD83 CAR construct into the *TRAC* locus. To assess whether CD83 expression on activated T cells causes CAR-mediated fratricide, the *CD83* gene was disrupted. To increase potency further, two additional gene disruptions were introduced: *ZC3H12A* (which encodes Regnase-1) and *TGFBR2* (which encodes TGFBRII).

Results We found that CD83 knockout (KO) improved the *in vitro* expansion of anti-CD83 CAR-T cells and enhanced *in vivo* activity. In a THP-1 tumor model, treatment with CD83 KO anti-CD83 CAR-T cells improved median survival when compared with wild-type cells (not reached vs. 59 days). In a xenogeneic GvHD model, CD83 KO cells were more effective at delaying GvHD at a dose of 1e6 CAR+ cells (median survival 71.5 vs. 51 days) and prevented GvHD entirely at a dose of 3e6 CAR+ cells. Activity could also be enhanced by combining CD83 KO cells with belatacept, a CTLA4-Fc fusion protein that blocks co-stimulation of T cells.

Anti-CD83 CAR-T cells with KO of Regnase-1, TGFBRII, and CD83 (R/T/83 KO cells) maintained robust expansion *in vitro*, demonstrated increased target cell killing *in vitro*, and showed enhanced *in vivo* activity. In a THP-1 tumor model, durable complete responses were observed in all animals (5/5) treated with R/T/83 KO cells and in 60% of animals (3/5) treated with CD83 KO cells. In a xenogeneic GvHD model, a single dose of 1e6 CAR+ R/T/83 KO cells prevented GvHD while CD83 KO cells delayed GvHD onset.

Conclusions Collectively, these data support the clinical evaluation of gene-edited, potency-enhanced, allogeneic anti-CD83 CAR-T cells in relapsed/refractory AML patients.

368 CF33-CD19T ONCOLYTIC VIRUS (ONCARLYTICS) TARGETS HEPATOCELLULAR CARCINOMA (HCC) AND IN COMBINATION WITH ARTEMIS® CD19 T CELLS RESULTS IN SIGNIFICANT TUMOR KILLING

[1]Isabel Monroy*, [1]Anthony Park, [1]Colin Cook, [2]Guangyan Xiong, [2]Vivien Chan, [2]Cheng Liu, [1]Saul Priceman, [3]Monil Shah, [3]Nimali Withana, [3]Leslie Chong, [1]Yuman Fong. *[1]City of Hope, Duarte, CA, USA; [2]Eureka Therapeutics, Emeryville, CA, USA; [3]Imugene, Sydney, Australia*

Background Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related deaths in the world with a 5-year survival rate at less than 12%. Currently, curative treatments include ablation, surgical resection, and liver transplantation. For majority of patients with advanced-stage disease, treatment with agents such as sorafenib, lenvatinib, and atezolizumab/bevacizumab and other investigational agents yield modest success rates and justify the need for further development of new therapies. T cell therapy against HCC targeting antigens such as alpha-fetoprotein (AFP) and glypican-3 (GPC-3) have shown some efficacy in clinical trials with conventional challenges against solid tumors including antigen heterogeneity, the immunosuppressive tumor microenvironment, and off-tumor on-target activity. Therefore, novel therapies are desperately needed to improve clinical outcomes for patients with HCC.

Methods We have developed a novel chimeric vaccinia-based oncolytic virus, called onCARlytics (CF33-CD19t, Imugene Limited in collaboration with City of Hope), that delivers a non-signaling, truncated CD19t (CD19t) antigen to tumors that allows for targeting of solid tumors by CD19 T cells. Once the CD19 is expressed on solid tumor cells, to enable cell killing, we have combined onCARlytics with CD19 ARTEMIS® T cell, a CD19-targeting adoptive engineered T cell powered by the ARTEMIS® antibody-T-cell receptor (AbTCR) platform (Eureka Therapeutics, Inc). The ARTEMIS® AbTCR distinguishes itself from CAR by recruiting the endogenous CD3 complex and utilizing the same activation and regulatory signaling pathways employed by natural TCRs, which enables both potent killing activity against CD19+ tumor cells and a superior safety profile.

Results When administrated after onCARlytics, CD19 ARTEMIS® T cells were able to induce potent cytolytic activity against HCC tumor cells and demonstrated robust *in vivo* anti-tumor efficacy against human HCC tumor xenografts.

Conclusions In summary, ARTEMIS® CD19 T cells combined with onCARlytics is a potentially effective immunotherapy strategy for the treatment of patients with HCC and can be applied to other solid tumors.

369 ENHANCERS OF INNATE AND ADAPTIVE IMMUNITY COMBINE WITH MEMBRANE BOUND IL15 TO INCREASE THE EFFICACY OF TUMOR INFILTRATING LYMPHOCYTE (TIL) THERAPY FOR TUMORS WITH IMMUNOSUPPRESSIVE MICROENVIRONMENTS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0369

Carmela Passaro*, Balazs Koscso, Sean Smith, Violet Young, Theresa Ross, Benjamin Primack, Natasha Ly, Patricia Timpug, Shabnam Davoodi, Rachel Burga, Gauri Kulkarni, Scott Lajoie, Meghan Langley, Nirzari Shah, Dexue Sun, Dan Jun Li, Raina Duan, Arman Aksoy, Mithun Khattar, Jeremy Tchaicha, Dhruv Sethi, Jan ter Meulen, Michelle Ols. *Obsidian Therapeutics, Cambridge, MA, USA*

Background The clinical impact of tumor infiltrating lymphocytes (TIL) cell products is currently limited by suboptimal persistence and potency, as well as the need for high-dose adjuvant IL-2 treatment, which is associated with severe toxicities. Thus, we engineered an IL-2-independent TIL product, based on regulated expression of interleukin 15 (cytoTIL15^{TM} cells), which has shown anti-tumor efficacy and persistence in human melanoma PDX models. Since the immuno-suppressive tumor microenvironment (TME) hinders cell therapies, we hypothesized that combining pleotropic cytokines of the interferon (IFN), IL-1, or TNF families with IL-15 would further enhance antitumor activity and that our cytoDRiVE® platform would allow pharmacologic control of these potent immune mediators. We tested constitutive and regulated combinations of a representative member of these cytokines with IL-15 in human TIL for *in vitro* polyfunctionality and *in vivo* antigen-independent persistence. We also engineered mouse pmel-TCR cells with cytokine combinations for evaluation in the syngeneic B16 melanoma model.

Methods Human TIL were expanded and engineered with lentiviral vectors to express IL-15 with IFN-alpha, IL-18 (IL-1 family member) or undisclosed TNFSF-X (TNF superfamily member). Expanded TIL were immunophenotyped and assessed for polyfunctionality by flow cytometry after CD3/CD28 stimulation. Engineered TIL were transferred into NSG mice to assess antigen-independent TIL persistence in the absence of exogenous IL-2. Cytokines modified with our carbonic anhydrase 2 (CA2)-based cytoDRiVE® drug responsive domain (DRD) were evaluated for control of protein levels with the CA2 ligand, acetazolamide (ACZ). Cytokine expression was evaluated in flow cytometry and Meso Scale Discovery assays. To assess anti-tumor and TME remodeling capabilities, we used a syngeneic model with transduced pmel-TCR cells adoptively transferred into mice bearing B16 melanomas.

Results Engineered TIL expressing both IL-15 and either IFN-alpha, IL-18 or TNFSF-X showed similar fold expansion, immunophenotype and polyfunctionality *in vitro* as TIL expressing only IL-15. Combination cytokine-expressing TIL showed similar *in vivo* antigen-independent persistence in the absence of IL-2 as TIL engineered with only IL-15. As compared to control pmel cells, sub-optimal cell doses of pmel T cells expressing both IL-15 and either IFN-alpha or, IL-18, showed improved efficacy and TME remodeling, while combining IL-15 with TNFSF-X resulted in significant tumor growth arrest of B16 melanoma tumors without escape.

Conclusions While IL-15 drives expansion and persistence of cytoTIL15^{TM} cells without IL-2, adding pleotropic and highly immune-stimulatory members of the IFN, IL-1 or TNF families may provide enhanced efficacy for patients with solid tumors marked by an immunosuppressive TME.

Ethics Approval All animal studies were IACUC approved

370 THE EPI-R™ TECHNOLOGY PRODUCES A POLYCLONAL TIL PRODUCT (LYL845) WITH A GREATER EXPANSION SUCCESS RATE ACROSS HOT AND COLD TUMORS, IMPROVED PRODUCT PHENOTYPE, AND MAINTENANCE OF TCR DIVERSITY

Yogin Patel*, Benjamin Harris, Melissa Bedard, Joanna Kritikou, Meritxell Galindo Casas, Carson Harms, Melissa DeFrancesco, Purnima Sundar, Nicholas Restifo, Gary Lee, Shobha Potluri, Suman Kumar Vodnala. *Lyell Immunopharma, South San Francisco, CA, USA*

Background Adoptive cell therapy (ACT) with tumor-infiltrating lymphocytes (TIL) can mediate durable responses in advanced solid tumors.[1-3] Effectiveness is driven by tumor-antigen recognition and maintenance of the diversity of T-cell receptors (TCR) found in the source tumor. As with all ACT, T-cell quality also impacts treatment efficacy, with more stem-like qualities associated with improved outcomes.[4-5] Current rapid-expansion protocols reduce TIL stemness and TCR diversity through progressive differentiation during *ex vivo* expansion. Therefore, strategies that enrich for stemness and preserve polyclonality, while maintaining a high production success rate, are needed. LYL845 is an autologous TIL product produced with our proprietary Epi-R™ epigenetic reprogramming protocol, which was developed to preserve polyclonality and tumor-reactive clones and enhance stem-like qualities and anti-tumor function of manufactured TIL products.

Methods TIL products were produced from 3 different tumor types (melanoma, lung and colorectal cancer) treated with/without checkpoint inhibitors [CPI] using the Epi-R technology and standard protocol. Characteristics of the resulting products (LYL845 and control, respectively) were compared using a matrix of assays and methods, including flow cytometry, bulk RNA sequencing (RNA-seq), and TCR beta sequencing.

Results Epi-R technology resulted in 100% success rate of TIL expansion across all three tumor types, versus 70% with the control process. LYL845 was enriched for CD8+ T cells without compromising polyclonality compared to control TIL. LYL845 was also enriched for stem-like CD4+ and CD8+ T cells with reduced terminal differentiation and exhaustion, as demonstrated by flow data and transcriptomic profiling. In addition, LYL845 exhibited better metabolic fitness as evidenced by low glycolysis and hypoxia gene signatures. Metabolic fitness and enrichment of stemness indicate that LYL845 has attributes that correlated with positive clinical outcome in previous ACT trials. Furthermore, polyclonality was preserved in LYL845 as measured by Simpson clonality index using bulk TCR sequencing data. Finally, LYL845 maintained these favorable characteristics regardless of prior patient CPI use. These key product attributes were further translated to LYL845 large-scale products.

Conclusions Results from research- and large-scale productions demonstrate that the Epi-R technology enables successful TIL expansion from both immunologically hot and cold tumors, while maintaining a greater proportion of stem-like T cells that demonstrate better metabolic fitness with preserved polyclonality (i.e., maintenance of tumor-reactive TCR diversity) across all 3 tumor types investigated. These findings support the clinical development of LYL845 in an upcoming first-in-human Phase 1 clinical trial.

371 CHIMERIC ANTIGEN RECEPTOR MACROPHAGES (CAR-M) SENSITIZE SOLID TUMORS TO ANTI-PD1 IMMUNOTHERAPY

[1]Stefano Pierini*, [1]Rashid Gabbasov, [1]Cecilia Nunes, [1]Alison Worth, [1]Yumi Ohtani, [1]Michael Ball, [1]Rehman Quereshi, [2]Olga Shestova, [2]Saar Gill, [3]Serody Jonathan, [1]Sascha Abramson, [1]Thomas Condamine, [1]Michael Klichinsky. *[1]Carisma Therapeutics, Philadelphia, PA, USA; [2]University of Pennsylvania, Philadelphia, PA, USA; [3]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC, USA*

Background Despite the remarkable efficacy achieved by CAR-T therapy in hematologic malignancies, application in solid tumors has been challenging. Given that CAR-M are M1-polarized macrophages with the potential to remodel the tumor microenvironment (TME) and act as professional antigen presenting cells, we developed an immunocompetent animal model to evaluate the interaction of CAR-M with the TME and the adaptive immune system. A Phase 1 FIH study evaluating the safety and feasibility of CT-0508 (a first in class CAR-M comprised of autologous human monocyte derived macrophages expressing an anti-HER2 CAR) is ongoing.[1]

Methods Murine bone marrow-derived macrophages were engineered to express an anti-HER2 CAR using the chimeric adenoviral vector Ad5f35. To evaluate the safety and efficacy of CAR-M therapy, immunocompetent mice were engrafted with HER2+ tumors and treated with syngeneic CAR-M monotherapy or in combination with a PD1 blocking antibody. Tumors were collected at various time points and dynamic changes in the TME were assessed using flow cytometry, immunohistochemistry, multiplexed immunofluorescence, gene expression analysis and TCR sequencing.

Results CAR-M, but not control macrophages, phagocytosed and killed HER2-overexpressing tumor cell lines. CAR-M induced MHC-I expression on tumor cells and enhanced the cytotoxicity of $CD8^+$T cells. In vivo, CAR-M led to significant tumor regression and improved overall survival in multiple syngeneic models. Analysis of the TME showed that CAR-M led to increased infiltration of intratumoral CD4+ and CD8+ T, NK, and dendritic cells as well as enhanced epitope spreading. Transcriptomic analysis of post-treatment biopsies collected from patients enrolled in the CT-0508 CAR-M Phase 1 clinical trial demonstrated remodeling of the TME, increased T cell infiltration, T cell activation/proliferation, and increased T cell clonality in the TME. In some patients, increased T cell exhaustion and increased expression of checkpoint receptors was detected post-treatment. Given these results, we evaluated the combination of CAR-M with anti-PD1 in tumors resistant to anti-PD1 monotherapy and found that the combination further reprogrammed the TME, significantly enhanced tumor control, and improved overall survival compared to monotherapy with either agent. Mice that achieved complete responses after CAR-M therapy were protected against antigen-negative relapse, indicating long-term anti-tumor immunity. Finally, the combination of CAR-M with anti-PD1 was well tolerated across numerous safety assessments.

Conclusions These results demonstrate that CAR-M reprogram the TME, induce epitope spreading, and orchestrate a systemic immune response against solid tumors. Moreover, our findings provide pre-clinical and clinical rationale for the combination of CAR-M with immune checkpoint inhibitors for the treatment of solid tumors.

372 AGENT-797, A NATIVE ALLOGENEIC "OFF-THE-SHELF" INVARIANT NATURAL KILLER T (INKT) CELL THERAPY PRODUCT IMPROVES EFFECTOR FUNCTIONS WITHIN THE TUMOR MICROENVIRONMENT

[1]Sapana Pokharel*, [2]John Chamberland, [2]Yu Qin, [1]Darrian Moskowitz, [1]Reed Masakayan, [1]Xavier Michelet, [2]Dhan Chand, [1]Burcu Yigit, [1]Marc Van Dijk. *[1]MiNK Therapeutics, Lexington, MA, USA; [2]Agenus Inc, Lexington, MA, USA*

Background T cell exhaustion is a common phenomenon that occurs in the tumor microenvironment (TME) due to prolonged exposure of T cells to tumor antigen. This is in part governed by the suppressive microenvironment created by myeloid cells. Immune checkpoint inhibitors have shown promising outcomes in clinical trials treating patients with solid cancer. However, not all patients with cancer respond to checkpoint therapy, demonstrating an unmet need to optimize the current approaches including cell therapies and combination strategies. We show here that agenT-797 can reinvigorate exhausted T-cells and differentially target myeloid cells

Methods We developed a multi-platform to evaluate interaction of agenT-797 with exhausted antigen-specific T cells and myeloid cells. Briefly, we transduced pan T cells with an NY-ESO-1 specific TCR and co-cultured them for multiple rounds with melanoma cell line, A375 that endogenously expresses HLA-A*02:01 and NY-ESO-1 antigen. Killing capacity, cytokine profile and phenotype of T cells were analyzed at each round of antigen exposure. We observed progressively reduced activity with each successive round. To assess whether addition of agenT-797 rescues functional impairment of partially exhausted T cells, we performed co-culture experiments of agenT-797 (or conditioned media) with T cells and A375 cells and monitored tumor cell killing and activation of T cells. In addition, we generated M1 and M2 macrophages and DCs and co-cultured them with agenT-797 to monitor activation and killing.

Results NY-ESO-1 specific T cells with progressive degree of exhaustion show reduced proliferation and IFNg production along with increased TIGIT expression. Upon addition of agenT-797 into co-culture (or conditioned media), we observed increased IFN-g production and activation of CD8 T cells followed by restored cytotoxic capacity of partially exhausted T cells. agenT-797 was observed to selectively kill M2 macrophages over M1 macrophages, while increasing DC activation.

Conclusions iNKT cells are known to modulate the tumor microenvironment they are part of. Immune-infiltrated tumors contain T cells in different exhaustion states as well as suppressive myeloid cells. We addressed whether iNKT cells can reinvigorate such exhausted T cells and target suppressive macrophages. Our data demonstrates that agenT-797 can improve the function of partially exhausted T cells, selectively kill M2 macrophages, and enhance DC activation in addition to exhibiting their intrinsic natural anti-tumor activity. This highlights the potential of iNKT cells as a cell therapy platform and sheds more light on the mechanisms by which they can act.

373 COMBINATION VACCINE, ADOPTIVE NK CELL TRANSFER AND CHECKPOINT BLOCKADE REDUCE MURINE NEUROBLASTOMA PROGRESSION AFTER BONE MARROW TRANSPLANT

[1]Aicha Quamine*, [1]Nicholas Mohrdieck, [1]Chloe King, [1]Anastasia Griggs, [1]Paul Bates, [1]Sean Rinella, [1]Katharine Tippins, [2]Tyce Kearl, [2]Bryce Johnson, [1]Christian Capitini. *[1]University of Wisconsin Madison, Madison, WI, USA; [2]Medical Collage of Wisconsin, Milwaukee, USA*

Background Despite use of intense multimodal therapy for treatment of high-risk neuroblastoma, poor survival outcomes persist. While autologous stem cell transplant (SCT) is standard of care for high risk patients, allogeneic SCT has been explored to produce a graft-versus-tumor (GVT) effect but has been hampered by tumor relapse and graft-versus-host disease (GVHD). We propose enhancing GVT by combining adoptive Natural Killer (NK) cells, anti-PD1 checkpoint blockade, and a neuroblastoma vaccine engineered to express CD54, CD80, CD86, and CD137L (AgN2a-4P) to stimulate donor T and NK cells.

Methods NK cells or T cells were isolated from C57BL/6 (B6) mice and expanded *in vitro* with IL-15/IL-15Rα alone (NK), IL-2 (T cells) with/without AgN2a-4P for 7 days. All groups were analyzed by flow cytometry. For *in vivo* studies, on day +0, recipient mice received lethal radiation and either syngeneic (B6 to B6) or allogeneic (B6 to B6AJF1) SCT. Mice were inoculated with 9464D or NXS2 neuroblastomas to model relapse, and then treated with anti-PD1 antibody. Select groups received irradiated AgN2A-4P and/or donor-derived NK cells on days 14, 21, and 28. B6 $Rag1^{-/-}$ mice were used as bone marrow donors to analyze the role of donor B and T cells, while select B6 recipients were injected with anti-NK1.1 every 4 days to analyze the role of NK cells. All groups were analyzed for tumor growth, GVHD and overall survival. Tumors were also analyzed for relative gene expression by bulk RNA-Seq.

Results T cells exposed to AgN2a-4P showed a significant increase in CD69, PD-1 and TIM-3 after 7 days, while NK cells exposed to AgN2a-4P expressed high levels of NKG2D and NKp46 in vitro. After autologous and allogeneic SCT, combination NK cells, anti-PD1 and AgN2a-4P led to a significant decrease in tumor growth and increase in survival. Multiple NK infusions were superior to a single infusion. Usage of $Rag1^{-/-}$ donors abrogated the benefits of combination immunotherapy on tumor growth, whereas depleting NK cells abrogated the benefits of AgN2a-4P alone more than AgN2a-4P and anti-PD1.

Conclusions AgN2a-4P vaccine activates both T and NK cells in vitro. Combination NK cell therapy with anti-PD1 and AgN2a-4P vaccination significantly decreases neuroblastoma tumor growth in vivo. T and NK cells are required for therapeutic benefit, and modulation of myeloid gene expression is observed within the TME. These studies provide the first evidence that adoptive NK cell therapy, checkpoint blockade and tumor vaccines show safety and efficacy in combination after SCT.

374 DISCOVERY OF A PUBLIC HPV16-E6 DIRECTED T CELL RESPONSE THAT IS ASSOCIATED WITH OVERALL AND PROGRESSION FREE SURVIVAL

[1]Klaudia A Szymonowicz, [1]Bo Jiang, [2]Laurene Cheung, [1]Weihong Xiao, [1]Alexa J Halliday, [1]Emily Bontekoe, [1]Keiko Akagi, [1]Gregory Lizee, [2]Kellie Smith, [1]Maura Gillison, [1]Nils-Petter Rudqvist*. [1]*The University of Texas MD Anderson Cancer Center, Houston, TX, USA*; [2]*Johns Hopkins School of Medicine, Baltimore, MD, USA*

Background Human papillomavirus (HPV) infection causes at least 650,000 anogenital and oropharyngeal cancers (OPC) worldwide annually. Despite the viral immunological target, immune checkpoint inhibitors produce responses only in a minority of patients, and cancer therapies that directly target HPV-antigens represent an attractive alternative therapeutic approach. With this work, we introduce a high-throughput and epitope-agnostic pipeline for HPV16-reactive T cell discovery and validation.

Methods Using the FEST assay [1], T cell responses against HPV16 were assessed in 3 patients with HPV16-positive OPC that participated in an open-label phase I clinical trial studying the safety and immunogenicity of vaccination with a DNA-based HPV16-E7 vaccine. T cell receptor (TCR) motifs were constructed using GLIPH2 [2]. Enrichment of motifs in tumors and HLA alleles among patients was determined using Wilcoxon signed-rank test and Fisher Exact test, respectively. Association between TCR motifs and survival was assessed using a log-rank test. Single cell sequencing (sc-seq) was performed using the 10x platform. Expression of TCRs in effector cells was achieved using electroporation. All studies were approved by MD Anderson IRB (PA17-0149, PA19-0470, and 2019-1059).

Results Sixteen HPV16-reactive TCRs were identified in 3 patients with HPV16-positive OPC, and responses were found against most HPV16 proteins. Five clones were associated with commonly shared TCR motifs identified in our combined patient cohort. A TCR motif against HPV16-E6 (E6-TCR-motif) was found enriched in tumors ($p=0.007$; figure 1) of patients who expressed a common HLA allele ($p=0.0019$; figure 2). Strikingly, no patients that naturally harbor the E6-TCR-motif died ($p=0.04$) nor progressed ($p=0.023$; figure 3). Recognition of a region within E6 by a T cell belonging to the E6-TCR-motif was validated via transgenic TCR expression in Jurkat cells co-cultured with HLA-matched peptide-pulsed target cells, and eventually the minimal epitope was determined. Impressively, an interaction between TCR and epitope was still detectable at 10^{-15} M peptide concentration, a factor 1000 lower compared to our positive control TCR [3] against HPV16-E6 (figure 4).

Conclusions We have identified a common HPV16-E6 specific TCR motif shared among patients with HPV16-positive OPC cancer that is associated with survival. We are currently working to translate this finding to the clinic as an adoptive cellular therapy. Given the success of this approach, we are working to map the antigenic/TCR landscape in patients with HPV16-positive tumors, with the goal of developing a suite of TCR-based therapies restricted to common HLA alleles and to construct a therapeutic vaccine against persistent HPV16 infection.

Acknowledgements This research was supported by The University MD Anderson HPV-Related Cancers Moon Shot, the MD Anderson Oropharynx Cancer Program, and Intramural Startup funds. FEST assays were performed by the FEST and TCR Immunogenomics core at Johns Hopkins University. We would also like to thank Drs. Alexandre Reuben and Minying Zhang for sharing reagents.

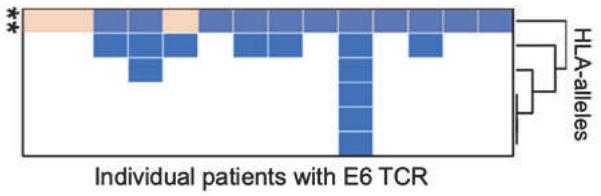
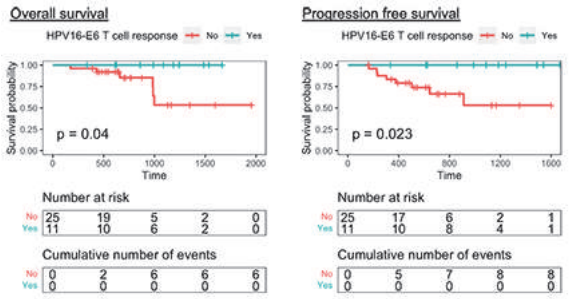
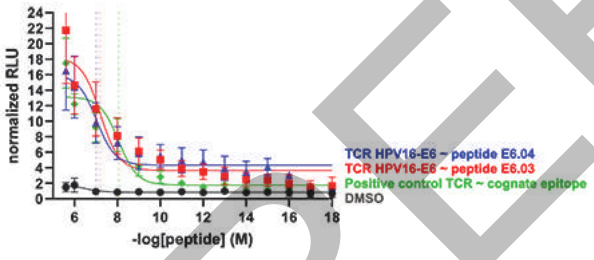
Abstract 374 Figure 1 HPV16-E6 TCR motif is enriched in tumors of patients with HPV16-positive oropharyngeal cancer. Frequency of T cell clones that belong to the HPV16-E6 TCR motif constructed using the GLIPH2 algorithm is shown. Statistical significance was determined using a Wilcoxon signed-rank test. Color represents data source (not shown). Line indicates paired tumor and blood data.



Abstract 374 Figure 2 Specific HLA-allele is enriched among patients that harbor HPV16-E6 TCR motif. Rows represent a specific HLA allele, columns represent individual patients. Enriched HLA allele is highlighted in orange (top row). Statistical significance was calculated using Fisher Exact test; ** indicate p-value < 0.01.



Abstract 374 Figure 3 Harboring the HPV16-E6 TCR motif is associated with survival. Natural presence of T cells from the HPV16-E6 TCR motif in tumors and/or blood was associated with overall (left) and progression free (right) survival in HPV16-positive oropharyngeal cancer patients that express the shared HLA allele.



Abstract 374 Figure 4 HPV16-E6 TCR motif T cells recognize their cognate epitope with high sensitivity. A full-length paired TCR belonging to the E6-TCR motif was expressed in Jurkat T cells without endogenous TCR expression and that has been genetically modified to produce luciferase upon TCR engagement. Peptide-pulsed and HLA-matched CD3 PBMC was used as target cells. DMSO (negative control) is shown in black and a positive control TCR that recognize the HPV16-E629-38 epitope [3] is shown in green. Blue and red represent the HPV16-E6 TCR we have discovered when pulsed with two different 15 amino acid long peptides that share a region of 11 amino acids; the minimal epitope reside in the overlapping region.

375 IN VIVO GENERATION OF UNIVERSAL CAR T CELLS THAT MEDIATE DURABLE ANTI-TUMOR IMMUNITY THROUGH COMBINATORIAL TARGETING WITH BISPECIFIC SMALL MOLECULE ADAPTERS

Kristen Mittelsteadt*, Isabel Leung, Kelsey Lynch, Haiyan Chu, Chang-Chih Wu, Seungjin Shin, Ryan Larson, Andrew Scharenberg, Byoung Ryu, Laurie Beitz. *Umoja Biopharma, Seattle, WA, USA*

Background Chimeric antigen receptor (CAR) T cell therapies have demonstrated limited efficacy against solid tumors, in part due to challenges overcoming solid tumor heterogeneity and CAR T cell exhaustion associated with the immunosuppressive tumor microenvironment (TME). Our integrated platform aims to overcome these roadblocks by engineering T cells in vivo to express a universal TagCAR which binds to a common tag on bispecific adaptor TumorTags, bridging TagCAR T cells to TumorTag-bound tumor- and TME-associated antigens, including folate receptor (FR) which is upregulated on many tumor types as well as immunosuppressive tumor-associated macrophages. Additionally, our TagCAR T cells are engineered to express a rapamycin-activated cytokine receptor (RACR) which selectively provides survival signals to TagCAR T cells in the presence of rapamycin. Here, we identify a universal TagCAR that demonstrates potent in vitro and in vivo anti-tumor polyfunctionality against FR^+ target cells with a folate receptor-targeting TumorTag (UB-TT170).

Methods PBMCs from healthy donors were transduced in vitro with surface-engineered lentiviral vectors with TagCAR/RACR payloads. Resultant TagCAR T cell anti-tumor activity and persistence was assessed using a co-culture approach with FR-expressing tumor cells and titrated doses of UB-TT170. To assess in vivo anti-tumor activity, lentiviral particles containing TagCAR/RACR payloads were administered to PBMC-humanized NSG mice with established FR^+ xenograft solid tumors to generate TagCAR T cells in vivo. Mice were treated with UB-TT170 and efficacy was determined by assessing tumor regression and UB-TT170-mediated TagCAR T cell expansion.

Results TagCAR T cells containing a CD8α hinge/transmembrane domain and 41bbζ endodomain were superior to other construct candidates in eliminating FR^+ target cells in the presence of UB-TT170 in vitro. These TagCAR T cells demonstrated UB-TT170-mediated expansion and proinflammatory cytokine production in the presence of FR^+ target cells, and repeated elimination of target cells and enhanced persistence properties with serial antigen-exposure. Cells transduced with this vector exhibited RACR-mediated expansion and improved function in the presence of rapamycin. Administration of TagCAR/RACR payload-containing lentiviral particles to PBMC-humanized NSG mice resulted in generation of TagCAR T cells in vivo, which expanded and mediated clearance of FR^+ solid tumors with UB-TT170

Conclusions We have identified a universal TagCAR that displays robust anti-tumor activity and persistence qualities against FR^+ target cells in vitro and in vivo with UB-TT170. These data support development of this platform as a new cellular therapy approach against solid tumors, using combinatorial targeting of tumor- and TME-associated antigens with an in vivo-generated universal TagCAR and multiple TumorTags.

376 MACROPHAGES ENGINEERED TO EXPRESS SYNTHETIC CYTOKINE SWITCH RECEPTORS ACT AS LIVING MICROENVIRONMENT CONVERTERS

Chris Sloas*, Yuhao Huangfu, Thomas Condamine, Michael Klichinsky, Yumi Ohtani. *Carisma Therapeutics, Philadelphia, PA, USA*

Background Cytokines in tissue microenvironments regulate the balance between pro- and anti-inflammatory signaling. Dysregulated cytokine expression causes deleterious immunosuppression or inflammation, underpinning the pathophysiology of numerous diseases. As examples, anti-inflammatory cytokines in solid tumors suppress immune activation and safeguard the tumor, whereas pro-inflammatory cytokines in rheumatoid arthritis drive chronic inflammation. Rebalancing inflammation/immunosuppression by targeting aberrant cytokine signaling offers a generalizable approach to treating many diseases, but systemic cytokine blockade carries risks such as increased risk of infection. Cellular immunotherapies may offer a localized platform that could activate in response to cytokines then proportionately remodel the microenvironment's inflammatory state as needed. Macrophages are tissue-infiltrating homeostatic regulators responsible for initiating and resolving inflammation. Engineered macrophages have demonstrated a promising ability to target tumor cells utilizing chimeric antigen receptors. Here, we leveraged the ability of macrophages to regulate inflammation by generating macrophages that express synthetic cytokine switch receptors. We termed this platform "Engineered Microenvironment Converters" (EM-C) and evaluated its modular ability to convert immunosuppressive M2 signals into pro-inflammatory M1 responses for solid tumor microenvironment conversion, or *vice versa* for inflammatory disease.

Methods EM-C were generated by expressing switch receptors (SR) in primary human macrophages. To convert IL10, a prevalent immunosuppressive cytokine in the TME, into a pro-inflammatory signal, an IL10 SR was designed and delivered to macrophages using VPX-Lentiviral particles. The *in vitro* response of IL10 EM-Cs to IL10 was monitored using phenotypic characterization of surface molecules, measurement of cytokine production, and biochemical analysis of downstream signaling. To assess the ability of EM-Cs to alter the inflammatory status of their environment, *in vitro* co-culture assays were established with M2-polarized bystander cells, and the phenotype of bystanders and EM-Cs was assessed individually. Similarly, EM-Cs targeting TGFβ or IFNγ were characterized.

Results IL10 EM-Cs converted IL10 into a pro-inflammatory signal. Unlike wildtype macrophages, IL10 EM-Cs treated with IL10 upregulated M1 markers and cytokines in a dose-dependent manner. Furthermore, IL10 EM-Cs repolarized bystander M2 macrophages towards a pro-inflammatory phenotype following co-culture. Additionally, TGFβ EM-Cs were generated and converted TGFβ to a pro-inflammatory signal. IFNγ EM-Cs were generated and converted IFNγ, a canonical M1 cytokine, into an M2 signal.

Conclusions We present for the first time a novel immunotherapy platform that harnesses macrophages as "living converters" to locally regulate inflammation for oncology and inflammatory applications. By demonstrating EM-Cs in the M2-to-M1 and M1-to-M2 direction, this platform offers modularity in controlling the inflammatory status of tissue microenvironments without systemic cytokine antagonism.

377 ADOPTIVE CELL THERAPY WITH CYTOKINE-INDUCED KILLER CELLS RETARGETED WITH IMMUNOTOOLS AGAINST HER-2 POSITIVE BREAST CANCER

[1]Roberta Sommaggio*, [2]Elisa Cappuzzello, [2]Annavera Ventura, [2]Sara Perpinello, [1]Anna Dalla Pieta, [2]Emilia Vigolo, [2]Giulia D'accardio, [1]Pierangela Palmerini, [1]Antonio Rosato. [1]*University of Padova, Padova, Italy*; [2]*Veneto Institute of Oncology IOV-IRCCS, Padova, Italy*

Background Cytokine-Induced Killer (CIK) cells are a heterogeneous population of $CD3^+CD56^+$ effector cells easy to expand from PBMCs in clinically relevant numbers, which are endowed with T and NK cells phenotypic and functional properties.[1] They show an MHC-unrestricted cytotoxicity and exert Antibody-Dependent Cell-mediated Cytotoxicity (ADCC) when combined with monoclonal antibodies (mAbs).[2] In the present study, CIK cells were combined either with Trastuzumab (TRS) or with the engineered TRS V90Lec13, which bears two amino acid substitutions (S239D/I332E) and lacks Fc fucosilation or with a bispecific antibody (bsAb) directed against HER-2 and CD3 (HER2xCD3).

Methods CIK cells were obtained from PBMCs by the addition of IFNγ, OKT3 and IL-2. The effector cell cytotoxicity and the dose-dependent activity of HER2xCD3 and TRS V90lec13 were evaluated with a 4-hours Calcein-AM assay and with a 72-hours real-time cell analysis against HER-2-expressing breast cancer cell lines. The concentration of cytokines produced upon the co-colture of CIK cells with target cells was assessed with a multiplex assay. The biodistribution of the bsAb was evaluated in NSG mice upon the chemical conjugation of HER2xCD3 with a fluorophore.

Results The combination of CIK cells with HER2xCD3 or TRS V90lec13 resulted in a significant improvement of the antigen-specific cytotoxic activity against breast cancer cell lines when compared to the combination of CIK cells with clinical mAb TRS. In particular, the real time analysis showed that even at a very low effector/target (E/T) ratio, such as 0.1:1 E/T ratio, CIK cells combined with HER2xCD3 showed a remarkable cytotoxicity, completely restraining target cells growth. Interestingly, TRS-resistant tumor cell lines showed to be sensitive to HER2xCD3-redirected CIK cell lytic activity. Moreover, bsAb resulted to be effective also at very low concentrations, and the cytokines released from CIK cells matched with a proinflammatory profile, with no significant concentration of cytokines correlated with Cytokines Release Syndrome (CRS), such as IL-6 and IL-5. The analysis of the *in vivo* biodistribution showed that the bsAb arrives efficiently at the tumor site where accumulates and reaches the maximum concentration 8 hours after i.v. injection.

Conclusions Taken together, these results highlight the potentiality of using recombinant immunotools to improve the antigen-specific cytotoxic activity of CIK cells against HER-2 positive tumor cells.

378 CHIMERIC ENGULFMENT RECEPTOR (CER) T CELLS WITH A TLR2 DOMAIN SYNERGIZE WITH AN EGFR INHIBITOR TO TARGET NSCLC CELLS IN VITRO AND DEMONSTRATE APC-LIKE FUNCTION

Sunil Thomas*, Harini Kethar, Linh Nguyen, Brandon Cieniewicz, Alex Arballo, Priya Baichoo, Damoun Torabi, Ankit Bhatta, Daniel Corey. *Cero Therapeutics, South San Francisco, CA, USA*

Background A barrier to successful adoptive cell therapy for solid tumors is target antigen heterogeneity and antigen escape. Activated T cells, including CAR T cells, have limited innate antigen capture/presentation capabilities.[1] We engineered a novel TIM-4 CER that bears a toll/interleukin-1 (TIR) signaling domain from TLR2 designed to induce both direct cell-mediated cytotoxicity and initiate secondary immune responses, leading to improved solid tumor clearance and durability of response. CER-T cells offer potential pairing with multiple small molecule drugs to enhance the TIM-4 target ligand. We tested for antigen-presenting cell (APC)-like function, characterized transcriptional signatures, and quantified cytotoxic responses against EGFR-mutant NSCLC cells in combination with the epidermal growth factor inhibitor (EGFRi) osimertinib.

Methods CER-1236 contains a TIM-4 extracellular signaling domain fused with a TLR2-TIR domain, CD28 and CD3zeta. Using PS-coated beads labeled with a pH-sensitive dye (pHrodo), we quantified CER-1236 phagocytic uptake by FACs and fluorescent microscopy. Cytotoxic and proliferative responses against osimertinib-treated H1975 NSCLC cells was tested in vitro. We quantified APC activity by evaluating autologous HPV E7 TCR T cell activation and proliferation following CER-1236 co-culture with HLA-matched HPV-16 E7+ SCC152 tumor cells. To characterize transcriptional states, we performed bulk RNA-sequencing at rest and following activation. TLR2 inhibition was used to examine signaling pathway induction.

Results In combination with subtherapeutic osimertinib doses, CER-1236 eliminated 97% of targets by 72h at low effector: target ratios. EGFR inhibition drove target-dependent proliferation, production of TH1 cytokines (IFN-gamma, TNFalpha) and granzyme-B. Upon co-culture with PS-coated beads, 60% of CER-1236 T cells demonstrated increased bead uptake compared to untransduced or CER T cells expressing a TIM-4 PS-binding mutant ($p<0.0001$), APC assays demonstrated higher activation of E7-TCR T cells by CER-1236 than untransduced T cells, indicating occurrence of antigen uptake and presentation. Both cytokine production and antigen presentation were inhibited by a TLR2 inhibitor. Finally, transcriptional profiling identified a distinct signature related to APC-like function upon CER-1236 stimulation with enrichment of NF-kB, MAP kinase, TNFalpha and chemokine signaling.

Conclusions Novel TIM-4-containing CER T cells that include a TLR2 signaling domain synergize with osimertinib to eliminate EGFR-mutant NSCLC cells in vitro. Notably, CER T cells capture and present tumor cell antigen, and demonstrate APC-like transcriptional signatures. Antigen presentation, alongside inducible, target-specific cytotoxic function in single T cells, represent a potential advantage to initiate host immune responses against novel antigens for solid tumors.

379 **ENGINEERING OF GAMMA/DELTA T CELLS DERIVED FROM CORD BLOOD FOR CHIMERIC ANTIGEN RECEPTOR-T CELL THERAPIES**

[1]Chelsia Qiuxia Wang*, [2]Alice Cheung, [1]Andy Hee-Meng Tan. [1]*Bioprocessing Technology Institute (BTI), Singapore, Singapore*; [2]*Singapore General Hospital (SGH), Singapore, Singapore*

Background Adoptive cellular immunotherapy as a new paradigm to treat tumors is exemplified by the FDA approval of six different chimeric antigen receptor (CAR)-T cell therapies targeting hematological malignancies in recent years. Conventional alpha/beta (ab) T cells applied in these therapies have proven efficacy but with hitherto disappointing outcomes when applied to solid tumors, largely due to poor survival and reduced efficacy of CAR-T cells in the immunosuppressive solid tumor microenvironment (TME). Moreover, these therapies are confined exclusively to autologous use since, upon infusion, they elicit devastating graft-versus-host disease (GvHD) in human leukocyte antigen (HLA)-mismatched patients. One way to overcome these challenges is to use allogeneic immune cell types, in particular gamma/delta (gd) T cells, which occupy the interface between innate and adaptive immune cells and recognize a wide variety of ligands expressed on transformed cells. Importantly, specific gd T cell subsets such as Vd1 T cells, have a natural propensity to home to solid tissues.

Methods We propose to harness these characteristics of gd T cells by generating CAR-T cells using cord blood (CB)- compared with peripheral blood (PB)-derived gd T cells. We expanded CB- and PB-gd T cells using a feeder cell-based protocol and transduced them with a HER2-targeting CAR bearing CD28 co-stimulatory endodomain and CD3z activation domain (4D5-28z CAR) via two-step retrovirus-based delivery. Both *in vitro* and *in vivo* cytotoxicity of 4D5-28z CB- and PB-gdT cells against selected solid tumor cell lines were assessed using bioluminescence-based methods.

Results We found that CB-gd cells were less amenable to CAR transduction, resulting in substantially lower frequencies of CAR-positive CB-gd T cells compared with PB-gd counterparts. Efforts are underway to optimize transduction to enhance CAR expression in CB-gd T cells. Despite fewer CAR-positive CB-gd T cells, we consistently observed that these cells exhibited increased *in vitro* cytotoxicity against SK-OV-3 ovarian tumor cells compared with non-CAR counterparts. However, our preliminary results demonstrated that both CAR- and non-CAR CB-gdT cells lacked persistence *in vivo*, alluding to the need for further genetic modifications of gd CAR-T cells to secrete cytokines which can help them overcome the immunosuppressive effects of TME and improve their *in vivo* functionality.

Conclusions Taken together, our findings highlight the potential of CB-gd T cells in allogeneic CAR immunotherapy by increasing the efficiency of their genetic engineering and *in vivo* anti-tumor efficacy.

380 DEVELOPMENT AND CHARACTERIZATION OF A CAR T CELL POTENCY ASSAY WITH 3D CANCER SPHEROID MODELS

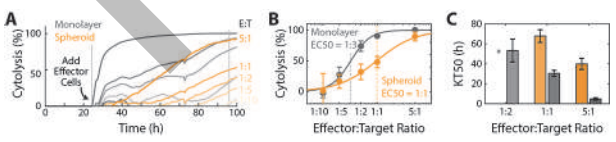
Omari Weems, Denise Sullivan, Austin Passaro*, Stacie Chvatal, Daniel Millard. *Axion Biosystems, Atlanta, GA, USA*

Background The tumor microenvironment poses a significant challenge to immune therapies, like CAR T cells, for solid tumor indications. Development of in vitro 3D models may provide a more accurate assessment of CAR T potency. Here, we developed a real-time, label-free potency assay for evaluation of CAR T cell-mediated cytotoxicity of 3D cancer spheroids.

Methods In this study, the Maestro Z impedance system was used to develop a real-time, label-free potency assay for immune-cell mediated killing of 3D cancer spheroids. Cancer spheroids were produced with SKOV3 cells in ultra-low attachment U-bottom microplates for four days and then transferred to the CytoView-Z plate. The attachment and growth of SKOV3 spheroids was monitored using the resistance measurement of the Maestro Z. After 24 hours, the SKOV3 spheroid and monolayer groups were treated with HER2-specific CAR T cells at matched effector-to-target cell ratios and cytolysis was computed for the following 72 hours of real-time measurement.

Results The spheroid potency assay was used to compare CAR T cell-mediated cytolysis of SKOV3 spheroids and monolayer cultures with HER2-specific CAR T cells. The steady increase in resistance for the untreated group indicated continued spheroid growth after transfer to the CytoView-Z 96-well plate. CAR T effector cells were added at five E:T ratios at 24 hours post-plating of the target cells. The monolayer groups (gray) had higher rates of cytolysis than their respective spheroid groups (orange) for the same E:T ratios (figure 1A). Cytolysis was compared at 72 hours post-addition of the CAR T effector cells (figure 1B) and potency was quantified via a dose response regression. The EC50 E:T ratio of the HER2-specific CAR T cells was 1:3 for the monolayer target cells and 1:1 for the spheroid target cells. These results suggest a decreased potency of HER2-specific CAR T cells against a 3D tumor model in vitro. CAR T potency was also evaluated via the KT50, a measure of the kinetics of immune cell-mediated killing (figure 1C). There was a dose dependance of CAR T killing within the monolayer and spheroid groups, with monolayer groups having shorter KT50s than the matched spheroid groups.

Conclusions These results suggest that 3D cancer spheroid had a higher resistance to CAR T killing than monolayer cultures, which may reflect an improved representation of the tumor microenvironment for an in vitro potency assay.



Abstract 380 Figure 1 CAR T cells exhibit reduced cytolysis against spheroids
(A) Cytolysis over time of 10k SKOV3 spheroids and monolayers treated with 4-1BB (HER2 targeting) CAR T cells at effector-target ratios of 1:10, 1:5, 1:2, 1:1, and 5:1. (B) Cytolysis between spheroids and monolayer in respect to their effector-target ratios. EC50 measured the 4-1BB CAR T ratio required to achieve 50% cytolysis. (C) KT50 between spheroids and monolayer groups, displaying both dose dependance for both groups and differences in duration to achieve 50% cytolysis between groups. *indicated 1:2 spheroid group did not reach a KT50.

381 LARGE-SCALE EXPANSION AND ENGINEERING OF HUMAN NK CELLS SOURCED FROM PERIPHERAL BLOOD VERSUS UMBILICAL CORD BLOOD

Michael Whang*, Ming-Hong Xie, Kate Jamboretz, Chang Kim, Sombeet Sahu, Hadia Lemar, Nafees Rahman, Ivan Chan, Erik Whiteley, Ralph Brandenberger, Sasha Lazetic, James Trager. *Nkarta Therapeutics, South San Francisco, CA, USA*

Background Healthy adult peripheral blood natural killer (PBNK) cells are mature cytotoxic innate lymphocytes possessing an inherent capacity for tumor cell killing, making them attractive candidates for adoptive cell therapy. These NK cells are also amenable to chimeric antigen receptor (CAR) genomic engineering for enhanced functions. Moreover, NK cells possess an inherent capacity for off-the-shelf therapy since they are not known to cause graft-versus-host disease, unlike T cells. Approved CAR cell therapies are custom-made from each patient's own T cells, a process that can limit patient eligibility and contribute to product variability. In this study, we compare PBNK cells to umbilical cord blood NK (CBNK) cells to evaluate both as candidate starting materials for clinical and commercial supply of CAR NK cells.

Methods PBNK and CBNK cells were expanded using either a 14-day protocol and a single stimulation with Nkarta's NKSTIM cell line plus IL-2, or with 5 stimulations over 70 days.[1] IL-12 and IL-18 were added at the beginning and end of the 70-day expansion to drive memory-like NK cell differentiation. We transduced NK cells to express CD19-targeted CAR and membrane-bound IL-15 following the first NKSTIM pulse. We measured cytotoxicity against 3 tumor cell lines by IncuCyte, and phenotyped cells for NK markers including differentiation markers CD57 and NKG2C, and NKG2A and KIR.

Results Purified NK cells from 1 PBNK donor and 4 CBNK donors were successfully expanded and engineered to express high levels of CAR. The 70-day final product (FP) CBNK cells were $CD57^{-}KIR^{lo/-}$ and $NKG2A^{+}$, consistent with an immature phenotype, whereas the FP PBNK cells were educated, at more than 80% $NKG2A^{-}KIR^{+}$. CBNK cells expanded to approximately 11-million-fold, whereas PBNK cells surpassed 250-billion-fold expansion, without appearing to have reached a terminal expansion limit. At the end of the study, Nkarta's standard 14-day process (SP) cells [1], and FP PBNK cells were as potent or trended towards greater potency than CBNK cells against 3 different tumor targets in a 72-hour IncuCyte assay. Furthermore, FP PBNK cells were as or more potent than SP PBNK cells, depending on the tumor target.

Conclusions We demonstrate healthy donor-derived PBNK cells can expand over 250 billion-fold while maintaining potency. These results show robust expansion capability of educated, potent NK cells and provide a rationale for the development of off-the-shelf CAR NK cell therapies using NK cells from donors selected to provide optimal product characteristics.

382 A NOVEL PERIPHERAL BLOOD MONONUCLEAR CELL HUMANIZED MOUSE MODEL FOR PRECLINICAL EFFICACY AND TOXICITY EVALUATION OF CHIMERIC ANTIGEN RECEPTOR T-CELL IMMUNOTHERAPY

[1]Jiwon Yang*, [1]Won Lee, [2]Heather Gustafson, [2]Blair Amrstrong, [2]Katelym Burleigh, [1]Mingshan Cheng, [1]James Keck. [1]*The Jackson Laboratory, Sacramento, CA, United States*; [2]*Seattle Children's Research Institute, Seattle, WA, United States*

Background Chimeric antigen receptor T (CAR T)-cell therapy has emerged as a revolutionary treatment for certain hematological malignancies. While several CAR T therapies showed an efficacious response in selected patients, wider adoption of the therapy is challenged due to toxicity which can be life-threatening, and high relapse potentials (~50%). Clinically we are unable to predict CAR T-cell therapy-associated toxicities and efficacy and thus, need to be addressed and modeled at the individual level. Here, we developed a novel peripheral blood mononuclear cell (PBMC)-humanized mouse model to assess the efficacy and toxicity of CAR T-cell therapy simultaneously. This model reflects individual donor variations recapturing observed clinical levels of toxicity and efficacy.

Methods NSG™ variants, including NSG™-MHC I/II-double knock-out mice that show delayed graft-versus-host disease, were humanized using human PBMCs. PBMC-humanized mice were treated with autologous CAR T-cells targeting CD19, and efficacy, toxicity, and CAR T-cell expansion were assessed. To evaluate these parameters in the presence of tumors, humanized mice were injected with luciferase-tagged human B-cell lymphoma Raji tumor cells.

Results Autologous CD19 CAR T-cell treatment in highly humanized mice showed significant mortality compared to the PBS treatment. When the humanization level was optimized by adjusting the number of PBMCs, the humanized mice showed great efficacy by reducing the target cells in the blood and spleen, and significant human cytokine release, including IFN-γ, IL-10, IL-6, IL-3, and RANTES. This model measures differential toxicity, human cytokine release, and CAR T-cell expansion in different PBMC donors, suggesting that the model can address the individual difference. In the presence of tumor, CAR T-cell treatment induced significantly higher human cytokines (IL-10: ~12,000 pg/mL, IL-6: ~850 pg/mL), as well as greater CAR T-cell expansion, compared to the mice without the tumor.

Conclusions In summary, we have developed a novel humanized mouse model to test the preclinical efficacy and toxicity of CAR T-cell immunotherapy. The assay is rapid that can be completed in 12-16 days. The model captures donor variability and CAR T dose-response, in both efficacy and toxicity, such as cytokine release and body weight loss. Our novel humanized mouse model can potentially be used to predict an outcome in the clinic at the individual level.

Ethics Approval The Jackson Laboratory Institutional Animal Care and Use Committee and institutional review board approved all protocols used.

383 TARGETING IGE-PRODUCING BLOOD CANCERS USING EMPD-SPECIFIC CHIMERIC ANTIGEN RECEPTOR T CELLS

[1]Shenyu Zhang*, [2]Zhengyu Ma, [2]Brittany Fay. [1]*University of Delaware, Wilmington, DE, USA*; [2]*Nemours Children's Hospital, Wilmington, DE, USA*

Background Neoplasm of IgE-producing B lineage cells gives rise to IgE myeloma, chronic B cell leukemia and Hodgkin's lymphoma. Although several chimeric antigen receptor (CAR) T-cell therapies have been approved for treating B cell malignancies by targeting the B cell lineage marker CD19 or B cell maturation antigen (BCMA), these approaches indiscriminately eliminate both cancerous B cells and most normal B cells. This leads to general B cell and plasma aplasia and compromised humoral immune responses.

Methods To specifically target IgE-producing cancer cells, we developed a CAR that targets the extracellular membrane-proximal domain (EMPD) of membrane IgE (mIgE) expressed on the surfaces of IgE-producing cells. EMPD is a 52-residue peptide that exists only on mIgE but not on secreted IgE. Specifically, we generated a human EMPD-specific hybridoma 2E3E10, cloned the heavy and light chain variable regions, and constructed an EMPD-specific second-generation CAR with intracellular 4-1BB and CD3ζ signaling domains. To determine the activity of the CAR, we used a human myeloma cell line U-266 expressing low levels of mIgE as target. In addition, to minimize alloreactive $CD8^+$ T-cell-mediated background killings, we eliminated HLA class I expression on U266 cells by knocking out (KO) beta-2-microglobulin (β2m) using CRISPR/Cas9. We also modified the U-266 cells to express firefly luciferase, enabling a bioluminescence-based killing assay.

Results Through lentiviral transduction, the EMPD-specific CAR was successfully expressed on more than 50% of primary human $CD8^+$ and $CD4^+$ T cells stimulated with anti-CD3/CD28 beads. The expression persisted for more than three weeks in cultures. Coculturing engineered U-266-b2mKO-luci target cells with primary human T cells that expressed the EMPD-specific CAR led to significant T cell cytokine production and target cell killing.

Conclusions The EMPD-specific CAR is capable of mediating primary human T cell activation and cytotoxicity through recognition of the mIgE on IgE-expressing cancer cells. The results demonstrate the proof-of-concept for using EMPD-specific CAR T cells to treat IgE-producing B cell malignancies. Although the CAR T cell eliminates both IgE-producing cancerous and normal B cells, since the vast majority of B cells produce IgG, this approach should not cause general B cell aplasia.

384 SYSTEMATIC, ANTIGEN-AGNOSTIC DISCOVERY OF TUMOR-REACTIVE TCRS POWERED BY REPERTOIRE-SCALE TCR GENE SYNTHESIS AND THE USE OF BANKED ALLOGENEIC CANCER CELL LINES

[1]Xi Chen, [1]Yue Zhao, [1]Ely Porter*, [1]Danielle Cook, [1]Jiekun Xuan, [2]Xiao-Wu Huang, [3]Bin Li, [4]Jingwei Zhang, [5]Lili Ren, [5]Teng Wei, [5]Ning Li. *[1]RootPath, Inc., Watertown, MA, USA; [2]Zhongshan Hospital, Fudan University, Shanghai, China; [3]Shanghai Jiao Tong University, Shanghai, China; [4]Fudan University, Shanghai, China; [5]Shenzhen People's Hospital, Shenzhen, China*

Background Both neoantigen-reactive and wildtype tumor-associated antigen- (TAA) reactive TCRs contribute to anti-tumor immunity. While neoantigens can be identified by deep sequencing, the spectrum of TAA is harder to define. Although some TAAs are well studied, the majority of TAAs are likely undiscovered. Therefore it is difficult to survey the landscape of TAA-reactive TCRs for a given patient. Antigen-agnostic approaches have been reported,[1,2] where patient-derived TCR genes are synthesized and used to make TCR-transgenic T cells, which are co-cultured with autologous tumor cells to observe cytokine secretion. However, these approaches are limited by the number of TCRs tested and the availability of autologous tumor cells.

Methods We have developed a new approach to solve both problems. First, we developed an ultrahigh-throughput TCR gene synthesis technology called PathFinder DNA Assembly™ [3] (figure 1, figure 2a), which bring the cost of TCR gene synthesis to <$1 per TCR (100-folder lower than existing technologies). Second, we use banked cancer cell lines, which express a large swath of known and undiscovered TAAs. This method is justified in part by the similar gene expression profiles between many tumor tissues and many cell lines.[4,5] We developed a simple method to inactivate the endogenous HLA genes of the cell lines and replace them with the HLA genes from the patient, a process we call 'HLA-personalization' (figure 2b, figure 2c).

Results For example, we have synthesized 1,575 TCRs from a liver cancer patient and screened them against HLA-personalized liver cancer cell lines HepG2, Huh6 and Huh7. We have discovered several tumor-reactive TCRs including one that reacts strongly to HepG2, restricted by HLA-C*03:04 (figure 3a). We further confirmed that this TCR can sense and kill HLA-C*03:04-expressing HepG2 cells and autologous tumor cells, but not PBMC of a C*03:04+ donor (figure 3b). We have similarly synthesized 1,053 TCRs from a cervical cancer patient and identified 4 TCRs reactive to HLA-personalized cervical cancer cell lines SiHA or C33A (figure 4). Two of these TCRs were confirmed to be reactive to HPV E7, restricted by HLA-B*38:15. Using this approach, we have synthesized ~50,000 TCRs from 9 patients and identified >70 tumor-reactive TCRs, restricted by a wide array of HLAs, from every patient tested.

Conclusions To our knowledge, this work represents the largest scale of TCR functional screening. The TCRs discovered may be used both as fully personalized TCR-T therapy, and as a repository of TAA-reactive TCRs for conventional TCR-T development after their deorphanization.[6, 7]

385 ENGINEERING A TGF-β SWITCH RECEPTOR ENHANCES CAR-T CELL FUNCTION IN A SUPPRESSIVE TGF-β-ENRICHED TUMOR MICROENVIRONMENT

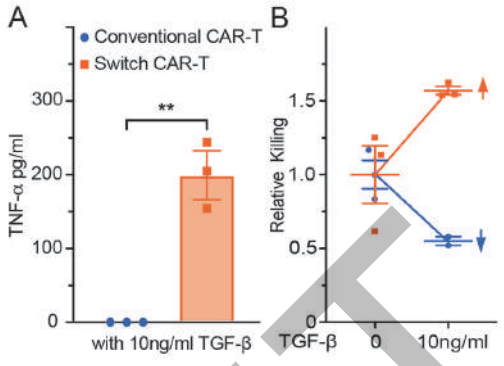
Joe Jiang Zhu*, Criselle DSouza, Vicky Qin, Niko Thio, Michael Kershaw, Joe Trapani, Phillip Darcy, Paul Neeson. *Peter MaCallum Cancer Centre, Melbourne, Australia, Melbourne, Australia*

Background Chimeric antigen receptor T (CAR-T) cells have performed poorly in patients with advanced solid cancers. A critical hurdle for CAR-T cell efficacy is the immunosuppressive tumor microenvironment (TME). CAR-T cell function is profoundly inhibited by transforming growth factor-beta (TGF-β) enriched in the TME. Current strategies to address this issue focus on the abrogation of TGF-β signaling. However, these strategies can have toxic side effects due to an imbalance in T cell homeostasis induced by complete blockade of TGF-β signaling.

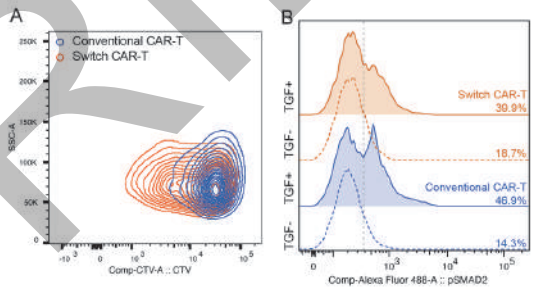
Methods We engineered a novel chimeric switch receptor comprising a TGF-β receptor domain and a T cell costimulatory domain to initiate T cell costimulation upon TGF-β binding. To maintain T cell homeostasis balance, we optimized the intracellular sequence of the switch receptor to reduce its effect on endogenous TGF-β signaling and decrease the potential side effects. The switch receptor was co-expressed in LeY-specific CAR-T cells (switch CAR-T). The *in vitro* function of switch CAR-T cells were investigated in the presence of TGF-β. We also performed RNAseq to explore genes involved in the switch receptor activation. Finally, we demonstrated the anti-tumor efficacy of switch CAR-T cells *in vivo*.

Results In the presence of TGF-β, switch CAR-T cells showed significantly enhanced cytotoxicity and higher levels of TNF secretion compared with conventional CAR-T cells (figure 1). In the presence of both CAR stimulation and TGF-β, but not TGF-β alone, switch CAR-T cells also had significantly higher proliferation and increased mitochondrial biogenesis, indicating an antigen-specific response. Furthermore, both switch and conventional CAR-T cells had equivalent levels of SMAD2 phosphorylation in response to TGF-β, indicating that switch CAR-T cells retained endogenous TGF-β signaling (figure 2). RNAseq analysis showed that switch CAR-T cells have a unique gene expression profile in response to CAR stimulation and TGF-β. Finally, tumor-bearing mice treated with switch CAR-T cells showed significantly better tumor control compared with conventional CAR-T cells (figure 3). This finding was associated with decreased TGF-β and increased IFN-γ levels within the tumor.

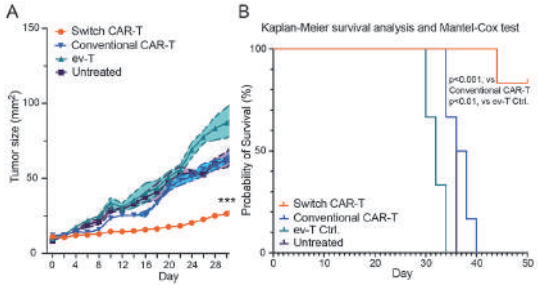
Conclusions The novel switch receptor activated CAR-T cells in response to immunosuppressive TGF-β leading to improved CAR-T cell function. This effect also required CAR-T cell activation through CAR-stimulation, suggesting a tumor-specific response. Furthermore, these switch CAR-T cells provided improved *in vivo* anti-tumor control. By fine-tuning the intracellular sequence of the switch receptor, we also successfully retained the endogenous TGF-β signaling. Switch CAR-T cells can preserve this important homeostatic mechanism and will be safe to use in the clinic.



Abstract 385 Figure 1 Switch CAR-T cells exhibited superior cytotoxicity and cytokine production. (A) Cytokine production of TNF-α after 16 hours of co-culture with LeY+ DU-145 cells and switch CAR-T cells or conventional CAR-T cells with or without TGF-β, measured by AlphaLISA assay (mean ± SEM of triplicate cultures). (B) Relative lysis of LeY+ DU-145 after 16 hours co-culture, measured by 51Cr release assay (mean ± SEM of triplicate cultures).



Abstract 385 Figure 2 The switch receptor enhanced the proliferation of switch CAR-T cells in the presence of TGF-β and maintained endogenous TGF-β signaling. (A) Contour plots showing proliferation of switch CAR-T cells and conventional CAR-T cells labelled with cell trace violet when cultured in the presence of TGF-β. (B) Histogram overlay of phosphorylated SMAD2 gated on CAR+ cells when cultured with TGF-β.



Abstract 385 Figure 3 Switch CAR-T cells showed significantly enhanced tumor control in vivo. (A) NSG mice were inoculated subcutaneously with DU-145 cells and treated with CAR-T cells when tumors were established. The growth kinetics was plotted (n=6). *** p<0.001. (B) Survival analysis was assessed, and the significance of Kaplan-Meier survival analysis was determined by log-rank Mantel-Cox test.

386 **EFFICIENT EX-VIVO EXPANSION OF ADAPTIVE NKG2C+/CD57+ NK CELLS FROM CMV-POSITIVE DONORS USING DENDRITIC CELLS DERIVED FROM THE ACUTE MYELOID CELL LINE DCONE**

Haoxiao Zuo, Remco Bos, Alex Karlsson-Parra, Satwinder Kaur Singh*. *Mendus AB, Leiden, Netherlands*

Background Human cytomegalovirus (CMV) infection profoundly affects NK cell compartment, as documented by the presence of a long-lived adaptive NK cell subset co-expressing NKG2C and CD57. Several features render adaptive NK cells a potentially attractive contributor to the efficacy of mAb-based therapeutic strategies and predict a lower sensitivity to immunosuppressive signals in the tumor microenvironment. Moreover, a recent work showed that CAR-transduced adaptive NK cells exhibit superior effector functions when compared to other NK subsets. The requirements for adaptive NK cell expansion ex vivo have however not been fully characterized. Ex-vivo expansion of NKG2C+ memory NK cells can be achieved by coculturing NK cells from CMV-positive subjects with CMV-infected fibroblasts + IL-2 , HLA-E-transfected cell lines + IL-15, or IgG-opsonized tumor cells + IL-2. However, the reported fold-expansion after 14-21 days in culture in vitro is generally below 30-fold.

Methods PBMCs isolated from buffy coat of CMV-positive healthy donors. NK cells were co-cultured with or without DCOne-derived mature DCs (DCOne mDCs) in the presence of cytokines for 2 weeks. After 1 week, cells were restimulated by the addition of DCOne-derived mature DCs and cytokines. NK cell proliferation, viability and phenotype were monitored on day 7 and 14.

Results DCOne-derived mature DCs (high expression of HLA-DR, CD40/80/86 and CD83) were found to highly express CD58 and CD155, two ligands known to participate in adaptive NK cell activation and expansion. When these tumor cell/dendritic cell "hybrids" were co-cultured for 2 weeks with isolated NK cell from CMV-positive healthy donors, a selective (figure 1) and strong (>200-fold) median expansion (figure 2) of adaptive NKG2C+/CD57+ NK cells was found when cocultures were performed in medium supplemented with IL-2 or IL-15. Characterization of the functional profile, including ADCC, cytokine production and long-time survival, after target cell interaction by these expanded NKG2C+/CD57+ NK cells is ongoing.

Conclusions The presented data indicate that DCOne-derived mature DCs are endowed with the capability to promote strong and selective ex vivo expansion of adaptive NKG2C+/CD57+ NK cells from healthy CMV+ donors. Such expanded NK cells could potentially be used for adoptive immunotherapy, including combinations with tumor-targeting antibodies, in different hematological and solid tumor indications.

387 EXPANSION AND IDENTIFICATION OF NEOANTIGEN REACTIVE TUMOR INFILTRATING LYMPHOCYTES (TIL) FROM METASTATIC COLORECTAL CANCER (CRC)

[1]Matthew Beatty*, [1]MacLean Hall, [1]Holly Branthoover, [1]Mary Rau, [2]Jake Nikota, [2]James Bender, [2]Jake Ceccarelli, [2]Timothy Langer, [1]Jamie Teer, [1]Jason Fleming, [1]Shari Pilon-Thomas. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Turnstone Biologics, Hamilton, Canada*

Background Previously we have shown that neoantigen specific TIL can be enriched from cryopreserved TIL product from melanoma patients. TCGA data for colorectal cancer (CRC) show a median variant count of 111 but with a subset of patients having much higher mutation frequency. Additionally, patients with higher tumor mutation burden (TMB) have been shown to have improved response to immune checkpoint therapy compared to patients with low TMB. Thus, CRC samples with higher mutational frequency may be an ideal candidate for enrichment of neoantigen specific TIL. The purpose of this study is to expand, identify, and enrich neoantigen reactive TIL from CRC patients.

Methods Patient-derived CRC tissue and PBMC were collected at Moffitt Cancer Center under an Ethic's Board approved study (Advarra Pro00043972). TIL was expanded from digested tumor tissue. Whole exome sequencing and RNA sequencing were performed on DNA and RNA extracted from tumor tissue and autologous PBMC. Sequencing and expression data were utilized to identify protein-modifying mutations. Peptides were predicted for their ability to be presented on MHC molecules, prioritized, and synthesized. Neoantigen peptides were loaded onto patient-derived B-cells and co-cultured with autologous TIL. These TIL were then sorted by FACS by upregulation of 4-1BB and OX40 and expanded through the rapid expansion protocol (REP). Enriched TIL were screened for neoantigen reactivity and analyzed by flow cytometry for 4-1BB/OX40 upregulation and cytokine release and degranulation via the ELLA platform.

Results TIL expansion was successfully achieved in 9 of 10 liver metastasis (90%) while only 4 of 10 (40%) samples from the peritoneal cavity expanded TIL. Of the CRC samples that expanded TIL, one patient showed a high mutation frequency with 1710 mutations identified. Restimulation of enriched neoantigen-specific TIL resulted in upregulation of 4-1BB/OX40 from the positive sorted TIL but minimal upregulation from the negative control sorted TIL. This coincided with increased granzyme B, IFNγ, and TNFα in response when compared to their non-reactive TIL counterpart. Of the 196 peptides screened, one peptide corresponding to a known mutation in HDHD3 stimulated 4-1BB/OX40 enriched TIL.

Conclusions TIL from metastatic colorectal cancer patient samples were successfully expanded from multiple disease sites. TIL from these samples can be screened for neoantigens and enriched for neoantigen-reactive TIL. These enriched TIL maintained increased reactivity against these predicted peptides upon restimulation when compared non-reactive TIL. These data support further investigation into the use of neoantigen-enriched TIL products to enhance efficacy of ACT.

Ethics Approval The study was approved by Moffitt Cancer Center's Institutional Review Board, approval number 00043972. Patients gave informed consent before taking part in this protocol.

388 TARGETED OVARIAN CANCER IMMUNOTHERAPY THROUGH ENGINEERING OF FOLLICLE STIMULATING HORMONE RECEPTOR (FSHR) ANTIBODY TO ENGAGE T CELLS

Devivasha Bordoloi*, Pratik Bhojnagarwala, Alfredo Perales-Puchalt, Abhijeet Kulkarni, Xizhou Zhu, Kevin Liaw, Ryan O'Connell, Daniel Park, Daniel Kulp, Rugang Zhang, David Weiner. *The Wistar Institute, Philadelphia, PA, USA*

Background Ovarian cancer is the deadliest gynecologic malignancy, resulting in the highest mortality among cancers of the female reproductive system. The most prevalent subtype of epithelial ovarian cancer (EOC) is high-grade serous cancer which results in 70–80% of cases.[1] OC is a high need area for novel therapeutic interventions; with a focus on identification of targets for immune therapy approaches expressed in the tumor microenvironment being of particular relevance. Follicle stimulating hormone receptor (FSHR) is one such important target with expression in 50-70% of serous OC cells.[2] To date just handful of studies have targeted FSHR. Here we describe development of biologics targeting FSHR and study their impact against multiple ovarian tumors.

Methods We developed monoclonal antibody clones which target FSHR and focused our studies on a potent FSHR cell binding clone for detailed characterization, including binding and evaluation of its effect on antibody dependent cellular cytotoxicity (ADCC). We expanded this work to develop bispecific T cell engager (TCE) targeting FSHR and evaluated for its specificity, functionality, and efficacy in OC models.

Results We observed that the anti-FSHR clone D2AP11 bound specifically to FSHR positive cells and tissues. D2AP11 IgG2a antibody could induce ADCC in OC cells (IC50: 28.5 µg/ml). We sought to improve on its potential through design of D2AP11-TCE. Besides exhibiting strong bidirectional binding, this TCE induced potent in vitro killing of multiple human OC cells; CaOV3, OVISE, Kuramochi, OVCAR3-FSHR, OVCAR4 and PEO-4 which exhibit resistance to different drugs targeting HDAC, microtubule stabilizer, DNA alkylating agents, mTORC, AKT, PARP etc. (table 1)[3,4] and tumor lines harboring mutations in BRCA1&2. IC50 values of D2AP11-TCE killing were obtained at 24.7 and 15.9 ng/ml in OVISE-FSHR and OVCAR3 cells respectively, indicating 1000-fold higher efficacy than IgG2a FSHR biologic (figures 1 and 2). In the NSG in vivo tumor challenge studies, this TCE significantly attenuated tumor burden of a model K562-FSHR, and relevant OVISE-FSHR and OVCAR3-FSHR challenged mice. Median survival of D2AP11-TCE treated mice was increased by 10 days compared to control group.

Conclusions These studies extend published data that FSHR appears to be an important target for further study in the context of OC immunotherapy. We present new tools for studying FSHR in OC and report development of a potent TCE with pM activity to impact OC growth in multiple preclinical models. Additional studies of these new tools for different ovarian as well as other cancers expressing FSHR are of high interest.

389 MULTIPLEXED TCR-T CELL THERAPY TARGETING MAGEA1 AND PRAME ENHANCES THE ACTIVITY OF ADOPTIVE T CELL THERAPY IN PRE-CLINICAL MODELS

Cagan Gurer, Gavin MacBeath, Mollie Jurewicz, Nancy Nabilsi, Antoine Boudot, Jenny Tadros, Tary Traore, Maytal Bowman, Elizabeth Hall, Yifan Wang, Cagan Gurer*, Qikai Xu, Victor Ospina. *TScan Therapeutics, Waltham, MA, USA*

Background Adoptive cell transfer with genetically engineered T cells holds great promise for treating solid tumors. To date, clinical investigations of TCR-engineered T cell therapies (TCR-T) have targeted one antigen at a time and have produced response rates ranging from 30-50%. Unfortunately, complete responses have been rare, and responses are often short-lived. One possible reason why patients rapidly relapse is that their tumors exhibit substantial heterogeneity of antigen expression: not every cancer cell within a tumor expresses the target of a mono TCR therapy and, even when they do, the target is expressed at variable levels among the individual tumor cells. This suggests that TCR-T targeting one antigen could allow the cells lacking the treated antigen to escape and drive relapse.

Methods To address antigen heterogeneity, we are developing multiplexed TCR-T cell therapy in which a patient is treated with multiple TCR-T cell products, chosen from a collection of pre-vetted TCRs matched to the patient's tumor antigens and HLA type. As proof-of-concept, we selected two different cancer/testis antigens targeted by two different TCRs. One of these antigens, MAGEA1, was identified as the target of expanded tumor infiltrating T-cells from a head & neck cancer patient using TScan's screening technology.[1] The other one, PRAME, is highly expressed in a variety of cancers. Using our ReceptorScan platform, we developed two high affinity TCRs that recognize HLA-A*02:01-restricted epitopes from MAGEA1 and PRAME, and assessed the benefits of combining these two TCR-T cell products using a variety of pre-clinical models.

Results Individually, both TCRs show strong cytotoxic activity *in vitro* when co-cultured with HLA-matched cancer cell lines expressing endogenous MAGEA1 and PRAME. Additionally, in xenograft mouse models, each TCR was able to control the growth of tumors expressing their cognate antigens. To test whether the two TCRs exhibit additive or synergistic activity, we developed two different tumor models. In one model, we used a cancer cell line that expresses both MAGEA1 and PRAME. In the other model, a mixture of two different cell lines expressing either MAGEA1 or PRAME were grown as xenograft tumors in mice. Notably, when treated with multiplexed MAGEA1/PRAME TCR-T, the mice achieved longer lasting tumor control compared to TCR-T targeting a single antigen.

Conclusions These findings support the hypothesis that multiplexed TCR-T mimics the natural oligoclonal T-cell response to cancer and has the potential to overcome antigen heterogeneity, which may contribute to the observed lack of durability in monotherapy TCR-T clinical trials.

390 **DIGITAL SPATIAL PROFILING AND ANTIGEN-DEPENDENT PHENOTYPIC ANALYSIS OF IL15-ENGINEERED TUMOR-INFILTRATING LYMPHOCYTES (CYTOTIL15® THERAPY) IN AN ALLOGENEIC MELANOMA PDX MODEL**

Rachel Burga*, Zheng Ao, Arman Aksoy, Scott Lajoie, Kyle Pedro, Jack Tremblay, Gauri Kulkarni, Alonso Villasmil Ocando, Benjamin Primack, Meghan Langley, Theresa Ross, Jeremy Tchaicha, Michelle Ols, Jan ter Meulen, Mithun Khattar. *Obsidian Therapeutics, Cambridge, MA, USA*

Background CytoTIL15® therapy is an IL2-independent, engineered TIL product which allows pharmacological control of membrane-bound IL15 (mbIL15). We have previously shown that cytoTIL15® TILs demonstrate enhanced persistence and anti-tumor efficacy in a human allogeneic melanoma PDX model. Here we use digital spatial profiling and single cell sequencing to characterize the RNA expression profile and phenotypic markers of tumor infiltrating immune cells as well as tumor cells in this model and compare the results to unengineered, IL2-dependent TIL.

Methods cytoTIL15® therapy contains TILs engineered with mbIL15 under the control of a carbonic-anhydrase-2 drug responsive domain, regulated by the ligand acetazolamide (ACZ). cytoTIL15® cells were generated from human melanomas through a proprietary rapid expansion process. Expanded TILs were phenotyped and assayed for *in vitro* polyfunctionality, cytotoxicity, and frequency of tumor-associated antigen-specific TCR. *In vivo* phenotype and anti-tumor functionality was examined through adoptive transfer of TILs into NSG mice bearing subcutaneous, HLA-matched, patient-derived-xenograft (PDX) tumors expressing melanoma-associated antigen MART-1, in IACUC approved animal studies. Tumors, spleen, bone marrow, and blood were harvested 14-21 days following adoptive cell transfer and assessed by flow cytometry, GeoMx digital spatial profiling, and single cell sequencing for characterization of TIL and the tumor microenvironment (TME).

Results cytoTIL15® cells demonstrated enrichment and reactivity for melanoma antigen-specific TCRs, while maintaining TCRβ diversity. Fifteen days post-ACT, tumors from animals treated with cytoTIL15® cells exhibited significantly ($p=0.0175$) higher frequency (3.4-fold) of TILs, in which MART-1 tetramer positive cells demonstrated increased T-cell factor 1 (TCF-1) and CD69 expression, and secreted significantly greater amounts of IFNγ and TNFα cytokines into the TME, compared to unengineered TILs with IL2. In addition, cytoTIL15® TILs had a distinct differential gene expression profile, demonstrating an increase in effector genes such as IL2RB, GZMB, GNLY and CCL5 and reduction in exhaustion-related genes such as EOMES. cytoTIL15® cells accumulating in the bone marrow exhibited a lower frequency of CD39+ terminally differentiated CD8+ T cells, while maintaining higher levels of memory phenotype makers.

Conclusions In this allogeneic melanoma PDX model, cytoTIL15® cells showed a distinct profile of RNA expression and phenotypic markers, consistent with their increased persistence and anti-tumor efficacy. Interestingly, the subpopulation of cytoTIL15® cells reactive to tumor-associated antigen MART-1 displayed increased expression of TCF-1, which in melanoma patients has been associated with responses to immune checkpoint blockade, in addition to progression-free and overall survival.

Ethics Approval All animal studies were IACUC approved.

391 DEVELOPMENT OF A GMP-COMPATIBLE, VIRUS-FREE CRISPR CAR T CELL MANUFACTURING PROCESS

Dan Cappabianca*, Madison Bugel, Sarah Caroline Gomes de Lima, Ross Schwartz, Krishanu Saha, Christian Capitini. *University of Wisconsin-Madison, Madison, WI, USA*

Background Chimeric antigen receptor (CAR) T-cells are engineered immune cells that can be taken from a patient and redirected to fight cancer. Recently, we developed a virus-free process to create anti-GD2 CAR T cells using CRISPR-Cas9 ribonucleoproteins that endows cells with a stem cell memory-like and less exhausted phenotype that improves their ability to induce regression of GD2 positive solid tumors.
Methods To improve this workflow, we systematically modified the media conditions, electroporation timing, and small molecule treatment to improve the cell yield and memory-like characteristics of CAR T cells.
Results We find that optimal non-viral knock-in is dependent on activation time, and two key small molecule inhibitors.
Conclusions Key reagents have been made GMP-compatible, and therefore this process could be readily implemented in existing cell manufacturing facilities.
Ethics Approval The study was approved by the IRB at University of Wisconsin-Madison, approval number 2018-0103

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0391

392 ENGINEERING CD70-DIRECTED CAR-NK CELLS FOR THE TREATMENT OF HEMATOLOGICAL AND SOLID MALIGNANCIES

[1]Jae Woong Chang*, [1]Joshua Kreuger, [1]Joseph Skeate, [1]Erin Stelljes, [1]Walker Lahr, [1]Nicholas Slipek, [1]Emily Pomeroy, [2]Meghan Walsh, [2]Jennifer Johnson, [2]Charlotte Franco, [2]Simarjot Pabla, [2]Jared Sewell, [2]Eugene Choi, [2]Vipin Suri, [1]Beau Webber, [1]Branden Moriarity. [1]*University of Minnesota, Minneapolis, MN, USA*; [2]*Catamaran Bio, Boston, MA, USA*

Background While effective, CAR-T therapies are limited by a lack of scalability for patient-derived starting material. Alternatively, allogeneic CAR-NK cell therapies have the potential to overcome these limitations by providing an off-the-shelf product capable of delivering clinical benefits without the safety and manufacturing challenges associated with CAR-Ts. CAR-NK cell therapies are attractive in treating AML as the inherent graft-versus-leukemia activity of NK cells can be effectively augmented by a CAR directed to an AML-expressed antigen. CD70 is an attractive target for CAR therapy in AML since it is highly expressed on leukemic stem cells and blasts and is not detectable on normal bone marrow hematopoietic stem cells.[1] Additionally, aberrant CD70 expression is associated with several solid tumors and hematological malignancies, including AML and renal cell carcinoma (RCC) while expression in normal tissue is restricted to immune cells including T, B, DC, and NK cells.[2]

Methods Here we demonstrate that CD70 is not expressed in resting peripheral blood NK cells but is strongly upregulated in response to NK cell activation by engineered feeder cells. As such, integration of a CD70-targeting CAR into activated NK cells leads to substantial reduction of NK cell expansion due to fratricide. Knockout (KO) of CD70 by CRISPR/Cas9 editing does not inhibit NK cell expansion nor impair cytotoxicity against various types of tumor cells, therefore a successful engineering strategy where CAR integration and self-expression of the CAR ligand is knocked out via CRISPR/Cas9 would allow for successful propagation of such a CAR-NK therapy. Using the non-viral *TC Buster* transposon system, we were able to deliver transposons containing a CD70 CAR or CD70 CAR/IL15 expression cassette while simultaneously knocking out CD70 by CRISPR/Cas9 in primary human peripheral blood NK cells.

Results This single-step process resulted in >75% CD70 CAR integration/expression and >80% knockout of endogenous CD70. The resulting CD70 knockout CAR-NK cells were resistant to fratricide and expanded comparably to mock-engineered NK cells following feeder cell activation. The IL15 expression cassette enabled enhanced persistence of CAR-NK cells *in vitro* and *in vivo* without exogenous cytokine support. In functional assays, CD70 knockout CAR-NK cells mediated cytotoxicity against multiple CD70-positive tumor cell lines including AML and RCC both *in vitro* and *in vivo*.

Conclusions Overall, the results demonstrate the potential for targeting CD70 with CAR-NK cell therapy for the treatment of AML, RCC, and other CD70-positive malignancies while overcoming fratricide issues by engineering with a non-viral transposon delivery system in combination with CRISPR/Cas9 editing.

393 ATAK RECEPTORS, A NEW CLASS OF CHIMERIC ANTIGEN RECEPTOR THAT HARNESS INNATE IMMUNITY IN MYELOID CELLS TO TARGET CANCER

Neha Diwanji, Edward Cochran, Michael Gorgievski, Thomas Prod'homme, Yuxiao Wang*, Bruce McCreedy, Daniel Getts. *Myeloid Therapeutics, Cambridge, MA, USA*

Background For the majority of patients with advanced solid tumors, sustained clinical benefit with immunotherapy has yet to be achieved. Myeloid cells, including monocytes and macrophages are the primary orchestrators of immune responses and are found to accumulate in tumors, in some cases contributing up to 75% of the tumor mass. Myeloid cells express a wide range of innate immune sensors such as Toll-like receptors, RIG-I and cGAS-STING as well as co-stimuulatory molecules like CD40. The activation of these innate immune pathways in myeloid cells can be associated with anti-tumor immune response. Notwithstanding the ability of the myeloid cells to infiltrate tumors and elicit broad immune responses, technologies capable of harnessing these cells to target cancer remains elusive.

Methods Here we designed and engineered a new class of chimeric antigen receptors that couple tumor recognition with multiple innate immune signal domains, referred to as **A**ctivate, **T**arget, **A**ttack & **K**ill (ATAK^{TM}) receptors. By combining cancer recognition domains with intracellular signaling domains from innate immune receptors such as Fcg, TLR and cytokine receptors, we show that myeloid cells can be controlled and programmed to recognize cancer and elicit a broad and tunable immune response. Critically, in mice with established, highly immunosuppresive B16 melanoma tumors, delivery of monocytes engineered to express ATAK receptors results in anti-tumor activity. Our data show the versatility of building ATAK receptors by harnessing innate immune pathways and support their clinical development in cell therapies.

394 USING CO-STIMULATORY CARS IN NATURAL KILLER CELLS TO SAFELY TARGET SOFT-TISSUE SARCOMAS AND THEIR INHIBITORY MICROENVIRONMENTS

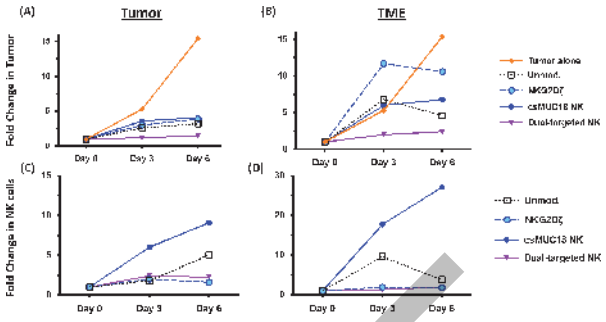
Stephanie Fetzko*, Ishwar Navin, Matthew Dysthe, Tim Sauer, Cliona Rooney, Robin Parihar. *Baylor College of Medicine, Houston, TX, USA*

Background Outcomes for patients with refractory or relapsed soft-tissue (ST) sarcomas are poor. Immunotherapy with chimeric antigen receptor (CAR)-expressing lymphocytes has shown promise in pre-clinical models. However, efficacy has been limited by the suppressive tumor microenvironment (TME). Furthermore, because sarcoma associated antigens are also expressed on normal tissues, maximizing tumor killing while minimizing off-tumor toxicity has been challenging with traditional CAR approaches. The current study aimed to (1) design a natural killer (NK) cell immunotherapy that utilizes a "co-stimulation only" CAR to safely target the sarcoma antigen, MUC18; (2) define the optimal endodomain for the co-stimulatory (cs) MUC18 CAR that enhances NK cell proliferation without adding cytotoxicity; and (3) combine an optimal MUC18-csCAR with a cytotoxic CAR, NKG2D.ζ, that simultaneously eliminates sarcoma cells and inhibitory cells of the TME such as myeloid-derived suppressor cells (MDSCs) and M2 macrophages (M2s). By using this novel combinatorial antigen-recognition approach, we hypothesized that dual-targeted NK cells (co-expressing MUC18-csCAR and NKG2D.ζ) would be activated only within the TME co-expressing MUC18 and TME-associated ligands, but not in MUC18+ normal tissues, resulting in enhanced anti-tumor efficacy against MUC18+ ST sarcomas without toxicity.

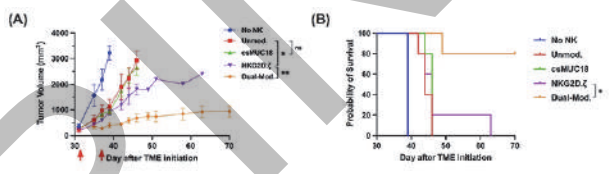
Methods We generated MUC18-cytotoxic and csCARs with 4-1BB, OX40, 2B4, and DNAM-1 endodomains and confirmed specificity and functionality using MUC18 overexpressing and knockout targets and a long-term TME co-culture comprised of alveolar rhabdomyosarcoma, Rh4, and inhibitory macrophages (M2s). Safety of MUC18-csCARs was tested against the MUC18+ liver sinusoidal endothelial cell (LSEC) line. Anti-tumor activity of dual-targeted NK cells compared to unmodified and singly-modified NK cells was assessed *in vivo* using a novel TME xenograft model with Rh4 and MDSCs.

Results MUC18 cytotoxic CAR-NK cells killed MUC+ high targets, while exhibiting low killing against an Rh4-MUC18 KO cell line, confirming CAR specificity and function. MUC18-OX40csCAR NK cells expanded without additional killing in the TME compared to NK cells with other co-stimulatory endodomains. MUC18-OX40csCAR NK cells did not exhibit killing of LSECs. Dual-targeted NK cells demonstrated enhanced tumor control in TME co-cultures (2.4-fold change in tumor vs. 4.6 by unmodified NK, 10.6 by NKG2D.ζ, and 6.8 by cs.MUC18) compared to either singly-modified NK population (figure 1). Dual-targeted NK cells demonstrated superior tumor control in the *in vivo* TME xenograft model compared to controls (p=0.007 versus NKG2D.ζ) and prolonged survival (p= <0.0001) (figure 2).

Conclusions Dual-targeted NK cells demonstrate enhanced anti-tumor activity without toxicity against normal tissue. Use of co-stimulation-only CARs in NK cells may allow exploitation of previously non-targetable sarcoma antigens.



Abstract 394 Figure 1 The dual-targeted CAR NK cells were compared to unmodified NK cells, NKG2D.? CAR NK cells, and csMUC18 CAR NK cells in a TME co-culture system. A) Rh4 fold expansion in the tumor alone conditions and B) in the TME conditions was determined for each time point. C) Fold change in NK cells in the tumor alone conditions. D) Fold change in NK cells in the TME conditions.



Abstract 394 Figure 2 (A) Mice (n=5 per treatment group) received two NK cells doses at 31 and 38 days post tumor inoculation and three times per week IL-2 and IL-15 to promote NK cell survival. (B) Survival probability of each treatment cohort.

395 ENGINEERING NON-ACTIVATED CAR T CELLS WITH ENHANCED POTENCY AGAINST ADVANCED CANCERS

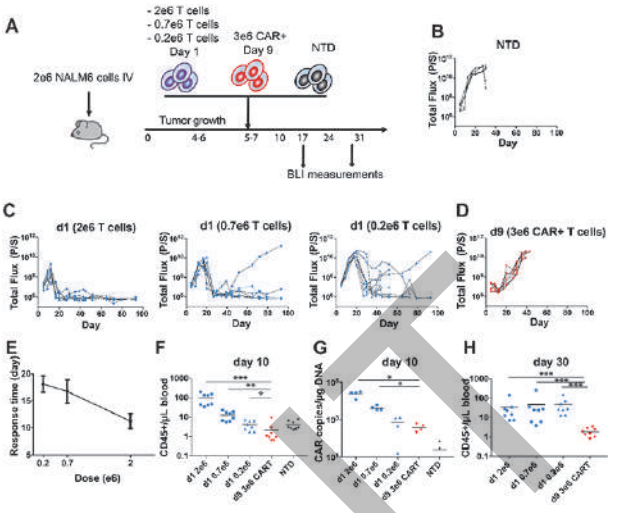
Saba Ghassemi*, Joseph Durgin, Frederic Bushman, Saar Gill, Roddy O'Connor, Michael Milone. *University of Pennsylvania, Philadelphia, PA, USA*

Background Chimeric antigen receptor (CAR) T cells can generate durable clinical responses in B-cell hematologic malignancies. The effectiveness of this approach led to several FDA-approved CAR T cell therapies against cancer. Despite their therapeutic promise in blood-based malignancies, CAR-T cells do not effectively kill solid tumors. Several factors contribute to success including tumor entry, CAR engagement, T cell expansion, and persistence. In several solid tumor models, CAR T cells can enter solid tumors and undergo antigen-specific stimulation. "Failure" coincides with a diminished ability to proliferative and persist.

Methods CAR T cell manufacturing is an iterative process with several important steps. Initially, T cells are activated through their T cell receptor, followed by lentiviral transduction and expansion ex vivo for several weeks. Unfortunately, activating and expanding CAR T cells in this manner drives differentiation with a corresponding loss of anti-tumor activity. Here we provide evidence that functional CAR T cells can be generated within 24 hours without any need for T cell activation or ex vivo expansion. We show that the efficiency of viral transduction in this process is substantially influenced by the formulation of the medium and the surface area-to-volume ratio of the culture vessel.

Results Remarkably, these cells exhibited higher anti-leukemic in vivo activity per cell than standard CAR T cells (activated and expanded for 9 days prior to adoptive transfer) in preclinical models of human leukemias (figure 1). Our preliminary findings position the non-activated system as a superior alternative against solid tumors where terminally differentiated T cells are so often ineffective. Our findings imply that quiescent T cells retain key attributes that influence engraftment and survival following adoptive transfer.

Conclusions In summary, the ability to generate genetically-modified T cells with superior therapeutic potential in a shorter time period has important implications for CAR-T manufacturing and therapy. Our results indicate that extended ex vivo culture is unnecessarily costly and redundant. Leveraging the unique ability of lentiviral vectors to enter and integrate into the genome of non-dividing cells, effective CAR-T cell products with durable engraftment in vivo can be generated in as little as one day. Minimizing ex vivo manipulation also conserves limited resources such as human serum and manufacturing space as expansion occurs entirely in vivo. Finally, more rapid product generation will lead to a shorter period of time between apheresis collection and re-infusion of CAR T cells. This will be of particular benefit to those patients with rapidly progressive disease.



Abstract 395 Figure 1 Non-activated CAR T cells induce durable remission
(A) Schematic of the xenograft model and CART19 cell treatment in NSG mice. (B-D) serial quantification of disease burden by bioluminescence imaging. (B) Total bioluminescence flux in mice treated with non-transduced (NTD) control non-activated T cells. (C) Total bioluminescence flux in mice treated with a single high (2x106), medium (0.7x106) or low (0.2x106) dose of non-activated T cells. (D) Total bioluminescence flux in mice treated with 3x106 CAR+ T cells stimulated with anti-CD3/CD28 microbeads and expanded over 9 days. There are 8 mice in each group. (E) Time to initial anti-leukemic response (i.e. first reduction in bioluminescence) after infusion of non-activated CART19 in relationship to T cell dose. (F) Absolute peripheral blood CD45+ T cell counts in blood collected from mice at day 10 following T cell transfer. (G) Vector copy number in peripheral blood collected at day 10 measured by qPCR and normalized to DNA concentration. H) Absolute peripheral blood CD45+ T cell counts in blood collected from mice on day 30 following T cell transfer. *P< 0.05, **P< 0.01 and ***P< 0.001. The mean of each group is indicated by the solid black line. Groups were compared using the two-tailed, unpaired Mann–Whitney test.

396 INVESTIGATING THE ROLE OF THE ENDOGENOUS CD28 CO-STIMULATORY RECEPTOR IN ACHIEVING OPTIMAL CAR-T CELL THERAPEUTIC EFFICACY

[1]Mackenzie Honikel*, [2]Kelvin Lee, [1]Scott Olejniczak. [1]*Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA*; [2]*Indiana University School of Medicine, Indianapolis, IN, USA*

Background Multiple myeloma (MM) remains an incurable hematological malignancy by conventional chemotherapeutic approaches. Chimeric antigen receptor T (CAR-T) cells targeting B cell maturation antigen (BCMA) on MM have shown remarkable efficacy in relapsed/refractory patients, leading to the recent FDA approval of two CAR-T cell products. Despite initially promising responses, many MM patients fail to achieve durable remissions leading to relapse in the months following treatment, highlighting the need to better understand mechanisms of CAR-T cell failure.

CD28, the prototypical T cell co-stimulatory molecule, is commonly expressed on MM and was previously shown to protect MM from chemotherapy-induced cell death, implicating its role in promoting therapy resistance. However, the role of the endogenous CD28 receptor on CAR-T cells is largely unexplored.

Methods To specifically target CD28 on the surface of adoptively transferred CAR-T cells we employed a novel, inducible $CD28^{-/-}$ genetically engineered mouse model as the T cell source.

Results We demonstrate that genetic deletion of the endogenous CD28 receptor does not impair CAR-T cell activation in response to stimulation by BCMA-expressing target cells, nor the subsequent cytotoxic response as assessed by intracellular cytokine production in two second-generation CAR-T cell models. However, the complete absence of a CD28 co-stimulatory signal has unveiled a previously uncharacterized role for the endogenous receptor in mediating an anti-tumor response *in vivo*. Specifically, $CD28^{-/-}$ BCMA-targeted 4-1BBζ CAR-T cells display a pronounced defect in their ability to control tumor growth in multiple disease models, while the function of $CD28^{-/-}$ 28ζ CAR-T cells is unaffected. Preliminary results suggest that CD28 deletion enhances persistence of the CAR-T cell population which may lend a more durable response to adoptive cellular therapies.

Conclusions These findings suggest that targeting the endogenous CD28 receptor with an FDA approved biologic CTLA4-Ig (Abatacept) may represent a viable clinical strategy to increase the efficacy of a potent 28ζ CAR-T cell design through two independent mechanisms: 1) Blockade of CD28 on MM abrogates a critical survival signal in the bone marrow microenvironment which may enhance their sensitivity to CAR-T cell mediated killing 2) Blockade of CD28 on CAR-T cells dampens the CAR-T cell activation signal which may promote differentiation into longer-lived memory T cell subsets for enhanced therapeutic durability as compared to effector T cells.

This work has contributed to the unveiling of a novel CD28 axis in CAR-T cell biology and provides insight into identifying optimal levels of co-stimulation while offering a therapeutic strategy to improve adoptive cellular immunotherapeuties.

397 DEEP MYELOID CELL PROFILING PROVIDES NEW INSIGHTS INTO MODULATORS OF CAR T CELL EXPANSION IN PATIENTS WITH SOLID TUMOR MALIGNANCIES

[1]Sabina Kaczanowska*, [2]Sneha Ramakrishna, [2]Tara Murty, [1]Cristina Contreras, [3]Ahmad Alimadadi, [3]Norma Gutierrez, [4]Aashna Jhaveri, [4]Yang Liu, [4]Jennifer Altreuter, [4]Franziska Michor, [2]Caroline Duault, [2]Priyanka Balasubrahmanyam, [2]Warren Reynolds, [2]Reema Baskar, [2]Mina Pichavant, [2]Bita Sahaf, [2]Sean Bendall, [2]Holden Maecker, [1]Melinda Merchant, [2]Crystal Mackall, [3]Catherine Hedrick, [1]Rosandra Kaplan. *[1]National Cancer Institute, Bethesda, MD, USA; [2]Stanford University School of Medicine, Palo Alto, CA, USA; [3]La Jolla Institute for Immunology, La Jolla, CA, USA; [4]Dana-Farber Cancer Institute, Boston, MA, USA*

Background Chimeric antigen receptor (CAR) T cells have shown remarkable results in hematological malignancies but limited efficacy in the setting of solid tumors. GD2 is a tumor antigen expressed on neuroblastoma and osteosarcoma, and previous studies of T cells expressing 1st generation GD2-CAR were shown to be safe and mediated modest antitumor activity in patients with refractory neuroblastoma. Myeloid cells orchestrate immune responses with the ability to either activate or limit T cell responses. In the setting of solid tumors, myeloid-mediated immune suppression is known to play an important role in dampening antitumor activity. We hypothesized that myeloid cells impact CAR T cell expansion in patients with solid tumors.

Methods A phase I trial (NCT02107963) was performed to determine the feasibility and safety of administering 3rd generation GD2-CAR (GD2-CAR.OX40.28.z.ICD9) T cells in children and young adults with $GD2^+$ neuroblastoma and osteosarcoma. Peripheral blood patient samples were analyzed retrospectively by qPCR for CAR expansion, multiplex ELISA for cytokine levels, mass cytometry (CyTOF) for phenotype analysis, ATAC-seq for epigenetic determination, and RNA-seq for transcriptomic evaluation.

Results 15 patients were enrolled on four dose levels, of which 13 patients were infused. While 76.9% of patients had stable disease by day 28, eventually all patients had disease progression. GD2-CAR T cells expanded in all patients receiving treatment, half of whom had expansion similar to that seen in clinically active CD19 and CD22 CAR T cells, but with limited persistence. To gain insight into the immune compartment in patients with good versus poor CAR T cell expansion, we evaluated immune profiles in patient pre-treatment apheresis and post-treatment peripheral blood samples. The main findings of this study indicate that a higher proportion of monocytes in pre-treatment apheresis was associated with poor CAR T cell expansion and CXCR3 expression on monocytes in pre-treatment apheresis was the most robust marker of good CAR T cell expansion in this cohort. Longitudinal analysis demonstrated that $CXCR3^+$ monocytes were low following treatment in both good and poor CAR T cell expanders, demonstrating a transition in myeloid populations in response to GD2-CAR T cell treatment.

Conclusions Together, these data suggest that GD2-CAR T cell administration is associated with changes in the myeloid cell compartment in solid tumor patients. This study provides evidence of novel myeloid-based pre-treatment biomarkers of CAR T cell expansion and rationale for the combination of CAR T cells with myeloid-modulating therapies as a strategy to improve outcomes for patients with solid tumors.

398 EXPANSION OF THERAPEUTIC NK CELL LINE UNDER HYPOXIC AND HYPERBARIC CULTURE CONDITIONS ENHANCES ANTI-TUMOR POTENCY

James Lim, Ann Lu*, Yunmin Li, Yelena Bronevetsky. *Xcellbio, San Francisco, CA, USA*

Background Harnessing NK cells is proving to be an attractive strategy for cancer immunotherapy, either by activating endogenous NK cells or through adoptive cell transfer. NK cells can also be sourced from immortalized cell lines like NK-92 that are currently being evaluated in the clinic. However, the immunosuppressive solid tumor microenvironment (TME) can inhibit NK-92 function thereby limiting its cytolytic properties against tumor cells. To overcome the immunosuppressive effects of the TME, we applied a culturing strategy in which NK-92 cells were serially passaged and expanded under hypoxic and hyperbaric conditions. We then tested the potency of NK cells expanded under TME conditions.

Methods To investigate the short- and long-term effects of TME conditions on NK cell function, we cultured NK-92 cells under several environmental conditions and performed cytotoxic, transcriptional and protein expression analysis. NK-92 cells were either cultured in a conventional CO_2 incubator at 21% O_2 and 0 PSI, or in an AVATAR cell control system which can be precisely tuned to different O_2 and pressure levels that mimic TME conditions. We first assessed the effects of culture conditions on the ability of NK-92 cells to kill tumor cells in both normoxic and TME conditions. To this end we used the AVATAR AI instrument, which employs the environmental control of the AVATAR incubator paired with a specialized plate that enables real-time, label free cell killing analysis via electrical impedance.

Results In normoxic conditions, NK-92 cells that had been exposed to TME conditions for 24 hours exhibited reduced killing, as compared to controls, with slower kinetics of killing and lower total cytolysis. Interestingly, cells that had been adapted to TME conditions for more than 3 months exhibited increased cytotoxic activity, with faster killing kinetics and higher total cytolysis. When cell killing experiments were repeated under TME conditions, the differences between NK-92 culture conditions were even more stark. NK cells grown under standard conditions showed a reduction in total cytolysis, as compared to their killing activity under normoxic conditions. In contrast, TME-conditioned NK cells exhibited robust tumor cytolysis in both normoxic and TME conditions.

Conclusions This initial study supports the hypothesis that NK-92 cells can both react and adapt to different microenvironments. TME-adaptation strategies during cell expansion can enhance potency and efficacy of cell therapies designed to work in a solid tumor microenvironment.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0398

399 DEVELOPING A NEW TARGETED THERAPY FOR PEDIATRIC RHABDOMYOSARCOMA: αVβ3 AND HER2 AS PROMISING TARGETS FOR BISPECIFIC CAR T-CELL THERAPY

Amanda Lulu*, Joseph Caruso, Dustin Cobb, Daniel Lee. *University of Virginia, Charlottesville, VA, USA*

Background Even though rhabdomyosarcoma (RMS) is the most prevalent sarcoma in children, therapy relies on decades-old, multi-agent chemotherapy, radiation and surgery, which are ineffective in the salvage or metastatic disease setting, with only 30% of patients surviving three years[1]. Therefore, more effective treatments are desperately needed.

Chimeric antigen receptor T-cell (CAR-T) therapy has been highly successful for relapsed/refractory hematologic malignancies, but antigen downregulation by tumors have not uncommonly led to immunotherapy escape across several platforms [2–5]. **We hypothesize that simultaneously targeting two RMS antigens with a bispecific CAR-T will provide a new treatment modality while reducing the likelihood of antigen escape.** We previously established the efficacy of alpha$_5$beta$_3$ (αvβ3) and HER2 CAR-Ts against diffuse intrinsic pontine glioma/glioblastoma[6] and medulloblastoma[7], respectively. HER2 is known to be expressed on RMS[8], and one child with RMS experienced a temporary remission with HER2-CAR-T[9]. Therefore, targeting αvβ3 and HER2 using a bispecific CAR-T approach may be effective for RMS.

Methods Six alveolar and embryonal RMS cell lines were evaluated by flow cytometry for αvβ3 and HER2 expression. The *in vitro* kinetics of αvβ3 and HER2-CAR-T killing of RMS were assessed at varying effector-to-target ratios in an xCelligence analyzer, with CD19-CAR and non-transduced T-cells as controls. Antigen-specificity was evaluated by pre-incubating targets with αvβ3/HER2 blocking or control antibodies or by targeting *ITGB3* or *ERBB2* CRISPR knock out tumor cells. CAR-Ts were then evaluated for changes in activation marker expression by flow cytometry.

Results (1) αvβ3 and/or HER2 are expressed on 6/6 RMS cell lines. Five express both antigens (figure 1A). (2) Separately, αvβ3 and HER2-CAR-Ts rapidly and robustly kill antigen^{pos} RMS in an antigen- and dose-dependent manner. Furthermore, αvβ3 and HER2-CAR-Ts are sensitive, achieving 70% cytolysis at 300 and 1100 targets/cell, respectively (figure 1B) suggesting a lower likelihood of disease escape by antigen down-regulation. (3) Cytolysis is antigen-specific (figure 2). (4) Co-culture of both CARs with RMS drives increased expression of the activation markers CD107a, CD137, CD25, CD69 and PD-1, demonstrating antigen-driven induction of a strong effector response (figure 3).

Conclusions Our data demonstrate that αvβ3 and HER2 are viable RMS targets for a bispecific CAR-T approach. αvβ3 and HER2 CAR-Ts independently control RMS well. They exhibited robust and low-level antigen-specific killing and effector cell activation *in vitro*, supporting further investigation into their control of RMS *in vivo*. αvβ3/HER2 bispecific CAR-Ts are being developed, which we expect to perform as well as or better than each CAR independently.

400 PDGFRα-SPECIFIC CAR T CELL THERAPY OF PEDIATRIC HIGH-GRADE GLIOMA

Kathryn Eckholdt, Sara Mazrimas*, Paul Hauser, Wafik Zaky, Amer Najjar. *MD Anderson Cancer Center, Houston, TX, USA*

Background Platelet-derived growth factor receptor alpha (PDGFRα) is a tyrosine kinase receptor that plays a pivotal role in tumorigenesis and is associated with tumor proliferation and progression. Pediatric gliomas are known to express high levels of PDGFRα, designating the receptor a viable target for chimeric antigen receptor (CAR) T cell therapy.

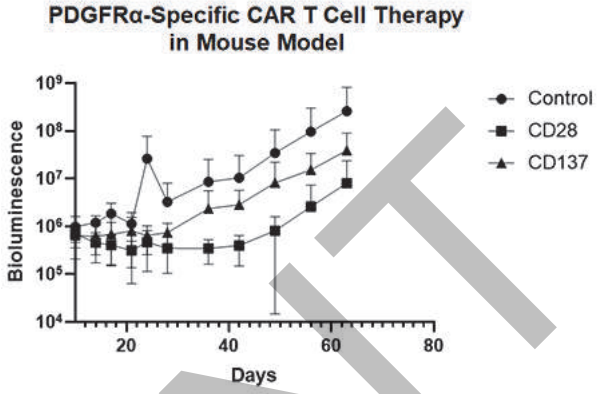
Methods Lentiviral vectors encoding PDGFRα-specific CAR-coding sequences were constructed by fusion of a single chain Fv (scFv) to a human CD8a stalk and transmembrane domain linked to either a CD28 or CD137 intracellular signaling domain fused with a terminal CD3ζ domain. PDGFRα-specific CAR T cells were expanded with IL-2 and artificial antigen presenting K562 cells (aAPC) expressing truncated PDGFRα. The cytotoxic function of PDGFRα-CAR T cells was assessed using *in vitro* killing assays. The therapeutic efficacy was evaluated in a mouse KNS42 glioma model. KNS42 cells expressing firefly luciferase and green fluorescent protein (ffLuc-GFP) were engrafted into the right parietal lobe of NSG mice using screw-guided injections. Intratumoral treatment with PDGFRα-CAR T cells was carried out one week later, and tumor growth was monitored weekly over the course of nine weeks by bioluminescence imaging.

Results All CAR T cells demonstrated over 75% CAR expression two weeks following transduction and expansion. *In vitro* cytotoxicity assays demonstrated PDGFRα-specific lysis of KNS42 and PDGFRα-U87 glioma cells. PDGFRα-CAR T cells expressing the CD28 signaling domain exhibited a higher level of cytotoxicity against target KNS42 cells. Both PDGFRα-CD28 and -CD137 CAR T cell products resulted in decreased tumor progression when compared to the control mice injected with saline (figure 1). However, PDGFRα-CD28-CAR T cells exhibited a higher level of antitumor activity than PDGFRα-CD137 CAR T cells (97% vs 85% inhibition), consistent with the *in vitro* cytotoxicity observations (figure 1).

Conclusions In this study, we evaluated and compared the efficacy of PDGFRα-CAR T cells expressing the CD28 or CD137 costimulatory domains in controlling the growth of pediatric glioma cells. We have demonstrated that PDGFRα-CD28 CAR T cells exhibited more immediate anti-tumor response resulting in a more significant long-term reduction of tumor progression. Repeated administration of PDGFRα-CD28 CAR T cells may be warranted in future studies to further improve outcomes and preserve long-term responses. Our preclinical studies demonstrate the therapeutic potential for PDGFRα-CAR T cell in the treatment of pediatric high-grade glioma and set the stage for future clinical translation.

Acknowledgements We wish to acknowledge the staff of Small Animal Imaging Facility (SAIF) at MD Anderson Cancer Center for assistance in conducting all imaging-related aspects of our studies. We also wish to acknowledge the Department Veterinary Medicine and Surgery for facilitating all procedures related to our animal studies.

Ethics Approval All animal studies were conducted at MD Anderson with approval and in accordance with Institutional Animal Care and Use Committee (IACUC) guidelines. Mice were housed in pathogen-free conditions and were monitored daily for welfare and any signs of discomfort or pain. All efforts were made to minimize animal suffering, and moribund mice were humanely euthanized according to IACUC guidelines. The ID number of approval for the animal study is 00001237-RN02.



Abstract 400 Figure 1 PDGFRa-Specific CAR T Cell Therapy in Mouse Model
Time-dependent quantification of KNS42 tumor burden following intratumoral injection of CAR T cells. NSG mice were implanted with 2x105 KNS42 ffLuc-GFP cells in the right parietal lobe using skull screw-guided injections. One week later, intratumoral injections of PDGFRa-CD28 or PDGFR-CD137 CAR T cells (2x106 cells/5 μL saline) were performed via the guide screws. Control mice received a 5 μL injection of saline. Tumor growth was monitored weekly by bioluminescence imaging for 63 days.

401 HINGE LENGTH: A NOVEL METHOD OF PREDICTING CYTOTOXICITY OF CAR CONSTRUCTS AGAINST ANTIGEN-LOW LEUKEMIA

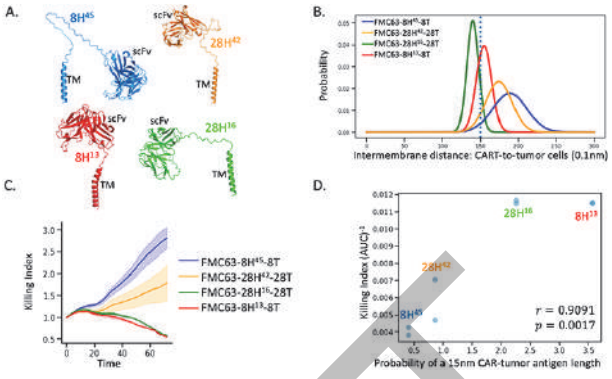
[1]Justin Mirazee*, [1]Dongya Jia, [2]Xiang Chen, [1]Sooraj Achar, [1]Chris Chien, [1]Marie Pouzolles, [1]Kniya DeDe, [1]Philippe Youkharibache, [2]Kylie Walters, [1]Grégoire Altan-Bonnet, [1]Naomi Taylor. *[1]National Cancer Institute, Bethesda, MD, USA; [2]Frederick National Laboratory for Cancer Research, Frederick, MD, USA*

Background Genetic engineering of T-cells to target tumors through the expression of synthetic chimeric antigen receptors, or CARs, has led to a breakthrough in the treatment of relapsed/refractory B-cell leukemia. However, despite impressive initial clinical performance, 30-50% of patients eventually relapse, with the emergence of tumor cells expressing the targeted antigen at a level that is insufficient to induce CAR T responsiveness. We and others have shown that the hinge domain of CARs is critical in altering cytotoxic responsiveness of the CAR.[1,2] Thus, we evaluated whether optimal hinge length could be evaluated for a given scFv *in-silico*, given the epitope location, thereby accelerating optimal CAR design.

Methods Golden gate assembly was utilized to generate anti-CD19 (FMC63) and anti-CD22 (M971) CAR constructs. The lengths of the CD28 and CD8-alpha hinge domains were varied while intracellular 4-1BB and TCR-zeta signaling sequences remained constant. CAR structures were modeled with Alpha-Fold and intermembrane lengths modeled using Xplor-NIH. CAR function was evaluated by ex vivo cytotoxicity assays (Incucyte) against NALM6 cells engineered to express calibrated numbers of CD19 and CD22 molecules.

Results Through truncations and extensions of the CD28 and CD8-alpha hinge domains, we show that optimal hinge lengths for targeting CD19 and CD22 through their respective FMC63 and M971 scFvs are distinct and depend on the epitope location. Specifically, short and long hinges enhance cytotoxicity against membrane-distal epitope and membrane-proximal epitopes, respectively. Using Xplor-NIH and Alphafold (figure 1A-1B), we were able to model hinge dynamics. As signaling of the TCR by MHC-presented peptide antigen (pMHC) is tightly regulated by the dimensions of the TCR-pMHC interaction, with an optimal intermembrane distance of 15nm,[3] we assessed whether this distance would confer enhanced function to CAR T-cells following ligand encounter. Importantly, CAR constructs providing a predicted intermembrane CAR-ligand distance of 15nm exhibited enhanced cytotoxicity against antigen-low leukemic cells (figure 1C-1D).

Conclusions CAR responsiveness against a specific epitope can be modeled as a function of intermembrane distance, allowing a rapid optimization of CAR constructs by adjusting hinge length. The modeling presented here, based on epitope location and target protein dynamics, can be utilized to rapidly design CARs with optimized cytotoxic potential against a wide range of novel targets.



Abstract 401 Figure 1 Modeling of intermembrane CART-tumor cell distances promotes the generation of CAR constructs with increased cytotoxic potential. A: Alphafold-generated models of anti-CD19 (FMC63) CAR constructs reveal apparent differences in hinge length. CD8α hinge = 8H; CD28 hinge = 28H; TM=transmembrane domain. Superscripts refer to the number of amino acids within the hinge. B: A distance of 15nm has been shown to optimize signaling secondary to TCR-MHC interaction3. Distributions of the end-to-end distances of hinges of variable lengths were combined with the distribution of the CD19 target epitope to predict the probability that the combined distribution is 15nm, as evaluated by Xplor-NIH. C: Anti-CD19 CAR constructs with altered hinge lengths exhibit significant differences in ex vivo killing, as evaluated against a CD19low leukemia cell line. Killing index was evaluated in an Incucyte assay and is presented as a function of time (E:T ratio = 1:2). D: Killing indices of anti-CD19 CAR constructs correlate significantly with the modeling prediction of a 15nm optimum CAR-antigen intermembrane length. Data are from two replicates and the identity of the hinges are indicated.

402 T CELL KILLING IS FACILITATED BY MULTIPLE CYTOTOXIC PATHWAYS

Melisa Montalvo*, Irfan Bandey, Ali Rezvan, Kwan-Ling Wu, Arash Saeedi, Yongshuai Li, Rohan Kulkarni, Xingyue An, Navin Varadarajan. *University of Houston, Houston, TX, USA*

Background Chimeric antigen receptor (CAR) T cell therapies show remarkable progress in treating liquid tumors, with a complete remission rate of over 57%.[1] Translating the success of CAR T cells to solid tumors will need an understanding of the key mechanisms responsible for the cytotoxicity of CAR T cells. The primary factors contributing to tumor resistance against CAR T therapies are widely contested[2], therefore, we seek to explore the impact of different CAR T cell killing mechanisms of tumors.

Methods We examine CAR T cell killing of a leukemic cell line, NALM6, and an ovarian cancer cell line, SkOV3-CD19, in the presence of Granzyme B inhibitors and a Fas ligand inhibitor. We develop a fluorescent membrane reporter that translocates to the nucleus upon specific proteolytic cleaving by Granzyme A and B.

Results
- Overexpressing native Granzyme B inhibitor, Protease Inhibitor-9 (PI-9), in NALM6 and SkOV3-CD19 does not affect killing frequencies in CAR(19-41BBζ and 19-28ζ) T cell cytotoxicity assays.
- Treating 19-41BBζ with a small molecule inhibitor of Granzyme B does not impact killing frequencies in cytotoxicity assays against NALM6 and SkOV3-CD19.
- Overexpressing PI-9 in NALM6 and SkOV3-CD19 does not affect 19-41BBζ CAR T killing frequencies or killing kinetics in single cell time-lapse assays.
- Inhibition of Fas ligand on 19-41BBζ CAR T cells does not impact killing frequencies against NALM6 and SkOV3-CD19.

Conclusions Our findings suggest that suppressing Granzyme B activity with small molecules or native proteins does not impair killing frequencies of 19-41BBζ CAR T cells en masse or at the single cell level. We hypothesize that Granzyme A facilitates CAR T killing in the absence of Granzyme B, implying redundancy in granzyme expression. This study provides a comprehensive understanding of the main mechanisms associated with CAR T cell-mediated killing.

403 RAPID AND MULTIPLEXED IDENTIFICATION OF NOVEL TCRS FOR TCR-T CELL THERAPY

Tamson Moore*, Bindu Hegde, John Leonard, Nathan Katz, Akshay Sharathchandra, Bryan Xie, Joanna Dreux, May Khadilkar, Marvin Gee, Leah Sibener. *T Biosciences, South San Francisco, CA, USA*

Background T cell receptor (TCR)-based therapeutics have displayed clinical proof-of-concept, however challenges remain to robustly identify both novel targets and therapeutically active TCRs against endogenous targets.

Methods Here, we have developed a multi-plexed platform to efficiently identify novel TCRs towards non-mutated, tumor specific targets. We have developed a functional expansion protocol, combined with single cell sequencing, that enables the discovery of diverse TCRs in both function and sequence to multiple targets simultaneously.

Results These novel TCRs are highly sensitive, with sub-nanomolar EC50s. Furthermore, these novel TCRs display in vitro killing of target-bearing cells. To interrogate the specificity of these TCRs, we utilized 3T-TRACE, a highly diverse pHLA-target library platform to identify potential cross-reactive peptides that could identify potential liabilities pre-clinically. We find that although sequence distinct TCRs display the same on-target reactivity, they vary considerably in their cross-reactivity.

Conclusions Altogether, we have developed a robust platform to identify and select therapeutically active TCRs for TCR-T based therapy.

404 ENRICHMENT OF NEOANTIGEN REACTIVE TIL IN A CRC PATIENT SAMPLE BY FACS: THE TIDAL-01 PROCESS

Jake Nikota*, Larissa Pikor, Anna Fritzsche, Zachary Jilesen, Sara Fallahi, Barbara Sennino, David Stojdl. *Turnstone Biologics, Hamilton, Canada*

Background Tumor infiltrating lymphocyte (TIL) therapy has proved to be most effective in melanoma. Additionally, enhancing tumor reactivity by selective expansion of individual TIL subpopulations, screened for neoantigen reactivity, has demonstrated some success in breast cancer.[1] However, while other solid tumors such as colorectal cancer (CRC) have been shown to contain neoantigen reactive TIL,[2] the ability to selectively enrich these cells has been challenging. Here we demonstrate that the TIDAL-01 process, which utilizes tumor-specific mutation containing peptides to select neoantigen reactive TIL by fluorescence-activated single cell sorting (FACS), can lead to a neoantigen targeted Selected TIL product in CRC.

Methods TIL were expanded from a cryopreserved dissociated CRC tumor sample and antigen presenting cells (APCs) were generated from patient-matched blood. Mutations were identified by sequencing and 13-40 amino acid peptides containing the mutation were generated. TIL were selected by FACS from a coculture of TIL and peptide pulsed APCs based on the activation markers CD134 and CD137. Selected TIL were cultured with a rapid expansion protocol (REP) and the expanded TIL were phenotyped and co-cultured with neoantigen pulsed APCs to confirm reactivity. The unselected TIL was expanded by REP as a bulk control for comparison.

Results A clear positive population of activated TIL (3.93%) were selected from the co-culture and expanded >1000 fold. The final TIL product was 93.6% CD4 cells and 4.60% CD8 cells and >90% of CD4 and CD8 cells expressed markers of an effector memory phenotype. Single cell sequencing of the T cell receptor repertoire revealed 12 clonotypes that were enriched in sorted TIL vs bulk TIL. In response to co-culture, 31.2% of CD8 cells and 25.6% of CD4 cells in the selected TIL product were positive for IFN-g by intracellular cytokine staining. IFN-g and TNF-a were 53 and 360-fold higher in the co-culture supernatants of selected TIL compared to bulk TIL, respectively. As a measure of killing potential, 20.9% of CD8 cells degranulated in co-culture based on CD107 expression and granzyme B secretion was increased 16.5-fold over bulk TIL. Deconvolution of the peptide pool identified one CD4 and one CD8 antigen driving the neoantigen reactivity.

Conclusions These data provide non-clinical proof of concept that neoantigen enriched TIL can be selected by FACS and expanded into a TIL product that contains a marked increase in neoantigen reactive TIL compared to bulk expanded TIL from a CRC tumor.

405 A NON-CANONICAL ROLE FOR CCL2 IN T CELL MIGRATION: IMPROVING DUAL-INTERFERON-TREATED AUTOLOGOUS MONOCYTES AS A THERAPY FOR OVARIAN CANCER

Franklin Ning*, Thomas Meyer, Brittney Harrington, Christina Annunziata. *National Cancer Institute, Bethesda, MD, USA*

Background Ovarian cancer is the fifth leading cause of cancer-related death in women in the US and the most lethal gynecologic malignancy. Although many patients respond initially to platinum-based chemotherapy, over 70% of patients diagnosed with advanced stage ovarian cancer relapse within 24 months and have limited second-line treatment options. Our group pioneered an approach manipulating innate immunity where autologous monocytes, interferon-gamma, and interferon-alpha2b (AMIGA) were given intraperitoneally to women with recurrent, ovarian cancer in order to directly kill tumor cells and mitigate the immunosuppressive tumor microenvironment.

Methods 18 patients were enrolled in the Phase 1 clinical trial (NCT02948426). Peripheral blood mononuclear cells (PBMCs) were collected from patients pre- and post-treatment cycles. Malignant ascites was collected when present. PBMCs were used for bulk and single-cell RNA-sequencing. Downstream analysis was completed on the NIH's Integrated Data Analysis Platform. LegendPlex Essential Immune Response kit (Biolegend #740930) was used to quantify ascites' cytokines. For migration assays, conditioned media from 2D and 3D ovarian cancer cell cultures treated with AMIGA was used to assess T cell migration. Migration was assayed 24 hours after T cells were exposed to conditioned media by flow cytometry or spinning disk confocal microscopy.

Results Of the 18 enrolled patients, two had partial responses and four had stable disease. Of these, both responders and two of the four patients with stable disease maintained clinical benefit for five or more months, and were thus labelled as long-term responders (LTRs). Through bulk-cell RNA-sequencing, the PBMCs of these LTRs showed increased levels of T cell activation and migration genes compared to the 14 non-responders (NRs). In light of this, we assessed patient malignant ascites for relevant chemokines and found CCL2, a known monocyte, and less so T cell, trafficking molecule, had increased in response to treatment. We then validated *in vitro* that CCL2 is significantly increased in the supernatants of AMIGA-treated ovarian cancer cells, but that this increase correlated with increased T cell, and not monocyte, migration. Furthermore, by manipulating the CCL2-CCR2 signaling axis *in vitro*, we were able to significantly alter T cell migration.

Conclusions Overall, our findings suggest AMIGA aids T cell migration towards ovarian cancer by increasing the production of CCL2. By further understanding how AMIGA contributes to T cell migration and function in the ovarian cancer tumor microenvironment, we seek to combine innate- and adaptive-based immunotherapies to improve the treatment options and, ultimately, survival of women with ovarian cancer.

AN UNBIASED SURVEY OF TUMOR REACTIVITY AND TRANSCRIPTIONAL LANDSCAPE OF 1,000 CLONES OF PD-1^{HI} T-CELLS FROM PERIPHERAL BLOOD DURING ICB TREATMENT REVEALS BREATH AND DYNAMICS OF ANTI-TUMOR IMMUNITY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0406

[1]Danielle Cook*, [2]Immaculada Creus, [2]Andrea Garcia-Garijo, [2]Pierre Levy, [1]Seon Kinrot, [2]Rodrigo Toledo, [2]Elena Garralda, [1]Ely Porter, [1]Xi Chen, [2]Alena Gros. *[1]RootPath, Watertown, MA, United States*; *[2]Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Background Immune checkpoint blockade (ICB) treatment often results in drastic changes in the TCR repertoire and T-cell phenotypes in the tumor and periphery. While scRNA-Seq allows the sequencing of thousands of T-cells, the high cost of TCR synthesis (>$100 per TCR) makes it cost-prohibitive to identify which clones are tumor-reactive, particularly in peripheral blood where tumor-reactive cells are rarer. This severely hinders our mechanistic understanding of these treatments and the possibility to develop non-invasive personalized T-cell-based therapies. To solve this problem, we developed a novel technology, named PathFinder DNA Assembly^{TM}, that allows parallel synthesis and cloning of thousands of TCRs simultaneously for a cost of **under $1 per TCR**. This enables the high-throughput experimental screening of up to 1000 TCRs for tumor reactivity. We have applied this technology to survey peripheral bulk or PD-1^{hi} T-cells from a melanoma patient before and after ICB treatment, since previous studies have demonstrated that PD-1 may be a biomarker for tumor-reactive T-cells from both tumor-infiltrating and peripheral T-cells.[1 2]

Methods We obtained PBMCs of a melanoma patient at multiple time points before and after the ICB treatment. Next, we obtained scRNA-Seq data for both bulk CD3^{+} sorted and PD-1^{hi} sorted T-cells. We then synthesized, cloned, and expressed 1,000 TCR sequences in peripheral T-cells from unrelated donors while ensuring each T-cell only expresses a single TCR, creating polyclonal TCR-T-cells, which were then screened for tumor reactivity by co-culturing with autologous tumor or melanoma cell lines expressing the patient-matched HLAs. After co-culture, activated TCR-T-cells were sorted based on an activation marker, sequenced to identify the enriched TCRs, and then validated individually.

Results Both pre- and post-treatment PMBCs harbor T-cell clones that are also found in the tumor, with many emerging after ICB treatment. More than 30 TCRs were identified to be tumor-reactive, many of which emerged during the ICB treatment. Interestingly, 12 out of the 14 tumor-reactive TCRs obtained from screening on 3rdparty cancer cell lines also appeared to be reactive to the autologous tumor.

Conclusions These results not only reveal previously hidden details of ICB treatment but also exemplify the approach to affordably identify tumor-reactive TCRs for each patient without any tumor tissue resection. These TCRs can be used to produce highly potent, autologous, polyclonal TCR-T products that have the potential to be the next generation of adoptive cell therapy.

407 MITOCHONDRIAL TRANSCRIPTION IS REQUIRED FOR THE ENHANCED ANTI-TUMOR ACTIVITY OF ADOPTIVELY TRANSFERRED STEM-LIKE MEMORY T CELLS

[1]Guillermo Rangel RIvera*, [2]Connor Dwyer, [1]Hannah Knochelmann, [3]Aubrey Smith, [4]Anna Cole, [4]Megan Wyatt, [4]Chrystal Paulos, [5]Jessica Thaxton, [1]Shikhar Mehrotra, [4]Haydn Kissick, [6]Mark Rubinstein, [4]Gregory Lesinski. *[1]Medical University of South Carolina, Atlanta, GA, United States; [2]Werewolf Therapeutics Inc., Watertown, MA, United States; [3]Orange Grove Bio, Decatur, GA, United States; [4]Emory University, Atlanta, GA, United States; [5]University of North Carolina, Chapel Hill, NC, United States; [6]The Ohio State University, Columbus, OH, United States*

Background Durable responses have been observed with adoptive T cell therapy in chemotherapy and immunotherapy refractory patients. However, current T cell products do not always lead to therapeutic responses. T cell intrinsic factors that lead to failure in immunotherapy have been attributed to T cell exhaustion and poor mitochondrial quality. T cell mediated immunity can be impaired by overt PI3Kδ signaling through altering transcriptional rewiring and metabolism. Recently, chronic PI3K signaling is associated with loss of mitochondrial transcription and mitochondrial DNA. We hypothesized that PI3Kδ inhibition would generate stem-like memory T cells (T_{scm}) that provide protection against melanoma by sustaining stemness and enhancing mitochondrial fitness.

Methods To test this, we primed melanoma specific $CD8^+$ pmel-1 T cells in the presence of increasing concentrations of Idelalisib, a PI3Kδ specific inhibitor, and infused them into B16F10 tumor bearing, following non-myeloablative total body irradiation. We modeled both high and low immunogenic tumors using two different tumors lines of B16F10 melanoma (expressing low affinity mouse gp100) and a modified B16F10 line (expressing high affinity human gp100 antigen). *In vitro* we tested T cell stemness by flow cytometry and RNA sequencing. We assessed mitochondrial qualities such as mass, membrane potential, reactive oxygen species, and respiratory capacity. Mitochondrial transcription was measured via mitochondrial mRNA relative quantification and protein levels of electron transport proteins. We further tested the effect of ablating mitochondrial transcription by CRISPR knockout using guides against a known regulator of mitochondrial transcription.

Results We found that PI3Kδ inhibited T cells provide potent antitumor activity in both poor and highly immunogenic tumor models of melanoma. The adoptively transferred T cells transcriptionally resemble intratumoral T_{scm} cells. Transcriptionally they showed elevated *Tcf7*, and *Lef1*, and suppressed *Havcr2*, and *Prdm1*. Metrics of improved mitochondrial quality were elevated in a dose dependent manner. Mitochondrially encoded electron transport chain gene expression was selectively enhanced at the RNA and protein level. Ablation of mitochondrial transcription vastly impaired the antitumor activity of stem-like memory T cells generated with PI3Kδ inhibition.

Conclusions These findings indicate that blocking PI3Kδ in T cells mediates lasting tumor immunity of adoptively transferred T cells by preserving stemness features and improving mitochondrial fitness. We discovered that enhanced mitochondrial transcription is required for T_{scm} anti-tumor immunity. These findings suggest that modulating mitochondrial transcription is a potential target to bolster the activity of tumor specific T cells.

408 NEUTRALIZING OXIDATIVE DAMAGE AT TELOMERES PREVENTS T CELL DYSFUNCTION AND IMPROVES ADOPTIVE CELL THERAPY

[1]Dayana Rivadeneira*, [1]Sanjana Thosar, [2]Konstantinos Lontos, [1]Jessica Jana, [3]Marcel Bruchez, [1]Patricia Opresko, [1]Greg Delgoffe. [1]*University of Pittsburgh, Pittsburgh, PA, United States*; [2]*University of Pittsburgh Medical Center, Pittsburgh, PA United States*; [3]*Carnegie Mellon University, Pittsburgh, PA, United States*

Background The functional state of tumor infiltrating lymphocytes (TIL) is a critical determinant of antitumor immunity and response to immunotherapy. One of the key factors responsible for T cell dysfunction are metabolic barriers such as nutrient competition, low oxygen tension, and damaging byproducts in the tumor microenvironment. One of these metabolic barriers is the accumulation of oxidative stress, a critical contributor of T cell dysfunction observed during aging as well as in the tumor microenvironment. We and others have shown that accumulation of reactive oxygen species (ROS) accumulation drives T cell exhaustion. ROS can affect many cellular functions, but notably can induce DNA damage. We asked whether TIL accumulate DNA damage at telomeres as a consequence of terminal differentiation, and used a chemo-optogenetic approach to specifically induce telomeric DNA damage to explore its role in T cell biology, especially within the context of cancer.

Methods In this study we perform telomeric and centromeric FISH assays to analyze TIL for DNA damage accumulation. We used a chemo-optogenetic FAPS-TAPS to generate singlet oxygen and consequent 8-oxo-guanine lesions specifically at telomeres.[1] We tethered GPX1 to TRF1 to generate a telomere-guided antioxidant protein.

Results Telo-FISH analysis demonstrated an accumulation of telomeric DNA damage, but not telomere shortening, in exhausted TIL from B16 mouse tumors, coordinate with presence of 53BP1 and gammaH2AX. Our data show that specific induction of mitochondrial and telomeric ROS cause the accumulation of DNA damage at telomeres, and consequent development of telomere fragility. These cells ultimately become dysfunctional showing a diminished capability for cytokine production. Importantly, targeting the ROS scavenger GPX1 directly to telomeres reduced telomere fragility and improved the function of therapeutic T cells in the B16 melanoma model.

Conclusions Our data suggest that dysfunctional T cells in cancer are not classically senescent, bearing short telomeres, but rather harbor damaged telomeres due to exposure to oxidative stress. Telomeric damage is sufficient to drive a dysfunctional state in newly activated T cells. Protecting telomeres through expression of a telomere-targeted antioxidant protein may preserve T cell function in the tumor microenvironment and drive superior responses to immunotherapy.

409 MANUFACTURING OF A CLINICAL SCALE CD8 TIL PRODUCT, AGX148, WITH AND WITHOUT GENE SILENCING OF PD-1 USING SELF-DELIVERING RNAI INTASYL™ PH-762

[1]Colin Thalhofer*, [2]Simon Fricker, [1]Ryan Montler, [1]Elaine Ballinger, [1]Nick Morris, [1]Jake Moses, [2]Dingxue Yan, [3]Tarsem Moudgil, [3]Bernard Fox, [3]Nelson Sanjuan, [3]Eric Tran, [2]James Cardia, [1]Andrew Weinberg. *[1]AgonOx Inc., Portland, OR, United States; [2]Phio Pharmaceuticals, Marlborough, MA, United States; [3]Providence Cancer Institute, Portland, OR, United States*

Background Adoptive Cell Therapy (ACT) with Tumor Infiltrating Lymphocytes (TIL) can induce durable clinical responses in a percentage of patients with melanoma, however, the efficacy of standard TIL therapy (Bulk TILs) can be limited. We hypothesize that the therapeutic efficacy of TIL therapy is dependent on the abundance of tumor-reactive T cells in the ACT product, as well as the functionality of the T cells in the product. Our approach enriches for tumor-reactive TIL by sorting CD8+ T cells from patient tumors that co-express CD103 and CD39 prior to expansion of the ACT product,[1] termed AGX148. To mitigate PD-1-induced immune suppression in the Tumor Microenvironment (TME) and further enhance the therapeutic potential of AGX148 we have utilized Phio Pharmaceuticals' self-delivering RNAi INTASYL™ PH-762 to knock down PD-1 during the expansion.

Methods Surgically resected human tumor samples were provided through a collaboration with the Earle A. Chiles Research Institute's clinical research program at the Providence Cancer Institute. We have adapted our research expansion method into an optimized clinical manufacturing process. In collaboration with the Providence Cancer Institute's Cell Processing Facility and Phio Pharmaceuticals, we have completed three full scale IND-enabling manufacturing runs of our ACT product AGX148 w/wo PH-762 INTASYL™.

Results Our data demonstrate that the AGX148 ACT product can be successfully manufactured at a clinical scale and that AGX148 treated with PH-762 during the expansion process is effective at reducing the steady-state level of PD-1 protein. We also tested AGX148 ACT product for autologous tumor recognition and killing in co-culture assays in vitro and in vivo. AGX148 and AGX148 combined with PH-762 were able to recognize and kill autologous tumor lines in vitro and PH-762-treated cells had increased 4-1BB expression in TIL/tumor cocultures. PH-762 induced knockdown of PD-1 was observed in circulating T cells after ACT in a xenograft model with autologous tumor.

Conclusions We have generated a potent tumor-specific ACT TIL product (AGX148) at clinical scale through the isolation and selective expansion of tumor-reactive T cells. Knocking down PD-1 with PH-762 INTASYL™ has the potential to further enhance the function of the AGX148 product and this ACT product will soon be tested in cancer patients.

410 PRIMING OF SYNNOTCH CAR T CELLS VIA CNS-SPECIFIC ANTIGEN ALLOWS SPATIAL AND TEMPORAL REGULATION OF CAR EXPRESSION, EFFECTIVE HOMING AND PERSISTENCE OF T CELLS IN THE CNS, RESULTING IN THE COMPLETE ERADICATION OF AGGRESIVE GLIOBLASTOMA

Payal Watchmaker*, Milos Simic, David Diebold, Psalm Pineo-Cavanaugh, Jason Duecker, Wei Yu, Wendell Lim, Hideho Okada. *UCSF, San Francisco, CA, United States*

Background The CAR T cell therapies have failed to produce long-term remission in glioma patients. One of the key challenges in the development of an effective CAR-T therapy is the absence of target antigens that are tumor-specific and have homogenous expression. To safely target glioblastoma-associated antigens (GAAs) in the tumor without attacking normal tissue expressing the same GAAs outside of the brain, we adopted a novel synthetic Notch (synNotch) receptor system and established a "prime and kill" sequential two-receptor CAR circuit. We used glioblastoma- (GBM) specific neoantigen EGFRvIII as a priming signal for synNotch receptor and have reported robust antitumor response in the mice bearing intracerebral PDX tumor with heterogenous EGFRvIII expression. However, less than 20% of adult GBM cases express EGFRvIII. Furthermore, EGFRvIII expression can diminish over time even after its detection in the primary GBM, and the EGFRvIII-synNotch primed CAR T cells may deplete EGFRvIII-expressing GBM cells via their cytotoxic effects, thereby losing the priming signal. To overcome these inherent challenges of the EGFRvIII-priming strategy, we used CNS (Central Nervous System) tissue-specific antigens as the priming signal to drive localized expression of the CAR against EphA2 and IL-13Rα2 and bypassed the need for tumor-specific antigen.

Methods We have found BCAN (also known as Brevican) as the most promising priming antigen based on the specific and robust priming among several CNS-specific cell surface proteins that we evaluated. We created a synNotch-CAR circuit in which BCAN primes the T cells to induce expression of a CAR that recognizes IL-13Rα2 and EphA2.

Results When mice bearing intracerebral GBM6 PDX received a single intravenous (IV) infusion of T cells engineered with the α-**B**CAN **syn**Notch α-EphA2/IL-13Rα2 **C**AR (B-SYNC) circuit, all mice (10/10) demonstrated complete regression of the tumor. Furthermore, these B-SYNC T cells were significantly more efficacious than constitutively expressed EphA2/IL-13Rα2 CAR T cells. The enhanced in vivo efficacy and superior persistence of B-SYNC T cells were associated with its tissue-resident and memory stem-cell-like phenotype.

Conclusions Taken together, the B-SYNC approach represents a robustly efficacious and conceptually novel T cell therapy with the CNS tissue-specific CAR activation. This also enhances the translational significance of synNotch-CAR T cells by widely extending the eligibility to EGFRvIII-negative glioma patients. We are currently developing a phase I study to evaluate the safety as well as the homing and priming status (i.e. expression of CAR) of the IV-infused B-SYNC T cells in patients with GBM.

411 **THE MULTI-OMICS ANALYSES OF "OFF-THE-SHELF" CD19-CAR-T CELLS IDENTIFIES THE SUBPOPULATION COMPLEXITY AND THE DEEP CHARACTERIZATION OF THE ANTI-TUMOR PROPERTIES**

[1]Asma Al Sulaiti, [1]Mohammed El-Anbari, [1]Shana Jacob, [1]Toufiq Mohamed, [1]Saroja Kotegar Balayya, [1]Suruchi Mohan, [1]Damilola Olagunju, [1]Chiara Cugno, [1]Sara Deola, [1]Jean-Charles Grivel, [1]Damien Chaussabel, [2]Chiara Bonini, [2]Monica Casucci, [1]Cristina Maccalli*. *[1]Sidra Medicine, Doha, Qatar; [2]San Raffaele Hospital, Milano, Italy*

Background The goal of this study is to generate and optimize the manufacturing of "off-the-shelf" CD19-CAR-T cells utilizing umbilical cord blood (UCB) as starting material.

Methods T cells were isolated from UBCs (N=15) through negative magnetic selection and upon activation *in vitro* using CD3 and CD28 mAbs. The T lymphocytes were then transduced with lentiviral vectors encoding for CD19-CD28z-or CD19-4-1BBz-CARs. CD19-CAR-T cells were also generated from the peripheral blood lymphocytes (PBL; N=5) as reference. The multiparametric phenotype analysis was performed assessing the expression of markers associated with T cell differentiation and activation by CAR-T cells. Functional assays, through either Elispot, FluoroSpot or Luminex platforms, were carried out to assess cytokine, chemokine and cytotoxic profiles of the T cells. A machine learning technique called L0-regularized logistic regression,[1] [2] implemented in the R packageL0Learn. was used to select the optimal values of the tuning parameters. The metabolomic and transcriptomic profiles of CD19-CAR-T cells was determined upon the antigen-specific or not engagement of the CARs.

Results The enrichment of both $CD4^+$ and $CD8^+$ CD19-CAR-T cells with stem memory-like or early stage of differentiation ($CD45RA^+$) phenotype and co-expressing either ICOS or BTLA was observed in UCB- vs. PBL-derived CD19-CAR-T cells ($p<0.0002-<0.05$). Moreover, differential phenotype of CAR-T cells was associated with the variable costimulatory signals comprised in the structure of the CARs (CD28z or 4-1BBz). The differential antigen-specific anti-tumor activity of these CAR-T cells was identified, with diversities depending on the type and source of engineered T cells. Distinct metabolomic profiles, including pathways related to amino acid, tryptophan and nucleotide sugar metabolism and protein biosynthesis were detected in relation to the antigen-specific or unrelated stimulation and the manufacturing procedures. Integration of multi-omics results, including the transcriptomic profile allowed to identify the complexities of CD19-CAR-T cells phenotypes and functions.

Conclusions The characterization of phenotype and functional properties of CAR-T cells through multi-omics platforms allowed to prove the suitability of UCB to generate "off-the-shelf" CAR-T cells and to identify sub-populations endowed with superior anti-tumor activity.

412 SYNTHETIC PD-1 CO-STIMULATORY MOLECULE PRESERVES A CYTOLYTIC CAR T CELL IMMUNE SYNAPSE WHILE REDUCING TONIC SIGNALING

Rebecca Brock*, Jessica Morris, Ahmed Gad, Daniel Landi, Shoba Navai, Zeid Nawas, Sujith Joseph, Nabil Ahmed, Alexandre Carisey, Meenakshi Hegde. *Baylor College of Medicine, Houston, TX, United States*

Background It is well established that solid tumors upregulate checkpoint inhibitor ligands to suppress anti-tumoral immunity. This in turn can have a negative impact on the functionality of cell therapeutics such as chimeric antigen receptor (CAR) T cells by promoting exhaustion and cell death. In tumors such as glioblastoma (GBM), pro-inflammatory cytokines produced by T cells further contribute to this feedback loop, resulting in increased expression of PD-L1 and PD-L2. We have developed CAR T cells to modulate PD-1/PD-L1 (or PD-L2) signaling through engagement with a synthetic PD-1 molecule. Here, we hypothesize that the first generation CAR T cells with synthetic PD-1 co-stimulatory molecule form a functional immune synapse with tumor cells while maintaining a more physiological signaling state.

Methods HER2-specific CAR T cells expressing a synthetic PD-1 co-stimulatory molecule were generated from primary human T cells using a bicistronic vector and retroviral gene delivery. Appropriate control T cells were manufactured in parallel from the same donors under similar conditions. CAR T cell and HER2+ LN229-GBM cell conjugates (doublets) were studied using imaging flow cytometry for CAR immune synapse (CARIS) formation and composition. Phosphorylation of CD3ζ was assessed at rest and over time after exposure to tumor cells by western blotting. Supernatant from T cell and HER2+ GBM co-cultures were analyzed using a multiplex assay to evaluate patterns of cytokine release.

Results Imaging of the CARIS revealed that PD-1 is recruited within 60 minutes of CAR T cell and tumor cell engagement. Synthetic PD-1 receptor was recruited to the CARIS within 60 minutes with tumor cells exhibiting constitutive/inducible PD-L1 or PD-L2 expression. Further, first generation CAR T cells with a PD-1 co-stimulatory molecule demonstrated enrichment of actin, indicative of "mature" immune synapse formation, comparable to a second-generation CAR. At baseline, PD-1 co-stimulatory molecule expressing CAR T cells with split signaling exhibit lower phosphoCD3ζ compared to second generation control CAR T cells. Consistent with our imaging findings, CAR T cells with split signaling demonstrated robust CD3ζ phosphorylation similar to that of second generation CAR T cells by 60 minutes. Upon additional assessment, we found that CAR T cells with split signaling showed a pattern of pro-inflammatory cytokine secretion distinct from second generation CAR T cells.

Conclusions Co-stimulation through synthetic PD-1 molecule confers a favorable functional profile to CAR T cells and may enhance their safety, longevity and antitumor function after adoptive transfer.

413 GENETIC DELETION OF TIGIT ENHANCES CAR-NK CELL FUNCTION IN THE SOLID TUMOR MICROENVIRONMENT

Ishwar Navin*, Matthew Dysthe, Corrine Baumgartner, Robin Parihar. *Baylor College of Medicine, Houston, TX, United States*

Background Natural killer cells (NKs) expressing chimeric antigen receptors (CAR-NKs) were successful in hematological malignancies.[1] However, solid tumors resist CAR-NKs via a tumor microenvironment (TME) that includes myeloid derived suppressor cells (MDSCs) and M2 macrophages (M2s).[2] We demonstrated that ex vivo manufacture of therapeutic CAR-NKs significantly upregulated **T** cell immunoreceptor with **Ig** and **ITIM** domains (TIGIT), an inhibitory NK receptor. Analysis of pediatric neuroblastoma and sarcoma patient tumors confirmed high expression of TIGIT ligands on tumor cells and intra-tumoral MDSCs and M2s. ***Our main objective*** was to determine influence of TIGIT on CAR-NK function in the TME. Current TIGIT-targeting approaches using antibodies are handicapped by poor bioavailability and transient binding in the TME. ***We hypothesized*** that genetic deletion of TIGIT on CAR-NKs will lead to a more profound and durable anti-tumor response within the TME.[3]

Methods TIGIT knockout (KO) CAR-NKs expressing a GD2.4-1BB.zeta CAR were generated by concurrent CRISPR/cas9 and retroviral transduction of expanded primary human NK cells. Degranulation (CD107a) and IFN-γ by $TIGIT^{KO}$. GD2.CAR-NK were assessed in short-term TME co-cultures containing LAN-1 neuroblastoma and human MDSCs. A novel long-term TME co-culture wherein human monocytes and CHLA255 neuroblastoma pre-established a suppressive TME for 72 hours prior to addition of $TIGIT^{KO}$ GD2.CAR-NK was used to assess tumor growth and CAR-NK proliferation over 96 hours using Incucyte. We assessed phosphorylated mTOR (pMTOR) in CAR-NKs by intracellular flow cytometry.

Results CRISPR/Cas9 and retroviral transduction generated stable $TIGIT^{KO}$.CAR-NKs (>90% TIGIT deletion; 60% GD2.CAR expression). $TIGIT^{KO}$ enhanced GD2.CAR-NK cytokine secretion but not degranulation in short-term TME co-cultures. In long-term tumor co-cultures, $TIGIT^{KO}$.GD2.CAR-NKs eliminated more tumor vs control NKs (<10% viable tumor vs 35% viable tumor, $p<0.01$; n=4 donors). In TME co-cultures, $TIGIT^{KO}$.GD2.CAR-NK rapidly proliferated and controlled tumor compared to $TIGIT^{wt}$.CAR-NKs (37% viable tumor vs 57% viable tumor, $p<0.05$; n=4 donors). $TIGIT^{KO}$ did not increase CAR-NK degranulation or Fas ligand expression, nor did it alter CAR-NK surface expression of DNAM-1, NKG2D, NKG2A, TIM-3, PD-1 or LAG-3. While $TIGIT^{wt}$. CAR-NKs massively downregulated pMTOR within the TME, $TIGIT^{KO}$.CAR-NKs maintained pMTOR expression. Ongoing studies using a novel in vivo TME xenograft model of neuroblastoma will determine benefit of $TIGIT^{KO}$ vs. TIGIT antibody therapy on CAR-NK activity.

Conclusions We defined a role for TIGIT in inhibition of CAR-NK function and suggest TIGIT deletion as a novel NK therapeutic platform to evade immune suppression in the TME. This highlights the potential of gene-edited CAR-NKs to improve clinical outcomes in patients with solid tumors.

414 TARGET EPHRIN A3 ON CANCER CELLS AND TUMOR MICROENVIRONMENT IN BRAIN CANCER

Ekene Ogbodo*, Reona Sakamura, Michael Ruff, Claudia Roman, Truc Huynh Huynh, James Girsch, Olivia Sirpilla, Kun Yun, Carli Stewart, Ismail Can Can, Mohamad Adada, Lionel Fonkoua, Mehrdad Hefazi, Elizabeth Siegler, Saad Kenderian . *Mayo Clinic, Rochester, MN, United States*

Background Glioblastoma multiforme (GBM) is the most lethal form of brain cancer with a median survival of < 2 years despite treatment advances. Evidence indicates that GBM has been shown to reprogram immune responses to promote its progression. A predominant component of the immunosuppressive tumor microenvironment (TME) is glioblastoma-associated macrophages (GAM). GAM represents up to 50% of the bulk cell population in the GBM microenvironment and is crucial in tumor progression and persistence. We and others have shown the expression of the Ephrin A3 (EphA3) receptor in both tumor and GAM. We hypothesize that dual targeting of both the cancer cell and the immunosuppressive TME with EphA3-specific chimeric antigen receptor T (EphA3-CART) cells would enhance antitumor.

Methods We first investigated the expression of the EphA3 receptor on GBM patient-derived xenografts using immunohistochemistry (IHC) and Western blot. We then polarize primary monocyte or THP-1 monocytic cell line into M2-like macrophages and investigated the expression of the EphA3 receptor on both flow cytometry and then studied the effect of EphA3-CART against EphA3$^+$ SNB-19 GBM cell line using the polarized macrophage. We also assessed the antitumor activity of the EphA3-CART in vivo. NSG mice were subcutaneously injected with 1 x 10^6 Luc+ SNB-19 GBM cell line and monitored for tumor growth using bioluminescence imaging (BLI) and/or tumor size using vernier calipers. At BLI of >1 x10^8 p/s and/or tumor volume of 200-300 mm^3, mice were randomized and treated with 5 x 10^6 EphA3-CAR T cells. And were further monitored by both BLI and/or tumor size using vernier calipers.

Results Our immunohistochemical analysis data revealed EphA3 expression on 26.623% of the PDX representing the area of the human cancer tissue and was confirmed using the western blot analysis of the selected GBM PDX lines in our biobank (figure 1). EphA3-CART cells exhibited potent antitumor activity against EphA3$^+$ GBM cell line SNB-19 (figure 2). M2 polarized macrophage marker expressing a high level of CD206 as well as EphA3 compared to M1 polarized macrophages. EphA3-CART cells were effective in eliminating M2 macrophages (figure 3) and ameliorated M2-induced CART cell inhibition. Finally, EphA3-CART cells exhibited superior tumor control in GBM xenografts compared to the control un-transduced T cells (UTD), (figure 4).

Conclusions In summary, we have developed EphA3-CART cells that target both the tumor cells and GAM within GBM TME which holds promise in improving CART antitumor activity within the immunosuppressive solid tumor milieu.

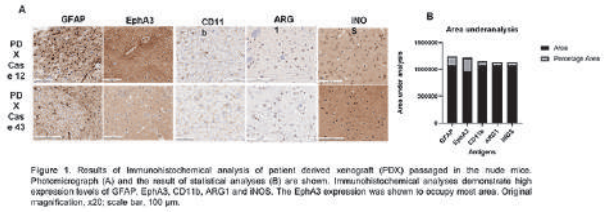

Figure 1. Results of Immunohistochemical analysis of patient derived xenograft (PDX) passaged in the nude mice. Photomicrograph (A) and the result of statistical analyses (B) are shown. Immunohistochemical analyses demonstrate high expression levels of GFAP, EphA3, CD11b, ARG1 and iNOS. The EphA3 expression was shown to occupy most area. Original magnification, x20; scale bar, 100 µm.

415 PD-1 IMMUNE CHECKPOINT BLOCKADE ENHANCES ERADICATION OF DISSEMINATED OVARIAN CANCER

Rita Serda*. *University of New Mexico, Albuquerque, NM, United States*

Background Clinical trials for ovarian cancer using immune checkpoint inhibitors (ICI) as monotherapy have failed to show an improvement in survival, however, improved response rates and survival have been achieved with combination therapy. A novel cancer vaccine platform based on silicified cancer cells that are masked on the surface with microbial-associated molecules has been shown in preclinical trials to reduce tumor burden in mice with disseminated ovarian cancer.[1] Here we evaluate the therapeutic efficacy of combination ICI and vaccination.

Methods Female FVB mice were administered intraperitoneal (IP) injections of BR5-Akt-Luc cells. Mice were given two weekly IP vaccinations, with and without anti-mPD-1 antibody, beginning 8 days post tumor challenge. Bioluminescent imaging was performed using the IVIS Spectrum.

Results Bioluminescent imaging (figure 1) and animal weights indicated excessive tumor burden in untreated mice with animals sacrificed around 25 days post tumor challenge. ICI monotherapy provided no therapeutic benefit, however when combined with vaccination, tumor was undetectable in 80% of the mice 10 days post vaccination, with all mice surviving to Day 49. Tumor did not engraft in surviving mice when rechallenged on Day 50.

Conclusions A silicified cancer vaccine delivery system when combined with ICI is able to reduce tumor burden and enhance survival in mice with established ovarian cancer.

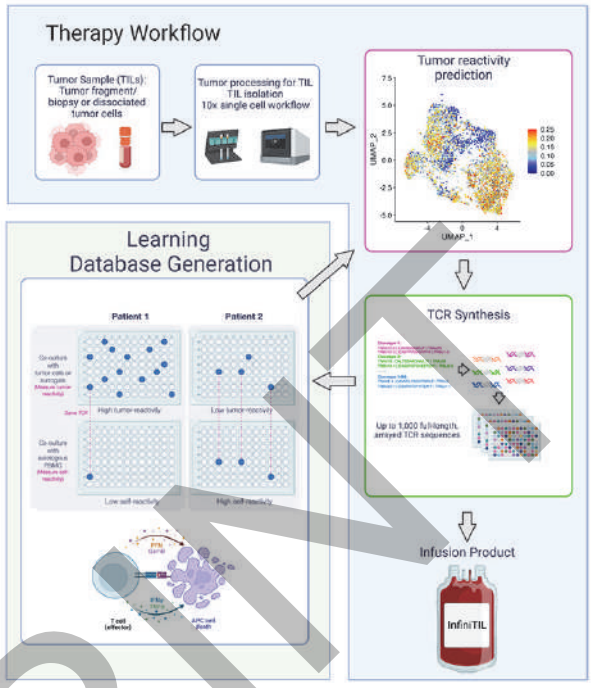
417 RAPID DISCOVERY OF PERSONALIZED TCRS THROUGH A SINGLE-CELL TRANSCRIPTOMIC SIGNATURE THAT PREDICTS TUMOR REACTIVITY

[1]Ely Porter*, [1]Yue Zhao, [1]Danielle Cook, [1]Seon Kinrot, [1]Shuang Mao, [1]Yanzhen Ye, [1]Jiayu Ou, [2]Dandan Hu, [1]Xi Chen. *[1]RootPath, Inc., Watertown, MA, United States; [2]State Key Laboratory of Oncology in South China, Guangzhou, China*

Background Personalized T cell therapies are currently limited by complex manufacturing, unreliable potency, long timelines, and the associated high cost. An ideal personalized workflow would simplify this process by leveraging affordable sequencing and commoditized cell manufacturing, while still resulting in a potent therapeutic without time-consuming and costly experimental validation. The T cell population that mediates response, the cells containing tumor-reactive TCRs, is undefined by traditional phenotypic characterization. To better understand this cryptic population critical for therapy, we devised a workflow that involves scRNA-Seq of thousands of cells, synthesizing 1000s of TCRs per patient, and screening them for reactivity (figure 1). We then applied this workflow across a broad spectrum of cancer types. The synthesis of 100,000s of TCRs to enable this survey is cost-prohibitive using traditional vendors. To solve this problem, we developed a novel technology, named PathFinder DNA Assembly™, that allows parallel synthesis of thousands of TCRs simultaneously for a cost of **under $1 per TCR**. The tumor-reactivity of these TCRs can then be experimentally tested, and their reactivity profile mapped back to high-complexity scRNA-Seq data to better define the population responsible for mediating therapeutic responses.

Methods To date, we've queried 26 patients across 10 different cancer types, synthesized between 350-2,800 TCRs per patient, and identified reactive TCRs against autologous tumor and allogeneic HLA matched cell lines. This database allows us to correlate the reactivity profile of a TCR with the transcriptomic profile of the original, unexpanded tumor infiltrating lymphocytes (TIL). In doing so, we've identified a transcriptomic profile (TR1.0) that enriches for tumor reactivity and is corroborated when we interrogating public scRNA-Seq datasets

Results To demonstrate the utility of our TR1.0 signature, we performed scRNA-Seq on a liver cancer sample, selected TCRs based on TR1.0, synthesized 192 TCRs from more than 4,500 cells encompassing high-scoring CD8 and CD4 populations, as well as TCRs predicted by other published metrics. Reactivity of the synthetic TCRs was established by ELISPOT assays against autologous tumor in a 384-well microplate and the highly reactive TCRs highlighted on the UMAP. The TR1.0 score correctly identifies the small population of T cells containing the reactive TCRs where other published metrics fail to predict the reactive population. This data, in combination with ongoing work, demonstrates the feasibility of a personalized therapy with simplified manufacturing and clinically viable timelines while maintaining a high potency of the product.



Abstract 417 Figure 1 RootPath InfiniTIL Workflow
Overview of the InfiniTIL workflow. Tumor samples are collected from as small amount of material as a biopsy, T cells selected, and single-cell sequenced. TCRs from T cells that score highly by TR1.0 metric are then selected for production. Additionally, each patients TCRs are screened in a companion assay to establish each TCR's reactivity profile. This establishes a database of reactivity information and it's correlation with transcriptomic and cell surface marker expression, that can then be leveraged to improve TR1.0 scoring and enable new therapies.

Checkpoint Blockade Therapy

418 6-GINGEROL SUPPRESSES ANGIOGENESIS AND PROMOTES T-CELL CYTOTOXICITY IN MICE MODEL OF COLORECTAL CANCER

[1]Babajide Ajayi*, [2]Anuoluwapo Adeshina. [1]*Ajayi Crowther University Oyo, Oyo, Nigeria*; [2]*All Saint School of Medicine Dominica, Roseau, Dominica*

Background Colorectal cancer (CRC) is the second most common adult cancer in women and the third most common in men, and it is the fourth leading cause of cancer death worldwide. Angiogenesis is a critical step in CRC progression and metastasis. Immune checkpoint proteins (ICP) such as programmed cell death 1 (PD1), PD1 ligand 1 (PD-L1) and cytotoxic T lymphocyte antigen 4 (CTLA4) act as inhibitory immunoreceptors that prevent cytotoxic T-cells from killing tumor cells. Studies have reported the contribution of angiogenesis and ICP to anti-tumor immunity. Indeed, targeting angiogenesis and use of ICP blockage have revolutionized colorectal cancer treatment and improved patients' survival. However, the use of immune checkpoint inhibitors has been shown to induce immune-related adverse reactions such as colitis. 6-gingerol (6G), the most pharmacologically active compound discovered in Zingiber officinale (ginger), We have reported the anti-tumor effects of 6-gingerol. However, there is a lack of information on the effect of 6G on angiogenic drivers and T-cell cytotoxicity in a mouse model of CRC. Herein, we investigated the effects of 6G angiogenesis and cytotoxic T-cell signaling in mice model of CRC.

Methods Male BALB/c mice were divided into three groups of 20 mice each. Group 1 mice served as controls Group 2 (CRC model) mice received a single dose of azoxymethane (AOM) 10mg/kg and, after one week, they received three cycles of dextran sulfate sodium (DSS) 4% in drinking water. Group 3 mice received 6G 10mg/kg/day by oral gavage in combination with AOM and three cycles of 4% DSS (W/V) in drinking water. The colons of the mice were observed daily for tumor development, and the experiment was terminated after confirmation of colorectal adenocarcinoma.

Results Tumor burden was observed to be decreased in CRC mice treated with 6G. Also, 6G decreases the expression of collagen (type I and I), vascular endothelial growth factor (VEGF), VEGF receptor, epidermal growth factor (EGF), and EGF receptor in mice with CRC when compared with control. Furthermore, mice administered 6G+AOM/DSS had increased expression of CD4 and CD8+ T-cells and decreased expression of tumor necrosis factor (TNF-α), cyclooxygenase-2 (COX-2), PD1, PD-L1, and CTLA4 when compared to mice with CRC. Using computational oncology, we observed a high binding affinity of 6G with VEGF, VEGFR, EGF, EGFR, PD1, PD-L1, and CTLA4.

Conclusions The result obtained from this study showed that 6-gingerol suppresses angiogenic drivers and promotes T-cell cytotoxicity in colorectal cancer.

419 COMBINED ANTI-VEGF, ANTI-CTLA4 AND ANTI-PDL1 TREATMENT INDUCES STRONG IMMUNE RESPONSES IN PATIENTS WITH CHOLANGIOCARCINOMA: RESULTS FROM A CLINICAL TRIAL/IN DEPTH CORRELATIVE STUDIES AND MOUSE STUDIES

[1]Reda Benmebarek*, [2]Tim Greten, [1]Cecilia Monge, [1]Benjamin Ruf, [1]Yuta Myojin, [2]Cihan Oguz, [2]Justin Lack, [1]William Telford, [1]Changqing Xie, [1]Tim Greten. *[1]NCI, Bethesda, MD, United States*; *[2]National Institutes of Health, Bethesda, MD, United States*

Background The addition of durvalumab (anti-PD-L1) to chemotherapy with gemcitabine and cisplatin has become standard of care for patients with cholangiocarcinoma. Both anti-CTLA4/anti-PD-L1 and anti-VEGF/anti-PDL1 are FDA approved immune checkpoint inhibitor regimens. Here we tested the combination of anti-CTLA4 + anti-VEGF + anti-PD-L1 in patients with cholangiocarcinoma (CCA).

Methods In this open-label phase II study patients with histologically confirmed HCC and CCA were treated with 300 mg tremelimumab, 7.5 mg/kg bevacizumab and 1150 mg durvalumab on day 1 followed by 7.5 mg/kg bevacizumab and 1150 mg durvalumab every 3 weeks. Primary objective was the 6-month progression-free survival (PFS). Secondary endpoints include safety and correlative studies including single cell RNA-sequence analysis of PBMC, spectral flow cytometry analysis using a 22-color pan-immunological panel and a 25-color T cell-specific panel and multiplex serum cytokine analysis as well as bulk mRNA analysis from paired tumor biopsies. Immune and tumor responses were tested in mice with subcutaneously injected SB1 cholangiocarcinoma cells after treatment with anti-VEGF/anti-CTLA4 and anti-PD-L1.

Results A total of 7 patients (6 CCA and 1 HCC) were enrolled into this study before the study was halted for unexpected high rates of immune related AEs. 4/7 patients developed grade 3 AEs including 2 patients with myositis, 1 patient with colitis, 1 patient with hepatitis, 2 patients with thyroiditis and 1 patient who developed a myocarditis, myositis, myasthenia gravis and immune thrombocytopenia. Here we present the unexpected clinical responses in CCA with 2/6 CCA patients demonstrating long-lasting partial responses (10.3 and 3.5 months) and a median OS of 13.6 months despite early treatment discontinuation. Analysis of immune correlates are ongoing. Preliminary spectral flow cytometry results demonstrated a significantly higher frequency of regulatory T cells (Tregs), proliferating $CD4^+$ and $CD8^+$ T cells, as well as non-classical monocytes following anti-VEGF/anti-CTLA4/anti-PD-L1 treatment. Within the CD8 T cell compartment, a $CD39^+Ki67^+PD\text{-}1^{hi}$ fraction expanded in the anti-VEGF/anti-CTLA4/anti-PD-L1 treated cohort. 10x single cell sequencing analysis confirmed the findings of the flow cytometric analysis and revealed expanded TCR clonotypes in the treated cohort. In murine studies anti-VEGF, anti-CTLA-4 and anti-PD-L1 combination resulted in marked tumor control in tumor-bearing mice mimicking results we obtained in patients with CCA.

Conclusions Here, we show that combined anti-VEGF, anti-CTLA4 and anti-PD-L1 induces exceptional immunological and therapeutic responses in patients with cholangiocarcinoma. The study is continuing to enroll with a modified dosing schedule. Murine studies will help better to further elucidate the immunological mechanism.

420 DOXYCYCLINE REGULATABLE β-CATENIN DEMONSTRATES INDUCIBLE IMMUNE EVASION IN A MELANOMA GEM MODEL

[1]Alexandra Cabanov*, [1]Thomas Gajewski, [2]Stefani Spranger, [2]Elen Torres-Mejia. [1]*University of Chicago, Chicago, IL, United States*; [2]*Koch Institute, Cambridge, MA, United States*

Background Lack of response to checkpoint blockade immunotherapy has been linked to a deficiency of immune cell infiltration within the tumor microenvironment (TME). One demonstrated mechanism sufficient for the non-T cell inflamed TME is tumor cell-intrinsic activation of the β-catenin signaling pathway. Using genetically engineered mouse models (GEMMs), tumors constitutively expressing active β-catenin lack a robust endogenous T cell infiltrate and fail to respond to immunotherapies. In support of these mouse studies, human melanoma metastases with increased active β-catenin signaling exhibit decreased numbers of tumor infiltrating Batf3-driven cDC1 and $CD3^+$ T cells. However, whether temporal activation and inactivation of b-catenin within the same developing tumor would alter immune cell infiltration is not known.

Methods A model was created in which tamoxifen-regulated Cre-recombinase mediates $BRAF^{V600E}$ oncogene activation and PTEN tumor suppressor gene deletion as well as expression of a doxycycline regulatable reverse transactivator. Upon administration of doxycycline via the drinking water to these animals, a non-degradable form of nuclear β-catenin becomes expressed. Immunofluorescence assays were performed assessing the β-catenin expression status in the tumor cells as well as immune cell infiltration within the TME. Additionally, immunotherapy efficacy experiments were performed.

Results We observed that administration of doxycycline to these animals drove expression of an active form of nuclear β-catenin. Activation of nuclear β-catenin resulted in a 2-fold decrease in the overall $CD3^+$ T cells infiltration into the TME. Moreover, this decrease in immune infiltration also resulted in loss of anti-PD-L1 + anti-CTLA-4 therapy efficacy. We next performed studies assessing the kinetics with which β-catenin levels diminish upon doxycycline removal. Switching animals to regular drinking water resulted in complete reduction of nuclear β-catenin levels seven days after doxycycline removal. Interestingly, once nuclear β-catenin levels diminished, we observed re-infiltration of the TME however, these tumors remained unresponsive to anti-PD-L1 + anti-CTLA-4 therapy.

Conclusions We describe a novel mouse model in which we induce autochthonous melanoma tumors in mice along with inducible expression of a non-degradable, nuclear β-catenin modulated by doxycycline in the drinking water. While removing doxycycline resulted in re-infiltration of CD3+ T cells within the TME, it did not result in restored anti-PD-L1 + anti-CTLA-4 efficacy. Single cell RNAseq and spatial transcriptomics are being performed to determine if an additional immune regulatory event becomes established when b-catenin is on from the birth of the tumor that needs to be overcome.

422 KZR-540 IS A NOVEL ORAL SMALL MOLECULE INHIBITOR OF SEC61 COTRANSLATIONAL TRANSLOCATION THAT POTENTLY AND SELECTIVELY BLOCKS PD-1 EXPRESSION

Cristina Delgado-Martin*, Neel Anand, Janet Anderl, Chengguo Dong, Andrea Fan, Ying Fang, Christopher Kirk, Tony Muchamuel, Yu Qian, Jinhai Wang, Jennifer Whang, Patricia Zuno-Mitchell. *Kezar Life Sciences, South San Francisco, CA, United States*

Background Blocking the PD-1/PD-L1 pathway with antibodies has been effective in treating multiple types of cancers. However, orally administered small molecules can allow for better tumor penetrance and more convenient dosing than antibody-based therapies. Most secreted and transmembrane proteins utilize unique signal sequences (ss) to enable translocation through the Sec61 complex into the endoplasmic reticulum. Targeting Sec61 with small molecule inhibitors such as KZR-261, currently in a clinical trial for solid tumors (NCT05047536), has anti-tumor effects through inhibiting the expression of multiple therapeutic targets, including PD-1, in preclinical models. Here we describe KZR-540, an oral small molecule Sec61 inhibitor that potently and selectively blocks PD-1 expression.

Methods Inhibition of Sec61 clients was assayed in HEK-293 cells overexpressing the ss of interest fused to a luciferase reporter. Human T cells pre-treated *in vitro* with test compounds and stimulated were monitored for expression of PD-1 and other markers by flow cytometry and mass spectrometry (MS)-based proteomic profiling. Cytokine production was measured from allogeneic mixed lymphocyte reaction (MLR). T cell-mediated killing was assessed in co-culture assays with A375 cells. Pharmacokinetics (PK) was assessed using liquid chromatography-tandem MS. *In vivo* evaluation of PD-1 expression was conducted in humanized PBMC NSG™ and B-hPD-1 mice dosed orally with KZR-540 and treated with anti-CD3 antibody. Human PD-1 expression on T cells was assessed by flow cytometry of splenocytes.

Results We have discovered a series of Sec61 inhibitors that potently and selectively block ssPD-1 expression. In human T cells treated with these compounds *in vitro* prior to activation, surface expression of PD-1 was inhibited while other T cell activation markers were unaffected. KZR-540 demonstrated good liver microsome stability and a robust oral PK profile and was selected for further studies. The selectivity of KZR-540 was also demonstrated by global Sec61 client proteomic profiling of treated T cells. Treatment with KZR-540 increased IL-2 and IFNgamma production in MLR and enhanced killing of A375 melanoma cells by human T cells. Furthermore, oral dosing of KZR-540 potently suppressed anti-CD3-induced PD-1 expression in both humanized NSG mice and human-PD-1 knock-in mice.

Conclusions KZR-540 is a small molecule inhibitor of Sec61 that can potently and selectively block PD-1 expression and increase T cell activity *in vitro*, as well as inhibit surface PD-1 expression when dosed orally *in vivo*. Future studies will examine whether there is an enhanced anti-tumor response in a tumor model.

Ethics Approval Animal studies were approved by the Institutional Animal Use and Care Committee.

423 TREATMENT OF RELAPSED AND REFRACTORY LYMPHOMAS WITH NIVOLUMAB IN A LIMITED RECOURSE COUNTRY

[1]Lusine Harutyunyan*, [1]Anahit Ter-Grigoryan, [1]Hayk Grigoryan, [1]Marina Kazaryan, [1]Miranush Saaryan, [1]Nerses Ghahramanyan, [2]Artem Oganesyan, [1]Levon Evoyan, [1]Marina Melik-Andreasyan, [1]Anahit Aynajyan, [1]Karapet Hakobyan, [1]Astghik Voskanyan, [1]Karen Meliksetyan, [1]Yervand Hakobyan. *[1]Armenian Hematology Association, Yerevan, Armenia; [2]Hematology Center aft. Prof. R. Yeolyan, Yerevan, Armenia; National Institute of Health, Yerevan, Armenia*

Background Programmed cell death proteins and their ligands have been under research in recent years, as their inhibitors provide promising results in relapsed and refractory lymphoma treatment.[1] However, in Armenia, number of patients receiving Nivolumab is small and does not represent a real indication number, since it is problematic to provide it. The main aim of this monocenter retrospective study is to evaluate the outcome with Nivolumab among Armenian lymphoma cases.

Methods Data was taken from the Hematology Center after prof. R. Yeolyan ambulatory cards. Study duration: 2013-2021. Patient number: 10. Eight patients were diagnosed with Hodgkin's lymphoma (HL), one patient with Primary mediastinal B large cell lymphoma (PMBCL), another one with ALK-positive T-large cell anaplastic lymphoma (ALK+ ALCL). In all patients, the primary diagnosis was established in advanced stages.

Results Nivolumab performed after 2nd relapse in 5 patients, of which 4 were with HL and one with ALK+ ALCL. First-line therapy was started with BEACOPP scheme in all HL patients, after which BV, ABVD, VGPP, DHAP, CVPP, ViG-EPP3 were also the regimens of choice over Nivolumab. The PMBCL patient was treated with R-CHOEP, R-DHAP before Nivolumab + Venetoclax. At initial diagnosis he had skin necrosis of about 15 cm, which worsened after radiation, but partial skin recovery was observed after Nivolumab + Venetoclax regimen, skin biopsy showed no tumour activity. The patient with ALK+ ALCL was treated with R-CHOP, BV-CHP, BV before Nivolumab. 3 patients received Nivolumab after initial therapy failure, 1 of them with PMBCL and 2 with HL. One patient did not attend after Nivolumab+ BV courses, but no mortality status. One HL patient was diagnosed with HIV and is currently in partial remission (PR) after BEACOPP + Nivolumab + auto-HSCT. CR after Nivolumab was achieved in 3 patients, 2 of them with HL and 1 with PMBCL. PR was achieved in one HL patient. Progression after Nivolumab was observed in 5 patients, of which 4 had HL and one had ALK+ ALCL. Auto-HSCT was performed in 3 patients, 2 of them with HL and 1 with PMBCL, and CR was achieved in PMBCL.

Conclusions Overall, CR was achieved in 30% of lymphoma patients, among whom patients received Nivolumab at doses of 100, 160 and 200 mg. Some patients received reduced doses of Nivolumab 40 mg and did not respond to a treatment. Based on a limited number of patients, additional studies are needed for a definitive conclusion.

424 AN ALLOSTERIC, ORALLY ADMINISTERED CBL-B INHIBITOR REMODELS THE TUMOR MICROENVIRONMENT AND ENHANCES IMMUNE-MEDIATED TUMOR GROWTH INHIBITION

Yilin Qi*, Jun Kuai, Yingzhi Bi, Huadong Sun, Samira Jaeger, David Greco, Ken Carson, Timothy Reilly, Geraldine Harriman, Fang Wang. *Hotspot Therapeutics, Boston, MA, United States*

Background Casitas B-lineage lymphoma proto-oncogene b (CBL-B), an E3 ubiquitin-protein ligase, is a critical regulator of immunity. Genetic ablation or inactivation of CBL-B bypasses the requirement of a co-stimulatory signal for T cell activation in an antigen-dependent manner. CBL-B knockout mice spontaneously reject tumor growth, and the effect is largely dependent on CD8+T cells. Therefore, CBL-B represents a novel target for cancer immunotherapy. Previously, Hotspot has disclosed a series of allosteric CBL-B inhibitors which exhibited potent *in vitro* and *in vivo* properties.

Methods Our CBL-B inhibitor (CBL-Bi) was evaluated in a set of syngeneic mouse tumor models. In addition to the measurement of tumor growth, tumor gene expression immune signatures were characterized by Nanostring analysis. Immunohistochemistry and flow-based immunophenotyping were used in profiling the tumor microenvironment.

Results CBL-Bi, as a single agent, demonstrated a spectrum of anti-tumor responses. It not only showed anti-tumor activity in immunologically hot tumor models, such as H22 and CT26, but also in immunologically cold tumor models, such as B16-F10. Responding tumors showed enhancement of antigen presentation, T cell cytotoxicity, and interferon and TNF pathway activation. Furthermore, an *in vivo* study using the CT26 model demonstrated that the anti-tumor effect was mediated by the immune system, as there was no tumor growth inhibition observed in immune deficient NCG mice. We further investigated the combinational effect of CBL-Bi with anti-PD1 in the CT26 syngeneic mouse tumor model. Additive or synergistic anti-tumor activity was observed. Tumor microenvironment profiling demonstrated significant enhancement of T cell tumor infiltration, and a shift of tumor associated macrophages to a pro-inflammatory status was observed in the combination group.

Conclusions Taken together, the pre-clinical *in vivo* data presented here demonstrate that inhibition of CBL-B induces immune mediated tumor growth inhibition; the anti-tumor effect is further enhanced when combined with anti-PD1. Thus, CBL-B inhibition has the potential to overcome the low-antigen and high immune suppressive tumor environment.

425 KVA12.1: AN ANTI-VISTA MONOCLONAL ANTIBODY WITH STRONG SINGLE AGENT ANTI-TUMOR ACTIVITY AND NO EVIDENCE OF CYTOKINE MEDIATED TOXICITY

Thierry Guillaudeux*, Kurt Lustig, Emily Frazier, Neda Kabi, Chen Katz, David Peckham, Mei Xu, Shawn Iadonato. *Kineta Inc., Seattle, WA, United States*

Background V-domain Immunoglobulin Suppressor of T cell Activation (VISTA), an immune checkpoint regulator, is highly expressed in myeloid cells in the tumor microenvironment (TME). It has been shown in vitro and in vivo that VISTA inhibits T cell activation and prevent T cell recruitment into tumors. In patients, high VISTA expression is associated with poor prognosis and is also a potential mediator of resistance to current checkpoint therapies. VISTA is a very attractive new target for cancer immunotherapy.

Methods Kineta has developed a clinical candidate anti-VISTA monoclonal antibody, KVA12.1, which demonstrates in human VISTA KI mice strong anti-tumor activities as a single agent and in combination with other check-point inhibitors in multiple syngenic tumor models. KVA12.1 is an IgG1 antibody targeting a unique epitope on VISTA that has been engineered to extend its half-life and reduce its immunoreactivity. These modifications introduced in the IgG1 backbone of the antibody could prevent possible adverse events related to a Cytokine Release Syndrome (CRS) when injected into cancer patients.

Results We show here that the engineered IgG1 of KVA12.1 increases binding of the antibody to neonatal Fc-Receptor compared to the wild type IgG1 and reduces the binding to different FcRg receptors in particular FcgRIIIa involved in a strong immunoreactivity. We have also shown in previous work that KVA12.1 binds with the same potency and specificity to human and Non-human primate (NHP) VISTA. We have therefore conducted Non-GLP and GLP toxicological studies and demonstrated that KVA12.1 is very well tolerated in NHP, even after multiple high dose injections over a one-month period. No mortality or overt clinical signs have been observed, as well as no treatment-related findings for clinical pathology endpoints and no change of CRS cytokine levels, in particular IL6 and TNFa. The absence of CRS markers has also been confirmed in whole blood obtained from multiple human healthy donors. Besides, we have confirmed in these same NHP studies the extended PK of our antibody. KVA12.1 will be tested in a clinical trial in cancer patients with advanced solid tumors that have failed previous therapies with current standard of care. To guide our inclusion criteria, VISTA expression has been evaluated by immunohistochemistry on a large panel of human cancer tissue samples.

Conclusions The clinical trial will start by the end of 2022 and will evaluate the safety and tolerability of KVA12.1 injected alone or in combination with pembrolizumab, as well as the Recommended Phase 2 dose (RP2D) or maximum tolerated dose (MTD) as a primary objective. Pharmacokinetics, immunogenicity and tumor responses will also be evaluated in this trial.

426 ES005, A HIGH AFFINITY ANTI-LAG3 MONOCLONAL ANTIBODY, INHIBITS THE INTERACTIONS BETWEEN LAG3 AND MULTIPLE LIGANDS AND ENHANCES ANTI-TUMOR ACTIVITY OF T CELLS IN PRECLINICAL MODELS

Xiaofeng Niu*, Chunnian Wang, Jinfeng Zhao, Yefeng Lu, Yingchao Liu, Rui Gao, Zhihao Wu, Yangsheng Qiu, Zheng Song, Hongtao Lu. *Elpiscience Biopharma, Shanghai, China*

Background Lymphocyte-activated gene 3 (LAG3) is a cell surface inhibitory receptor expressed by both activated and exhausted $CD4^+$/$CD8^+$ T cells, as well as regulatory T cells (Tregs). It plays an important role in regulating immune homeostasis with multiple biological activities related to T cell functions and is considered a next-generation immune checkpoint after programmed cell death protein 1 (PD-1) and cytotoxic T-cell lymphocyte antigen-4 (CTLA-4). The first identified LAG3 functional ligand is major histocompatibility complex class II (MHC-II). Recently other LAG3 ligands, like fibrinogen like 1 (FGL1), liver and lymph node sinusoidal endothelial cell C-type lectin (LSECtin), and galectin-3, were also found to be responsible for the inhibitory function of LAG3, suggesting that blocking these interactions simultaneously may bring greater clinical benefit in cancer treatment. We have developed a high affinity LAG3 blocking antibody ES005 that inhibits the interactions between LAG3 and multiple ligands and it enhances anti-tumor activity of T cells in preclinical models.

Methods LAG3 binding activity and affinity were evaluated by FACS and surface plasmon resonance system (Biacore). Blocking activity was determined by competition assay. *In vitro* functional activity was determined by NFAT reporter assay and antigen specific T cell activation assay. *In vivo* efficacy was evaluated in a syngeneic mouse breast tumor model with human LAG3 knock-in mice. Epitope analysis was performed by ELISA and hydrogen deuterium exchange mass spectrometry (HDX-MS). Lead clone was humanized via CDR grafting and back mutation screening. Non-human primates (NHPs) models were used to assess the safety and pharmacokinetics of the humanized candidate.

Results ES005 specifically recognizes human LAG3 with high affinity. It binds to a unique epitope on LAG3 that is distinct from known competitor molecules. ES005 potently blocks LAG3 binding to multiple ligands (MHC-II, LSectin, FGL1). ES005 can reverse LAG3-driven inhibition of NFAT reporter gene expression and T cell activation in a dose-dependent manner. In a syngeneic mouse breast tumor model, ES005 significantly inhibited tumor growth *in vivo*. ES005 has excellent pharmacokinetics and safety profile in NHPs.

Conclusions In summary, anti-LAG3 mAb ES005 is a multiple-ligand blocker and demonstrated potent single-agent activity in *in vivo* mouse tumor models, indicating great potential to be used as next-generation immune checkpoint inhibitor in cancer treatment. We are currently advancing the development of ES005 into clinical candidate.

427 **APPROVAL TIMINGS AND REVIEW SPEED OF IMMUNE CHECKPOINT INHIBITORS (ICIS) IN CANCER THERAPY BETWEEN THE FOOD AND DRUG ADMINISTRATION (FDA) AND THE EUROPEAN MEDICINES AGENCY (EMA) FROM 2010-2022**

[1]Numair Rizwan, [2]Ali Raza Khaki*, [3]Aakash Desai, [4]Jeremy Warner, [5]Jonathan Krell, [5]Mark Lythgoe. *[1]Independent, Boston, MA, United States; [2]Stanford, Stanford, CA, United States; [3]Mayo Clinic, Rochester, MN, United States; [4]Brown University, Providence, RI, United States; [5]Imperial College London, London, UK*

Background ICIs targeting cytotoxic T-lymphocyte-associated protein 4 (CTLA-4), programmed cell death protein 1 (PD-1) or its ligand (PD-L1) have transformed outcomes in many cancer types. Prompt regulatory approval is essential to ensure timely access for patients. We have previously shown that over the past decade most new oncology therapies are approved earlier and faster by the FDA compared to the EMA. [1 2] However, less is known about the regulatory evaluation of ICIs, and if any significant review timing differences exist between initial and subsequent indication approval. In this study, we analyzed regulatory review and approval speed for ICIs at the FDA and EMA following the first ICI approval in 2011.

Methods We performed a cross-sectional analysis of regulatory databases for the FDA and EMA to identify approved ICIs, licensed indications and regulatory review time. ICIs with more than one indication by either the FDA or EMA were included. From each regulatory database we calculated number of approved indications, classified indications by tumor type and calculated the review speed (defined as time from application submission to approval) for each approval. We then compared the regulatory approval timings for initial and supplementary indications (pooled).

Results We identified 8 ICIs, including 7 anti-PD1/PDL1 and 1 anti-CTLA-4 monoclonal antibodies, approved for cancer indications by both the FDA and EMA. There were 93 approved subsequent indications for ICIs, across 14 tumor types with 3 agnostic indications by the FDA with 84 for anti-PD-1/PD-L1, 6 for anti-CTLA4/PD-1 combination therapy and 3 for anti-CTLA-4 monotherapy. This compared to 64 approved indications across 14 tumor types with 1 agnostic indication for the EMA, including 55 anti-PD1/PDL1, 6 for anti-CTLA4/PD-1 combination therapy and 3 for anti-CTLA-4 monotherapy. The median review time for initial ICI approval at the FDA and EMA was 195 days (IQR:172-228 days) and 440 days (IQR: 376-489 days), respectively. For supplementary ICI indication approval, the pooled review time was shorter for each regulator with 180 days (6% shorter) for FDA and 279 days (37% shorter) for the EMA.

Conclusions Eight ICIs have been approved, for similar cancer types, for use in the US and Europe, however, the US has ICIs approved for more indications and agnostic-use labels. ICIs are reviewed more quickly, for both initial and supplemental indications, by the FDA compared to the EMA. Compared to initial approval review, the regulatory review of supplemental indications was relatively unchanged by the FDA but faster by the EMA.

428 DIFFUSING ALPHA-EMITTERS RADIATION THERAPY PROMOTES A PRO-IMMUNOGENIC TUMOR MICROENVIRONMENT AND SYNERGIZES WITH PD-1 BLOCKADE

[1]Sara Roumani*, [1]Yossi Nishri, [1]Amit Shai, [1]Margalit Efrati, [2]Itzhak Kelson, [2]Yona Keisari, [1]Vered Domankevich, [1]Robert Den. *[1]Alpha Tau Medical Ltd., Jerusalem, Israel; [2]Tel Aviv University, Jerusalem, Israel*

Background Diffusing alpha emitters radiation therapy (DaRT) utilizes Ra-224 loaded seeds that continuously release alpha-emitting atoms inside the tumor.[1] The treatment effectively ablates many types of human and mice xenografts[2] and shows 100% response rates in patients with recurrent and locally advanced squamous cell carcinoma (SCC) of the skin and head and neck.[3] DaRT was previously shown to trigger specific- and systemic- antitumor immune responses in mice, that synergize with immunomodulation and immune stimulation. [4-6] Nevertheless, the gene expression profile induced by DaRT treatment and its local and systemic immune response in combination with immune checkpoint inhibition by programmed cell death protein 1 (PD-1) blockade were not yet investigated.

Methods Balb/c mice bearing intracutaneous SCC murine tumors (SQ2 cells) were treated with an inert seed, a Ra-224 loaded DaRT seed, aPD-1or DaRT+aPD-1. Anti-PD-1or an isotype control was administered intraperitoneally at the dose of 10 mg/kg. Flow Cytometry Analysis (FACS) of dendritic cells, myeloid-derived suppressor cells (MDSCs) and lymphocytes was performed in tumors and spleens 16 days after DaRT/ inert seed insertion. Furthermore, tumors were subjected to IHC analysis for the detection of tumor infiltrating lymphocytes (TILs). In addition, similar FACS analysis and transcriptional profiling of immune-related target genes in tumor tissues were characterized using the Nanostring technology seven days post-DaRT seed insertion. Combination of DaRT with aPD-1 was also tested for retardation of tumor growth.

Results DaRT in combination with aPD-1 delayed tumor development, induced T lymphocytes infiltration and granzyme B secretion, and reduced systemic MDSCs more efficiently than each of the monotherapies. Gene expression and gene set enrichment analysis of mRNA levels 7 days after DaRT insertion indicated that DaRT upregulated apoptosis, p53 signalling, interferon signalling and myeloid related transcription, while downregulating DNA repair, cell proliferation and notch related transcription. Immunophenotyping analysis at this timepoint showed that DaRT induced dendritic cell activation and affected the distribution of myeloid-derived suppressor cells populations.

Conclusions DaRT exerts a synergistic effect with aPD-1 in inhibiting tumor growth in a murine model of SCC and promotes a pro-immunogenic state both locally and systemically. DaRT potentiates not only a higher T-effector cells infiltration but also their cytotoxic potential under checkpoint molecule blockade. Therefore, the current study provides a rationale for a potential combination treatment in SCC patients.

429 **HUMAN TUMOR RESPONSE TO A STANDARD MONOTHERAPY CHECKPOINT INHIBITOR IN A HUMANIZED HSC-NCG MOUSE MODEL ENGRAFTING ADULT HEALTHY DONOR-MOBILIZED HUMAN CD34$^+$ HEMATOPOIETIC STEM CELLS**

Jenny Rowe*, Christoph Eberle, Ann Fiore, Robert Mihalek, Brianna Schoen, Stephen Festin.
Charles River Laboratories, Inc., Wilmington, MA, United States

Background Checkpoint inhibitors, including those of the PD-1/PD-L1 pathway, are immunotherapies used for the standard of care for cancer patients. New treatments or immunotherapies are compared to those that are currently approved for use. Continual focus is placed on cancers ranked amongst the most common worldwide, including breast, lung and colon cancer. In this study we assessed the ability of NCG mice to support engraftment of adult mobilized hCD34$^+$ stem cells as a model for determining tumor growth modulation using anti-hPD-1 monotherapy driven cellular responses over time.

Methods We evaluated the anti-tumor effects of an anti-human PD-1 checkpoint inhibitor in three human tumors (A549 lung, Colo-205 colon and MDA-MB-436 breast cancer) in NCGs humanized with adult healthy donor-mobilized hCD34$^+$ stem cells. Humanized mice were implanted subcutaneously with cancer cells, and tumor bearing mice (TBM) were randomized into treatment groups when the average tumor size reached comparable volumes for each tumor type. Vehicle control mice were treated with isotype control IgG antibody, whereas TBM were dosed with anti-hPD-1 antibody. Clinical observations, body weights and tumor growth kinetics were recorded throughout the study. At time of euthanasia whole blood, spleen and tumor tissues were collected and processed for immune profiling by multi-color flow cytometry.

Results In the mobilized hCD34$^+$ humanized mice anti-hPD-1 monotherapy modulated tumor growth in lung, colon and breast cancer tumors compared to the IgG isotype control treated. We observed that growth kinetics varied between tumor types. At study termination common human lymphocytes were distributed in peripheral blood, spleen and tumors of surviving mice. After PMA/Ionomycin stimulation in vitro polyfunctional ex vivo T-cell responses were detected within tumor-infiltrating lymphocytes. NCG mice injected with adult healthy donor-mobilized hCD34$^+$ stem cells sustained engraftment out to 34 weeks post-injection. The anticipated human immune cell types were detected in bone marrow, spleen and lung at ~18-19 weeks.

Conclusions Adult healthy donor-mobilized hCD34$^+$ humanized mice can be successfully engrafted with human tumors and be used as a model for studying pharmacological interventions targeting immune cell responses. Levels of humanization were sustained throughout the course of the study. The ability to monitor tumor growth kinetics and observe a response to an anti-hPD-1 checkpoint inhibitor across multiple tumor types indicates that this model is useful when assessing immunotherapies. Future considerations of this model would expand upon monotherapies to evaluate additional treatment methods such as bispecific antibodies or cell-directed therapies.

Ethics Approval Animal studies were executed in compliance with local Charles River IACUC guidelines, IACUC number IO33.

430 REAL-WORLD OUTCOMES OF PATIENTS WITH RESECTED STAGE IIIA MELANOMA TREATED WITH ADJUVANT NIVOLUMAB IN A US COMMUNITY SETTING

[1]Wolfram Samlowski, [2]Phillip Chan, [3]Anna Pavlick*, [4]Justin Moser, [2]Nicholas Robert, [5]Tayla Poreta, [5]Andriy Moshyk, [5]Leon Sakkal, [5]Jennell Palaia, [2]Nicole Niehoff, [2]Jonathan Rajkumar, [6]Asim Amin. [1]*Comprehensive Cancer Centers of Nevada, Las Vegas, NV, United States*; [2]*Ontada, Irving, TX, United States*; [3]*Weill Cornell Medical Center, New York, NY, United States*; [4]*HonorHealth Research and Innovation Inst, Scottsdale, AZ, United States*; [5]*Bristol Myers Squibb, Lawrenceville, NJ, United States*; [6]*Atrium Health, Charlotte, NC, United States*

Background Nivolumab is approved in the US and EU for the adjuvant treatment of resected stage III-IV melanoma. Limited data is available regarding outcomes of patients with resected stage IIIA melanoma treated with adjuvant nivolumab. This observational study is an update to the prior study evaluating treatment patterns, outcomes, safety, and healthcare resource utilization in a US community oncology setting in resected stage IIIa patients who received adjuvant nivolumab.

Methods A follow-up to the previous study analysis was conducted by including an additional 15 months of follow-up data and newly matriculated patients. Data were sourced from The US Oncology Network chart review data examining patients with resected stage IIIA melanoma, treated with adjuvant nivolumab between 01-Jan-2018 and 31-Dec-2020, and followed until 30-June-2021. Patients were followed up to 42 months after their sentinel lymph node biopsy. Baseline demographic and clinical characteristics, treatment-related adverse events (TRAEs) and healthcare resource utilization were analyzed descriptively. Overall survival (OS), time to treatment discontinuation (TTD), and recurrence-free survival (RFS) were analyzed using the Kaplan-Meier method.

Results 40 stage IIIA melanoma patients treated with adjuvant nivolumab were included. The median age was 55 years (range 19,90+), 52.5% were male, and 77.5% were Caucasian. Among patients with a documented Eastern Cooperative Oncology Group (ECOG) performance status half had an ECOG score of 0 or 1. Median follow-up time was 27.7 months (range 2.8-39.0). Overall survival was not reached as no deaths occurred during the study period. The median TTD and RFS were also not reached. TRAEs were reported in 23 patients. Among all 40 patients, the most frequent TRAEs were rash (12.5%), hypothyroidism (12.5%), fatigue (10.0%), diarrhea (10.0%), and nausea (10.0%); the treatment-related hospitalization rate was 2.5%.

Conclusions This real-world analysis of patients with stage IIIA melanoma treated with adjuvant nivolumab demonstrated that the vast majority of patients were recurrence free and all patients were alive at the end of the study period, suggesting a favorable prognosis and low rates of healthcare resource utilization. Additional follow-up and investigations with other real-world data sources are warranted to substantiate the clinically relevant outcomes reported in this study of patients with resected stage IIIA melanoma.

Ethics Approval The study was approved by US Oncology, Inc. Institutional Review Board, approval number 20-020E-2020-0224-01.

431 ESTIMATING SCENARIOS FOR SURVIVAL TIME IN PATIENTS WITH METASTATIC MELANOMA RECEIVING IMMUNOTHERAPY OR TARGETED THERAPY

[1]Megan Smith-Uffen*, [2]John Park, [2]Andrew Parsonson, [3]Anuradha Vasista. *[1]McMaster University, Hamilton, Canada*; *[2]Nepean Blue Mountains LHD, Penrith, Australia*; *[3]NSW Health, Penrith, Australia*

Background It is important for advanced cancer patients to understand their prognosis. This allows patients to plan appropriately for end-of-life. Unfortunately, many patients do not understand their life expectancy, often overestimating their likely survival time. Estimating survival in metastatic melanoma is particularly difficult, as immunotherapy and targeted therapies extend survival time and revolutionize care. We have previously shown that three survival scenarios (worst-case, typical, best-case), calculated using simple multiples of median overall survival ([OS], 0.25x, 0.5-2x, 3x, respectively), is a useful framework to estimate and communicate survival time to advanced cancer patients.

Methods This study aimed to determine whether three survival scenarios accurately estimate prognosis for metastatic melanoma patients receiving immunotherapy or targeted therapy. We searched Medline, EMBASE, and Cochrane Central Register of Controlled Trials for phase II/III randomized controlled trials (treatment arms n $\geq$90) of patients with unresectable stage IIIC/IV cutaneous melanoma receiving immunotherapy or targeted therapy from January 2001 to February 2022. We extracted OS data from Kaplan Meier curves and compared it to our multiples of median OS.

Results 26 trials (12,345 patients) were included. Our estimates of worst-case scenarios ranged from 3.29 (interquartile range [IQR] 2.82-3.76) to 6.82 (IQR 4.48-18.93) months; most-likely lower-typical from 6.57 (IQR 5.64-7.52) to 13.64 (IQR 8.96-18.93) and upper-typical from 26.28 (IQR 22.58-30.07) to 54.55 (IQR 35.83-75.73) months; and best-case from 39.43 (IQR 33.87-45.11) to 81.83 (IQR 53.74-113.60) months, among patients receiving first-line targeted and immunotherapy, respectively. Our multiples of the median OS accurately estimated survival from anywhere between 16.7% to 100% of estimates.

Our scenarios tended to be more accurate for those receiving targeted (most between 70% to 100% accuracy) than immunotherapy (some as low as 16.7%); and second- (all between 50% to 100%) than first-line (some as low as 16.7%) treatment. We were unable to estimate scenarios for patients receiving first-line combination immunotherapy, as none of the treatment arms in this group met median OS. When we were inaccurate, we tended to overestimate survival.

Conclusions This study was limited by small sample sizes and immature data. The accuracy of our scenarios was more variable than previous work done by our team. Future research should include mature data and novel interventions when determining frameworks to communicate survival in metastatic melanoma.

432 EVALUATION OF NOVEL ANTI-TIGIT ANTIBODY M6223 AS A SINGLE AGENT AND IN COMBINATION WITH AVELUMAB ON HUMAN NATURAL KILLER (NK) CELL CYTOTOXICITY

Anton Titov*, Nancy Sun, Christie Kelton, Mirek Jurzak, Hong Ma, Chunxiao Xu. *EMD Serono, Billerica, MA, United States*

Background M6223 is a fully human antagonistic anti-TIGIT immunoglobulin (Ig) G1 antibody with fragment crystallizable (Fc)-mediated effector function. Preclinical studies demonstrated that M6223 could induce an anti-tumor immune response through several mechanisms, including direct blockade of the TIGIT pathway, stimulation of CD226 dimerization/activation, and depletion of TIGIT+ immune subsets by Fc-mediated effector function. Avelumab is a human IgG1 anti–PD-L1 antibody with a wild-type Fc region that has been shown to induce antitumor activity in vitro via both adaptive effector cells (T cells) and innate immune effector cells (antibody-dependent cell-mediated cytotoxicity [ADCC] via NK cells). It is approved for urothelial carcinoma (UC), renal cell carcinoma, and Merkel cell carcinoma. We report an evaluation of the effects of M6223 as a single agent and in combination with avelumab on human NK cell cytotoxicity.

Methods NK cell anti-tumor cytotoxicity was measured against the cancer line MDA-MB-231 with beta-2 microglobulin (B2M) knockout using fluorescent live cell imaging. NK cells were treated with M6223 or its Fc effector null version PPB1791. Avelumab was also tested alone or at a single dose combination with M6223 to evaluate additive potential of these antibodies. A variety of CD155 (poliovirus receptor [PVR]) knockout and partial knockouts were generated to assess the dependence of anti-tumor cytotoxicity on expression of this ligand.

Results M6223 induced significant NK cell anti-tumor cytotoxicity in 4 different NK donors at doses above 0.3 mcg/mL (t-test: $p<0.05$) with an EC50 value of approximately 100 ng/mL. There was limited *in vitro* NK fratricide. An Fc-mutant version of M6223 had reduced anti-tumor cytotoxicity (at 0.3 mcg/mL: $p=0.28$). M6223 in combination with avelumab was more effective than either antibody alone, indicating that CD16-mediated ADCC is likely additive with TIGIT blockade. Anti-tumor cytotoxicity was retained with PVR (CD155) expression on target MDA-MB-231 cells at a wild-type level of 30–50% and was almost completely eliminated in $CD155^{-/-}$ cells. CD112 alone did not facilitate significant M6223-induced anti-tumor cytotoxicity, consistent with a weaker role of DNAX accessory molecule 1 (DNAM-1)-mediated recognition of this receptor.

Conclusions This study confirmed that NK cell cytotoxicity plays an important role in the anti-tumor activity of M6223 and demonstrated the additive effect of avelumab and M6223 in enhancing NK cell activation, especially in CD155+ human leukocyte antigen (HLA) class I-deficient target tumors. Currently, M6223 plus avelumab is being studied as first-line maintenance therapy for advanced UC in the phase 2 JAVELIN Bladder Medley umbrella trial (NCT05327530).

433 PREVALENCE OF PD-L1 EXPRESSION AMONG PATIENTS WITH RECURRENT AND METASTATIC HEAD AND NECK SQUAMOUS CELL CARCINOMA IN TAIWAN

[1]Chia-Jui Yen, [2]Ming-Yu Lien, [3]Rebecca Cheng, [3]Yu-Wen Su*, [3]Han-Nan Lin, [4]Michael Thomas Wong, [4]Song Ling Poon, [5]Chih-Yen Chien, [6]Ruey-Long Hong. *[1]National Cheng Kung University Hospital, Tainan City, Taiwan; [2]China Medical University Hospital, Taichung, Taiwan; [3]MSD (I.A.) LLC, Taipei, Taiwan; [4]MSD International GmbH, Singapore, Singapore; [5]Kaohsiung Chang Gung Memorial Hospital, taipei, Taiwan; [6]National Taiwan University Hospital, Taipei, Taiwan*

Background Tumor programmed death-receptor/ligand-1 (PD-1/PD-L1) expression negatively correlates with cancer prognosis and overall survival, [1-6] and has been shown to predict clinical responses to immunotherapy for head and neck cancers.[7] In Taiwan, head and neck cancers continue to show a high prevalence associated with betel quid chewing, a practice endemic to the island. This study aims to evaluate the prevalence of PD-L1 expression in recurrent and metastatic head and neck squamous cell carcinoma (R/M HNSCC) patients in Taiwan.

Methods For this multi-centered prospective study, we recruited R/M HNSCC patients who are aged 20 years or older, have an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, are ineligible for re-irradiation or curative surgery, and had a biopsy obtained before treatment. PD-L1 expression measured by combined positive score (CPS) and tumor proportion score (TPS) was determined by the PD-L1 IHC 22C3 pharmDx™ kit. The primary endpoint was to estimate the prevalence of PD-L1 expression, characterized by CPS≥ 1. Exploratory analyses were conducted to evaluate PD-L1 positivity by CPS≥ 20 and TPS≥ 50%, and to explore the association of prior first- or second-line systemic treatment and PD-L1 expression.

Results Between December 2019 and February 2021, 280 patients from 4 centers were enrolled, including 264 (94.3%) males with median age of 58.0 years. Notably, 211 (75.4%) had a history of betel nut chewing. The primary sites were oral cavity in 192 cases (68.5%), followed by oropharynx 43 (15.4%), hypopharynx 26 (9.3%), and larynx 20 (7.1%). Among patients with oropharyngeal cancer, 13 (30.2%) were p16 positive. Prior to enrollment, 171 (61.1%) patients had received first-line systemic treatment and 68 (24.3%) second-line. The prevalence of PD-L1 (CPS≥ 1) was 94.3% (264/280) in the total cohort, 93.8% (198/211) in the betel nut exposed subgroup, and 96.6% (56/58) in the non-betel nut exposed subgroup. Furthermore, 46.1% (129/280) of all patients were CPS≥ 20, and 17.1% (48/280) were TPS≥ 50%. A total of 159 (93.0%) and 64 (94.1%) patients were CPS≥ 1 among those that received first-line and second-line systemic treatment, respectively.

Conclusions PD-L1 expression was observed in a vast majority (94.3%) of R/M HNSCC patients. There is no difference in PD-L1 prevalence between those with betel nut exposure history and betel nut non-exposed patients. PD-L1 prevalence also does not differ in those that had received prior first-line or second-line therapy, compared to the overall study population.

434 TARGETING THE EXPRESSION OF NEUROPILIN-1 BY LOCKED NUCLEIC ACID MODIFIED ANTISENSE OLIGONUCLEOTIDES RESULTS IN POTENT ANTI-TUMOR ACTIVITY IN VIVO

[1]Richard Klar*, [2]Clara Seger, [2]Nicole Kirchhammer, [1]André Maaske, [1]Julia Festag, [2]Laura Fernandez Rodriguez, [2]Mélanie Buchi, [1]Monika Schell, [1]Stefanie Raith, [1]Sven Michel, [2]Alfred Zippelius, [1]Frank Jaschinski. *[1]Secarna Pharmaceuticals GmbH & Co. KG, Planegg / Martinsried, Germany; [2]University Hospital Basel, Basel, Switzerland*

Background Despite the remarkable success of immune modulating cancer therapies, the majority of patients does not benefit from the currently available therapies. Therefore, there is a high need for the identification of novel therapies targeting cancer-induced immunosuppression.

The membrane-bound protein neuropilin-1 (NRP1) is a molecule with diverse functions and interaction partners that has been shown to contribute to tumor cell migration and survival as well as neoangiogenesis. Furthermore, NRP1 contributes to the suppressive capacity of immune cells like e.g. tumor associated macrophages and regulatory T cells. As the different functions of NRP1 are mediated by multiple domains of NRP1, there is a conceptual advantage to downregulate the expression of the whole protein over the functional or steric blockade of individual domains e.g. by monoclonal antibodies.

Methods We used our in-house Oligofyer™ bioinformatics system to design human and mouse Nrp1-specific antisense oligonucleotides (ASOs). The ASOs were modified in the flanks with locked nucleic acids to increase stability and affinity to the target RNA. RNA knockdown efficacy in vitro was investigated in different cells without the use of a transfection reagent. We furthermore investigated the anti-tumor activity of selected mouse Nrp1-specific ASOs in different syngeneic mouse tumor models after systemic administration of unformulated ASOs. In vivo target knockdown in different cell types was investigated by flow cytometry.

Results Treatment of different cell types with LNA-modified ASOs in vitro led to downregulation of NRP1 mRNA as well as protein expression by >85%. Systemic treatment of immune-competent tumor bearing mice with mouse Nrp1-specific ASOs without the use of a delivery reagent strongly delayed tumor growth or completely eradicated tumors. Furthermore, long-term anti-tumor immunity has been observed in immune-competent responder mice after re-challenge with tumor cells. The anti-tumor effects were almost completely absent in immune-compromised NSG mice.

Conclusions Our encouraging results indicate that downregulation of NRP1 with LNA-modified ASOs has the potential to become a promising treatment option for patients in the future. Currently, further studies are performed to investigate therapeutic activity in additional tumor models, combination therapies as well as to fully elucidate the mechanisms that underlie the observed anti-tumor efficacy of ASO-mediated NRP1 downregulation.

435 INTRATUMORAL PLASMA CELLS PREDICT OUTCOMES TO PD-L1 BLOCKADE IN NON-SMALL CELL LUNG CANCER

Namrata Patil*, Barzin Nabet, Sören Müller, Hartmut Koeppen, Wei Zou, Jennifer Giltnane, Jason Cheng, Chikara Takahashi, Avantika Chitre, Linda Rangell, Sangeeta Jayakar, William O'Gorman, Marcus Ballinger, Romain Banchereau, David Shames. *Genentech Inc., South San Francisco, CA, United States*

Background Inhibitors of the programmed cell death-1 (PD-1/PD-L1) signaling axis are approved to treat non-small cell lung cancer (NSCLC) patients, based on their significant overall survival (OS) benefit. However, the mechanisms behind this efficacy are not completely understood and there remains a significant unmet need for patients who do not respond to these therapies.

Methods To better understand the mechanisms behind the survival benefit associated with atezolizumab, we performed transcriptomic analysis of 891 NSCLC tumors from patients treated with either the PD-L1 inhibitor atezolizumab or chemotherapy from two large randomized clinical trials.

Results We found a significant B cell association with extended OS with PD-L1 blockade, independent of CD8+ T cell signals. We then derived gene signatures corresponding to the dominant B cell subsets present in NSCLC from single-cell RNA-seq data. Importantly, increased plasma cell signatures were predictive of OS in patients treated with atezolizumab, but not chemotherapy. B cells were also associated with the presence of tertiary lymphoid structures (TLS) and organized lymphoid aggregates.

Conclusions Our results suggest an important contribution of B and plasma cells to PD-L1 blockade efficacy in NSCLC. The association of plasma cells and TLS with improved outcomes suggests that novel therapeutics targeting these mechanisms that can be combined with PD-(L)1 blockade to improve their overall efficacy.

Acknowledgements This study was performed using tissue samples from the open-label, randomized Phase 2 POPLAR (NCT01903993) and Phase 3 OAK trials (NCT02008227).

Trial Registration NCT01903993, NCT02008227

Ethics Approval Both the POPLAR and OAK studies were performed in full accordance with the guidelines for Good Clinical Practice and the Declaration of Helsinki, and all patients gave written informed consent. Protocol approval was obtained from independent ethics committees for each participating site for both studies and an independent data monitoring committee reviewed the safety data.

Consent Both the POPLAR and OAK studies were performed in full accordance with the guidelines for Good Clinical Practice and the Declaration of Helsinki, and all patients gave written informed consent.

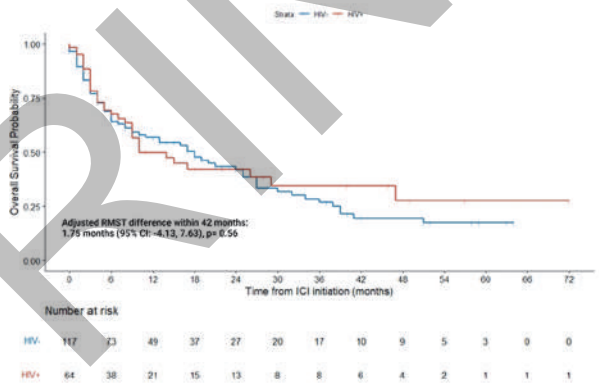
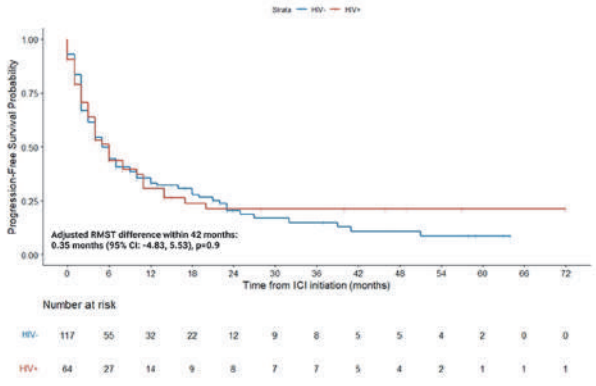
Background Due to limited inclusion of PLWH in most ICI clinical trials, there is a paucity of data evaluating their safety and efficacy in this unique population, especially among PLWH and metastatic NSCLC.

Methods In this retrospective, international multi-center study, we identified 64 HIV positive (HIV+) patients and 117 matched HIV negative (HIV-) controls with metastatic NSCLC treated with ICI between January 2015 and October 2021 at 16 institutions in the U.S. and Europe. At each institution, we matched 1 HIV+ patient to 2 or 1 HIV- controls (1:2 or 1:1 ratio) by age, sex, class of ICI, use of concurrent chemotherapy, and number of prior lines of systemic therapy. We estimated overall survival (OS) and progression-free survival (PFS) by the Kaplan-Meier method. When the proportional hazards assumption was violated, we used restricted mean survival time (RMST) to compare survival outcomes. We fitted a linear regression model with RMST as outcome and HIV infection as predictor, adjusting for race, ECOG performance status, histology, smoking status and PD-L1 expression. We compared categorical variables using chi-square tests.

Results In our cohort, median age was 60 years, 77% were males, 61% received ICI as 1st line therapy, 89% received anti-PD-1 based therapy, and 46% received concurrent chemotherapy. Blacks/African Americans were more represented among HIV+ vs. HIV- patients (42% vs 23%, p <0.01). At baseline, HIV+ patients had a median CD4 count = 386 cells/uL (range: 6 – 1,721), 19/31 had undetectable HIV viral load (VL) while 12/31 had a median detectable VL= 60 copies/mL (range: 10 – 223,408). Grade ≥3 immune-related adverse events occurred in 11% HIV+ vs. 9% HIV- patients. Overall response rate was similar between both groups (28% HIV+ vs. 37% HIV-, p=0.25). Comparing HIV+ vs. HIV- pts, the adjusted RMST difference within 42 months was 1.75 months (95% CI: -4.13, 7.63, p=0.56) for OS, and 0.35 months (95% CI: -4.83, 5.53, p=0.90) for PFS (figures 1 and 2). In addition, the 24-month OS rates were 41.7% for HIV + vs. 42.9% for HIV- patients while the 24-month PFS rates were 18.1% HIV+ vs 18.7% HIV- patients.



Abstract 437 Figure 1 Kaplan-Meier curves for Overall Survival stratified by HIV status



Abstract 437 Figure 2 Kaplan-Meier curves for Progression-Free Survival stratified by HIV status

Conclusions In this matched cohort study, PLWH and metastatic NSCLC had similar toxicity profiles and clinical outcomes to HIV- counterparts receiving ICI supporting their use in PLWH and their inclusion in clinical trials. Larger

prospective studies are needed to inform a broader usage of ICI among PLWH presenting with other cancer types, low CD4 counts (i.e., <200 cells/uL) and high VL.

Ethics Approval Our study was exempt from institutional review board (IRB) review at DFCI (Protocol #21-342) and was approved by local IRBs at participating sites per institutional policy, according to the principles of the Declaration of Helsinki.

438 INTERROGATION OF IMMUNE TOXICITY IN PATIENTS WITH THYMIC EPITHELIAL TUMORS (TETS)

Meredith McAdams*, Shannon Swift, Madison Ballman, Abigail Wong-Rolle, Renee Donahue, Claudia Palena, Jeffrey Schlom, James Gulley, Arun Rajan, Chen Zhao. *National Cancer Institute, Bethesda, MD, United States*

Background Immune checkpoint inhibitors (ICIs) are well tolerated and clinically active against a wide variety of cancers. However, the risk of immune toxicity in patients with thymic epithelial tumors (TETs), especially thymomas, remains unacceptably high due to underlying defects in immune tolerance.[1-3] Mechanisms of immune toxicity remain poorly understood and the mainstay of treatment is immunosuppression with systemic corticosteroids, which can potentially impact the anti-tumor activity of ICIs.

Methods To understand mechanisms of organ-specific immune toxicity, we evaluated blood and tissue samples from patients with TETs enrolled in an ongoing NIH IRB-approved clinical trial (NCT03076554; NCI protocol number: 17C0066) of avelumab, an anti-PD-L1 antibody who developed multi-organ immune-related adverse events (irAEs) following treatment. Participants received avelumab 10 mg/kg IV every two weeks until disease progression or development of intolerable AEs. Toxicity was assessed with CTCAE 5.0. Immune profiling was conducted using one or more of the following methods: evaluation of biopsies with routine hematoxylin and eosin staining and immunohistochemistry (IHC), peripheral blood immune cell subset analysis by flow cytometry, RNAscope for IL-6, IL-8 and TGF-ß1 mRNA expression, and spatial transcriptomics using the nanoString Digital Spatial Profiler platform to investigate T-cells' transcriptional profiles at tumor and irAE sites.

Results Between April 2017 and February 2022, 32 participants were enrolled (median age: 55 years; 16 female; 16 thymoma;). Five (16%) participants developed multiple irAEs during treatment. Objective anti-tumor responses were observed in 2 (40%) of 5 participants. table 1 includes clinical characteristics and results of immune analyses. Histopathology and IHC were notable for a T-cell infiltrate and paucity of B cells across irAE sites. IL-6 and TGF-ß1 mRNA expression was variable in cases of upper gastrointestinal inflammation. Spatial transcriptomic analysis of 1811 genes in tumor and irAE samples (bone marrow) from subject 3 revealed distinct T-cell activation profiles in the bone marrow compared with tumor infiltrating T cells (figure 1).

Conclusions Organ-specific heterogeneity in mechanisms of ICI-related immune-mediated toxicity in individuals with TETs needs further evaluation. If confirmed, these findings highlight the need to tailor immunosuppressive treatments to specific irAEs and develop strategies for primary or secondary prophylaxis to decrease the risks associated with immunotherapy while maintaining clinical benefit in this population.

439 HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH PRE-EXISTING AUTOIMMUNE DISEASES WHO RECEIVED IMMUNE CHECKPOINT INHIBITORS IN THE MARKETSCAN DATABASE

[1]Jennell Palaia, [2]Anna Pavlick*, [1]Radhika Pisupati, [1]Benjamin Fu, [1]Keith Wittstock, [1]Ying Zhang. *[1]Bristol Myers Squibb, Lawrence Township, NJ, United States; [2]Weill Cornell Medical Center, New York, NY, United States*

Background Autoimmune diseases (ADs) affect more than 24 million people in the United States. As patients with ADs are excluded from clinical trials of immune checkpoint inhibitors (ICI), management of AD after ICI initiation is not well understood. Our study explored healthcare resource utilization (HCRU) before and after initiation of an ICI in cancer patients with pre-existing ADs.

Methods This retrospective, observational study included adult patients who were treated with ICIs and had ≥1 inpatient or ≥2 outpatient claims for melanoma (Mel), renal cell carcinoma, lung cancer (LC), head and neck cancer, hepatocellular carcinoma, or bladder cancer, between January 1, 2015 and March 31, 2020 in the MarketScan Commercial, Medicare Supplemental and Medicaid claims databases. Patients also had administrative claims for ADs (rheumatoid arthritis (RA), psoriasis/psoriatic arthritis (P/PA), multiple sclerosis (MS), Crohn's disease (CD)/ulcerative colitis (UC)/inflammatory bowel disease (IBD) and Others) within 12 months prior to the index date (first ICI treatment date). HCRU included outpatient visits, hospitalizations, and ER visits. Total HCRU and AD-related HCRU were calculated per patient per month (PPPM) for all patients. Generalized linear models (GLM) were used to calculate differences in HCRU pre- and post- ICI initiation over the entire follow-up period. Analyses were also conducted using the first 6 months of the pre- and post-index period.

Results Of the 525 eligible patients, mean age was 61 years, 58.9% were female; over half (50.7%) had a Charlson Comorbidity Index of 2+, 29.1% had Mel, and 55.6% had LC. The most common AD types were IBD/CD/UC (24.9%) and RA (19.0%). Mean total visits over the total follow-up period were 3.5 and 5.8 PPPM in the pre- and post-periods, respectively. Mean AD-related visits over the total follow-up period were 0.4 and 0.5 PPPM in the pre- and post-periods, respectively. Breakdown of outpatient visits, hospitalizations, and ER visits in the pre-and post-periods are described in (table 1). GLM showed that total HCRU increased in the post-period over total follow-up, but AD-related HCRU were not significantly different between pre-and post-periods, over the entire follow-up period.

Conclusions This real-world analysis is one of the largest claims-based analysis describing a patient population treated with ICI therapy with pre-existing ADs. Using HCRU as a proxy for management of the AD post ICI initiation, this study showed that care related to AD was similar in the prior and post periods.

Abstract 439 Table 1 Outpatient visits, hospitalizations, and ER visits in the pre-and post-periods

	Visit type	Mean (SD) Prior Period	Mean (SD) Post Period
All visits, PPPM	Outpatient	3.5 (3.5)	5.8 (4.6)
	Hospitalization	0.1 (0.1)	0.1 (0.2)
	ER	0.1 (0.2)	0.2 (0.3)
AD-related visits, PPPM	Outpatient	0.4 (1.3)	0.5 (1.7)
	Hospitalization	0.01 (0.01)	0.01 (0.01)
	ER	0.01 (0.01)	0.01 (0.01)

440 OUTCOMES IN PATIENTS WITH PRE-EXISTING AUTOIMMUNE DISEASES WHO RECEIVED IMMUNE CHECKPOINT INHIBITORS: A REAL-WORLD STUDY

[1]Anna Pavlick*, [2]Jennell Palaia, [2]Radhika Pisupati, [2]Benjamin Fu, [2]Keith Wittstock, [2]Ying Zhang. *[1]Weill Cornell Medical Center, New York, NY, United States; [2]Bristol Myers Squibb, Lawrence Township, NJ, United States*

Background Autoimmune diseases (ADs) affect more than 24 million people in the United States. Although patients with AD are usually excluded from ICI clinical trials, real world evidence suggests ICIs are used in this population. In this analysis, we describe the clinical outcomes of patients on ICI therapy with pre-existing ADs.

Methods This retrospective, observational study used the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database to describe characteristics and outcomes in patients with pre-existing ADs (rheumatoid arthritis (RA), psoriasis/psoriatic arthritis (P/PA), multiple sclerosis (MS), Crohn's disease/ulcerative colitis/inflammatory bowel disease (CD/UC/IBD) and Others) who were treated with ICIs for advanced melanoma (aMel), metastatic renal cell carcinoma (mRCC), advanced non-small cell lung cancer (aNSCLC), hepatocellular carcinoma (HCC), or advanced bladder cancer (aBC). Overall survival (OS), Progression free survival (PFS), and Time to treatment discontinuation (TTD) were evaluated from the index date (first ICI treatment date). Baseline and clinical characteristics were analyzed using descriptive statistics, and time to event analysis for OS, PFS, and TTD were analyzed using Kaplan Meier methods. All analyses were conducted for the overall cohort and by subgroups including cancer type, AD type, line of therapy and ICI treatment group (monotherapy or combination). The ICI combination group included ICI + Chemo, ICI + targeted therapy, and ICI+ICI.

Results This study included 453 pts diagnosed with aMel, mRCC, aNSCLC, HCC, or aBC and treated with ICI from Jan 2015 to Oct 2021, with a pre-existing AD within 12 months of index date. Median age was 69.4 years; 55.4% were female and 76.8% were white. In the overall cohort, median OS was 11.1 months (95% CI: 9.0-14.0); median PFS was 4.2 months (95% CI: 3.5-4.8), and median TTD was 2.6 months (95% CI: 2.1-3.0). There were 301 patients who received ICI in the first line (1L) and 152 in the second line or later (2L+). OS and AD type by tumor type (1L and 2L+ combined) are described in (table 1).

Conclusions This real-world analysis is one of the largest studies describing clinical outcomes in patients with pre-existing ADs receiving ICI therapy. Further research is warranted to evaluate adverse event profiles and reasons for ICI discontinuation in this patient population.

Abstract 440 Table 1

	aMel (N=62)	mRCC (N=46)	aNSCLC (N=302)	HCC (N=21)	aBC (N=23)

441 CHECKPOINT INHIBITOR-ASSOCIATED INFLAMMATORY ARTHRITIS IS COMPRISED OF MULTIPLE CLINICAL ENDOTYPES CHARACTERIZED BY DISTINCT TRANSCRIPTIONAL PROGRAMS

Gary Reynolds*, Mazen Nasrallah, Neal Smith, Molly Thomas, Leyre Zubiri, Alice Tirard, John McGuire, Kasidet Manakongtreecheep, Jessica Tantivit, Steven Blum, Daniel Zlotoff, Elaina PuiYee Chan, Dejan Juric, Ryan Sullivan, Genevieve Boland, Andrew Luster, Sara Schoenfeld, Minna Kohler, Kerry Reynolds, Chloe Villani. *Massachusetts General Hospital, Boston, MA, United States*

Background Immune checkpoint inhibitor (ICI) therapy has revolutionized cancer treatment but is associated with a range of immune toxicities.[1] ICI-associated inflammatory arthritis (ICI-IA) is a complication that affects around 5% of patients on ICI therapy. Clinical manifestations mimic those of rheumatoid arthritis or seronegative spondyloarthropathies and often require treatment with glucocorticoids or other immunosuppressive medications. In severe cases, irArthritis results in interruption or discontinuation of ICI therapy and is a significant cause of morbidity. Understanding why ICI-IA develops and rationalizing our approach to its treatment could improve outcomes for this expanding patient cohort.

Methods Comprehensive clinical and demographic data were collected for patients with malignancy, treated with ICI, and subsequently diagnosed with inflammatory arthritis (n=41). Peripheral blood and synovial fluid were collected and profiled when possible. Presentations of ICI-IA included monoarthritis (n=5 total, n=4 profiled), oligoarthritis (n=10 total, n=5 profiled) and polyarthritis (n=26 total, n=7 profiled). Six additional patients with inflammatory arthritis after ICI that were not checkpoint-related were profiled. Samples were analyzed by paired single cell RNA sequencing, surface proteome of 204 protein targets, and T cell receptor (TCR) sequencing.

Results We captured data from 741,883 cells in total following quality-control (559,251 synovial fluid, 264,997 blood) and identified diverse cell populations in synovial fluid, including rare mast cells, AXL+SIGLEC6+ dendritic cells and cycling lymphocytes. Patients presenting with monoarthritis were ANA negative (0/6) with higher abundance of DC1 and DC2 (Dirichlet regression, p=1.1x10-3 and p=8.1x10-5), with DC1 having the highest per cell expression of *TNF* across all samples. Patients presenting with polyarthritis were significantly more likely to be antinuclear antibody positive (15/26, Fisher's test, p=0.04) with expansions of a macrophage population enriched for interferon response genes (*IFI44L, ISG15*) and peripheral helper CD4+T cells (*CXCL13, PDCD1*) previously described as expanded in seropositive rheumatoid arthritis.[2] TCR repertoire analysis demonstrated clonal expansion of specific CD8 T cell subsets, including shared clones across patients. Gene set enrichment analysis highlighted upregulation of distinct inflammatory pathways with existing biologic drugs in mono- and oligoarthritis presentations versus polyarthritis.

Conclusions These data demonstrate that ICI-IA is heterogeneous both in terms of clinical presentation and at the cellular and transcriptional level. It is likely that patients will benefit from better targeting of treatments that can simultaneously control arthritis and preserve anti-tumor efficacy and our data support new strategies for developing personalized medicine approaches for this patient population.

442 PRE-TREATMENT INTERSTITIAL ABNORMALITIES IS A RISK FACTOR FOR IMMUNE CHECKPOINT INHIBITOR PNEUMONITIS IN PATIENTS WITH LUNG CANCER

[1]Alexander Wong*, [2]Maria Riley, [3]Songzhu Zhao, [2]Jessica Zimmer, [2]Matthew Viveiros, [1]Jing Gennie Wang, [1]Vince Esguerra, [3]Mingjia Li, [3]Gabrielle Lopez, [3]Gregory Otterson, [3]Kari Kendra, [3]Carolyn Presley, [3]Lai Wei, [3]Dwight Owen, [1]Kevin Ho. *[1]The Ohio State University WMC, Columbus, OH, United States; [2]The Ohio State University COM, Columbus, OH, United States; [3]The Ohio State University James, Columbus, OH, United States*

Background Immune checkpoint inhibitors (ICIs) are a first line and adjuvant treatment in advanced stage lung cancer. One of the main complications of ICI treatment is pneumonitis with an overall incidence of 2-5%; however, patient specific risk factors for developing ICI-pneumonitis (ICI-p) haven't been well elucidated. [1,2] We evaluated potential pre-treatment risk factors for ICI-p including pre-treatment interstitial abnormalities on computed tomography of the chest (CT chest).

Methods We conducted a retrospective cohort study of consecutive patients with lung cancer who received at least one dose of ICI between 2015-2020 at The Ohio State University. Potential risk factors for ICI-p were recorded and summarized between those with and without pneumonitis. Among patients who developed pneumonitis, these factors were compared between Grade <3 and Grade >=3 severities as well as among patients with different cancer stage (3 vs 4). Multivariable survival analysis was used to examine the association of potential risk factors with pneumonitis. Pneumonitis cases were documented by the treating oncologist and retrospectively evaluated by an oncologist and pulmonologist.

Results 473 patients with lung cancer were included, 401 with Non-Small Cell Lung Cancer and 72 with Small Cell Lung Cancer. 38 developed ICI-p and 435 did not. Of the potential risk factors, the following were significantly associated with ICI-p: pre-existing interstitial abnormalities (30.8% vs 4.2%, p < 0.001), prior concurrent chemoradiation (17.7% vs 4.2%, p <0.001), stage of cancer (19.8% for stage III vs 4.4% for stage IV, p < 0.001),), and type of immunotherapy (12.5% for PD1 vs 3.6% for chemo-IO, p < 0.001) (table 1). Pre-existing interstitial abnormalities remained strongly correlated with development of pneumonitis on multivariable analysis including prior chemoradiation, pre-treatment interstitial abnormalities, and type of immunotherapy, (hazard ratio 8.54 [4.45-16.42], p<0.001) (table 2). Interstitial abnormalities also remained significant in subgroup analysis of both stage 3 and 4 lung cancer (p<0.001). Patients with grade 3/4 pneumonitis had decreased overall survival compared to those with grade 1/2 pneumonitis (p = 0.0342) (figure 1).

Conclusions Pre-existing interstitial abnormalities on CT chest is strongly associated with development of ICI-p in patients with lung cancer. It remains an independent risk factor after accounting for common treatment-related risk factors such as prior chemoradiation and chest radiation. Pre-treatment interstitial abnormalities could be utilized as a risk stratification tool to identify patients at highest risk for developing ICI-p, a devastating complication associated with higher mortality in more severe cases.

444 TNG260, A COREST-SELECTIVE DEACETYLASE INHIBITOR, REVERSES ANTI-PD1 RESISTANCE DRIVEN BY LOSS OF STK11

Leanne Ahronian*, Xinyuan Wu, Minjie Zhang, Chengyin Min, Alice Tsai, Jacques Ermolieff, Patrick McCarren, Margaret Wyman, Ye Wang, Alborz Bejnood, Kenjie Amemiya, Brian McMillan, Nikitha Das, Brian Doyon, Andre Mignault, Colin Liang, Vassil Elitzin, Yi Yu, Samuel Meier, Ashley Choi, John Maxwell, Alan Huang. *Tango Therapeutics, Cambridge, MA, United States*

Background Histone deacetylase 1 (HDAC1) was identified from a novel *in vivo* CRISPR screening platform as a target gene whose inhibition reverses α-PD1 resistance driven by loss of STK11. Histone deacetylases are a well-studied class of oncology drug targets, but existing non-isoform-selective HDAC inhibitors have few approved clinical applications due to toxicities that limit sufficient exposure in solid tumors. Our data suggest that HDAC3, an essential gene, is a primary driver of bone marrow toxicity caused by HDAC inhibitors that target multiple isoforms.

Methods We discovered and developed TNG260, a small molecule which inhibits HDAC1 with 10-fold selectivity over HDAC3 in cells, and 500-fold selectivity for the CoREST complex over the other HDAC1-containing complexes, NuRD and Sin3. Due to its CoREST-selective deacetylase inhibition, we have termed TNG260 a CoreDAC inhibitor.

Results Treatment of an α-PD1 resistant STK11-mutant MC38 syngeneic tumor model with TNG260 re-sensitizes this model to treatment with α-PD1. The combination of TNG260 and α-PD1 led to durable complete tumor regressions in the majority of treated animals. All mice with complete responses remained tumor-free until tumor rechallenge (21 days) and rejected engraftment of tumor cells. Unlike previously developed HDAC inhibitors designed for tumor cell cytotoxicity, TNG260 has no anti-tumor efficacy in immunocompromised mice, indicating the tumor cell killing with TNG260 is immune-mediated and not due to direct cell killing. Immune profiling of tumors following treatment with TNG260 and α-PD1 showed a decoupling of $T_{effector}$ and $T_{regulatory}$ cell recruitment caused by α-PD1 monotherapy, leading to a more active immune microenvironment. TNG260 also decreased intratumoral infiltration of neutrophils, an immune suppressive cell type associated with STK11-mutant NSCLC. Toxicity profiling of TNG260 shows it has less viability impact on erythroid and myeloid cells *in vitro* than other HDAC inhibitors, and *in vivo* toxicity studies showed bone marrow suppression only at TNG260 doses that are no longer selective for HDAC1/2.

Conclusions TNG260 is a potent, highly selective small molecule CoreDAC inhibitor with good drug-like properties. It reverses the immune evasion phenotype caused by loss of STK11 and induces tumor regressions in an STK11-mutant model in combination with α-PD1. The TNG260 clinical development plan will be among the first to combine the power of genetic patient selection and immunotherapy, evaluating patients with STK11 mutant cancers in a trial combining TNG260 and a checkpoint inhibitor.

445 **TREATMENT PATTERNS AND IMMUNOTHERAPY RECHALLENGE IN ADVANCED OR METASTATIC UPPER GASTROINTESTINAL CANCER IN A US REAL-WORLD SETTING**

[1]Jaffer Ajani*, [2]Marley Boyd, [2]Jenifer Wogen, [3]Ilia Ferrusi, [4]Peyman Nakhaei, [3]Lakshmi Menon-Singh, [5]Ailis Fagan. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX, United States; [2]Genesis Research, Hoboken, NJ, United States; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [4]Novartis Pharmaceuticals Canada Inc, Dorval, Canada; [5]Novartis Ireland Limited, Dublin, Ireland*

Background US regulatory approvals of immunotherapy (IO) for upper gastrointestinal (GI) cancers have notably increased treatment (tx) options. It is unknown which txs are often used in real-world practice. IO rechallenge shows potential efficacy in some cancers, although data are limited for upper GI cancers. We assessed tx patterns and use of IO rechallenge in patients (pts) with upper GI cancers in the US.

Methods This retrospective study evaluated pts aged ≥18 years with locally advanced or metastatic esophageal cancer (EC), gastric cancer (GC), or gastroesophageal junction cancer (GEJC) diagnosed on or after January 1, 2011. This study used the electronic health record–derived, de-identified Flatiron Health database (data cutoff: May 31, 2021). Eligible pts received ≥1 line of tx for advanced/metastatic disease and had tx data (or record of death) within 90 days of diagnosis. IO rechallenge was defined as IO given in any line after a prior IO-based regimen.

Results In total, 7672 pts with EC (46%), GC (30%), and GEJC (24%) were included (93% in community practices). Median follow-up after first-line (1L) tx start date was 8.8 mo. Median age was 69 years. Most pts had an Eastern Cooperative Oncology Group performance status of ≤1 (59%) and metastases (58%). The most common 1L chemotherapy was carboplatin + paclitaxel (2133/7672 [28%]) and IO was pembrolizumab alone (73/7672 [1%]). The most common 1L chemotherapy + IO regimen was fluorouracil + leucovorin + oxaliplatin + nivolumab (28/7672 [0.4%]). At the time of analysis, 3399 of 7672 pts (44%) had any second-line (2L) tx. The most common 2L chemotherapy was FOLFOX (458/3399 [13%]) and IO was pembrolizumab alone (286/3399 [8%]). A higher proportion of pts received IO in the post–IO approval period (2019; table 1). Overall, 1028 of 7672 (13%) had IO during any point on tx, most frequently first received in 2L (436/1028 [42%]); 75 of 1028 (7%) had IO rechallenge. The descriptive median time to rechallenge was 0.7 (IQR, 0.5-3.5) mo. Most pts (63/75 [84%]) had IO rechallenge in the immediate subsequent line of tx, with 2L to third line (3L) the most common setting (29/75 [39%]). Data from additional ongoing analyses will be presented.

Conclusions Analysis of tx patterns for upper GI cancers showed that few pts received 1L IO in the community setting. However, IO use and IO rechallenge are evolving in clinical practice. Further follow-up is warranted, including assessment of rechallenge effect on pt outcomes.

446 HR+BREAST CANCER: DEFINING INNATE AND ACQUIRED RESISTANCE TO IMMUNE CHECKPOINT INHIBITORS

[1]Aitziber Buqué Martinez*, [1]Norma Bloy, [2]Michal Hensler, [1]Giulia Petroni, [1]Ai Sato, [1]Takahiro Yamazaki, [1]Bhavneet Bhinder, [2]Jitka Fucikova, [1]Olivier Elemento, [1]Silvia Formenti, [1]Lorenzo Galluzzi. *[1]Weill Cornell Medicine, New York, NY, United States; [2]Sotio Biotech, Prague, Czech Republic*

Background Hormone receptor (HR)$^+$breast cancer (BC) is responsible for the majority of BCs and -related deaths in the US.[1] Standard treatment for local disease involves surgery, followed by adjuvant endocrine therapy (ET) ± radiation therapy (RT) and/or chemotherapy (CT), depending on risk for relapse. However, many women receive CT and experience its severe side effect to benefit only a few. Immune checkpoint inhibitors (ICIs) have successfully been implemented in the management of other solid tumors like melanoma.[2] Conversely, the clinical experience with single-agent ICIs has been disappointing in patients with HR$^+$ BC[3], at least in part reflecting a limited immune infiltration at baseline and calling for the development of combinatorial regimens unlocking ICI efficacy in this patient population. In this setting, progress has also been hampered by the lack of a preclinical model that would faithfully recapitulated key immunobiological features of human HR$^+$ BC. We have recently demonstrated that endogenous mammary carcinomas driven in immunocompetent mice by medroxyprogesterone acetate (M) plus 7,12-dimethylbenz[a]anthracene (D) represent a superior preclinical model to study HR$^+$BC resistance to ICI and identify strategies to overcome it.[4]

Methods We established M/D-driven mammary carcinomas in immunocompetent, female C57BL/6 mice and randomized them to: (1) no treatment; (2) PD1 clockers (on d0/d3/d6 or d3/d6/d9); (3) RT (3x10 Gy on d0/d1/d2); (4) recombinant FLT3L (from d0-d9 or d3-d12), or all the 2- and 3-agent combinations thereof. Besides monitoring local and systemic tumor control, we collected tumors for RNAseq, and spleens for immunoprofiling by flow cytometry.

Results RT controls primary ICI-resistant M/D-driven carcinomas and extends the overall survival (OS) of the hosts, with marginal benefits from the addition of a PD-1 blocker. Recombinant FLT3L improves local tumor control by RT, but fails to ameliorate OS, mainly due to compromised control of distant, unirradiated lesions. RT followed by PD-1 blockage plus recombinant FLT3L is superior to all other approaches at primary tumor control and exhibits a trend for improved OS over RT alone, reflecting partial control of distant lesions.

Conclusions RT is highly effective in ICI-resistant HR$^+$ BC tumors. Combination of RT with different immunotherapeutics alters the pattern of local vs systemic disease progression. This may define immunological signatures potentially linked to resistance/sensitivity and identify novel target to break through the resistance of HR$^+$ BC to immunotherapy.

447 DUAL TARGETING OF PD-1 AND CTLA-4 SYNERGIZES WITH FOCAL RADIATION TO DURABLY INCREASE SURVIVAL AGAINST GLIOBLASTOMA

[1]Mara De Martino*, [1]Camille Daviaud, [2]Claire Vanpouille-Box. *[1]Weill Cornell Medicine, New York, NY, United States; [2]Weill Cornell Medicine, Sandra and Edward Meyer Cancer Center, New York, NY, United States*

Background The immunogenic role of ionizing radiation raised the use of radiation therapy (RT) as an immune adjuvant in multiple cancers. However, clinical trials testing RT and immune checkpoint blockers (ICB) combination failed to improve the survival of glioblastoma (GBM) patients. We have previously shown that cancer-cell intrinsic type I interferon (IFN-I) is a prerequisite for synergy between RT and ICB in murine breast cancer; a phenomenon that is RT-dose dependent.[1] Therefore, we hypothesized that failure of RT-ICB combinations in GBM is due to the use of a suboptimal RT regimen (i.e. 2Gyx30). Here, we compared various RT doses and schedules to determine the best immunogenic RT schedule for combination with ICB in murine models of GBM.

Methods First, GL261 and CT2A murine GBM cell lines were used to determine the release of IFN-I related cytokines and the accumulation of double stranded DNA (dsDNA) in the cytoplasm 24h after single (0-20Gy) or fractionated (8Gyx3 or 6Gyx5) RT regimens. Next, GBM intracranial tumors were established in syngeneic animals and treated with focal RT (10Gyx1, 8Gyx3 or 6Gyx5). In some settings, mice received anti-PD-1 and/or anti-CTLA-4. Mice were followed for survival or euthanized for flow cytometry analysis. Tumor-free animals were rechallenged with a fresh tumor inoculum.

Results *In vitro*, fractionationated RT schedules enhanced the content of cytoplasmic dsDNA in GBM cells as compared to single RT doses, with 6Gyx5 resulting in the highest accumulation of dsDNA. Consistently, GBM cells irradiated with6-Gyx5 significantly improved the release of IFN-I cytokines as compared to any other RT schedules. *In vivo*, 6Gyx5 and 8Gyx3 RT regimens were superior in controlling GL261 or CT2A growth as compared to 10Gyx1. The addition of anti-PD-1 or anti-CTLA-4 to the immunogenic RT regimen of 6Gyx5 did not improve CT2A-bearing mice survival compared to RT alone. However, targeting both PD-1 and CTLA-4 with RT significantly improved survival with 100% of the animals being tumor-free. Tumor rechallenge confirmed the development of protective anti-tumor responses in anti-PD-1+anti-CTLA-4+RT treated animals. Tumor-infiltrating immune cells analysis revealed an increase of T cells in tumors treated with anti-PD-1+anti-CTLA-4+RT, thus reinforcing the role of T cells in this response.

Conclusions While 6Gyx5 RT combined with either anti-PD-1 or anti-CTLA-4 did not further improve mice survival, dual blockade of PD-1 and CTLA-4 successfully synergized with RT to durably increase survival against GBM. Overall, this study underscores the need to combine immunogenic RT with several ICB to elicit protective anti-tumor immunity against GBM.

448 DRIVER MUTATION ANALYSIS AS A SELECTIVE MARKER FOR IMMUNOTHERAPY IN PATIENTS WITH PHEOCHROMOCYTOMA AND PARAGANGLIOMA

[1]Katerina Hadrava Vanova*, [1]Ondrej Uher, [1]Leah Meuter, [1]Suman Ghosal, [2]Jiri Neuzil, [1]Karel Pacak. *[1]NIH, Bethesda, MD, United States; [2]Griffith University, Southport, Australia*

Background Metastatic pheochromocytomas and paragangliomas (PPGLs) are rare neuroendocrine tumors associated with poor prognosis and limited therapeutic options. Recent advances in oncology-related immunotherapy, specifically targeting of the programmed death 1 (PD-1)/-ligand 1 (PD-L1) pathways, have uncovered new treatment potential for a variety of tumors. The expression of PD-L1 and PD-L2 was recently found to be present in 18% and 16% of PPGL, respectively, but only PD-L2 expression correlated with malignancy, hypoxia markers, and shorter survival.[1] However, PD-L1 was suggested to be a malignant proliferation biomarker for PPGLs in another study.[2] Given the promising outcomes of a clinical study in 9 cases of PPGL using pembrolizumab, a humanized IgG4κ monoclonal antibody that targets the PD-1/PD-L1 pathway,[3] we examined the PD-Ls expression in our representative PPGL cohort to explore if PD-Ls expression can predict malignancy and/or be a predictive marker for PD-Ls targeted therapy in PPGL.

Methods The Cancer Genome Atlas (TCGA) provided 173 patient samples to allow for observation of gene expression across four PPGL driver mutation groups (Cluster I: SDHB, VHL; Cluster II: NF1, RET) and NAM samples. Tumor RNA from the 48-patient cohort (sporadic; Cluster I: SDHB, VHL, EPAS1; Cluster II: RET, NF1) was evaluated to validate the results.

Results Expression of PD-L1, but not PD-L2, was elevated in our PPGL cohort, which aligns with TCGA analysis. Expression of PD-L1 was decreased in Cluster I PPGLs but not in Cluster II, suggesting that sporadic and Cluster II PPGLs could benefit from PD-1/PD-L1 targeted therapy more than Cluster I PPGL tumors. Within Cluster I, expression of PD-L1 was significantly lower in SDHB- and VHL-mutated tumors compared to sporadic tumors. Expression of PD-L2 did not differ between PPGL clusters. Metastatic PPGLs had significantly elevated Ki-67 levels, however PD-Ls expression was not affected by malignancy status.

Conclusions We conclude that PD-Ls expression in our cohort of PPGL tumors was not linked to malignancy, however, driver mutation analysis could be a selective marker for PD-Ls-targeted therapy.

449 **CYCLIC DISRUPTION OF THE MITOGEN-ACTIVATED PROTEIN KINASE (MAPK) PATHWAY BY THE DUAL MEK INHIBITOR, IMM-6-415, ENHANCES PD1 AND CTLA4 CHECKPOINT BLOCKADE IN RAS MUTANT TUMORS**

Brett Hall*, Anna Travesa, Amy Yamamura, Amy Axel, Sarah Kolitz, Jason Funt, Kevin Fowler, Matthew Nord, Praveen Nair, Scott Barrett, Benjamin Zeskind, Peter King. *Immuneering, San Diego, CA, United States*

Background KRAS is the most frequently altered RAS gene (~85%) and is often mutated in pancreatic ductal adenocarcinoma (PDAC; 95%), non-small cell lung cancer (NSCLC; 40%) and colorectal cancer (CRC; 45%). KRAS-G12C inhibitors (sotorasib/adagrasib) have demonstrated single-agent activity in all three tumor types. However, acquired resistance and limited biomarker positive patients (e.g., only 1-3% of PDAC and CRC) limit broader access and overall response to G12C inhibitors, prompting evaluation of combination partners including immune therapies. In contrast to G12C-mutant focused KRAS inhibitors, MEK inhibitors may broaden the potential for immune therapy in RAS-mutant tumors but have largely proven ineffective in this setting.

Methods IMM-6-415 is a novel, third-generation dual MEK inhibitor that reduces both pMEK and pERK in RAS-mutant tumor models at sub-100 nM potencies. IMM-6-415 drug-like properties have been evaluated across a series of preclinical *in vitro* and *in vivo* models focusing on activity in those with mutant RAS. Cell-based 2D and 3D biochemical and pharmacologic assays were performed across multiple models, and several *in vivo* studies have been completed, including: (1.) A549 (KRAS-G12S NSCLC) xenograft model, (2.) Colon-26 (KRAS-G12D CRC) syngeneic model, (3.) CT-26 (KRAS-G12D) syngeneic model. The CT-26 *in vivo* study evaluated both single-agent IMM-6-415 and combinations with PD1 or CTLA4 checkpoint inhibitors.

Results IMM-6-415 reduced pERK and pMEK across all RAS mutant models tested. Humanized 3D tumor models revealed a promising sensitivity profile for IMM-6-415 in RAS-mutant CRC and PDAC. The maximum tolerated dose (MTD) of IMM-6-415 was 175 to 180 mg/kg BID PO from the Colon-26 (96.4% TGI) and A549 (93.9% TGI) studies, yet the optimal MEKio combination dose/schedule was 120 mg/kg BID PO in the CT-26 study. At 28 days treatment, 33% (4/12) mice remained on study in either the (10 mg/kg BIW IP) anti-PD1 or anti-CTLA4 alone treated groups, whereas 58% (7/12) mice remained in the IMM-6-415 treatment arm at 120 mg/kg BID PO. However, 92% (11/12) and 83% (10/12) mice remained in the IMM-6-415 plus anti-PD1 or anti-CTLA4 combination at the same doses, respectively.

Conclusions We demonstrate that IMM-6-415 displays single-agent activity in multiple RAS-mutant models, has a 0.3h half-life, is well tolerated in mice, and when combined at sub-MTD levels with either PD1 or CTLA4 checkpoint inhibitors, significantly improved responses in the CT-26 model (p-value < 0.05). Our data suggest that moderated, cyclic inhibition of the MAPK pathway in RAS mutant tumors is active and may enhance therapeutic activity of immune checkpoint inhibitors.

450 INCREASED ACTIVITY OF THE ATX/LPA AXIS DIMINISHES CD8+ T CELL CYTOTOXICITY VIA LPAR5 SIGNALING, DRIVING IMMUNE CHECKPOINT BLOCKADE RESISTANCE IN NON-SMALL CELL LUNG CANCER

[1]Jessica Konen*, [2]B Leticia Rodriguez, [2]Haoyi Wu, [2]Jared Fradette, [2]Lixia Diao, [2]Jing Wang, [2]Don Gibbons. *[1]Emory University, Atlanta, GA, United States; [2]MD Anderson Cancer Center, Houston, TX, United States*

Background Targeting immunosuppressive checkpoints has proven to be an efficacious treatment strategy for non-small cell lung cancer (NSCLC), in which response rates are as high as 35% in patients harboring Kras/p53 (KP) mutations.[1] However, most patients demonstrate no or only partial response to immune checkpoint blockade (ICB), underscoring the need to better understand the suppressive mechanisms in the tumor-immune microenvironment. Murine models of KP mutant lung cancer demonstrate upfront sensitivity to PD-1 checkpoint blockade but rapidly acquire resistance[2], providing useful tools to discover tumor-intrinsic mechanisms of resistance.

Methods We generated new KP syngeneic and autochthonous lung tumor models with intrinsic resistance to anti-PD-1 treatment via *in vivo* passaging in the face of ICB treatment. Additionally, we analyzed transcriptome data from anti-PD-L1 treated KP tumors, identified differentially expressed genes between response and resistance timepoints, and queried these in the newly generated anti-PD-1 resistant tumor models. We utilized flow cytometry to characterize the tumor-infiltrating immune microenvironment with manipulation of candidate gene expression.

Results Our data identified a stable upregulation of the phosphodiesterase enzyme, autotaxin (ATX), and the metabolite that it generates, lysophosphatidic acid (LPA), in ICB resistant tumors. Analyses of lung adenocarcinoma patient datasets revealed a significant positive correlation between ATX and immune signatures, including a previously published dataset encompassing immune checkpoints and suppressive molecules[3], suggesting that ATX is upregulated in the face of normal anti-tumor immunity. Mechanistic studies utilizing isogenic pairs of tumors demonstrated that ATX expression inversely correlated with CD8+ T cell proliferation and cytotoxic functionality, with ATX-overexpression in anti-PD-1 sensitive tumors promoting intrinsic resistance. We next sought to define LPA receptor (LPAR) expression on T cells. Flow cytometry on tumor-infiltrating CD8+ T cells demonstrated significantly altered expression of LPARs within anti-PD-1 resistant versus sensitive tumors, with upregulation of LPAR5 and downregulation of LPAR2. Additionally, analysis of previously published RNA-sequencing of CD8+ T cells from NSCLC patients[4] revealed that lower LPAR2 versus LPAR5 correlated with worse response to ICB. Importantly, targeting ATX or LPAR5 with PD-1 blockade caused significant tumor regressions in clinically relevant models of KP mutant lung cancer via invigoration of anti-tumor CD8+ T cells.

Conclusions Our data indicate that increased ATX/LPA activity occurs downstream of immune activation, which in turn stimulates LPAR5 signaling on CD8+ T cells to diminish cytolytic functions. These results provide evidence that this axis acts as an immunosuppressive checkpoint, providing rationale that co-targeting it with ICB should improve anti-tumor immune response.

451 SERUM ALBUMIN PREDICTS OUTCOME IN PATIENTS WITH EXTENSIVE STAGE SMALL-CELL LUNG CANCER (ES-SCLC) RECEIVING FIRST-LINE COMBINATION OF PD-(L)1 INHIBITORS AND PLATINUM-ETOPOSIDE CHEMOTHERAPY

Giuseppe Lamberti*, Biagio Ricciuti, Victor Vaz, Joao Victor Alessi, Federica Pecci, Alessandro Di Federico, Mark Awad. *Dana-Farber Cancer Institute, Boston, MA, United States*

Background The combination of platinum-etoposide chemotherapy with PD-L1 inhibitors (chemoimmunotherapy) has become the new standard for first-line treatment of patients with extensive stage small-cell lung cancer (ES-SCLC). Nevertheless, factors associated with outcomes in this setting are lacking. We sought to identify clinicopathological and genomic factors associated with outcome to first-line chemoimmunotherapy in patients with ES-SCLC.

Methods Among patients at the Dana-Farber Cancer Institute with ES-SCLC who received a combination of platinum (carboplatin or cisplatin), etoposide, and a PD-(L)1 inhibitor (atezolizumab, durvalumab, or pembrolizumab), baseline clinicopathological and genomic features were correlated with objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). For serum biomarkers (hemoglobin, sodium, albumin, lactate dehydrogenase [LDH], and derived neutrophile-to-lymphocyte ratio [dNLR]) a blood draw performed within 10 days from treatment start was considered. Patients who were on corticosteroids at the time of blood draw were not assessed for dNLR.

Results Among 89 patients included in the study, 53% were female, median age was 66 years, 17% had an Easter Cooperative Oncology Group performance status (ECOG PS) of 0, and 28% had baseline brain metastases (table 1). The most common treatment regimen was carboplatin-etoposide-atezolizumab in 82 patients (92%). Overall, ORR was 81% (N=71/88), median PFS was 5.0 months (95%CI: 4.7-5.6), and median OS 10.8 months (95%CI: 9.6-16.1), at a median follow-up time of 25.3 months (95%CI: 14.2-NA). Patients with an ECOG PS of 0 when compared to those with an ECOG PS of ≥1 had higher ORR (100% vs 77.0%, P=0.036), longer median PFS (6.2 vs 4.8 months; HR: 1.99 [95%CI: 1.07-3.70], P=0.029) and median OS (20.0 vs 10.3 months; HR: 3.36 [95%CI: 1.21-9.30], P=0.020) (figure 1). Patients with serum albumin levels ≥3.5g/dL (N=74 [84%]), compared to those with low albumin levels (<3.5g/dL, N=13 [16%]), had higher ORR (85% vs 54%, P=0.018), longer median PFS (5.5 vs 3.7 months; HR: 2.91 [95%CI: 1.53-3.53], P=0.001) and median OS (12.3 vs 5.9 months; HR: 4.32 [95%CI: 2.1-8.71], P<0.001). Neither dNLR (available in N=75 [84%]) nor tumor mutation burden (available in N=20 [22%]) were associated with outcome. After adjusting for confounding factors, a low albumin, but not ECOG PS, retained its association with ORR (adjusted odds ratio: 0.27 [95%CI: 0.07-0.96], P=0.025), PFS (adjusted HR: 2.58 [95%CI: 1.35-4.95], P=0.004), and OS (adjusted HR: 3.66 [95%CI: 1.80-7.44], P<0.001).

Conclusions Albumin levels might help predicting outcomes to first-line chemoimmunotherapy in patients with ES-SCLC. This can have implication in stratification of patients enrolled in prospective clinical trials.

Ethics Approval Patients at the Dana-Farber Cancer Institute who consented to institutional review board-approved protocols DF/HCC 02-180, 11-104, 13-364, and/or 17-000 which allowed for conducting translational research and tumor next-generation sequencing, respectively, were included.

452 EFFICACY AND SAFETY OF CAMRELIZUMAB COMBINATION THERAPY IN PATIENTS WITH RECURRENT OR METASTATIC CERVICAL AND ENDOMETRIAL CARCINOMA: A RETROSPECTIVE STUDY

Shuhuai Niu, Zhaohui Fang, Xi Chen, Siyang Liu, Ge Jin, Yunfeng Guo, Qianying Zhang, Hong Liu*. *The Fourth Hospital of Hebei Medical University, Shijiazhuang, China*

Background Recurrent or metastatic cervical and endometrial carcinoma is largely an incurable disease due to lack of effective therapies. New treatment strategies are needed to provide long-term anti-tumor responses. Blocking the interaction between PD-1 and its ligands is a promising treatment strategy, and has previously shown encouraging antitumor activity in cervical and endometrial carcinoma. Camrelizumab is a humanised anti-programmed death-1 (anti PD-1) antibody. Therefore, this study aimed to assess the efficacy and safety of camrelizumab combination therapy in patients with recurrent or metastatic cervical and endometrial carcinoma.

Methods Patients (pts) with recurrent or metastatic cervical and endometrial carcinoma were enrolled. Eligible patients were aged 30–70 years with an Eastern Cooperative Oncology Group performance status of 0-2. Pts received camrelizumab (200mg iv d1 q2w) with concurrent chemoradiotherapy (CRT)/radiation/chemotherapy. Paclitaxel and carboplatin are delivered with 175mg/m2 and AUC=5, respectively, d1, q3w for 6-8 cycles. Pts received radiation with external-beam radiotherapy 45~50.4Gy/25~28f, lymph node 60Gy/25~30f 5 times/week, brachytherapy 28~30Gy/4-5f. The primary endpoint was objective response (ORR). The secondary endpoints included disease control rate (DCR), median progression-free survival (mPFS) and safety.

Results 37 pts were enrolled from Sept. 2019 to Apr. 2022. 36 patients were evaluated for efficacy, the ORR and DCR was 53% (19/36) and 83% (30/36), respectively. In addition, 18 pts received camrelizumab combination CRT with the ORR of 76% (13/17) and DCR of 100% (17/17), and 8 pts received camrelizumab combination radiotherapy with the ORR of 12.5% (1/18) and DCR of 50% (4/8), and 11 pts received camrelizumab combination chemotherapy with the ORR of 45% (5/11) and DCR of 82% (9/11). 7 of 37 pts were still receiving the treatment, the mPFS was 12.5 months. Treatment-related adverse events occurred in 57% (21/37) of patients, and the most common adverse events were RCCEP (35%), Thyroid injury (14%) and diarrhea (14%). Treatment-related grade 3 adverse events occurred in 3% (1/37) of pts.

Conclusions Our Results indicates that Camrelizumab with chemoradiotherapy exhibites efficacy rather than combination with radiation/chemotherapy for recurrent or metastatic cervical and endometrial carcinoma. Further studies are planned to explore this new treatment option in a larger study population.

453 PHARMACOLOGIC TUMOR PDL1 DEPLETION AS A TRANSLATIONAL APPROACH TO INHIBIT TUMOR-INTRINSIC PDL1 SIGNALS AND CREATE NOVEL TREATMENT VULNERABILITIES

[1]Clare Murray*, [1]Haiyan Bai, [1]Anand Kornepati, [1]Carlos Ontiveros, [1]Yilun Deng, [1]Alvaro Padron, [1]Eva Galvan, [1]Myrna Garcia, [2]Tyler Curiel. *[1]UT Health San Antonio, Lebanon, NH, United States; [2]Dartmouth College, Lebanon, NH, United States*

Background Canonical tumor surface PDL1 signals to PD1 on immune cells to evade antitumor immunity are well-defined.[1] However, tumor-intrinsic PDL1 mediates additional pathologic signals.[2-5] Our lab recently showed that tumor PDL1 promotes homologous recombination DNA damage repair and ATM/Chk2 DNA damage sensing. Genetic tumor PDL1 depletion rendered tumors sensitive to Chk1 and PARP inhibitors. [6, 7] However, anti-PDL1 antibodies were unable to replicate treatment sensitivity,[6] and genetic PDL1 depletion is not yet clinically feasible. We hypothesized that pharmacologic tumor PDL1 depletion could replicate genetic PDL1 depletion to sensitize tumors to therapy as a translational application of tumor PDL1 depletion.

Methods We conducted a high-throughput drug screen enriched for FDA-approved molecules in RFP-PDL1 B16 cells to identify PDL1 depleting drugs (PDDs).[8] B16 cells were treated with 2.5 or 10 mM of screen drug for 48 hours, and RFP intensity was measured by fluorescence. We use various biochemical, cell biology, and genetic techniques to interrogate *in vitro* PDD mechanisms and *in vivo* studies of treatment and immune outcomes using human and transplantable murine cell lines of distinct cancers.

Results We identified the FDA-approved, structurally similar cephalosporin antibiotics cefepime and ceftazidime and the alkylating agent chlorambucil as PDDs with distinct signaling and treatment consequences. Cefepime and ceftazidime potently depleted PDL1 in several tumor lines and phenocopied genetic PDL1 depletion by inducing DNA damage and significantly depleting Chk2 protein. Cefepime and ceftazidime PDL1-dependently generated synthetic lethality to small molecule Chk1 inhibitors *in vitro*, and cefepime generated Chk1 inhibitor efficacy *in vivo*. Other beta-lactams failed to deplete PDL1, suggesting the beta-lactam ring is dispensable for PDL1 depletion. Cefepime and ceftazidime replicated additional genetic PDL1 depletion outcomes, including STING and autophagy induction and tumor stemness reduction *in vitro*. Cefepime induced an immune Th1 signature *in vivo* in tumor-bearing mice, consistent with STING induction and suggesting PDDs could improve immunotherapy efficacy. Strikingly, the PDD chlorambucil potently depleted ovarian cancer PDL1 and induced anti-PDL1 efficacy in PDL1-replete, anti-PDL1-resistant tumors through an NK-dependent mechanism. These data suggest tumor immunogenicity consequences of chlorambucil-mediated tumor PDL1 depletion.

Conclusions PDDs induce novel cancer treatment vulnerabilities with high clinical translational potential. We identify several FDA-approved drugs that deplete tumor PDL1, disrupt its pathogenic tumor-intrinsic signals, and induce small molecule synthetic lethality and anti-PDL1 efficacy improvement. We identified other PDDs offering opportunities as translational targets, which we are now progressing to phase I clinical trials.

454 **REAL-WORLD TREATMENT PATTERNS AMONG PATIENTS WITH LOCALLY ADVANCED HEAD AND NECK SQUAMOUS CELL CARCINOMA (LA HNSCC) IN A COMMUNITY ONCOLOGY SETTING**

[1]Eric Nadler, [2]Christopher Black*, [2]Karthik Ramakrishnan, [3]Wan-Yu Tseng, [3]Chuck Wentworth, [3]John Murphy, [3]Nicole Fulcher, [2]Liya Wang, [2]Melannie Alexander, [4]Gregory Patton. *[1]Texas Oncology, Dallas, TX, United States; [2]Merck & Co., Inc., Rahway, NJ, United States; [3]Ontada, Irving, TX, United States; [4]McKesson Life Sciences, The Woodlands, TX, United States*

Background For patients with unresectable, locally advanced head and neck squamous cell carcinoma (LA HNSCC), concurrent chemotherapy with radiation therapy (CRT) is preferred. CRT that includes platinum-based chemotherapy is the standard of care. Cetuximab is the alternative for patients who cannot receive platinum-based treatment. This study describes demographics and treatment patterns of patients with LA HNSCC receiving CRT in a community oncology setting.

Methods This retrospective observational study examined patients with newly diagnosed de novo LA HNSCC who received CRT in The US Oncology Network within the period 2015–2017 and were followed up through 2021. All adult patients with LA HNSCC who initiated CRT with ≥2 visits were included. Index date was defined as the date of initiation of CRT at initial LA HNSCC diagnosis. Patients were stratified based on index treatments received. Demographic and clinical characteristics and time to next treatment (TTNT) were summarized.

Results Table 1 summarizes demographic and clinical characteristics among the 1185 patients with LA HNSCC that met eligibility criteria, overall and by treatment groups. Overall, the median age was 61.8 (range 22.8–92.5) years, and the majority were male (n=952, 82.2%), Caucasian (n=947, 91.2%), had ECOG 0-1 at index (n=878, 89.4%), and had used or were using tobacco (n=783, 67.6%). Patients who received a cetuximab-containing regimen + radiotherapy (RT) (n=164, 14.2%) were slightly older and had a numerically higher Eastern Cooperative Oncology Group performance status (ECOG PS) score compared with cisplatin + RT (n=762, 65.8%) and cisplatin + other chemotherapy + RT (n=232, 20.0%). Distribution of patients by primary tumor site was consistent across the treatment groups, except that cetuximab + RT had a higher ratio of patients with laryngeal (n=32, 19.5%) to lip/oral cavity (n=10, 6.1%) compared to the other two treatment groups. The median TTNT was only reached by the cetuximab-containing regimen group, at 30.4 months. Overall, 80.7%, 68.1%, and 59.6% had initiated a subsequent treatment after index by 1, 3, and 5 years (figure 1).

Conclusions Patients who received a cetuximab-containing regimen + RT were slightly older and had numerically higher ECOG PS scores compared to the other treatment groups. This study provides real-world insights on patient profiles, treatment patterns, and TTNT among overall and by different CRT treatment groups for patients with LA HNSCC in the community oncology setting.

Ethics Approval All data were handled in compliance with the Health Insurance Portability and Accountability Act and the Health Information Technology for Economic and Clinical Health Act. The study protocol was granted an exemption and waiver of informed consent by the US Oncology Institutional Review Board on the basis of the use of deidentified patient data.

455 FOSTROX (MIV-818) IN COMBINATION WITH ANTI-PD-1 SHOWS INCREASED EFFICACY IN NONCLINICAL TUMOR MODELS IN VIVO

Fredrik Oberg*, Sujata Bhoi, Malene Jensen, Tom Morris, Karin Tunblad, Hans Wallberg.
Medivir AB, Huddinge, Sweden

Background Fostroxacitabine bralpamide (fostrox) is an orally administered liver-targeted troxacitabine-based nucleotide prodrug currently undergoing phase 1/2a clinical trial in advanced hepatocellular carcinoma (HCC), in combination with pembrolizumab or lenvatinib (NCT03781934). In phase 1 monotherapy fostrox has demonstrated proof-of-concept in advanced HCC, intrahepatic cholangiocarcinoma and liver metastasis from gastrointestinal solid tumors. Since liver-selective fostrox-induced DNA-damage and tumor cell killing has the potential to enhance the efficacy of checkpoint blockade we investigated the combination of fostrox with anti-PD1 in nonclinical tumor models in vivo.

Methods Combination of fostrox with anti-PD1 treatment was evaluated in the subcutaneous syngeneic mouse H22 model for HCC[1]. Pharmacodynamic response to fostrox, induction of DNA-damage (phospo-ser139-H2AX), was assessed by immunohistochemistry (IHC). Changes in tumor microenvironment was assessed by targeted RNA-sequencing of a panel of 1080 genes representing different immune cell types. Anti-tumor efficacy of fostrox in combination with pembrolizumab was further investigated in the chicken chorioallantoic membrane (CAM) model using H460 human lung carcinoma cells. Tumor infiltrating T-cells (TILs) were assessed by immunohistochemistry (IHC).

Results Both fostrox (twice daily for 5 days, p.o.) and anti-PD1 (twice weekly for 3 weeks, i.p.) showed dose-dependent tumor growth inhibition in the H22 model. The combined treatment with fostrox and aPD1 showed a significantly improved anti-tumor efficacy in the H22 model. Analysis of immune-related gene expression indicated increased TILs and included upregulation of genes involved in cancer antigen presentation. Addition of fostrox to pembrolizumab treatment in the H460 CAM model showed enhancement of efficacy (reduction in tumor weight). Fostrox induced increased tumor infiltration of T-cells, and this was further increased with the combination of fostrox and pembrolizumab.

Conclusions The combination of fostrox with anti-PD1 showed enhanced efficacy in nonclinical tumor models, and changes in the tumor microenvironment consistent with increased immune-mediated anti-tumor activity. The results indicate a potential for combining anti-PD1 with fostrox in the treatment of HCC.

Ethics Approval The study was approved by the Institutional Animal Care and Use Committee (IACUC) of CrownBio UK, and conducted in accordance with the regulations of the Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)

456 PATTERNS AND OUTCOMES OF PALLIATIVE RADIATION THERAPY WITH IMMUNOTHERAPY IN RECURRENT OR METASTATIC HEAD AND NECK SQUAMOUS CELL CARCINOMA

Logan Roof*, Anirudh Yalamanchali, David Buchberger, Shauna Campbell, Shlomo Koyfman, Neil Woody, Natalie Silver, Jessica Geiger, Emrullah Yilmaz. *Cleveland Clinic, Cleveland, OH, United States*

Background Immune checkpoint inhibitors (ICI) have been shown to improve outcomes in patients with recurrent or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). Radiation therapy (RT) is commonly incorporated into treatment of R/M HNSCC for symptom management and disease control. RT is a potential immunostimulatory treatment modality that may enhance the antitumor activity of ICI; however, ideal sequencing of RT and ICI in the palliative treatment setting is not defined. The objective of this study was to describe the patterns and outcomes of RT following ICI in R/M HNSCC.

Methods All adults ($\geq$ 18 years) with HNSCC who received palliative ICI for R/M disease from 2015-2021 were identified from the institutional electronic medical record via ICD codes under an IRB approved protocol. Patients who received ICI for non-HNSCC, had synchronous primary tumors, or had history of hematologic malignancy or immunodeficiency were excluded. Patients without documentation of clinical outcomes after palliative RT were excluded. Retrospective data were collected and underwent descriptive analysis.

Results We identified 148 patients who received palliative ICI for R/M HNSCC. Of these patients, 55 received palliative RT with documentation of outcomes. Twenty-two of these patients underwent palliative RT while on ICI. Twelve of these 22 patients had re-irradiation of their neck, 5 had palliative RT to the lung, 4 to bone, 2 to brain, 1 to the retroperitoneum, and two to other sites. There were 15 grade 3 events. There was 1 patient (5%) with complete response (CR), 9 patients (41%) with partial response (PR), 5 (23%) with stable disease (SD), and 7 (32%) with progressive disease (PD) in the radiation site. Sixteen of the 33 patients who underwent palliative RT separately from IO had re-irradiation of their neck, 7 had palliative RT to the mediastinum, 5 to the lung, 2 to brain, 3 to liver, and 4 to other sites. There were 11 grade 3 events. There were 2 patients with CR (6%), 11 with PR (33%), 6 with SD (18%), and 14 with PD (42%) in the radiation site.

Conclusions These data suggest that concurrent ICI and palliative RT for R/M HNSCC is tolerated with a high disease control rate. Although there was a small number of patients who underwent concurrent ICI and RT, the disease control rate in this group was 68%, which is promising. Further study on the optimal type and sequence of palliative RT in this patient population is warranted.

457 EFFICACY OF PEMBROLIZUMAB AS CROSS-LINE TREATMENT IN ADVANCED NON-SMALL CELL LUNG CANCER: A MULTI-CENTER NON-INTERVENTIONAL STUDY FROM CHINA

[1]Kexin Ruan*, [1]Jing Zheng, [1]Jianying Zhou, [2]Yuping Li, [3]Xiaodong Lv, [4]Xiaoyu Wu, [5]Liren Ding, [1]Jianya Zhou. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, Hangzhou, China; [2]PCCM The first affiliated hospital of Wenzhou Medical College, Wenzhou, China, Wenzhou, China; [3]The First Hospital of Jiaxing (The Affiliated Hospital of Jiaxing University), Jiaxing, China, Jiaxing, China; [4]Zhe Jiang Jin Hua Guang Fu Tumor Hospital, Jinghua, China, Jinghua, China; [5]The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, Hangzhou, China*

Background Pembrolizumab is a preferred drug in most major guidelines (e.g., NCCN, ESMO, Chinese consensus) for 1Line advanced non-small cell lung cancer (aNSCLC) patients (pts). However, whether Pembrolizumab treatment as cross-line is effective for aNSCLC has yet to be established.

Therefore, this study was conducted to describe the treatment patterns and determine the effectiveness of Pembrolizumab treatment as cross-line for aNSCLC in real-world setting in China.

Methods Data of the study was from a multi-center, non-interventional, ambispective cohort study (NCT04153097). aNSCLC pts who treated with Pembrolizumab and provide written informed consent will be included. The main objective of this study is to evaluate pembrolizumab efficacy and safety in the clinical practice and explore the prognosis-relevant factors.

Efficacy end points were Median Overall survival (mOS, defined as the length of time from the administration of the first-dose until death from any cause). Objective Response Rate (ORR, defined as the percentage of patients with complete response [iCR] and partial response [iPR] according to irRECIST), and Median Time to Treatment failure (mTTF, defined as the time from the start of first-dose to discontinuation for any reason, including disease progression, treatment toxicity, patient preference, or death.)

Results From May 2020 to May 2021, 224 NSCLC pts (including a 60 pts retrospective cohort from Mar 2018 to Jan 2020) were enrolled in this observational Study. 117 aNSCLC pts were treated with pembrolizumab in the 1line. 80 pts failed first-line therapy. 30 out of 80 treated with Pembrolizumab as cross-line therapy with different chemotherapy regimens and (or) angiogenesis inhibitor.

For the 30 pts of cross-line therapy, the 1line ORR was 50% (15/30), 1line mTTF 148 Day (95% CI: 121 to 216), 2line ORR 20% (6/30), 2line mTTF 120 Day (95% CI: 86 to 358).

For the other 50 non-cross-line pts, the 1line ORR was 60% (30/50), 1line mTTF 118 Day (95% CI: 75 to 158).

Compared with the 50 non-cross-line (mOS 538 Day [95%: 351 to NA]) pts, 30 cross-line (mOS NA [524 to NA]) pts showed a significant improvement (Logrank $p=0.036$) in survival benefits, HR (95% CI) 0.43 (0.19 to 0.97) (figure 1).

Conclusions In conclusion, the present study suggested that Pembrolizumab as cross-line treatment may serve as an option for aNSCLC patients to prolonged the OS. The efficacy should be confirmed in further investigations.

458 CHARACTERIZATION OF HZ-G206: A POTENT AND ORAL SMALL MOLECULE PD-L1 INHIBITOR

Yizhe Wu*, Xingguo Liu, Xinxin Jin, Jinglai Huang, Xinglu Zhou. *HangZhou HealZen, Hangzhou, China*

Background Blocking of PD-1/PD-L1 protein-protein interaction has been proven as an effective therapeutic strategy in multiple types of cancer. More than ten PD-1 or PD-L1 antibody drugs have been approved worldwide. Contrasting to antibody drug, small molecule PD-L1 inhibitor has shown potential advantages, including increased tissue penetration, less immune-related adverse effect and better clinical compliance. In recent years, several small molecule PD-L1 inhibitors entered clinical stage study. Herein, we described our state-of-the-art work in discovery and identification of HZ-G206, which is a oral small molecule PD-L1 inhibitor and exhibited the potential of best-in-class.

Methods In vitro PD-1/PD-L1 inhibition potency was determined using ALPHAlisa assay. Surface PD-L1 internalization and degradation was carried out in hPD-L1-MC38 cell line and human PBMC through flow-cytometry. Immune-activation effect after PD-1/PD-L1 inhibition was evaluated in NFAT-reporter assay and cytokine production assay. The in-vivo anti-tumor efficacy was assessed in C57BL/c mice which were engrafted with hPD-L1-MC38 cell line and the tumor-bearing mice were administrated with different dosage of HZ-G206 followed by monitoring of tumor volume.

Results HZ-G206 binds and strongly blocks PD-1/PD-L1 interaction in in-vitro ALPHAlisa assay with the IC50 value of 0.35nM. Binding of HZ-G206 in cell surface PD-L1 results in dimerization and destabilization of PD-L1 and followed by internalization and degradation in endosome, which is a distinct pharmacology effect comparing with traditional PD-L1 mAb drugs. HZ-G206 shows stronger PD-L1 internalization and degradation potency than clinical stage compounds INCB86550 and INCB99318 in hPD-L1-MC38 cell line and IFN-g stimulated human PBMC with IC90 values of 18.1nM and 105.6nM respectively. HZ-G206 also exhibits enhanced T-cell activation effect after stimulation with CD3/CD28 in presence of PD-L1 overexpressed cells. In in-vivo anti-tumor evaluation, oral administration of HZ-G206 BID can significantly suppress the growth of tumor in a dose dependent manner, the TGI of middle dose group is comparable to Atezolizumab. In the end of experiment, the tumor tissue was also collected. The PD-L1 level in tumor cell and T cell infiltration were analyzed by flow-cytometry. For the mice treated with HZ-G206, the MFI of PD-L1 is significantly decreased. The ratio of CD3+T cells in tumor tissue is enhanced which is in accordance with Atezolizumab group.

Conclusions HZ-G206 is a novel small molecule PD-L1 inhibitor with good drug-like prosperities. The compound is identified with potent in-vitro activity which translates to anti-tumor efficacy in pre-clinical animal study. In conclusion, HZ-G206 is an excellent drug candidate for further clinical development.

459 GENE THERAPY WITH P19ARF AND INTERFERON-BETA SENSITIZES CELLS TO PD-1 CHECKPOINT BLOCKADE AND ENHANCES ANTITUMOR IMMUNE RESPONSES IN RESISTANT MOUSE MODELS

[1]Ana Domingues*, [2]Nayara Tessarollo, [3]Bryan Strauss. *[1]Universidade de São Paulo, São Paulo, Brazil; [2]Instituto Nacional de Câncer, Rio de Janeiro, Brazil; [3]Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil*

Background Innate and acquired resistance are major concerns that limit the patient's response to immune checkpoint therapy.[1] Immune-boosting gene therapies have been shown to improve response in models of checkpoint blockade resistance.[2, 3] Our group has previously shown that a combined gene therapy with p19Arf and interferon-beta promotes immunogenic cell death in melanoma models.[4] However, even responsive mice often relapse, which we hypothesize to be partially due to PD-L1 superexpression. Thus, by combining our approach with anti-PD-1/PD-L1 monoclonal antibodies, we aim to overcome limitations of the gene therapy and increase sensibility to checkpoint blockade in resistant models.

Methods B16F10 cells were treated *in vitro* with non-replicating adenoviral vectors and were analyzed by flow cytometry. Tumor-bearing mice were treated *in situ* with the gene therapy and PD-L1 expression was analyzed by flow cytometry, RT-qPCR, and immunohistochemistry. Furthermore, tumor-bearing mice received intraperitoneal injections of the monoclonal antibodies and follow-up continued until reaching $1cm^3$. Blood serum was then collected for cytokine analysis and tumors were excised for immunophenotyping. Alternatively, B16OVA tumor-bearing animals were euthanatized on treatment day 12 and the splenocytes were pulsed with ovalbumin to assess specific tumor antigen presentation via MHC-I by antigen presenting cells by flow cytometry. Lastly, five different melanoma human cell lines were treated with the vectors and PD-L1 surface expression was analyzed by flow cytometry.

Results The analysis showed upregulation of PD-L1 both in vitro and *in vivo*, which led us to combine the gene therapy with PD-(L)1 inhibitors. In the *in vivo* model of B16F10, which is a known resistance model for PD-1 blockade, there was an increase of 10% and 20% responders when associating the gene therapy with anti-PD-L1 and anti-PD-1, respectively, in comparison to the gene therapy alone. Tumor immunophenotyping and cytokine profiling showed increased innate immune cell infiltrates in the conditions treated with the vectors and a high increase in NK cells and IFN gamma sera levels in the combination with both gene therapy and anti-PD-1. The gene therapy also increased tumor antigen presentation via MHC-I by antigen presenting cells, compared to mock group. Nevertheless, the gene therapy increased PD-L1 surface expression in all melanoma human cell lines analyzed.

Conclusions These data show that our immunogenic gene therapy approach increases sensibility to PD-1 and PD-L1 blockade in resistant mouse melanoma models and generates tumor antigen-specific immune responses, with further improved effector immune activity when combining it with checkpoint blockade.

460 **DISCOVERY OF POTENT CBL-B INHIBITORS DEMONSTRATING ENHANCED IMMUNE CELL ACTIVITY AND TUMOR GROWTH INHIBITION IN MURINE SYNGENEIC MODELS**

Silvana Leit, David Ciccone*. *Nimbus Therapeutics, Cambridge, MA, United States*

Background Casitas B-lineage lymphoma b (Cbl-b), a RING finger E3 ligase and a member of a highly conserved family of Cbl proteins, catalyzes the ubiquitination of substrate proteins to regulate multiple signaling events in a variety of cell types, including immune cells. In T cells, Cbl-b negatively regulates adaptive immune system signaling by establishing the threshold for the activation of antigen receptors. Additionally, Cbl-b regulates the function of other immune cell types, including NK cells, dendritic cells (DC) and monocytes. Cbl-b deficient T cells no longer require a costimulatory signal to be fully activated. Cbl-b KO mice spontaneously reject tumors via an enhanced immune response. Taken together, these findings point to Cbl-b inhibitors as having the potential to be highly efficacious immuno-oncology agents.

Methods A structure-based drug design approach was used to identify potent inhibitors of Cbl-b. Biochemical and biophysical assays, in vitro cellular assays, as well as primary human and mouse immune cell assays assays were used to profile inhibitor compounds. *In vivo* activity of Cbl-b inhibitors was evaluated using an anti-CD3 mouse model and a CT-26 syngeneic mouse model.

Results Cbl-b inhibitors potently bind to Cbl-b, preventing Cbl-b phosphorylation and binding to E2. In cells, compound treatment results in enhanced transcriptional activity and robust cytokine secretion from primary human and mouse T cells. *In vivo*, an increase in cytokines and T cell activation markers was observed after a single dose of compound. Repeated dosing of compound showed dose-dependent anti-tumor activity in the colorectal CT-26 syngeneic model.

Conclusions Potent Cbl-b inhibitors demonstrate strong T cell activation and anti-tumor activity in a syngeneic tumor model. These data support Cbl-b inhibitors as a promising therapeutic opportunity for cancer treatment.

461 GENERATION OF AZD7789, A NOVEL PD-1 AND TIM-3 TARGETING BISPECIFIC ANTIBODY, WHICH BINDS TO A DIFFERENTIATED EPITOPE OF TIM-3

[1]Eleanor Clancy-Thompson*, [1]Trinity Perry, [1]Stacy Pryts, [2]Ashvin Jaiswal, [1]Vaheh Oganesyan, [1]Nydia van Dyk, [1]Chunning Yang, [1]Andrew Garcia, [1]Wenhan Yu, [1]James Moynihan, [1]Caroline Miller, [1]Kathy Mulgrew, [1]Mark Cobbold, [1]Yariv Mazor, [1]Scott Hammond, [1]Kristen Pollizzi. *[1]AstraZeneca, Gaithersburg, MD, United States*; *[2]Takeda, Cambridge, MA, United States*

Background PD-1 and TIM-3 are expressed on tumor infiltrating lymphocytes (TIL) across multiple indications where dual receptor expression is associated with diminished functionality.[1,2] Studies have demonstrated that TIM-3 acts as a compensatory inhibitory mechanism post PD-1 blockade to reduce anti-tumor T-cell responses.[3] We developed a novel anti-TIM-3 antibody, O13, which engages the TIM-3 IgV domain without blocking phosphatidylserine (PS) binding, eliciting differential functionality. O13 was incorporated into AZD7789, a monovalent bispecific antibody that binds PD-1 and TIM-3. Herein we show preclinical work to support clinical investigation.

Methods Co-crystals of anti-TIM-3 antibodies and recombinant human TIM-3 IgV were generated by standard methods. TIM-3+ Jurkat T-cells were stimulated and treated with anti-TIM-3 antibodies and assessed for IL-2 production. PD-1+ TIM-3+ virally-reactive human T-cells were co-cultured with tumor cell lines expressing viral peptides in the presence of AZD7789 and controls to assess cytokine production and cytotoxicity of T-cells *in vitro*, and in immunodeficient mice for tumor growth inhibition and survival data *in vivo*. *In vitro*, monocyte-derived dendritic cells (Mo-DC) were assessed for the ability of AZD7789 to modulate efferocytosis and cross-presentation.

Results Crystallography revealed that O13 binds an epitope of human TIM-3 outside of the PS-binding cleft. This binding site confers unique biology. While O13 elicited enhanced IL-2 production from TIM-3+ Jurkat T-cells, a PS-blocking anti-TIM-3 antibody diminished IL-2 secretion. Recognition of PS was critical for this response as mutation of the PS-binding site in TIM-3, or use of T-cells that cannot expose extracellular PS, did not elicit an antibody-mediated effect. O13 and AZD7789 enhanced efferocytosis via TIM-3 recognition of PS on dying tumor cells, and increased cross-presentation of tumor antigen to T-cells. AZD7789 also increased anti-tumor T-cell responses compared to anti-PD-1 and a PD-1/TIM-3 bispecific antibody that blocks PS-binding to TIM-3. Additionally, subsequent AZD7789 treatment prolonged *in vivo* growth inhibition in tumors that progressed on anti-PD-1 monotherapy, and AZD7789 enhanced IFN-g secretion of *ex vivo* stimulated TIL derived from anti-PD-1 treated mice.

Conclusions AZD7789 enhanced primary human T-cell and Mo-DC anti-tumor responses over treatment with anti-PD-1 or a PD-1/TIM-3 bispecific antibody that blocks PS-binding to TIM-3. Our preclinical data shows AZD7789 modulates multiple immune functions, which may translate to clinical activity in both checkpoint inhibitor naïve and resistant tumors. AZD7789 is being tested in IO pretreated patients with NSCLC (NCT04931654) and cHL (NCT05216835).

Trial Registration NCT04931654; NCT05216835

462 **PD-L1/PD-L2 DUAL-SPECIFIC CYTOTOXIC ANTIBODIES AUGMENT SURVIVAL AND MEDIATE TUMOR REGRESSION ACROSS IMMUNE "HOT" AND "COLD" MURINE CANCERS**

Coline Couillault*, Anupallavi Srinivasamani, Shweta Hedge, Qinying Liu, Guillaume Trusz, Ashvin Jaiswal, Dongxing Zha, Michael Curran. *MD Anderson Cancer Center, Houston, TX, United States*

Background Inhibition of T cell activation and effector function via engagement of the co-inhibitory receptor PD-1 is a critical mechanism enabling tumors to evade host immunity. The two ligands for PD-1, PD-L1 and PD-L2, are expressed by a variety of immunosuppressive stromal cells, particularly the myeloid stroma and tumor endothelium, and by tumors themselves. In addition to PD-1, PD-L1 engages B7-1 in an additional co-inhibitory interaction. Blocking only PD-1 or only PD-L1 thus does not relieve all inhibitory components of this pathway. We hypothesized that dual-specific antibodies blocking both PD-L1 and PD-L2 could more fully restore tumor-specific T cell activation and potentiate anti-cancer immunotherapy. Furthermore, we speculated that enhancing the cytotoxic effector function of these antibodies might further enhance their efficacy through direct depletion of tumor cells and supportive stroma.

Methods We investigated the capacity of monoclonal antibodies capable of bivalent binding to both PD-L1 and PD-L2 to restore the function of PD-1-suppressed T cells *in vitro*. To assess the *in vivo* therapeutic efficiency of bispecific PD-Ligand antibodies with ADCC capacities, mouse IgG2a and effector enhanced human IgG1 versions were generated. Anti-tumor ADCC activity was assessed *in vitro* using a bioluminescent reporter assay, and therapeutic efficiency measured *in vivo* in syngeneic or human xenograft cancer models.

Results The dual-specific antibodies we generated restore the function of PD-1-suppressed T cells *in vitro* with equivalent efficiency to the FDA approved PD-1 antibody pembrolizumab. Moreover, our modified human dual-specific antibodies drive significantly higher FcγRIIa and FcγRIIIa activation and induction of NK cell ADCC versus FDA-approved PD-L1 antibodies *in vitro*. In syngeneic models of PD-L1/PD-L2 double positive colon carcinoma and melanoma, ADCC-capable PD-Ligand dual-specific antibodies demonstrate superiority to PD-1 blocking antibodies to limit tumor growth and increase survival. Furthermore, treatment with our dual-specific antibodies increases T cell proliferation and cytotoxicity and reduces density of immunosuppressive myeloid stroma *in vivo*. Our antibodies also suppress the growth of U2940 lymphoma in immunodeficient mice more efficiently than Rituximab.

Conclusions ADCC-capable PD-Ligand dual-specific antibodies display higher therapeutic potential than existing anti-PD-1 antibodies and represent a new class of PD-1 pathway therapeutics with significant potential to extend the efficacy of checkpoint immunotherapy to “cold” tumor patients.

463 INVESTIGATING THE T CELL-INTRINSIC REGULATORY ROLE OF VISTA IN ANTI-TUMOR IMMUNITY

Cassandra Gilmour*, Yikun Wang, Sachin Patnaik, Sarah Stone, Li Wang. *Cleveland Clinic, Cleveland, OH, United States*

Background Cancer immunotherapies, specifically checkpoint blockade therapies, are extremely successful at treating subpopulations of specific cancers long term. The goal is to disrupt the negative regulation of T cells and restore cytotoxic abilities allowing killing of the cancer cells and formation of memory T cells. One major limitation to checkpoint blockade is that it is has limited response rate, one theory as to why this is the case, is that there are multiple non-redundant pathways of T cell suppression. In response to the heterogeneous and suppressive tumor microenvironment (TME), T cells may enter a dysfunctional state which results in the concurrent expression of many checkpoint proteins, altered metabolic state, and lack of cytotoxic abilities.[1, 2] One of the many checkpoint proteins which is expressed on these dysfunctional T cells and negatively regulates the T cell is V-domain Immunoglobulin Suppressor of T-cell Activation (VISTA). VISTA's expression on naïve CD4 T cells controls quiescence and peripheral tolerance, but VISTA's role on cytotoxic lymphocytes (CTL) populations in the TME is largely unknown.[3]

Methods Our studies explore VISTA's role on cytotoxic T cells in the TME in an antigen dependent and polyclonal manner using complementary in vivo models

Results Our results suggest that VISTA KO T cells proliferate more, persist longer, and maintain a more robust metabolic program which likely contributes to the observed reduced tumor burden and overall survival of the mouse. Additionally, our results indicate that genetic deletion of VISTA on T cells provide an advantage of protective immunity against a re-challenge of antigen compared to wildtype or naïvely challenged mice.

Conclusions These studies provide context to the mechanism by which VISTA contributes to the dysfunctional state of CTLs and reaffirms the value in studying VISTA on CTLs and developing VISTA blocking immunotherapies to broaden the scope in which checkpoint blockade immunotherapies are successful.

464 ANTI-CTLA-4 THERAPY DEPLETES TREGS AND EXPANDS ICOS$^+$ T-CELLS IN NEUROBLASTOMA TUMORS WITH INDUCED DNA MISMATCH REPAIR DEFICIENCY

Megan Hong*, Rene Figueredo, Saman Maleki. *Western University, London, Canada*

Background Cytotoxic T lymphocyte-associated protein 4 (CTLA-4) highly expressed on regulatory T-cells (Tregs) inhibit the activation of pro-inflammatory T-cells responsible for eliminating cancer cells. Anti-CTLA-4 can enhance T-cell activation by increasing CD28 co-stimulatory signaling through CTLA-4 blockade or depletion of Tregs by Fc-dependent effector mechanisms. Strategies to improve its therapeutic efficacy are needed as patient response rates to anti-CTLA-4 are low. Response to anti-CTLA-4 has been positively correlated with tumor mutation burden (TMB). Defects in the DNA mismatch repair (MMR) pathway can increase TMB and the production of neoantigens that promote anti-tumor immune responses. Here we investigate the underlying mechanism(s) to which induced MMR deficiency in an immunologically-cold and low TMB tumor model can enhance the therapeutic effect of anti-CTLA-4. We hypothesize that induced MMR deficiency in tumors enhances anti-CTLA-4-mediated Treg depletion and increases the infiltration and activation of effector T-cells.

Methods MMR deficiency was induced in a syngeneic murine neuro-2a neuroblastoma cell line by knocking-out *MLH1* expression using CRISPR-Cas9. Wildtype MMR-proficient (pMMR) or induced MMR-deficient (idMMR) neuro-2a cells were inoculated into immunocompetent A/J mice and treated with anti-CTLA-4. Tumors were immunophenotyped by flow cytometry and mixed-lymphocyte reaction assays were used to examine the effects of MMR deficiency and anti-CTLA-4 on T-cell activation and proliferation.

Results Induced MMR deficiency in neuroblastoma tumors enhances the anti-tumor immune response induced by anti-CTLA-4. MMR deficiency in neuroblastoma tumors promoted anti-CTLA-4-mediated Treg depletion and increased intratumoral CD3$^+$ T-cells. idMMR neuroblastoma tumors had an increase of ICOS$^+$ T-cells compared to pMMR tumors. In addition, ICOS$^+$ T-cells were increased further with anti-CTLA-4 treatment.

Conclusions Our data show that inducing MMR deficiency in low TMB and immune-cold neuroblastoma tumors can enhance the anti-tumor effect of anti-CTLA-4 by increasing T-cell activation and depletion of Tregs. By understanding the underlying mechanism(s) of anti-CTLA-4 in idMMR tumors, it may justify targeting the MMR pathway to improve the response to immune checkpoint inhibitors in patients with immunologically-cold and/or low TMB tumors that are refractory to immunotherapy. Future studies will assess how inducing MMR deficiency alters the tumor microenvironment to enable anti-CTLA-4-mediated Treg depletion and the significance of ICOS$^+$ T-cells in the efficacy of anti-CTLA-4 therapy in this setting.

465 SYNERGISTIC APPROACH TO OVERCOME THE SOLID TUMOR MICROENVIRONMENT OF MESOTHELIOMA WITH NATURAL KILLER CELL-FOCUSED IMMUNOTHERAPY

Philippa (Pippa) Kennedy*, Quinlan Kile, Blake Jacobson, Brianna Ettestad, Sarah Miller, Jeffrey Miller, Manish Patel, Martin Felices. *University of Minnesota, Minneapolis, MN, United States*

Background Mesothelioma is a rare, but aggressive cancer that occurs in cells that surround internal organs. Immune checkpoint inhibitors (ICI) have been approved for the treatment of mesothelioma (nivolumab, ipilimumab and pembrolizumab), but currently approved strategies do not make use of natural killer (NK) cell mediated antibody-dependent cellular cytotoxicity (ADCC) of mesothelioma cells. We hypothesized that combining IL-15 treatment with an anti-PDL1 ICI that drives ADCC will enhance NK cell control of mesothelioma and lead to more robust immune control of the disease.

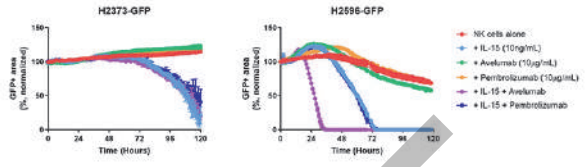
Methods In vitro assays challenged NK cells with three pleural mesothelioma lines, H2373, H2461 and H2596 and four peritoneal mesothelioma lines, ROB, YOU, HAY and ORT. Flow cytometry was used to assess degranulation and cytokine production by NK cells co-cultured with mesothelioma cells in short-term assays (5 hours). The tumor cells were treated overnight with IFNγ to mimic the inflammatory tumor microenvironment. Natural cytotoxicity was compared with ICI that do not drive ADCC (pembrolizumab), ICI that drive ADCC (avelumab) and IL-15, alone or in combination. Live cell imaging was used to track mesothelioma survival in three dimensional spheroids over 5 days when treated with NK cells and these drugs.

Results Mesothelioma lines showed a range of sensitivity to NK cell natural cytotoxicity, with H2373 cells being very resistant and H2596 being more sensitive. More resistant cells tended to have more HLA class I at the cell surface, which can inhibit NK cell function. IFNγ treatment increased the abundance of PDL1 and HLA class I on mesothelioma lines. Lines that lacked PDL1 and were resistant to avelumab treatment (ROB and YOU), were rendered sensitive by increased surface PDL1 following IFNγ treatment. However, lines that were already sensitive to avelumab treatment showed reduced NK cell responses with IFNγ (H2373 and ORT). In spheroid assays, H2596 and H2461, but not H2373, showed synergy between avelumab and IL-15 (figure 1).

Conclusions This study demonstrates a novel synergistic approach to treatment of mesothelioma, but variation in mesothelioma sensitivity to the combination of IL-15 and avelumab suggests other factors beyond PDL1 abundance are contributing to NK cell responses. Greater abundance of HLA class I decreased NK cell responses in our system, but would be beneficial for endogenous T cell responses. Optimizing for both the adaptive and innate arms of the immune response has the potential to limit tumor escape and enhance mesothelioma immunotherapy.

Acknowledgements Raffit Hassan (NIH) kindly provided the peritoneal mesothelioma lines. Daniel Vallera (University of Minnesota) kindly provided pleural mesothelioma lines. This project was supported in large part by the Meso Foundation and also by the Department of Defense (CA200922) and National Institutes of Health (R35 CA197292, P01 CA111412).

Ethics Approval This study was deemed not to constitute human research as determined by the University of Minnesota Institutional Review Board.



Abstract 465 Figure 1 NK cells with anti-PDL1 and IL-15 decrease the survival time of H2596 spheroids. Live imaging tracks the survival of three-dimensional spheroids made from GFP+ mesothelioma cells over 5 days. The relative two-dimension area observed in widefield microscopy images is plotted against time for one donor, representative of at least five donors.

466 COMBINATION THERAPY WITH ANTI-VSIG4 AND ANTI-PD-L1 SUPPRESS GROWTH OF TUMOR VIA CONDITIONING OF TUMOR MICROENVIRONMENT

Byoung S Kwon, Hye Jeong Kim, Joong Won Lee*. *Eutilex Co.,Ltd., Seoul, Korea, Republic of*

Background V-set and immunoglobulin domain-containing 4 (VSIG4) is a B7 family-related protein which includes PDL1, VISTA and CTLA4 ligand. The known functions of VSIG4 are a receptor for complement to inhibit complement activity and negative regulation of proliferating T cell. Although VSIG4 is highly expressed in tissue-resident macrophage and tumor-associated macrophage (TAM), the mechanism of the signal transduction in tumor microenvironment (TME) is not fully elucidated.

Methods

Conversion assay $CD14^+$ monocytes from PBMC were differentiated to M0 macrophages by rhM-CSF, and subsequently to M2 macrophages with rhIL-4/rhIL-13. The conversion of M2 macrophages to M1 was carried out by incubating the macrophages with LPS/rhIFN-gamma or EU103.

In vivo model Generation

PBMC-humanized mouse model shows a relative enrichment of human T cells but generally not enough numbers of human monocyte/macrophage. Therefore, a strategy of adding M2 macrophages was used in the tumor site. Human PBMC were injected i.v. into the NSG mice to humanize. To establish a lung cancer orthotopic model, A549-luci lung cancer cells were injected i.v. with differentiated M2 macrophages into the naïve NSG mice, followed by PBMC infusion. The degree of humanization was determined by measuring the ratio of human $CD45^+$ cells in the mouse PBMC. Tumor size was measured using IVIS twice a week.

Results Here we investigate the pivotal roles of anti-VSIG4 therapeutic antibody, EU103 in TAM. EU103 engagement altered a broad range of type II macrophage (M2) transcriptome which was related to immune-tolerance and increased the proliferation of cytotoxic $CD8^+$ T cells. EU103 induced phosphorylation of JNK and p38MAPK and in consequence, decreased the expression of M2 marker CD14, CSF-1R and CD163 while type I macrophage (M1) marker CD86 and CD40 were increased. In the PBMC-based humanized mouse, human orthotopic lung cancer model, stimulation of VSIG4 suppressed tumor growth and promoted infiltration of IFN-gamma-producing $CD8^+$ T cells into tumor tissue. Furthermore, treatment of EU103 showed synergistic anti-cancer activity with an anti-PD-L1 therapy.

Conclusions Our finding suggests that EU103 directly act on TAM and induce repolarization of TAM to tumor suppressive M1 macrophages, leading to a $CD8^+$ T cell proliferation and tumor suppression. Since the main cause of Immune Checkpoint Inhibitor (ICI) resistance is an immune-suppressive TME, EU103 could be an option for ICI-resistant patients, and synergistic anti-tumor effect could be expected with a combination with ICIs. Overall, targeting the VSIG4 would be an advantageous approach in cancer therapeutics.

467 YH38560, A NOVEL BISPECIFIC FUSION PROTEIN TARGETING 5T4 AND CD47 IN A TUMOR-SELECTIVE MANNER FOR THE TREATMENT OF SOLID CANCERS

Narae Lee*, Eunjeong Jeong, Jung-Hoon Pyun, Minji Choi, Young Bong Park, Yoon ha Hwang, Eunjung Lee, Junhwan Kim, Se-Woong Oh. *Yuhan Corporation, Yongin-si, Korea, Republic of*

Background 5T4 (also known as trophoblast glycoprotein; TPBG) is highly expressed across a wide range of solid cancer indications, including NSCLC (non-small cell lung cancer), head and neck, colorectal, gastric, renal, pancreatic, bladder, breast, ovarian and cervical cancers, with limited expression in normal tissues, making it an attractive target as a tumor-specific antigen. CD47 (Cluster of Differentiation 47), a ubiquitously expressed innate immune checkpoint receptor, is also overexpressed in most solid and hematological cancers. CD47 interacts with signal-regulatory protein alpha (SIRPα) on myeloid cells, and this leads to the inhibition of tumor cell phagocytosis and anti-tumor immune responses. However, the development of novel treatment agents targeting CD47 is hampered by its ubiquitous expression, which often leads to rapid drug elimination and hemotoxicity including anemia or thrombocytopenia. Herein, YH38560 is a bispecific fusion protein targeting 5T4 and CD47 designed to overcome the on-target hematological toxicities and limited efficacies of monospecific CD47 blockers.

Methods *In vitro* binding potencies of YH3860 to human cancer cell lines and RBC (red blood cells) were analyzed by flow cytometry. The tumor selectivity of YH38560 was determined in co-culture system with human cancer cells and RBC *in vitro*. The FcγR-mediated activities of YH38560 were quantified with ADCC (antibody-dependent cellular cytotoxicity) and ADCP (antibody-dependent cellular phagocytosis) reporter bioassays. The tumor cell killing activities of YH38560 were measured in the co-culture system with NK (natural killer) cells or macrophages. *In vivo* anti-tumor effects of YH38560 were evaluated in human 5T4/CD47 expressing MC38 tumor model using hSIRPα knock-in (KI) mice as monotherapy and in combination with anti-PD-1 or PD-L1 antibody (Ab).

Results YH38560 exhibited stronger binding potency to human cancer cells than RBC and this is consistent with the preferential binding of YH38560 to cancer cells when co-cultured with RBC. YH38560 facilitated potent phagocytosis against tumor cells via CD47/SIRPα blockade and FcγRIIa-dependent ADCP. YH38560 demonstrated superior NK-mediated cytotoxicity to tumor cells through FcγRIIIa-dependent ADCC. Correspondingly, YH38560 alone showed significant tumor growth inhibition superior to monospecific CD47 blockers and it exerted synergistic and durable anti-tumor effects when combined with either anti-PD-1 or PD-L1 Ab in MC38 syngeneic mouse model.

Conclusions These findings suggest that YH38560 holds promising potential to improve patient outcomes over CD47-targeted therapies currently under development.

468 APPLICATION OF ORGANOID-BASED DISCOVERY PLATFORM FOR INNOVATIVE SCREENING, EVALUATION, AND IDENTIFICATION (ODISEI) IN IMMUNOTHERAPY

Bo Eun Lee, Sarang Kim, Yuri Shin, Hee-Ra Lee, Suyoung Jo, Dong Wook Han*, Jongman Yoo. *ORGANOIDSCIENCES LTD., Seongnam, Korea, Republic of*

Background Immuno-oncologic therapies are known to activate patients' endogenous immune system, resulting in the enhanced tumor-killing effects in cancer patients. These therapeutic strategies have been gradually preferred as a prior regimen to cure cancer patients due to relatively fewer side effects and prolonged efficacy. Although many new immunotherapeutic drugs have been developed, almost all new drugs failed in clinical trials, strongly necessitating the development of *in vitro* screening platform for pre-evaluating the efficacy of the immunotherapeutic drug candidates.

Methods Moreover, for the precise efficacy prediction of immunotherapy, *in vitro* platform in which the interaction between patient-specific Major Histocompatibility Complex (MHC) and T-cell receptor (TCR) could be mirrored is essentially required. MHC, an antigen molecular in the tumor cells, binds to the TCR of the T-cells, and T-cells can exhibit their tumor-killing effects via MHC and TCR matching. However, tumor cells can evade T-cell-mediated tumor killing effects through the interaction between immune checkpoint (ICP) in tumor cells and their receptors in T-cells.

Results Here we describe a robust and novel efficacy evaluation platform, namely "ODISEI" in which patient-specific immune system could be recapitulated using tumor organoids and PBMC from same donors. The improved performance of our ODISEI platform as an efficacy evaluation platform of immunotherapy drugs was carefully examined using PD-1/PD-L1 blocker antibodies. Moreover, we also developed a series of ODISEI platforms in which the specific interactions between tumor organoids and each immune sub-populations (T-cells, macrophages, regulatory T-cells, dendritic cells) were replicated. Indeed, we were able to validate our ODISEI platforms using multiple drug candidates by assessing their tumor-killing effects through the specific interaction of tumor and reactive immune cell types.

Conclusions In conclusion, we have successfully established novel and robust ODISEI platforms which could serve as a useful efficacy screening platform for the immunotherapeutic drug candidates.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0468

469 PRECLINICAL STUDIES SUPPORT CLINICAL DEVELOPMENT OF AZD2936, A MONOVALENT BISPECIFIC HUMANIZED ANTIBODY TARGETING PD-1 AND TIGIT

[1]Karin Lee, [1]Deepali Malhotra, [1]Stacy Pryts, [1]Eleanor Clancy-Thompson, [1]Bilal Omar, [1]Brian Naiman, [1]Michael Overstreet, [1]Devon Taylor, [1]Chunning Yang, [1]Kathy Mulgrew, [1]Zhan Xiao, [2]Yue Wang, [1]Gordon Moody, [1]Mark Cobbold, [1]Yariv Mazor, [1]Scott Hammond, [1]Kristen Pollizzi*. *[1]AstraZeneca, Gaithersburg, MD, United States*; *[2]Innovent Biologics, Rockville, MD, United States*

Background Although checkpoint inhibition has improved the treatment of metastatic non-small cell lung cancer (NSCLC), up to 65% of patients progress after initial response to PD-1/PD-L1 targeting strategies, suggesting additional immune therapies are required to further improve patient outcome.[1] TIGIT is a receptor of the Ig superfamily, which plays a role of limiting T cell and NK cell activity. TIGIT expression has high correlation with PD-1 and both are expressed on dysfunctional tumor-infiltrating lymphocytes.[2] Here we introduce AZD2936, a monovalent, bispecific, humanized IgG1 antibody that specifically binds to human TIGIT and PD-1 with high affinity and enhances T cell activity within preclinical models. AZD2936 is currently being evaluated in a Phase I/II study in participants with advanced or metastatic NSCLC, NCT04995523.

Methods Primary human immune cells and cells engineered to express either PD-1 and TIGIT or their ligands were co-cultured and incubated with AZD2936 to investigate its impact on T cell activation, cytokine production and cytotoxicity. Immune-compromised NSG mice bearing human tumors and administered human T cells were used to investigate the effect of AZD2936 on tumor growth and survival.

Results AZD2936 individually and concurrently bound TIGIT and PD-1 with high affinity and blocked interaction with their primary ligands, CD155 and PD-L1, respectively. The bispecific antibody triggered antigen-specific T cell-mediated lysis of tumor cell lines and enhanced IFN-g release as compared to anti-PD-1 treatment. Co-culture of antigen specific T cells in a tumor spheroid model showed an increase in tumor cell killing with the addition of AZD2936. The activity of AZD2936 was also investigated in two xenograft mouse models of human cancer. In these models, administration of AZD2936 to animals significantly inhibited tumor growth compared to controls and a combination of parental antibodies.

Conclusions AZD2936 represents a novel immunotherapy engineered to target PD-1 and TIGIT with the potential to enhance anti-tumor immunity. These preclinical results support the ongoing clinical development of AZD2936 in patients with cancer.

470 BOTENSILIMAB, AN FC-ENHANCED CTLA-4 ANTIBODY, ENHANCES INNATE AND ADAPTIVE IMMUNE ACTIVATION TO PROMOTE SUPERIOR ANTI-TUMOR IMMUNITY IN COLD AND I-O REFRACTORY TUMORS

[1]Chloe Delepine, [1]Daniel Levey*, [1]Shanmugarajan Krishnan, [2]Kwang-Soo Kim, [2]Adam Sonabend, [1]Margaret Wilkens, [1]Antoine Tanne, [1]Pilar Garcia-Brocano, [1]Claire Galand, [3]Haiyong Han, [1]Christopher MacDermaid, [1]Jacky Chow, [1]Sylvia Vincent, [1]Shalu Karkwal, [4]Yan Sun, [4]Racehl Smith, [4]Xavier Michelet, [1]Kah Teong, [1]Katherine Rosenthal, [1]David Savitsky, [1]Cailin Joyce, [1]Steven O'Day, [1]Joseph Grossman, [1]Jaymin Patel, [1]Dhan Chand, [1]Daniel Levey*. *[1]Agenus Inc., Lexington, MA, United States; [2]Northwestern University, Chicago, IL, United States; [3]The Translational Genomics Research Institute, Phoenix, AZ, United States; [4]Mink Therapeutics, Lexington, MA, United States*

Background Botensilimab is a novel fragment crystallizable (Fc)-enhanced anti-cytotoxic T-lymphocyte antigen 4 (CTLA-4) antibody designed to promote superior immune activation and tumor killing relative to first-generation IgG1 CTLA-4 antibodies. In patients with advanced solid tumors, botensilimab ± balstilimab (anti-PD-1), demonstrated durable clinical responses across nine different immunotherapy-resistant or poorly immunogenic tumor types. The deep and broad activity observed with botensilimab is attributed to its enhanced binding to Fc gamma receptor IIIA (FcγRIIIA). This binding strengthens the immune synapse between CTLA-4-expressing T cells and FcγRIIIA-expressing antigen-presenting cells (APC) or natural killer (NK) cells, resulting in superior T cell priming, memory formation, intratumoral regulatory T cell (Treg) depletion, and APC functionality. We show that this diversity of immune functions, distinct from that of first-generation anti-CTLA-4, correlates with more effective control of 'cold' tumors alone or in combination with other therapies.

Methods Human *ex vivo* peripheral blood mononuclear cells (PBMCs) assays were used to assess effects of botensilimab on T cell responses, APC activation and Treg depletion. Pre- and post-treatment tumor biopsies and PBMCs from botensilimab-treated patients from a Phase 1 dose-escalation trial were analyzed by next-generation sequencing (NGS), flow cytometry or immunohistochemistry to assess neoantigen burden, immune gene signatures, T cell clonality and CD8:Treg ratios in the tumor. The efficacy of a mouse surrogate (ms) of botensilimab, alone or combined with other agents, was assessed in poorly immunogenic and anti-PD-1 refractory mouse tumor models.

Results In human *ex vivo* cell-based assays, botensilimab enhanced T cell responses as measured by IL-2 secretion, increased the frequency of activated FcγRIIIA+ CD11c+ myeloid cells as determined by CD40, HLA-DR and CD86 expression, and promoted Treg depletion superior to a first-generation IgG1 anti-CTLA-4 antibody. Tumor-bearing mice (CT26 colon carcinoma, MC38 colon carcinoma, and CT2A orthotopic glioblastoma) treated with botensilimab^{ms} showed superior tumor shrinkage and survival compared to mice treated with first-generation anti-CTLA-4. When combined with chemotherapy, radiotherapy, vaccines, adoptive cell therapy, tumor-targeted ultrasound or iNKT-activation, botensilimab^{ms} was therapeutically effective across several tumor models including GL261 glioblastoma, KPC pancreatic cancer and B16 melanoma. In both preclinical and clinical studies, botensilimab enhanced peripheral T cell clonality and expansion of T cell clonotypes and increased intratumoral CD8/Treg ratio. Concordant with preclinical observations, response to botensilimab in patients with advanced solid cancers was independent of FcγR polymorphism or neoantigen burden.

Conclusions Botensilimab demonstrates unprecedented activity in 'cold' and immunotherapy-resistant tumors consistent with its novel mechanism of action.

471 TRANSIENT INHIBITION OF CYCLIN-DEPENDENT KINASE 4/6 WITH TRILACICLIB ENHANCES INHIBITORY RECEPTOR IMMUNOTHERAPY TO IMPROVE ANTITUMOR EFFICACY

[1]Kun-Hui Lu*, [1]Catherine Dietrich, [2]Sarah Ahn, [2]Subing Cao, [2]John Yi, [1]Shom Goel. [1]*Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*; [2]*G1 Therapeutics, Inc., Research Triangle Park, NC, United States*

Background Trilaciclib, an intravenously administered transient cyclin-dependent kinase (CDK)4/6 inhibitor, is indicated to decrease the incidence of chemotherapy-induced myelosuppression in adult patients with extensive-stage small cell lung cancer. In an open-label phase 2 trial in patients with metastatic triple-negative breast cancer, adding trilaciclib prior to gemcitabine plus carboplatin improved overall survival, potentially through protection and direct activation of immune function.[1] [2] Based on its broad effects on the cancer-immunity cycle, including enhanced antigen presentation and effector CD8 T-cell function, and sensitivity of Tregs to transient CDK4/6 inhibition, we hypothesized that trilaciclib may enhance the antitumor efficacy of inhibitory receptor immunotherapy (IRI).

Methods Syngeneic murine models of breast cancer (MMTV-PyMT) and colorectal cancer (CT26) were utilized to evaluate the synergy between trilaciclib and IRI. Trilaciclib 100 mg/kg was administered weekly, and α-PD-1 (5 mg/kg; clone RMP1-14), α-CD73 (5 mg/kg; clone TY/23), α-TIGIT (5 mg/kg; clone TY/23), α-TIM3 (5 mg/kg; clone RMT3-23), and α-LAG3 (10 mg/kg; clone C9B7W) administered biweekly. Treatment was administered intraperitoneally and continued until animals reached humane or study endpoint. Tumor volume and weight were measured 2–3 times a week.

Results In both MMTV-PyMT and CT26 models, adding trilaciclib to IRI delayed tumor growth and improved survival compared with treatment with IRI alone. In the CT26 model, the combination of trilaciclib plus α-PD-1 delayed tumor growth ($P=0.004$) and improved survival ($P=0.02$) versus α-PD-1 monotherapy. Additional benefit was observed when trilaciclib was added to α-TIGIT therapy compared with α-TIGIT alone, with delayed tumor growth ($P=0.007$) and improved survival ($P=0.002$; $P=0.04$) in the MMTV-PyMT and CT26 models, respectively. Trilaciclib plus α-LAG3 delayed tumor growth ($P=0.03$) compared with α-LAG3 alone in the CT26 model. When evaluating the combination of trilaciclib with multiple IRIs, an increase in survival was observed when trilaciclib was added to α-PD-1 plus α-CD73, α-TIGIT, or α-TIM3. Survival was significantly increased with trilaciclib plus α-PD-1 and α-LAG3 ($P=0.006$). Compared with α-TIGIT alone, trilaciclib plus α-PD-1 demonstrated efficacy irrespective of tumor model or starting day of treatment.

Conclusions Adding trilaciclib to IRI combinations heightened antitumor benefits. The combination of trilaciclib plus α-PD-1 was consistently effective, irrespective of when treatment was initiated, or the tumor model used. The data suggest that trilaciclib provides complementary immune modulatory benefits that support the mechanism of IRI and provide a rationale for combining trilaciclib with IRI to enhance clinical efficacy, including in populations resistant to checkpoint blockade or who have received prior IRI treatment.

472 KNOCKDOWN OF VISTA PROTEIN USING ANTISENSE OLIGONUCLEOTIDES PROMOTES SUPERIOR ANTI-TUMOR IMMUNITY COMPARED TO ANTIBODY BLOCKADE

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0472

[1]Brittany Morrow*, [1]Michael Curran, [1]Priyamvada Jayaprakash, [2]Alexey Revenko, [3]Patrick Younan. *[1]UT MD Anderson Cancer Center, Houston, TX, United States; [2]Ionis Pharmaceuticals, Carlsbad, CA, United States; [3]Seagen, Bothell, WA, United States*

Background VISTA is an immunosuppressive checkpoint that can be expressed by a diverse array of immune cells, including CD4+ and CD8+ T cells, natural killer cells, macrophages, dendritic cells (DCs) and neutrophils.[1] VISTA expression is specifically upregulated on tumor infiltrating myeloid cells such as DCs, tumor associated macrophages (TAMs) and myeloid derived suppressor cells (MDSCs).[1] Previous studies showed that antibody blockade of VISTA could reduce tumor growth in multiple melanoma models and enhance T cell responses within the tumor microenvironment (TME).[2] Antibody blockade of VISTA, however, may be sub-optimal therapeutic solution as VISTA has been shown to co-localize with a recycling endosomal protein that contributes to its rapid turnover on and off the cell surface. Also, VISTA blockade in non-myeloid tissues has the potential to cause dose-limiting toxicities.[1]

Methods We used a series of VISTA anti-sense oligonucleotides (ASO) to downregulate VISTA protein expression. Generation 2.5 Ionis ASO have minimal off-target inflammatory activity and are efficiently taken up by myeloid cells when delivered unformulated. We implanted C57Bl/6J mice with $1.5x10^5$ B16-Ova melanoma cells subcutaneously on the flank and treated with anti-mouse VISTA antibody 13F3 for five injections or daily VISTA ASO over three weeks. Flow cytometry was performed to determine VISTA expression levels on TAMs, DC, and MDSCs. Tumor growth and survival were followed until tumor volume endpoints were reached.

Results Flow cytometric analysis confirmed ASO-mediated VISTA knockdown across the tumor myeloid compartment. Our results indicate that VISTA ASO regressed pre-implanted B16-OVA tumors and cured 40% of mice compared to minimal benefit with the 13F3 antibody. Overall, we observed a decrease in tumor growth and improved survival with VISTA ASO treatment compared to 13F3. VISTA ASO was well-tolerated at efficacious doses.

Conclusions Together, these data suggest VISTA expression in tumor myeloid stroma can be effectively downregulated using anti-sense oligonucleotides. Therapeutic approaches that reduce VISTA protein (e.g. VISTA ASOs) may provide superior efficacy and reduced off-target toxicity due to lack of ASO accessibility compared with monoclonal antibody-based approaches.

473 PD-1 BLOCKADE ADMINISTERED BEFORE OR AT THE TIME OF T CELL ACTIVATION ENHANCES ANTI-TUMOR IMMUNITY

Jena Moseman*, Douglas McNeel. *University of Wisconsin-Madison, Madison, WI, United States*

Background Immune checkpoint inhibitors as monotherapies have been a successful treatment strategy for some cancer types, but have not been as effective at treating immunologically "cold" tumors. This is likely due to low tumor mutational burden, a highly immunosuppressive microenvironment, and low numbers of infiltrating CD8+ T cells. Our group has implemented DNA vaccines as a means to generate antigen-specific CD8+ T cells. We and others have shown that PD-1 blockade in combination with T cell activating agents (vaccines) are more effective when these agents are administered simultaneously. However, optimal scheduling of vaccination in combination with checkpoint blockade and mechanisms thereof have not been thoroughly explored. Therefore, we sought to address whether administering PD-1 blockade prior to, simultaneously, or after immunization would affect anti-tumor immunity.

Methods C57Bl/6 mice were inoculated with E.G7-OVA. PDL1^{hi} tumors. Mice received naïve OT-1 splenocytes (with TCRs specific for SIINFEKL peptide) by adoptive transfer and were then immunized with SIINFEKL peptide. PD-1 blockade was administered to mice either at the same time as peptide immunization, two days prior, or two days later. In a separate model, isolated OT-1 CD8+ T cells were co-cultured with dendritic cells and activated in the presence of SIINFEKL peptide and PD-1 blockade. These resulting pre-activated T cells were then assessed for phenotype and IFNγ secretion *in vitro* and were adoptively transferred to tumor-bearing mice and assessed for tumor growth kinetics and tumor infiltrating lymphocyte (TIL) analysis.

Results Mice receiving pre- or simultaneous- treatment of PD-1 blockade had prolonged survival and delayed tumor growth in comparison to the control and late PD-1 blockade treatment groups. OT-1 CD8+ T cells activated *in vitro* in the presence of PD-1 blockade exhibited greater IFNγ secretion, and mice receiving transferred OT-1 CD8+ T cells pre-activated in the presence of PD-1 blockade exhibited greater anti-tumor responses than control mice or mice receiving late administration of PD-1 blockade. Mice receiving transferred T cells pre-activated in the presence of PD-1 blockade had an increased percentage of CD8+ TILs exhibiting an effector-memory and short-lived effector phenotype.

Conclusions These results indicate PD-1 blockade may be best employed when administered before or at the same time as T cell activating agents such as vaccines, and that blockade affects the phenotype and function of T cells at the time of vaccine activation.

474 FIRST-IN-CLASS ANTI-PVR MAB NTX1088 RESTORES EXPRESSION OF DNAM1 AND AUGMENTS ANTITUMOR IMMUNITY

[1]Akram Obeidat, [1]Anas Atieh, [1]Alon Vitenshtein, [1]Guy Cinamon, [1]Keren Paz, [2]Tihana Roviš, [2]Paola Brilc, [2]Lea Hirsl, [3]Ofer Mandelboim, [2]Stipan Jonjic, [1]Pini Tsukerman*. *[1]Nectin Therapeutics, Jerusalem, Israel; [2]MEDRI, Rijeka, Croatia; [3]HUJI, Jerusalem, Israel*

Background Poliovirus receptor (PVR, CD155) is a novel oncology target, differentially overexpressed in a wide range of solid tumors, which recently emerged as a main resistance mechanism to approved immune checkpoint inhibitors (ICIs). It is a key regulator of immune activation, that modifies function through multiple mechanisms, through interaction with the immune receptors DNAM1 (CD226), TIGIT and CD96. Increased PVR expression levels on tumor cells have been associated with resistance to anti-PD1 and PDL1 therapy in patients, while loss of PVR led to reduced tumor growth. Targeting PVR offers an attractive therapeutic approach for patients with advanced cancers, who are not responding to other ICIs.

NTX1088 is a first-in-class, humanized, anti-PVR mAb, currently investigated in a Phase I. By binding PVR with high affinity, NTX1088 has a multi-faceted immune-stimulating role. It blocks the interaction between PVR and its receptors, leading to the restoration of DNAM1 expression and its immune activation function, while simultaneously neutralizing TIGIT and CD96 inhibitory signals in immune cells. DNAM1 downmodulation by PVR was recently identified as a key effector of immune surveillance, and its distinctive restoration by NTX1088 was never seen before by other therapies.

Methods In vitro mechanistic studies demonstrated that NTX1088, as a monotherapy, significantly increased immune cell activation, and was superior to TIGIT, CD112R, and PD1 antibody blockade, leading to superior immune-mediated tumor cell killing, IFNg release, and CD137 induction. Importantly, only NTX1088 was able to restore DNAM1 to the surface of immune cells in all settings. Synergy was observed when NTX1088 was combined with PD1 blockers or with the anti-CD112R mAb, NTX2R13, in line with the restoration of DNAM1 expression.

Results Numerous humanized murine xenograft models were investigated. NTX1088 as a monotherapy exhibited robust tumor growth inhibition of the PDAC cell line, HPAFII, co-engrafted with human PBMC in NOD/SCID mice. The effect was significantly improved when NTX1088 was combined with a PD1 inhibitor. Furthermore, tumor growth inhibition by NTX1088 was observed in humanized A549 xenograft in which TIGIT and PD1 blockers failed to impact tumor growth. Tumor-infiltrating lymphocytes, harvested from NTX1088-treated mice, demonstrated a significantly higher prevalence of CD137+, DNAM1+, CD8+ T cells compared to all other interventions.

Conclusions These promising preclinical findings, together with a clean safety profile in cynomolgus monkeys, paved the way to a Ph1 clinical study in which NTX1088 is tested as a monotherapy and in combination with pembrolizumab, in patients with locally advanced and metastatic solid tumors (NCT05378425).

475 **ANTI-TIGIT ANTIBODY TIRAGOLUMAB LEVERAGES MYELOID CELLS AND REGULATORY T CELLS TO IMPROVE PD-L1 CHECKPOINT BLOCKADE**

[1]Namrata Patil*, [1]Raymond Meng, [1]Robert Johnston, [1]Patrick Chang, [1]Shyam Srivats, [1]Yoonha Choi, [1]Xiangnan Guan, [1]Barzin Nabet, [1]Lisa McGinnis, [1]Eugene Chiang, [1]Thinh Pham, [1]Alexis Dunkle, [1]Bill O'Gorman, [1]Ira Mellman, [1]Ruozhen Hu, [1]John Silva, [1]Joy Han, [1]Amelia Au-Yeung, [1]Chikara Takahashi, [1]Nandini Molden, [1]Pallavi Daggumati, [1]Wendy Connolly, [2]Melissa Johnson, [3]Delvys Rodriguez Abreu, [4]Byoung Chul Cho, [5]Antoine Italiano, [6]Ignacio Gil Bazo, [7]Enriqueta Felip, [1]Sanjeev Mariathasan, [1]Carlos Bais, [1]David Shames. *[1]Genentech Inc., South San Francisco, CA, United States; [2]Sarah Cannon Research Institute, Nashville, TN, United States; [3]Hospital Universitario Insular, Las Palmas, Spain; [4]Yonsei University College of Medicine, Seoul, Korea, Republic of; [5]Institut Bergonie CLCC Bordeaux, Bordeaux, France; [6]Clínica Universidad de Navarra, Pamplona, Spain; [7]Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Background TIGIT is a co-inhibitory receptor and immune checkpoint associated with T cell and natural killer (NK) cell dysfunction in cancer. Tiragolumab is an anti-TIGIT antibody with an active, IgG1/kappa Fc. In a randomized double-blind phase 2 clinical trial in non-small cell lung cancer (NSCLC), tiragolumab + atezolizumab (anti-PD-L1) combination treatment demonstrated significant improvement relative to atezolizumab alone. However, the mechanisms underlying efficacy of this combination are not well understood.

Results Here, we show that tiragolumab functions as both a conventional checkpoint inhibitor and, via Fc gamma receptor (FcgR) engagement, as a modulator of immunosuppressive myeloid cells and T regulatory (Treg) cells. High levels of these cell subsets, which often mediate resistance to immunotherapy, were associated with treatment benefit in the tiragolumab + atezolizumab arm but not atezolizumab arm. Patients receiving the combination treatment exhibited transient on-treatment increases in serum proteins suggestive of myeloid cell activation, and decreases in circulating Treg cells. In preclinical experiments, treatment with Fc-active anti-TIGIT led to effector T cell and NK cell activation, Treg reduction, and proinflammatory modulation of myeloid cells and neutrophils.

Conclusions These findings reveal distinct mechanisms by which tiragolumab unleashes antitumor immune responses, and inform further clinical development of anti-TIGIT therapies.

Trial Registration NCT03563716

Ethics Approval Protocol approval was obtained from independent ethics committees for each participating site for both studies and an independent data monitoring committee reviewed the safety data.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0475

476 LAIR-1 INHIBITION ENHANCES ANTI-PD-1 EFFICACY

[1]Yoshiko Takeuchi*, [1]Corazon Arthur, [1]Heather Kohlmiller, [1]James White, [2]Betty Lee, [2]Bin Fan, [2]Jiawei Huang, [2]James Sissons, [2]Jonathan Sitrin, [2]Lee Rivera, [1]Robert Schreiber. [1]*Washington University School of Medicine, Saint Louis, MO, United States*; [2]*NGM Biopharmaceuticals Inc., South San Francisco, CA, United States*

Background Leukocyte-associated immunoglobulin-like receptor 1 (LAIR-1) is an immune inhibitory collagen-binding receptor that is aberrantly expressed in tumors. Recent work by others has led to conflicting views of immunoinhibitory versus immunoenhancing roles for LAIR-1 in solid tumors. Here, using well-defined syngeneic mouse tumor models, we assess the antitumor efficacy of LAIR-1 inhibition/depletion either alone or in combination with anti-PD-1.

Methods To evaluate the effect of LAIR-1 inhibition on *in vivo* tumor growth and control, we used either *Lair1*$^{-/-}$ mice or a LAIR-1 blocking monoclonal antibody (mAb). We used two antigenically distinct MCA-induced C57Bl/6 strain sarcoma lines (1956 and 7347), a 129S6 strain sarcoma line (F244) and a PD-1 sensitive clone of C57Bl/6 MC38 (MC38-5s). To assess the effects of LAIR-1 deficiency on tumor immunity, we injected either 1956, 7347, or MC38-5s cells into either syngeneic *Lair1*$^{-/-}$ or WT mice, and 10 days later, when tumor-bearing WT mice became insensitive to anti-PD-1 therapy, initiated either anti-PD-1 or Ctrl mAb therapy. To evaluate the efficacy of LAIR-1 blocking mAb as monotherapy or in combination with anti-PD-1, we treated 1956 or 7347 bearing WT C57Bl/6 mice and F244 bearing WT 129S6 mice continuously with either anti-LAIR-1 or Ctrl mAb. Ten-days after tumor inoculation, mice were additionally treated with either anti-PD-1 or Ctrl mAb.

Results Whereas 89% of anti-PD-1 treated *Lair1*$^{-/-}$ mice rejected 1956 sarcomas, only 22% of Ctrl mAb treated *Lair1*$^{-/-}$ mice and 6% of anti-PD-1 treated WT mice rejected their tumors. PD-1 blockade of *Lair1*$^{-/-}$ mice bearing 7347 sarcomas or MC38-5s tumors induced similar rejection responses. In WT mice, the anti-LAIR-1 and anti-PD-1 combination induced better anti-tumor efficacy than anti-LAIR-1 or anti-PD-1 monotherapy. Flow cytometry analysis revealed that tumor-specific T cells were significantly increased in anti-PD-1 treated *Lair1*$^{-/-}$ mice compared to anti-PD-1 treated WT mice. Depletion of CD4^{+} and/or CD8^{+} T cells in *Lair1*$^{-/-}$ mice inhibited anti-PD-1 mediated tumor rejection. High dimensional profiling via CyTOF analyses of the myeloid cell compartment from 1956 tumors in *Lair1*$^{-/-}$ mice treated with either anti-PD-1 or Ctrl mAb revealed a selective increase over similarly treated WT mice in a macrophage cluster expressing CD206 and folate receptor-b, suggesting that development of this macrophage cluster was LAIR-1 dependent.

Conclusions This study shows that inhibition of LAIR-1 in tumor bearing mice sensitizes advanced tumors to anti-PD-1 treatment.

477 HBM1047, A NOVEL FULLY HUMAN ANTI-CD200R1 ANTAGONIST ANTIBODY WITH POTENT ANTI-TUMOR EFFICACY IN PRECLINICAL MODEL

Yuhua Wang, Qiumei Du, Hongjie Pan, Geetika Bajpai, Tao Liu, Jason Noon, Yao Lu, Jinqiu He, Yan Li, Qingfang Chen, Yongqiang Wang, Xingxing Jia, Fei Chen, Youhong Wang, Yiping Rong, Yun He, Joe Zhao, Musheng Bao*. *Harbour BioMed, Shanghai, China*

Background Immune checkpoint inhibitors have revolutionized cancer immunotherapy, however, only a small subset of patients respond to the treatment. There is still a high unmet medical need, especially for those who are resistant to immune checkpoint inhibitors. Developing new therapeutic targets are urgently needed. CD200-CD200R1 signaling pathway has been shown to inhibit the functions of T cells and myeloid cells, and represents a promising therapeutic target for cancer treatment. In a PD1-resistant mouse tumor model, CD200R1 expression is highly upregulated in tumor infiltrating T cells from PD1-resistant group.[1] Thus, blocking CD200-mediated CD200R1 inhibitory signaling pathway offers promising therapeutic potential for PD1-resistant patients. Moreover, CD200 is highly expressed in many human cancers such as non-small cell lung cancer, pancreatic cancer and brain cancer, which are potential indications for anti-CD200R1 antagonist antibody.[2-4]

Methods Utilizing the unique Harbour Mice® antibody discovery platform, we generated fully human anti-CD200R1 antibodies that efficienctly blocked CD200-CD200R1 interaction. After further characterization and functional screening, we identified a novel fully human anti-CD200R1 antagonistic antibody – HBM1047.

Results HBM1047 demonstrated high binding affinity to both human and cyno CD200R1. It effeciently blocked CD200-CD200R1 interaction and inhibited CD200-induced CD200R1 reporter activity. In human primary cell assays, HBM1047 enhanced T cell activation when combined with anti-PD1 antibody. Furthermore, HBM1047 selectively bound to CD8+ T cells and myeloid cells in human tumor infiltrating lymphocytes from a variety of cancer types. More importantly, when used as monotherapy in preclinical models, HBM1047 showed potent anti-tumor efficacy in both CD200+ and CD200- humanized CDX models. In addition, HBM1047 had a favorable PK profile in mice and exhibited good developability properties.

Conclusions In conclusion, HBM1047 represents a novel fully human anti-CD200R1 antagonistic antibody with promising therapeutic potential for the treatment of cancer.

478 REAL-WORLD OUTCOMES IN PATIENTS WITH PENILE SQUAMOUS CELL CARCINOMA (PSCC) RECEIVING IMMUNE CHECKPOINT INHIBITORS (ICI)

Tony Zhuang*, Subir Goyal, Jacqueline Brown, Bradley Carthon, Omer Kucuk, Greta McClintock, Lauren Yantorni, Mehmet Bilen, Viraj Master, Bassel Nazha. *Emory University School of Medicine, Atlanta, GA, United States*

Background Penile squamous cell carcinoma (pSCC) is a rare and aggressive neoplasm with poor outcomes in advanced settings and limited treatment options beyond TIP chemotherapy (paclitaxel/ifosfamide/cisplatin). We evaluated real-world outcomes in patients treated with immune checkpoint inhibitors (ICI) for pSCC.

Methods We performed a retrospective review of patients with pSCC who received ICI from 2012-2022 at the Winship Cancer Institute at Emory University. Clinical benefit was defined as complete response, partial response, or stable disease based on RECIST 1.1 criteria. Overall survival(OS) and progression-free survival(PFS) were assessed by Kaplan-Meier method and univariate Cox regression(UVA).

Results Of 21 patients, 71.4% were white, 28.6% were black. Median age at diagnosis was 55 years (37-82). The majority (65%) had ECOG performance status ≥2. Most common histological subtype was keratinizing (42.9%). Eight of 9 (89%) patients were HPV+. Median tumor size was 6.75cm (0.30-19.5). At diagnosis, 4.8%/33.3%/61.9% were stage 2/3/4 respectively. Eight patients had initial distal metastases. At ICI initiation, the median level of C-reactive protein was 43.1 µg/mL (0-201.9), lactate dehydrogenase: 140.5 units/L (99-414), and neutrophil-to-lymphocyte ratio (NLR): 6.87 (2.49-45.46). Seven of 11 patients (63.6%) were PD-L1+. Median follow-up was 8.16 months(mo) and median time to ICI treatment from diagnosis was 15.6mo. Median OS and PFS for overall cohort were 8.2mo and 1.9mo respectively. Median OS was 8.4mo in white patients and not reached(NR) in black patients (1.3, NA). Median PFS was 2mo in white patients and NR in black patients (0, NA). On UVA, no differences were seen in outcomes with respect to race (figures 1,2) and PD-L1 status (figures 3,4). Three patients (14.3%) had clinical benefit and 76.2% progressed post-ICI. Only 14.3% were alive at last contact. Nearly all patients previously received chemotherapy. ICI was 1st line(1L) in 1 patient(4.8%), 2L in 13(61.9%), 3L in 6(28.6%), 4L in 1(4.8). Monotherapy with nivolumab or pembrolizumab was the most common regimen, others included combination ICI, cemipilimab, or clinical trial. Two patients received a second ICI regimen. Sites of progression included local invasion (66.7%), lymphadenopathy (57.1%), retroperitoneum (47.6%), lung (42.9%), and bone (42.9%). Three patients (14.3%) developed grade 3/4 ICI-related adverse events. Higher NLR and larger resection size were associated with shorter OS (table 1).

Conclusions Our real-world analysis confirms poor response rates of pSCC to ICI in an unselected approach and the critical need for biomarkers. NLR may be a potential biomarker to assess ICI response in pSCC. More prospective and multicenter studies are needed for confirmation.

Dia Roy*, Hieu Ta, Cassandra Gilmour, Timothy Chan, Keman Zhang, Li Wang, Sarah Stone. *Lerner Research Institute, Cleveland, OH, United States*

Background The tumor microenvironment (TME) gets infiltrated with numerous components of adaptive and innate immune system. However, the immune surveillance imparted by these components are often suppressed by numerous mechanisms in the TME in a context dependent manner. The tumor cells can mediate the signaling suppression of the immune cells which is reflected by the reduction in the activity of stimulatory immune-receptors and the concomitant activation of the inhibitory immune-receptors. In case of T cells, for instance, tumor cells facilitate the inhibition of the TCR-mediated activation signaling. Alongside, the tumor cells can also facilitate the up tuning of numerous inhibitory checkpoint receptors (ICRs). Several ICRs like CTLA-4, PD-1, and LAG3 have been studied in context of cancer immunotherapy in past decades. However, a great many drawbacks have begun to come to light with the gradual increase in accumulation of clinical data-the most obvious gridlock being its low response rate in most cancers thereby urging the need for the discovery of novel immune checkpoint molecules.

Methods Multi panel flow cytometry and Western blot analysis was done to check LRIG1 expression.[1] Bioinformatics analysis was done on the RNA seq data from the study by *Feldman et al.*[2]

Results The current study manifested the expression of Leucine-rich repeats and immunoglobulin-like domains protein 1 (LRIG1) on both CD4+ and CD8+T cells. Expression of LRIG1 can be detected in the tumor infiltrating lymphocytes (TILs) and also on the in-vitro activated T cells from both human and murine cancer models. Within the CD4 compartment, expression of this molecule on the immunosuppressive regulatory T cell was highly upregulated.

Further, the single cell RNA seq data from melanoma patients reanalyzed from the study obtained by *Feldman et al.* revealed the exclusive expression of LRIG1 among other exhausted markers such as TIM3, LAG3 and TIGIT.[2]

Conclusions LRIG1 has been identified as a potent immune suppressor molecule in numerous tissue but its role remains widely unexplored in context of the immune cells.

Detection of LRIG1 in different subsets of $CD4^+$ and $CD8^+$ might lead to interesting findings about its role in context of mounting anti-tumor immune response.

480 IMPACT OF INFECTIONS IN PATIENTS WITH ADVANCED OR METASTATIC NON-SMALL CELL LUNG CANCER (NSCLC) RECEIVING PEMBROLIZUMAB-BASED THERAPIES

[1]Ethan Burns*, [2]Jiaqiong Xu, [1]Ryan Kieser, [3]Ibrahim Muhsen, [3]Shivan Shah, [1]Godsfavour Umoru, [3]Charisma Mylavarapu, [3]Yuqi Zhang, [3]Aubrey Crenshaw, [1]Kai Sun, [1]Abdullah Esmail, [1]Carlo Guerrero, [1]Zimu Gong, [3]Kelly Gee, [1]Kirk Heyne, [1]Monisha Singh, [1]Jun Zhang, [1]Eric Bernicker, [1]Maen Abdelrahim. *[1]Houston Methodist Neal Cancer Center, Houston, TX, United States; [2]Houston Methodist Research Institute, Houston, TX, United States; [3]Houston Methodist Hospital, Houston, TX, United States*

Background Immune checkpoint inhibitor (ICI) therapy has improved outcomes in patients with NSCLC, particularly with the programmed death-1 inhibitor pembrolizumab. However, this therapy is not benign and while immune related toxicities are well-described, infections, a common cause of morbidity and mortality amongst patients with solid organ malignancies, are seldom studied. Herein, we investigate the incidence, risk factors, and impact of infections in patients receiving pembrolizumab regimens for NSCLC.

Methods Patients receiving pembrolizumab regimens for advanced/metastatic NSCLC from January 2017 through August 2021 across a seven-hospital network were retrospectively identified and dichotomized into infection and non-infection cohorts. Covariates included age, gender, race, comorbidities, ECOG, chronic infections, line of therapy, monotherapy/combination therapy, anti-infectives at ICI initiation, and growth factor use. Outcomes included all-cause emergency department (ED), inpatient, or intensive care unit (ICU) visits, median number of treatment cycles, overall survival (OS), and progression free survival (PFS). Univariable and multivariable analysis with reported odds ratio (OR) and 95% confidence intervals (CI) evaluated risk of developing infection, and OS/PFS was assessed via Kaplan-Meier methodology. P-value <0.05 was considered statistically significant.

Results Among 243 patients, 111 (45.7%) had $\geq$1 reported infection, with median time to first infection of 1.9 (0-48.8) months. Demographics were similar between cohorts. Compared to non-infected, infected patients had more ED [37 (33.3%) vs 26 (19.7%), p=0.016], hospital [87 (78.4%) vs 53 (40.1%), p<0.001], and ICU [31 (27.9%) vs 5 (3.8%), p<0.001]) visits. During course of infection, there were treatment delays and discontinuation in 56 (50.4%) and 28 (25.2%) patients. Median treatment cycles received by infected and non-infected was 5 (2-13) and 8 (4-12) (p=0.057), respectively. Median OS and PFS in infected and non-infected patients was 11 (95% CI 6.4-16.7) and 21 (95% CI: 14.7-24.2) (p=0.023), and 13.03 (95% CI 10.03-19.73) and 9.7 (95% CI: 7.13-12.83) (p=0.54) months, respectively. Anti-infective therapy (OR 3.32, [95% CI: 1.26-8.76], p=0.015) and ECOG of 2 (OR 5.79, [95% CI 1.72-19.47], p=0.005) at ICI initiation had higher associations with infection; no other covariates were significant. At last evaluation, 74 (66.7%) infected and 70 (53.0%) non-infected died (p=0.031). Of these, infection caused death in 11 (14.9%) and 4 (5.7%) patients (p=0.041), respectively.

Conclusions Infections are common in NSCLC patients receiving pembrolizumab regimens and associated with greater morbidity, treatment interruptions, and poorer survival. Risks factors included poorer baseline ECOG status and anti-infective therapies at ICI initiation. Prospective studies assessing infectious process prevention and anti-infective stewardship programs may be valuable to augment ICI benefit.

Ethics Approval This retrospective study was an institutional review board approved study (Approval ID: PRO00028635). Informed consent was not obtained due to the retrospective nature of this study.

481 AN AFFINITY-OPTIMIZED CD47XPD-L1 BISPECIFIC ANTIBODY FOR DUAL IMMUNE CHECKPOINT BLOCKADE

[1]Xavier Chauchet, [1]Sebastien Calloud, [1]Margaux Legrand, [1]Laura Cons, [1]Laurence Chatel, [1]Adeline Lesnier, [1]Nicolas Bosson, [1]Pauline Lloveras, [1]Pauline Malinge, [1]Ulla Ravn, [1]Valery Moine, [1]Bruno Daubeuf, [1]Yves Poitevin, [1]Giovanni Magistrelli, [1]Susana Salgado-Pires, [2]Dmitry Shchelokov, [2]Oleg Demin, [1]Limin Shang, [1]Krzysztof Masternak, [1]Walter Ferlin*. *[1]Light Chain Bioscience-Novimmune SA, Geneva, Switzerland; [2]InsysBio UK Ltd, Edinburgh, UK*

Background To enhance efficacy of anti-PD-1/PD-L1 antibodies, many combinations with various therapeutic agents are being investigated. Blocking the CD47/SIRPα checkpoint with monoclonal antibodies (mAbs) or decoy receptors is emerging as an effective approach to mobilize myeloid cells and support T-cell mediated antitumor responses. The benefit of combining CD47/SIRPα and PD-1/PD-L1 blockade to improve tumor control has been demonstrated in preclinical models and is being explored in patients. However, CD47 mAbs are hindered by ubiquitous CD47 expression leading to pharmacokinetic (PK) and safety issues.

Methods NI-2901, an IgG4 CD47xPD-L1 bsAb of optimized affinity, was generated using the κλ body platform.[1] *In vitro* assays were used to characterize its binding profile and checkpoint inhibition as well as its capacity to enhance T-cell activation and macrophage-mediated phagocytosis of tumor cells. PD-L1-independent CD47 antitumor activity was assessed *in vivo* in a PD-L1-negative xenograft model and compared to the humanized IgG4 anti-CD47 antibody, magrolimab. PK and tolerability of NI-2901 were evaluated in non-human primates (NHP), allowing for comprehensive modeling and simulations in humans.

Results Consistent with its intermediate CD47 affinity, NI-2901 shows low binding to red blood cells as compared to anti-CD47 mAbs and induces CD47/SIRPa blockade on PD-L1-negative cells, that is significantly enhanced once PD-L1 is expressed. As a result, the bsAb is able to enhance the phagocytosis of PD-L1-negative and -positive tumor cell lines induced by mAbs targeting tumor-associated antigens (e.g. CD20, HER2 and CD19) and demonstrates *in vivo* anti-tumor activity in the Raji B-cell lymphoma xenograft model. Given its high affinity for PD-L1, NI-2901 triggers effective blockade of the PD-1/PD-L1 interaction on cells, inducing T-cell activation *in vitro* similar to the anti-PD-L1 antibodies, atezolizumab and avelumab. After 4-weekly 30mg/kg injections in NHP, NI-2901 was well-tolerated showing no signs of hemotoxicity, while magrolimab induced a significant drop in RBC after a single 10mg/kg injection. Translational PK modelling and simulations from NHP to human suggest a more favorable dosing regimen is possible as compared to benchmark CD47-targeted approaches.

Conclusions As a dual immune checkpoint inhibitor, NI-2901 triggers effective T-cell activation, enhances phagocytosis of tumor cells and is expected to have improved efficacy over PD-1/PD-L1 blockade alone. The bsAb is well-tolerated in NHP at predicted therapeutic doses without inducing RBC or platelet depletion.

482 ATG-031, A FIRST-IN-CLASS ANTI-CD24 ANTIBODY, SHOWED POTENT PRECLINICAL ANTI-TUMOR EFFICACY BY BLOCKING "DON'T-EAT-ME" SIGNAL

[1]Peng Chen, [1]Min Deng, [1]Yun Liu, [1]Jiamei Luo, [1]Rong Guo, [2]Jay Mei, [2]Bo Shan, [2]Bing Hou*. *[1]Shanghai Antengene Corporation Limited, Shanghai, China*; *[2]Antengene Corporation Co., Ltd, Shaoxing, China*

Background By overexpressing anti-phagocytic surface proteins, often known as "don't eat me" signals, cancer cells can evade macrophage-mediated elimination. Therapeutic antibodies targeting "don't eat me" protein, such as CD47, demonstrates promising anti-tumor efficacy in preclinical models and in clinic. However, the clinical development of anti-CD47 mAbs that retain substantial FcR activating capacity (e.g. human IgG1) has been hampered by the on-target-off-tumor toxicity, such as erythrocyte depletion.[1] CD24, a GPI-anchored, highly glycosylated surface protein interacting with Siglec-10 on innate immune cells, was reported to be a novel "don't eat me" protein. CD24 is over-expressed in multiple tumor types. Knock-out of CD24 or blockade of CD24/Siglec-10 interaction enhances macrophage-mediated phagocytosis of tumor cells.[2] In this study, we developed a first-in-class, humanized anti-CD24 antibody, ATG-031. The *in vitro* and *in vivo* anti-tumor activity of ATG-031 was evaluated in preclinical models.

Methods The affinity of ATG-031 was measured using Surface Plasmon Resonance (SPR). Cell-based binding to HEK293, HEK293-CD24, human red blood cell (hRBC) and a panel of tumor cells was evaluated by flow cytometry. The ability of ATG-031 in enhancing macrophage-mediated phagocytosis of tumor cells was evaluated using human monocyte-derived M2 macrophage. *in vivo* efficacy of ATG-031 was test in mouse bearing MC38 murine syngeneic colorectal cancer cells stable-expressing human CD24 (MC38-hCD24). Expression profile of CD24 in human tumor and normal tissues were analyzed using TCGA/GTEx database or using an in-house developed companion diagnostic antibody on tissue microarray (TMA) by IHC staining.

Results CD24 is overexpressed in multiple types of solid tumors and hematological malignancies. ATG-031 specifically binds to human CD24 with a single-digit nM affinity. ATG-031 potently binds to CD24-postive tumor cells, while showed no binding with parental HEK293 cells or hRBC. ATG-031 blocks the interaction between CD24 and Siglec-10 and induced potent macrophage-dependent tumor cell phagocytosis (figure 1A, B). Upon phagocytosis, M2 macrophages start to release M1-like cytokines suggesting a repolarization from M2 to M1. ATG-031 significantly inhibited *in vivo* tumor growth in MC38-hCD24 mouse model. A dose of 3mg/kg ATG-031 administered biweekly induced tumor regression (figure 1C).

Conclusions Blocking CD24 by ATG-031 enhances macrophage-mediated phagocytosis of cancer cells, and polarized M2 macrophage towards anti-tumor M1 subtype (figure 2). It demonstrates potent *in vivo* anti-tumor tumor efficacy, suggesting promising therapeutic strategies against a broad range of solid tumor or hematological malignancies, which warrants further clinical investigation. A clinical study to investigate the safety and efficacy of ATG-031 in cancer patients is being developed.

483 PRECLINICAL EVALUATION OF JTX-1484, AN ANTI-LILRB4 ANTAGONIST ANTIBODY, FOR RE-PROGRAMMING OF IMMUNOSUPPRESSIVE MYELOID CELLS

Heather Condurso, Amy Mueller, Jessica Jimenez, Lauren Badalucco, Kelly Aldridge, Pauline Sarraf, Michelle Priess, Vikki Spaulding, Sarah Jaffe, Prashanna Balaji Venkatasubramanian, Alexa Diiorio, Geneva Young, Kameron Mori, Karl Wetterhorn, Jeffrey Smith, Morgan Thompson, Jean-Christophe Pignon, Changyun Hu, Brandon Chin, Briana Murphy, Matthew Southard, Katalin Kis-Toth, Monica Gostissa, Dmitri Wiederschain, Andre da Cunha*. *Jounce Therapeutics, Cambridge, MA, United States*

Background Immune checkpoint therapy has achieved durable clinical responses, but only in a subset of cancer patients. Immunosuppressive myeloid cells, a heterogenous group of innate immune cells, have emerged as key contributors to resistance to T cell based immune checkpoint therapy. Leukocyte immunoglobulin-like receptor B4 (LILRB4), also known as immunoglobulin-like transcript 3 (ILT3), is an inhibitory receptor selectively expressed on myeloid cells, enriched in the tumor microenvironment and contributes to myeloid-driven immunosuppression. Recently, fibronectin has been identified as a functional ligand for LILRB4, and the LILRB4-fibronectin interaction was proposed as a stromal checkpoint suppressing myeloid cell anti-tumor activity. Targeting LILRB4 could represent a strategy to reprogram immunosuppressive myeloid cells and promote anti-tumor response. We developed JTX-1484, a highly selective, high-affinity humanized monoclonal antibody that binds to and antagonizes LILRB4 and blocks its interaction with fibronectin.

Methods A diverse panel of high affinity monoclonal antibodies that bind specifically to LILRB4 was generated. JTX-1484 activity alone or in combination with an anti-PD1 antibody was evaluated in vitro in different functional assays. Human primary myeloid-derived suppressor cells (MDSCs) were used in a T cell suppression assay and treated with JTX-1484. Primary monocyte-derived tolerogenic dendritic cells (tDCs) were utilized in mixed lymphocyte reactions with T cells and treated with JTX-1484 in combination with anti-PD1. JTX-1484's ability to block fibronectin inhibitory activity on tDCs and THP-1 cells was also tested. Finally, the pharmacodynamic effect of anti-LILRB4 treatment in human tumor samples was evaluated by assessing gene expression changes in an ex vivo histoculture system.

Results JTX-1484 reprogramed tDCs to a stimulatory phenotype as evidenced by increased pro-inflammatory cytokine production and increased ability to induce T cell activation in combination with anti-PD1. LILRB4 antagonism by JTX-1484 also reversed fibronectin-mediated inhibition of tDC activation and reduced MDSC-mediated T cell immunosuppression. Moreover, LILRB4 blockade in ex vivo human tumor samples induced pharmacodynamic responses consistent with increased immune activation and reduced myeloid immunosuppression.

Conclusions Results from our preclinical studies demonstrate that JTX-1484 is a highly specific and potent antagonist of LILRB4 that leads to myeloid cell reprogramming and more efficient T cell activation that could result in enhanced anti-tumor responses. JTX-1484 immunostimulatory properties towards myeloid cells could be complementary to immune checkpoint blockade therapy. Our data therefore support clinical development of JTX-1484. Indication selection will be guided by multiple factors including predictive biomarkers such as target and ligand abundance, as well as complementarity and combination potential with other therapies.

Ethics Approval Human blood and tumor samples were acquired from commercial providers and from the CHTN and NDRI networks respectively. Specimens were collected under each provider's human subject research institutional review board approved protocols and were fully anonymized or otherwise permanently de-identified to recipient investigators.

484 BLOCKADE OF THE MYELOID CLEC-1 CHECKPOINT ENHANCES ANTITUMOR RESPONSES AND TUMOR ANTIGEN CROSS-PRESENTATION

[1]Vanessa Gauttier*, [1]Marion Drouin, [1]Isabelle Girault, [1]Irène Baccelli, [1]Sabrina Pengam, [1]Emmanuelle Wilhelm, [2]Javier Saenz, [1]Julien Taurelle, [2]Emmanuel Merieau, [2]Bérangère Evrard, [1]Caroline Mary, [1]Géraldine Teppaz, [1]Ariane Desselle, [1]Virginie Thépénier, [1]Nicolas Poirier, [2]Elise Chiffoleau. [1]*OSE Immunotherapeutics, Nantes, France*; [2]*Université Nantes, CHU, CR2TI – UMR1064, Nantes, France*

Background Myeloid cells represent one of the most abundant immune cell types in solid tumors that impede antitumor immune responses. We previously reported that the orphan CLR CLEC-1 is expressed by dendritic cells (DCs) and macrophages (MPs). Single cell transcriptional analysis of the tumor microenvironment (TME) confirms the expression by myeloids especially cDC1, best professional antigen presenting cells and tumor-associated macrophages (TAM).

Methods Damaged CLEC-1 ligand expressing tumor cells were used to identify the ligand of CLEC-1 by co-immunoprecipitation. CLEC-1 mechanism deciphering was performed with Clec1a deficient mice, notably by isolating dendritic cells. Human CLEC-1 knock-in animals were challenged for antitumor responses, administered with antagonistic anti-human CLEC-1 monoclonal antibodies in hepatocellular carcinoma (Hepa1.6) and in colorectal cancer (MC38) preclinical models.

Results Furthermore, we showed that the CLEC-1 senses dead cells induced by programmed necrosis and identified this CLEC-1 protein ligand (CLEC-1 ligand) over-expressed in cancers. Mechanistically, we identified CLEC-1 as a sensor of tissue-damage which increases the cross-presentation of dead-cell tumor associated antigens by cDC1 without breaking established tolerance against natural antigens. Interestingly, we observed that CLEC-1 blockade as a monotherapy or combined with chemotherapy prolongs mice overall survival in hepatocellular and colon carcinoma models. We revealed that loss of CLEC-1 reduced the accumulation of immunosuppressive myeloid cells in tumors and invigorated the activation state of dendritic cells (DCs), thereby increasing T cell activation & response. Importantly, we generated anti-human CLEC-1 antagonist antibodies able to enhance anti-tumor immunity in CLEC-1 humanized mice.

Conclusions Altogether, our results demonstrate that CLEC-1 acts as an immune checkpoint in myeloid cells and support CLEC-1 as a novel target for cancer immunotherapy.

485 **FUNCTIONAL CHARACTERIZATION OF THE INHIBITORY ACTIVITY AND IDENTIFICATION OF NOVEL T-CELL RECEPTORS FOR THE TUMOR-ASSOCIATED MACROPHAGE RECEPTOR VSIG4**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0485

[1]Tim Eitas*, [1]Edward van der Horst, [1]Faith Finley, [1]Thomas Thisted, [1]Kanam Malhotra, [1]Arnab Mukherjee, [1]Zuzana Biesova, [1]Anokhi Cifuentes, [2]Sandra Marder, [2]Paul Helbling, [1]Robert Pierce. *[1]Sensei Biotherapeutics, Boston, MA, United States; [2]Dualsystems Biotech AG, Schieren, Switzerland*

Background Tumor associated macrophages (TAMs) are important regulators of immunosuppression in the tumor microenvironment (TME) and are often associated with poor clinical responses in patients. VSIG4 (V-Set and Immunoglobulin domain containing 4) is a negative checkpoint regulator (NCR) and its expression has been well established on both tissue resident macrophages and TAM populations.[1-3] However, the inhibitory molecular mechanism of VSIG4 remains largely unknown[1 2] and many therapeutic strategies targeting TAMs in general have been limited either by a lack of TME-specificity or high target abundance leading to target-mediated drug disposition (TMDD).[4 5] The development of immunomodulatory antibodies that selectively target antigens in acidic environments, such as the TME, has the potential to increase tumor exposure and reduce toxicity.[6]

We have characterized endogenous expression patterns of VSIG4 and observed an absence of expression on peripheral immune cell populations but a significant induction on differentiated primary macrophages under conditions similar to the TME. Additionally, we have performed a proteomics screen for potentially novel T-cell receptor(s) that interact with VSIG4.

Methods Endogenous expression patterns of VSIG4 were characterized in primary human immune cell populations including whole blood, peripheral blood mononuclear cells (PBMCs), and polarized macrophage populations. The induction of VSIG4 expression in polarized macrophage populations was demonstrated by both flow cytometry and RNA expression analysis. A Ligand Receptor Capture-Trifunctional Chemoproteomic Reagents (LRC-TriCEPS)-based proteomics strategy was used to identify receptors on primary human T-cells that interact with recombinant VSIG4 protein.[7]

Results Our results show a robust upregulation of VSIG4 expression in polarized human macrophage populations. Additionally, we established multiple functional assays demonstrating VSIG4-mediated suppression of primary human T-cells. Finally, the LRC-TriCEPS-based proteomics screen yielded novel candidate receptors that interact with VSIG4.

Conclusions VSIG4 inhibits human T-cell activation in multiple assay formats and through numerous functional measurements. A group of T-cell receptors was found to be involved in novel interactions with VSIG4, and their potential roles in VSIG4-mediated regulation are currently being validated. Collectively, our work will lead to an enhanced mechanistic understanding of how VSIG4 suppresses T-cell activation and provide a strategy and tools for discovery of therapeutic relevant anti-VSIG4 antibodies.

486 COMPLEMENT DOWNREGULATION PROMOTES AN INFLAMMATORY SIGNATURE THAT RENDERS COLORECTAL CANCER SUSCEPTIBLE TO IMMUNOTHERAPY.

[1]Silvia Guglietta*, [2]Lukas Weber, [3]Bruno Fosso, [3]Marinella Marzano, [4]Gary Hardiman, [5]Monica Olcina, [6]Mark Robinson, [1]Carsten Krieg. *[1]Medical University of South Carolina, Charleston, SC, United States; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States; [3]Consiglio Nazionale Ricerche, Bari, Italy; [4]University of Belfast, Belfast, UK; [5]University of Oxford, Oxford, UK; [6]University of Zurich, Zurich, Switzerland*

Background The role of inflammatory immune responses in colorectal cancer (CRC) development and response to therapy is a matter of intense debate. While inflammation is a known driver of CRC, inflammatory immune infiltrates are a positive prognostic factor in CRC and predispose to response to immune checkpoint blockade (ICB) therapy. Unfortunately, over 85% of CRC cases are primarily unresponsive to ICB due to the absence of an immune infiltrate and even the cases that show an initial immune infiltration can become refractory to ICB. The identification of therapy supportive immune responses in the field has been partially hindered by the sparsity of suitable mouse models to recapitulate the human disease. In this study, we aimed to understand how the dysregulation of the complement anaphylatoxin C3aR, observed in subsets of CRC patients, affects the immune responses, the development of CRC and response to ICB therapy.

Methods We used a comprehensive approach encompassing analysis of publicly available human CRC datasets, inflammation-driven and newly generated spontaneous mouse models of CRC, and multi-platform high dimensional analysis of immune responses using microbiota sequencing, RNASeq, and mass cytometry.

Results We found that patients' regulation of the complement C3aR is associated with epigenetic modifications. Specifically, down-regulation of *C3ar1* in human CRC promotes a tumor microenvironment characterized by the accumulation of innate and adaptive immune cells that support anti-tumor immunity. Using our novel spontaneous mouse model of CRC ($APC^{Min/+}$/C3aR-/-) we showed that loss of C3aR resulted in enhanced immune infiltration in typically "cold" tumors and modified the intestinal microbiota. We also identified a species of *E. faecalis* that increased over time in the tumor microenvironment of $APC^{Min/+}$/C3aR-/- mice. Notably, treatment with a-PD1 in $APC^{Min/+}$/C3aR-/- but not $APC^{Min/+}$mice resulted in significant tumor reduction. Therefore, the lack of C3a in the colon activates a microbiota-mediated pro-inflammatory program, which promotes the development of tumors with an immune signature that renders them responsive to the ICB therapy.

Conclusions The complement system in the gastrointestinal tract is essential to avoid overt inflammation in health conditions. However, this regulatory mechanism may restrain the activation of immune responses during tumor development. Our findings reveal that C3aR may act as a previously unrecognized checkpoint to enhance anti-tumor immunity in CRC. C3aR can thus be exploited to overcome ICB resistance in a larger group of CRC patients.

487 THE ROLE OF VSIG4 AS AN IMMUNO-REGULATORY PROTEIN IN CANCER

William Huang*, Michele Doucet, Rupashree Sen, Andrew Pardoll, Sudipto Ganguly. *Johns Hopkins University, Baltimore, MD, United States*

Background V-set and Ig domain-containing 4 (VSIG4; also known as CRIg) is a myeloid-restricted complement receptor indispensable for phagocytosis of C3-opsonized bacteria. Being a B7-family member, Vsig4 has also been described as a negative regulator of T cell activation. Murine Vsig4 expression is restricted to tissue-resident macrophages and notably absent in tumor-infiltrating macrophages. In contrast, human Vsig4 expression is more promiscuous- observed on circulating monocytes, dendritic cells, and macrophages within the ovarian tumor micro-environment (TME). Importantly, Vsig4 expression in the TME correlates with increased tumor burden and poor prognosis. Whether Vsig4 signals through a T cell counter-receptor is unknown. Similarly, the immuno-regulatory effects on tumors by non-infiltrating VSIG4^{+} tissue-resident macrophages have not been studied.

Methods Tumor growth inhibition was assessed in vivo. Peritoneal, splenic and intra-tumoral macrophages were analyzed by flow cytometry. Single-cell RNA sequencing was performed on human ovarian tumor tissue and on murine melanoma.

Results Vsig4 was detected on both resting and thioglycolate-elicited peritoneal macrophages as well as liver-resident Kupffer cells with little to no expression in splenic macrophages. *In vitro* differentiation of bone marrow precursors to M1 or M2 macrophages showed no differential expression of respective hallmark genes (NOS2 and Fizz-1) between wild-type and Vsig4$^{-/-}$ precursors. Initially, our *in vivo* studies focused on the highly metastatic 4T1 model of breast cancer implanted orthotopically and found minimal Vsig4 expression (gene and protein) across different stages of tumor growth. However, when we implanted B16-F10 melanoma cells in VSIG4$^{-/-}$ mice, we observed robust tumor growth inhibition relative to wild-type mice. A similar phenotype was seen in bone marrow chimeras (myeloablated wild-type recipients of Vsig4$^{-/-}$ bone marrow), confirming the anti-tumor response was driven by the immune compartment. A dampened anti-tumor response in clodronate liposome-treated Vsig4$^{-/-}$ mice confirmed that the phenotype was dependent on macrophages. Yet, conditional deletion of Vsig4 in macrophages (using a LysM-cre delete and Vsig4$^{fl/fl}$ mice) did not phenocopy global knockouts when implanted with B16-F10 melanoma. *In vivo* Vsig4 expression kinetics revealed presence of Vsig4^{+} myeloid sub-populations in the bone marrow and liver of B16-F10 tumor-bearing mice with no early induction detected in the tumor or spleen.

Conclusions Vsig4 expression dynamics from myeloid progenitor to macrophage/ dendritic cell is being mapped. Transcriptomic/metabolic analyses of Vsig4+ myeloid populations from tumor-bearing mice will elucidate the temporal contribution of Vsig4 to immune regulation in cancer. Our goal is to develop Vsig4-targeting modalities targeting Vsig4 potentially in combination with PD-L1/1 and reset T-cell immunity in tumors.

Ethics Approval The study was approved by the Johns Hopkins OHSR-IRB (# IRB00287038). Participants gave informed consent before taking part.

All animal work was approved by the Animal Care and Use Committee (Protocol # MO22M67).

488 GNUV201, A NOVEL HUMAN AND MOUSE CROSS-REACTIVE PD-1 MONOCLONAL ANTIBODY FOR CANCER IMMUNOTHERAPY

Haemi Kim, Kyoung-Jin Kim, Myeong Jin Yoon, Jenny Choih*, Eun Ji Cho, Hak-Jun Jung, Kwanghyun Lee, Jayoung Kim, Chae Gyu Park, Sungho Han, Donggoo Bae, Heungrok Park. *Genuv, Seoul, Korea, Republic of*

Background Several PD-1 antibodies have been approved as anti-cancer therapies which work by blocking the interaction of PD-1 with its ligand PD-L1, thus restoring anti-cancer T cell activities. However, cross-reactive anti-PD-1 antibodies binding to both human and pre-clinically relevant animal models are still required to predict more precisely the efficacy and toxicity in humans, especially in various combination settings of anti-PD-1 with other treatments.

Methods Therefore, we have developed an anti-PD-1 named GNUV201, a highly selective and interspecies cross-reactive monoclonal antibody, with conventional hybridoma technology.

Results GNUV201 equally binds to mouse and human PD-1 (EC_{50}=32 pM and 28 pM, respectively), therefore successfully suppressed the growth of B16F10 (mouse melanoma) and MC38 (mouse colon cancer) in syngeneic mice models.

According to the results of co-crystal structure and alanine-scanning mutagenesis to examine the interaction mode between GNUV201 and human PD-1, the epitope recognized by GNUV201 is on the "FG loop" region of human PD-1, which is well conserved in both human and mouse PD-1, supporting GNUV201's interspecies cross-reactivity; this position is distinct from those of Keytruda ("C'D loop") and Opdivo (N-term). Notably, the structural feature in which the protruding epitope loop fits into GNUV201's binding pocket supports the enhanced binding affinity due to slower dissociation (8.5 times slower than Keytruda in SPR). Furthermore, GNUV201 shows a stronger binding affinity at pH 6.0 (KD = 0.9 nM at pH 6.0, 5.8 times smaller KD than at pH 7.4), which mimics more closely the hypoxic and acidic tumor micro-environments (TME), especially due to further improved K_{off} (32.8 times slower dissociation than Keytruda in SPR). This phenomenon is not observed with other anti-PD-1 competitors, implying that GNUV201 achieves selective binding to and better occupancy on PD-1 in tumors compared to its marketed competitors. GNUV201 was also shown to completely block the interaction of hPD-1 with hPD-L1 *in vitro* at similar single digit nM levels compared with Keytruda and Opdivo, which results in enhanced T cell proliferation and cytokine (IL-2 and INF-g) secretion.

Conclusions In summary, even though similar in vitro efficacy of GNUV201, we can expect GNUV201 to be an excellent antibody candidate with superior target occupancy due to its slow dissociation and preferential binding in low pH tumor microenvironments and whose efficacy and toxicity in the human system can be predicted from preclinical study results due to its human-mouse cross-reactivity.

489 NPX267, A FIRST-IN-CLASS MONOCLONAL ANTIBODY TARGETING KIR3DL3, BLOCKS HHLA2-MEDIATED IMMUNOSUPPRESSION AND POTENTIATES T AND NK CELL-MEDIATED ANTITUMOR IMMUNITY

[1]McKenna Lamb*, [2]Yao Wei, [2]Xiaoxin Ren, [1]Rachel O'Connor, [1]Austin Dulak, [1]Matthew Rausch, [1]Jamie Strand, [1]Bijan Etemad-Gilbertson, [1]Riale Gilligan, [1]Scott Chappel, [3]Tomonari Shigemura, [4]David McDermott, [3]Gordon Freeman, [2]XingXing Zang. *[1]NextPoint Therapeutics, Cambridge, MA, United States; [2]Albert Einstein College of Medicine, Bronx, NY, United States; [3]Dana-Farber Cancer Institute, Boston, MA, United States; [4]Beth Israel Deaconess Medical Center, Boston, MA, United States*

Background Killer cell immunoglobulin like receptor, three Ig domains and long cytoplasmic tail 3 (KIR3DL3) is a member of the killer cell Ig-like (KIR) receptor family and is expressed by both NK and T cells. KIR3DL3 has recently been shown to be a coinhibitory receptor for the B7 ligand, human endogenous retrovirus H long terminal repeat–associating protein 2 (HHLA2).[1,2] KIR3DL3, expressed on T and NK cells in the tumor microenvironment, suppresses immune responses following engagement with HHLA2. Upon HHLA2-induced KIR3DL3 activation, SHP-1 and SHP-2 are recruited to KIR3DL3's cytoplasmic immunoreceptor tyrosine-based inhibitory motif (ITIM) and downstream activation signals are blunted. As a result, T and NK cell activity is suppressed. HHLA2 has limited expression in normal tissues, but is highly expressed in many cancers and is often associated with poor patient outcomes. In renal cell carcinoma (RCC), HHLA2 expression is often not co-expressed with PD-L1. However, co-expression of HHLA2 and PD-L1 in tumors from patients with RCC is associated with worse progression free survival that those with tumors exclusively expressing PD-L1. Thus, the KIR3DL3-HHLA2 axis represents a novel immune checkpoint pathway and blockade of KIR3DL3 signaling may be a promising strategy to promote antitumor immunity.[3]

Methods To explore the therapeutic potential of HHLA2-KIR3DL3 blockade, we generated NPX267, a first-in-class, monoclonal antibody that binds with high affinity to human KIR3DL3.

Results NPX267 blocks HHLA2 engagement with KIR3DL3 on primary human NK and T cells in a dose dependent fashion. The ability of NPX267 to block KIR3DL3-mediated suppression of T cell activation was assessed with a T cell reporter system and primary $CD8^+$ T cell functional assays. KIR3DL3 blockade with NPX267 inhibited HHLA2-mediated suppression of T cell activation in a dose dependent manner. The anti-tumor activity of KIR3DL3 blockade with NPX267 was also demonstrated in NK-cell mediated cytotoxicity assays. NPX267 treatment augmented the ability of human NK cell lines and primary NK cells to kill $HHLA2^+$ tumor cells in vitro. Finally, NPX267 blockade of HHLA2 mediated KIR3DL3 signaling enhanced anti-tumor immunity in humanized mouse models bearing $HHLA2^+$ human tumors.

Conclusions Collectively, these data demonstrate that the KIR3DL3-HHLA2 pathway is a novel immune checkpoint axis that facilitates tumor escape by attenuating both innate and adaptive antitumor immune responses. NPX267, a first-in-class KIR3DL3 blocking antibody, potentiates anti-tumor immunity against $HHLA2^+$ tumors and may represent a promising approach to treat certain cancers.

490 GALECTIN-9 DRIVES TIM-3+ NATURAL KILLER CELL DYSFUNCTION IN HEAD AND NECK SQUAMOUS CELL CARCINOMA

[1]Lazar Vujanovic*, [1]Juncheng Wang, [1]Housaiyin Li, [2]Aditi Kulkarni, [2]Jennifer Anderson, [1]Lidia Arantes, [1]Hridesh Banerjee, [1]Lawrence Kane, [3]Xin Zhang, [1]Tullia Bruno, [1]Riyue Bao, [1]Robert Ferris. *[1]University of Pittsburgh, Pittsburgh, PA, United States; [2]UPMC Hillman Cancer Center, Pittsburgh, PA, United States; [3]Xiangya Hospital, Changsha, China*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0490

Background Natural killer (NK) cells are innate cytotoxic and immunoregulatory lymphocytes that play a critical role in tumor immunosurveillance. Their activation states are regulated by an interplay of activating and inhibitory surface receptors, including T-cell immunoglobulin and mucin-domain containing molecule 3 (TIM-3), an immune checkpoint receptor (ICR) that is expressed on terminally-differentiated NK cells. The role TIM-3 plays in the context of NK cell-mediated anti-tumor response remains evasive, partly because TIM-3 has four known ligands: galectin-9, phosphatidylserine, HMGB1 and CEACAM-1.

Methods In the context of head and neck squamous cell carcinoma (HNSCC), single-cell RNA sequencing and flow cytometry were implemented to study the prevalence, phenotypes and functional differences of TIM-3+ NK cells in patient tumors and blood. *In vitro* killing and proliferation assays were used to evaluate whether the four TIM-3 ligands differentially modulate TIM-3+ NK cell functions and whether abrogation of TIM-3/ligand interaction is a valid therapeutic strategy to enhance NK cell-mediated anti-tumor effector mechanisms. Finally, TCGA survival analysis and digital spatial profiling were employed to study the potential impact of etiology-associated differences on HNSCC patient survival.

Results We demonstrate that TIM-3 is the dominant NK cell ICR, that it marks dysfunctional NK cells in tumors but not in circulation, and that galectin-9 is the only TIM-3 ligand that consistently suppresses NK cell cytotoxic and proliferative capacity. Galectin-9-induced effects on cytotoxicity can be abrogated using the clinical-grade anti-TIM-3 blocking antibody, MBG453. Clinically, high intratumoral TIM-3+ NK cell gene signature associates with worse outcome in HPV+, but not HPV- HNSCC patients. This may be due to higher intratumoral galectin-9 protein expression in HPV+ HNSCC lesions, as well as higher frequencies of circulating and tumor-infiltrating TIM-3+ NK cells in HPV+ patients.

Conclusions Our data stress the importance of TIM-3 in the context of NK cells and suggest that targeting the TIM-3/galectin-9 pathway may be a cogent immunotherapeutic strategy to reinvigorate NK cell effector function in HPV+ HNSCC patients.

491 PRECLINICAL PHARMACOLOGY MODELING OF HX009, A CLINICAL STAGE FIRST-IN-CLASS PD-1XCD47 BSAB, FOR ANTI-LYMPHOMA APPLICATIONS

[1]Xiaoyu An, [2]Henry Li*, [2]Hang Ke, [1]Lingxin Xiong, [2]Faming Zhang, [1]Mingfa Zang, [1]Xiaolong Tu, [1]Jingjing Wang, [1]Demi Liu, [1]Cen Chen, [3]Cunxiang Ju, [3]Xianfei He, [2]Lei Zhang. *[1]Crown Bioscience Inc, San Diego, CA, United States; [2]Hanx Pharmaceuticals, Inc., Wuhan, China; [3]Shanghai Model Organisms Center, Inc., Shanghai, China*

Background The important immune checkpoint inhibitors (ICIs), e.g. PD1/PD-L1 and CD47/SIRPα blockers, have yet to be successful for the majority of non-Hodgkin's lymphoma (NHL), albeit efficacious in NK/T-cell and Hodgkin's lymphoma, as well as in many solid tumors. CD47 targeting in the clinic, predominantly for lymphoma and AML remains challenging due to reported toxicities (*e.g.* anemia/thrombocytopenia) as well as insufficient efficacy. Many important lymphomas, *e.g.* T-cell lymphoma, relapsed/refractory DLBCL etc., remain to be unmet medical needs, warranting new treatment options, particularly immunotherapies. We hypothesized that the dual targeting both innate (CD47) and adoptive (PD-1) immune check points with a bi-specific antibody (BsAb) can significantly enhance efficacy, and that the hematological toxicity can be minimized through specific engineering.

Methods HX009, a 2x2 symmetric BsAb molecule targeting PD1/CD47, was designed and constructed by grafting a low affinity $SIRP_{\alpha}$ to the 3' of Fc HX008 (anti-PD1 IgG1-Mab) frame with weakened CD47 binding. A series of *in vitro* characterizations on the target binding and functional blocking were performed, followed by *in vivo* pharmacology modeling using several preclinical lymphoma models (10mg/kg, twice weekly, i.p.), including subcutaneous xenograft (Karpas-299-T/Raji-B lymphoma), patient-derived lymphoma xenografts (PDXs), and humanized mouse syngeneic B-cell lymphoma A20 (HuGEMM^{TM} PD1Xcd47) . Tumor growth inhibition (TGI) was calculated by measuring tumor volume biweekly.

Results HX009 target binding, ligand blocking and biological effects were confirmed *in vitro*, with little binding to RBCs along as little hematological toxicity in the NHP studies due to the confirmed reduced affinity to CD47. All tested xenograft modeling using T-/B- cell lymphoma CDXs and PDXs revealed strong anti-lymphoma activity by HX009, which was solely attributed to the CD47 targeting due to the lack of T-cell immunity in the xenografts. The humanized syngeneic mouse B-lymphoma A20 model with the presence of competent autologous immune-system revealed that both single targeting, either PD1 (HX008) or CD47 (SIRPα), had anti-tumor activity, while the dual targeting of both by HX009 caused synergistic anti-tumor activity. Finally, a panel of fully annotated lymphoma PDXs were tested in order to discover potential predicative biomarkers.

Conclusions HX009 demonstrated strong preclinical anti-lymphoma activity of HX009, confirming the contributions from both targeting MOAs (CD47/PD1), as well the superior activity of dual targeting as designed, validating our hypothesis. A Phase I/II study for this first-in-class BsAb is ongoing in patients with relapsed/refractory lymphoma, including both B and T cell subtypes (ClinicalTrials.gov Identifier: NCT05189093).

492 SIRPα BLOCKADE RESULTS IN TUMOR INTRINSIC AND IMMUNE MICROENVIROMENT EFFECTS RESULTING IN THE INHIBITION OF BREAST-TO-BRAIN METASTATSIS

Elizabeth Stirling, Jessica Mackert*, Steven Bronson, Adam Wilson, Mitra Kooshki, Dawen Zhao, Pierre Triozzi, Glenn Lesser, David Soto-Pantoja. *Wake Forest School of Medicine, Winston-Salem, NC, United States*

Background Triple-negative breast cancer (TNBC) is a highly aggressive subtype of breast cancer characterized by a lack of specific targets and a 35% incidence of brain metastasis. There is no targeted treatment for managing brain metastasis associated with TNBC; therefore, new strategies are urgently needed to overcome disease mortality. The CD47/SIRPα signaling pathway is implicated in tumor progression due to bypassing innate and adaptive immune surveillance. Most strategies targeting this pathway focus on targeting the receptor CD47; however, targeting SIRPα as a potential strategy to mitigate metastatic tumor burden remains understudied.

Methods Breast cancer patient biopsies were stained with antibodies against SIRPα A Real-Time Cell Analysis (RTCA) impedance assay was used to determine migration, proliferation, and microglia-mediated cancer cell clearance changes. Female BALB/C mice were used in a TNBC brain metastasis model by intracardiac injection of the 4T1-Br3-Luc cell line. Brain metastatic burden was measured by the in vivo imaging system (IVIS) and quantified by luciferase luminescence. Differences in protein expression were measured by proteomic digital spatial profiling (DSP) of brain lesions and immune infiltrated regions of interest (ROIs).

Results Immunohistochemical staining of patient biopsies revealed a 3.5-fold increase in SIRPα expression in metastatic lesions compared to the primary tumor ($n=19$; $p \leq 0.0001$). Additionally, there was an 84% increase in SIRPα in brain-trophic 4T1-Br3 TNBC cells compared to 4T1 parental cells ($n=3$; $p \leq 0.05$). RTCA impedance assay revealed that SIRPα blockade inhibits brain-trophic 4T1-br3 cell migration (24h; $n=3$; $p \leq 0.05$) and proliferation (48h; $n=3$; $p \leq 0.05$) and promotes microglia-mediated cancer cell clearance ($n=3$; $p \leq 0.05$). Furthermore, SIRPα blockade reduced metastatic brain lesion formation *in vivo* by approximately 90%, determined by IVIS imaging ($n=4$-7; $p \leq 0.05$). DSP of the brain lesions revealed that immune checkpoints cluster of differentiation 152 (CTLA4), programmed cell death protein 1 (PD-1), programmed death ligand-1 (PD-L1), and cluster of Differentiation 276 (CD276 or B7-H3) were significantly reduced in anti-SIRPα treated brain lesions ($n=3$-6; $p \leq 0.05$). Furthermore, spatial profiling revealed that SIRPα blockade promotes pro-inflammatory microglia polarization in brain lesions ($n=3$-6; $p \leq 0.01$). Additionally, the extracellular matrix protein fibronectin, which contributes to invasion, metastasis, and immune evasion, was reduced by 70% in anti-SIRPα-treated brain lesions (n-3-6; $p \leq 0.05$).

Conclusions These data suggest that SIRPα blockade modulates immune and TNBC cells to limit metastatic spread. Therefore, targeting SIRPα may be a new immunotherapeutic strategy to treat TNBC brain metastasis.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0492

493 PH-804, AN INTASYL SELF-DELIVERING RNAI COMPOUND THAT TARGETS TIGIT ENHANCES NK CELL CYTOTOXICITY TO TUMOR CELLS

Melissa Maxwell*, Dingxue Yan, Brianna Rivest, Andrew Boone, Shenghua Zhou, Benjamin Cuiffo, James Cardia, Simon Fricker. *Phio Pharmaceuticals, Marlborough, MA, United States*

Background NK cells act as the body's first line of defense against cancer cells. They quickly recognize and kill tumor cells without prior exposure. Adoptive cell therapy (ACT) using NK cells shows promise against hematological cancers. Cytotoxic activity of these cells is restricted by inhibitory receptors that reduce NK cell-mediated cytotoxicity. Overcoming this inhibition would allow for a more potent antitumor response following ACT and potential application against solid tumors. We have developed a new class of stable, self-delivering RNAi compounds (INTASYL) that incorporate features of RNAi and antisense technology. INTASYL compounds demonstrate potent activity, stability, and are rapidly and efficiently taken up by cells. INTASYL PH-804 targeting the inhibitory receptor TIGIT enhances the cytotoxic activity of expanded human NK cells in vitro.

Methods Primary human $CD56^+$ NK cells were expanded using the ImmunoCult™ NK Cell Expansion Kit from StemCell Technologies. Following the 14-day expansion protocol, cells were collected, and the cell density was adjusted to 0.5 x 10^6 cells/mL in culture media containing IL-2. Cells were seeded directly into 24-well plates containing PH-804 ranging in final concentration from 1 μM to 5 μM. Taqman gene expression assays were used to determine expression levels of TIGIT following the RNA-to-Ct 1-step protocol. In addition, cells were stained using fluorescently labeled antibodies for flow cytometry. Cytotoxic capabilities of the PH-804 transfected NK cells against the K562 (Chronic Myelogenous Leukemia) cancer cell line were tested in a DELFIA cell cytotoxicity assay.

Results Transfection with PH-804 results in consistent mRNA and protein silencing without negative impact on NK cell viability. For example, treatment with 5 μM PH-804 results in a 60% reduction in TIGIT mRNA. The reduction is seen at >7 days post-transfection and results in a 45% reduction in surface expression of TIGIT by flow cytometry. Silencing of TIGIT with PH-804 resulted in increased expression of markers of NK cell activation and increased cytotoxic capabilities of NK cells against K562 cancer cells in the DELFIA cell cytotoxicity assay.

Conclusions Here, we demonstrate the potential of PH-804 to improve NK cell potency in ACT. By treating NK cells with INTASYL targeting the inhibitory receptor TIGIT ex vivo, during NK cell expansion, the anti-tumor response of these cells was enhanced potentially resulting in a more effective cell therapy for solid tumors and hematological malignancies.

494 CO-1: A NOVEL POTENT DUAL FUNCTION ANTI-CD47 ANTIBODY FOR CANCER THERAPY

Sittana Matar*, Seham Skah, Rolf Pettersen, Kjetil Hestdal, Nina Richartz. *Caedo Oncology, Oslo, Norway*

Background CD47 is a central part of the innate immune system through its interaction with signal regulatory protein alpha (SIRPα). This interaction is known as the "don't eat me" signal which inhibits cell phagocytosis by innate immune cells.[1,2] Cancer cells often evade recognition by the hosts' immune cells through overexpression of CD47, and several anti-CD47 monoclonal antibodies (mAbs) are undergoing development to inhibit this interaction.[3] Some anti-CD47 mAbs have been shown to have potential as treatment of human malignancy, but generally only in combination with other chemotherapeutic agents as their functionality primarily is due to the inhibition of the phagocytic signal.[1,4] Here, we characterize CO-1, a novel bifunctional anti-CD47 mAb that is capable of eradicating cancer cells through direct induction of programmed cell death (PCD) as well as by enhancing cancer cell phagocytosis.

Methods The binding properties of CO-1 to a wide range of cancer cell lines derived from solid and hematological tumors was determined by incubating the cells to FITC-conjugated antibodies, followed by flow cytometry analysis. The induction of PCD after treatment with different anti-CD47 mAbs at different time points was determined by Annexin V staining.[5]

The enhancement of tumor cell phagocytosis induced by CO-1 was determined by co-culturing DiO-labelled RAW264.7 macrophages with CFSE-labelled target cell lines. Double-positive DiO-RAW264.7 and CFSE-target cells indicated phagocytosed cells.

Xenograft models were established by injecting lentivirally transduced cancer cells into NOD-*scid* IL2Rγ^{null} (NSG) mice. The lentiviral vector contained sequences for firefly luciferase and enhanced green fluorescent protein.[6]

Results CO-1 binds to cancer cells with high efficiency and induces rapid (within 3 hours) and profound cell death in several cell lines derived from human hematological and solid tumors. No direct correlation was evident between CD47 expression and PCD response. In a xenograft model of B cell precursor acute lymphoblastic leukemia (BCP-ALL) in NSG mice, the mice were rapidly cured of their tumor even after only two injections of CO-1 as monotherapy. This demonstrates the PCD potency of CO-1 towards human tumor cells directly. Next, we determined the ability of CO-1 to block the "don't eat me" interaction and found that CO-1 potently and significantly enhanced tumor cell phagocytosis, even in cell lines that previously had responded less favorably with PCD to CO-1 treatment.

Conclusions CO-1 is a new and unique bifunctional anti-CD47 mAb that eradicates cancer cells by two mechanisms of action: 1)by direct induction of PCD, and 2)by enhancing cancer cell phagocytosis.

495 BYON4228, A PAN-ALLELIC SIRPα BLOCKING ANTIBODY WITH A FAVORABLE PRE-CLINICAL SAFETY PROFILE, ENHANCES ANTI-TUMOR IMMUNITY IN VITRO AND IN VIVO

[1]Mary van Helden*, [1]Roel Arends, [1]Seline Zwarthoff, [1]Monique van der Vleuten, [1]Marc Paradé, [1]Karin de Laat-Arts, [2]Hugo Olsman, [1]Ellen Mattaar, [1]Dirk Glaudemans, [1]Daniëlle van Wijk, [1]Lilian Driessen-Engels, [1]Inge Reinieren-Beeren, [1]Paul Boersema, [1]Eva Hanckmann, [1]Gerard Rouwendal, [1]Ruud Ubink, [1]Miranda van der Lee, [1]Gijs Verheijden, [1]Wim Dokter, [1]Timo van den Berg. [1]*Byondis, Nijmegen, Netherlands*; [2]*Sanquin Research, Amsterdam, Netherlands*

Background Preclinical data have established CD47-SIRPα interactions as a myeloid immune checkpoint in cancer, which is corroborated by preliminary evidence from the first clinical studies with CD47 blockers.

Methods However, the ubiquitously expressed CD47 mediates functional interactions with other ligands as well, and therefore targeting of the primarily myeloid cell-restricted inhibitory immunoreceptor SIRPα may represent a better strategy.

Results Here, we present preclinical results on a novel clinical candidate, BYON4228. BYON4228 is an antibody directed against SIRPa and recognizes both of the common allelic variants of human SIRPα which maximizes its potential clinical application in the broad human population. Notably, in contrast to several other anti-SIRPα antibodies in development, BYON4228 does not recognize the closely related T cell-expressed SIRPγ that has been reported to mediate interactions with CD47 as well, which are known to be instrumental in T cell extravasation and activation. BYON4228 binds to the N-terminal part of SIRPα and its epitope overlaps with the CD47-binding site. BYON4228 therefore prevents binding of CD47 to SIRPα and thus blocks inhibitory signaling through the CD47-SIRPα axis. Functional studies show that BYON4228 potentiates both macrophage- and neutrophil-mediated elimination of hematologic and solid cancer cells *in vitro* in the presence of several different tumor targeting antibodies like trastuzumab, rituximab, daratumumab and cetuximab, illustrating the broad potential clinical benefit and application of BYON4228. BYON4228 enhanced the efficacy of rituximab treatment *in vivo* when administered to human Non-Hodgkin lymphoma (NHL)-engrafted transgenic mice with a selective expression of huSIRPα$_{BIT}$ on myeloid cells (huSIRPα$_{BIT}$-scid mice). Single intravenous infusion of up to 100 mg/kg BYON4228 to male and female cynomolgus monkeys was well tolerated and did not elicit any adverse effects.

Conclusions Collectively, this defines BYON4228 as a pan-allelic anti-SIRPα antibody without T cell SIRPγ recognition that promotes the destruction of antibody-opsonized cancer cells. Clinical studies are planned to start in 2022.

Ethics Approval Appropriate ethics approvals were present before commencing studies in vivo.

496 HCB101: A SAFE AND EFFECTIVE LIGAND TRAP THERAPEUTIC TARGETING THE CD47-SIRPA SIGNALING PATHWAY FOR CANCER TREATMENT

Jiin-Tarng Wang, Chi-Ling Tseng, Han-Feng Teng, Pan-Hsien Kuo, Yun-Chih Cheng, Yi-Jing Chen, Yi-Hsuan Lu, Tsai-Kuei Shen, Hong-Fan Wang, Pei-Lun Tsai, Yu-Chen Wu, Chien_Hsin Ho, Wei-Tse Sun, Yen-Cheng Li, Yi-Hsuan Lee, Zong Sean Juo*. *HanchorBio Inc., Taipei, Taiwan*

Background Macrophages patrol intercellular spaces mainly through their receptor SIRPa, which interacts with CD47 on target cells. Such interaction elicits a 'do not eat' signal and spares the target cell from being phagocytosed. Many cancers take advantage of this mechanism via overexpressing CD47 to evade immune surveillance. Therefore, blocking SIRPa-CD47 interaction represents a promising approach for anti-cancer therapy. Numerous anti-CD47 antibodies and SIRPa fusion proteins have been developed with therapeutic potential, but their clinical progress was hindered by either severe side effects or lack of appreciable efficacy. To overcome this deficiency, we aim to produce a SIRPa-fusion biologic that exhibits superior efficacy against multiple hematological and solid malignancies while maintaining good safety profiles and protein stability.

Methods Using display technology combined with structure-guided protein engineering, we identified several SIRPa mutants that exhibited significant CD47-blocking activities and phagocytosis against tumor cells while minimizing side effects on CD47-expressing normal cells. To assess the impact of CD47 blockade on macrophages within the tumor microenvironment, these novel mutants were evaluated in multiple human tumor xenograft mouse models and compared with selected anti-CD47 monoclonal antibodies and/or SIRPa fusion proteins currently being investigated in clinical trials. The leading candidates were further analyzed for their respective CMC profiles to ensure good protein stability and straightforward manufacturability.

Results In comparison with prominent clinical candidates targeting the CD47 pathway (Magrolimab, TTI-622, ALX148, TJC4, IMM01), HCB101 demonstrated superior or compatible CD47-blocking activities; meanwhile, it triggered strong phagocytosis against tumor cells but not red blood cells. In all 7 human tumor xenograft NOD/SCID mouse models that we investigated, HCB101 consistently showed excellent efficacy against hematological and solid tumors as monotherapy, with tumor growth inhibition index (TGI) ranging from 60-100% at the dose of 0.5-10mg/kg over placebo. We observed an increase in the M1/M2 macrophage ratio and a reduction of CD24 expression in certain cases after the treatment with HCB101. This could partially account for its superior anti-tumor efficacy. There was no apparent adverse reaction observed during the exploratory cynomolgus monkey toxicology studies, suggesting a good safety profile of HCB101.

Conclusions Compared to relevant clinical candidates, HCB101 exhibits superior efficacy in 7 different CDX models of hematological and solid malignancies while maintaining good safety profiles. A highly effective blockade of the CD47-SIRPa pathway by HCB101 leads to robust pre-clinical results. Moreover, it exhibits outstanding protein stability and manufactural characteristics for large-scale production. Clinical development of HCB101 is currently underway both as monotherapy and in combination.

497 EVALUATION OF THE TIGIT+ IMMUNE SUBSET DEPLETION EFFECT OF THE ANTI-TIGIT ANTIBODY M6223

[1]Chunxiao Xu*, [1]Sireesha Yalavarthi, [1]Clotilde Bourin, [1]Jacques Moisan, [2]Andree Blaukat, [2]Laura Helming. *[1]EMD Serono, Billerica, MA, United States; [2]The Healthcare Business of Merck KGaA, Darmstadt, Germany*

Background T cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domains (TIGIT) is an inhibitory receptor expressed on lymphocytes and has recently emerged as a target in cancer immunotherapy. M6223 is a fully human antagonistic anti-TIGIT antibody in immunoglobulin (Ig) G1 format with Fc-mediated effector function. Preclinical studies demonstrated that M6223 can induce an anti-tumor immune response by complementary mechanisms, including but not limited to: direct blockade of the TIGIT pathway; stimulation of costimulatory receptor CD226 dimerization/activation; and depletion of TIGIT+ immune subsets by Fc-mediated effector function. This study was designed to understand the mechanism of action of the depletion effect.

Methods The TIGIT+ immune subset depletion effect of M6223 in the tumor microenvironment (TME) was investigated in humanized TIGIT knock-in mice using a flow cytometry assay. The anti-tumor efficacy of two chimeric M6223 antibodies, one with an effector competent mouse IgG2c constant region (M6223-muIgG2c) and the other with an effector null mouse IgG1-D256A constant region (M6223-muIgG1), was investigated in syngeneic tumor models in humanized TIGIT knock-in mice.

Results M6223 dose-dependently depleted TIGIT+ immune subsets in the TME at day 1 post-treatment, but had no significant effect on total infiltrated CD8+ T cells and natural killer (NK) cells. The depletion effect gradually weakened over time but remained at day 7 and day 14. M6223 treatment stimulated CD8+ T cell and NK cell infiltration and boosted CD226 expression at day 7 and day 14 post treatment. The ratio of CD226 to TIGIT was significantly increased in immune subsets at all time points tested. Further studies demonstrated that only M6223 surrogate with effector function could deplete TIGIT+ immune subsets at day 1; the effector null version of M6223 slightly decreased TIGIT-expressing immune subsets on day 7 and day 14. In addition, this effector null surrogate version of M6223 did not have anti-tumor efficacy in syngeneic tumor models in humanized TIGIT knock-in mice.

Conclusions The results demonstrate that innate depletion of TIGIT+ immune subsets by Fc-mediated effector function plays an important role in anti-tumor immunity and suggest that immune pharmacodynamics in clinical trials should be closely monitored at early time points. Currently, M6223 is being evaluated in combination with avelumab as first-line maintenance therapy for advanced urothelial carcinoma in the phase 2 JAVELIN Bladder Medley umbrella trial (NCT05327530).

498 PRECLINICAL CHARACTERIZATION OF OR502, AN ANTI-LILRB2 ANTIBODY THAT RESCUES INNATE AND ADAPTIVE IMMUNE RESPONSES FROM LILRB2 MEDIATED IMMUNE SUPPRESSION

Meghan Zuck*, Myriam Bouchlaka, Huyen Dinh, Kevin Green, Meilyn Sylvestre, Francisco Zapata, Ramya Chandrasekaran, Gajendra Naika, Lauren Loh, Ray Fox, Darbie Whitman, Tom Graddis, Kamal Puri, Peter Probst. *OncoResponse, Seattle, WA, United States*

Background The inhibitory receptor leukocyte immunoglobulin-like receptor subfamily B member 2 (LILRB2, ILT4) is expressed on immunosuppressive myeloid cells and expression correlates with poor survival in multiple cancers and contributes to anti-PD1 resistance. Interaction of LILRB2 with HLA class I ligands (e.g., HLA-G, HLA-A, etc.) mediates immune suppression by myeloid cells and promotes tumor immune evasion in the tumor microenvironment (TME). Blocking this interaction may enhance efficacy of T cell checkpoint inhibitors. Antibodies targeting LILRB2 are currently being evaluated in clinical trials for the treatment of cancer.

Methods Anti-LILRB2 antibodies were cloned from B cells derived from rabbits immunized with human LILRB2 recombinant protein. Clones were humanized after selection based on activity in a panel of functional and phenotypic assays using primary human macrophages and T cells. Humanized variants were screened for their ability to rescue T cell activity (proliferation and IFN-γ) from M2c macrophage-mediated suppression and enhance LPS-induced IFN-γ production by PBMCs. The top variants were also evaluated for cytokine release in whole blood. The pharmacokinetic profiles of lead LILRB2 antibodies were determined in humanized FcRn mice.

Results We have identified a panel of humanized anti-LILRB2 antibodies that specifically bind to human LILRB2-expressing cell lines and human myeloid cells without detectable binding to other LILRA or LILRB family members. These antibodies block LILRB2 interaction with HLA-G expressed on tumor cells. The lead antibody, OR502, enhanced LPS-induced IFN-γ production by PBMCs, and relieved M2c macrophage-mediated suppression of proliferation and IFN-γ secretion by anti-CD3-activated human $CD8^+$ T cells in coculture assays. Furthermore, OR502 restored the ability of exhausted T cells to secrete IFN-γ in the presence of M2c macrophages and significantly enhanced the activity of pembrolizumab in combination studies. OR502-treatment did not trigger inflammatory cytokine release or activation of neutrophils in human whole blood. The pharmacokinetics of OR502 in humanized FcRn mice demonstrated a half-life of 6-10 days.

Conclusions We have identified a novel humanized anti-LILRB2 antibody, OR502, that restores innate and adaptive immune responses by modulating immunosuppressive myeloid cells. These data provide a strong rationale for further development of OR502 for cancer treatment.

499 THE SMALL MOLECULE PD-L1 INHIBITOR CCX559 PREFERENTIALLY ACCUMULATES IN TUMORS, RESULTING IN DEPLETION OF CELL-SURFACE PD-L1 IN A MURINE PRECLINICAL MODEL

Kathleen Sullivan*, Linda Ertl, Zhenhua Miao, Pingchen Fan, Yibin Zeng, Carolyn Dunlap, Karen Ebsworth, Suprit Gupta, Shijie "Chris" Li, Ton Dang, Shichang Miao, Israel Charo, Thomas Schall, Penglie Zhang. *ChemoCentryx, San Carlos, CA, United States*

Background The small molecule CCX559 is a novel, highly potent inhibitor of human PD-L1 (hPD-L1) in development as an oral treatment for cancer patients.[1,2] *In vitro* studies showed that CCX559 inhibits PD-L1 binding to PD-1 and induces PD-L1 internalization from the cell surface. To investigate the mechanism of action *in vivo*, we examined the effect of CCX559 distribution and clearance on tumor cell PD-L1 dynamics and anti-tumor activity.

Methods CCX559 was administered orally at the clinically relevant dose of 30 mg/kg once daily for 7 days to human PD-L1 knock-in mice bearing MC38 tumors (average volume 60-100 mm^3). The MC38 cells were engineered to express hPD-L1, as CCX559 does not cross-react with mouse PD-L1. CCX559 levels in tumors and organs, including lung, liver, kidney, spleen, heart, and brain, were quantitated by mass-spectrum analysis at 1, 5 and 12 days after the last dose. Cell surface and intracellular PD-L1 were detected using flow cytometry and immunohistochemistry.

Results Dosing CCX559 for 7 days significantly reduced hPD-L1-MC38 tumor growth compared to vehicle control, and the reduction in tumor volume persisted post dosing until the end of study. The average CCX559 level on day 1 post dose was significantly higher in tumors than plasma and other organs (27.9 µg/g tissue vs. 0.007 – 1.4 µg/g). In tumors CCX559 induced hPD-L1 internalization into intracellular vesicles and reduced the cell surface level by over 90% compared to vehicle control. CCX559 levels dropped 98% in plasma, tumor and tissues by day 5 post dose, but the level in the tumors was still above the IC_{90} for inhibiting PD-L1; consistent with this, intracellular PD-L1 was also observed. The drug was completely cleared by day 12 post dose, but tumor cell surface hPD-L1 in the CCX559 arm was only partially recovered compared to the vehicle control.

Conclusions In a preclinical model, higher levels of CCX559 were observed in tumors than in plasma and other organs. Cessation of dosing led to clearance of CCX559 within days, but recovery of tumor cell surface PD-L1 levels was delayed, perhaps as a result of higher CCX559 levels in the tumor. The *in vivo* properties of CCX559 suggest that PD-L1 inhibition in tumors may be achieved at relatively low drug levels in the periphery, thus mitigating potential risk of adverse events. No DLTs, treatment-related SAEs or severe (Grade 3 or higher) AEs have been reported in an ongoing first-in-human dose escalation trial with CCX559 (ACTRN12621001342808).

500 **INV322, A TME SELECTIVE CD25 X CTLA4 BISPECIFIC ANTIBODY APPROACH FOR DEPLETION OF TUMOR RESTRICTED TREGS**

[1]Anna Ritter*, [1]Nicholas Marshal, [1]Dileep Pulukkunat, [1]Nikhil Pereira, [2]Alexander Rakhmilevich, [1]Joseph Gawdzik, [1]Jessica Wiwczar, [1]Jason Russell, [1]Laura McCormick, [1]Catherine Aversa, [2]Paul Sondel, [1]Hilario Ramos, [1]Bonnie Hammer, [1]Daniel Pereira. *[1]Invenra, Madison, WI, United States; [2]University of Wisconsin, Madison, WI, United States*

Background Tregs maintain immune homeostasis in healthy individuals by limiting excessive or aberrant immune responses to environmental or self-triggers. In the context of tumor immunity, Tregs are associated with increased tumor progression, poor patient prognosis, and limited responsiveness to immunotherapeutic approaches. Targeting of Tregs has shown promise in the clinic, though current approaches are limited by on-target, off-tumor induction of autoimmune related toxicities associated with global Treg blockade. To overcome these toxicities and improve efficacy, Invenra has generated INV322, a bispecific antibody designed to preferentially engage tumor microenvironment (TME) Tregs. By targeting Treg co-expressed targets, CD25 and CTLA-4 with lower-affinity monovalent interactions, INV322 is designed to drive avidity only in the presence of dual target engagement to support selective blockade of Treg function and depletion by Fc-mediated clearance.

Methods INV322 is a human-targeted bispecific antibody, engineered using Invenra's fully human B-Body® platform with a wild-type IgG1 for Fc-gamma-mediated effector function. Specificity of INV322 to CD25 and CTLA-4 was evaluated using both solid phase and cell-based read-outs. Potency of INV322 was evaluated by flow cytometry *in vitro* on overexpression cell lines and iTregs via NK-mediated cytotoxicity assays. A surrogate molecule, INV323, with specificity to murine CTLA-4 and CD25 was generated to evaluate *in vivo* potency in murine solid tumor models.

Results INV322 demonstrated selective lower-affinity monovalent binding to cells expressing CTLA-4 (single-digit-nM) and CD25 (triple-digit nM) independently. However, when bound to cells expressing both targets, these monovalent affinities result in combined avidity and result in improved sub-nM binding of INV322 to these cells. The strength of the avid binding was associated with improved Fc-mediated depletion as the potency of INV322 was increased on engineered lines expressing both targets compared with cell lines expressing single targets. *In vivo* evaluation of INV323 demonstrated Fc-dependent anti-tumor activity, and additive effects in combination with anti-PD-1 treatment after single – dose administration. The tumor-protective activity observed was associated with establishment of anti-tumor memory and correlated to Treg depletion and an increase in the Teff:Treg ratio within the TME.

Conclusions INV322 is an innovative bispecific approach for the selective depletion of tumor resident Tregs. The unique binding profile is designed to direct selective engagement of Tregs within the TME, providing a novel avenue for potential improvement of therapeutic index and patient outcome as compared to current Treg modulating therapeutics. IND-enabling activities are underway with INV322.

Ethics Approval All animal studies were reviewed and approved under Invenra's IACUC protocol (I-RP-A-07).

501 ANTI-PDL2 USES IL17-DRIVEN INTERFERON-GAMMA TO TREAT AGED BUT NOT YOUNG CUTANEOUS MELANOMA-BEARING MICE, AND TREATS OTHER TUMORS IN AN AGE- AND TME-DEPENDENT MANNER

[1]Myrna Garcia, [1]Yilun Deng, [1]Clare Murray, [1]Carlos Ontiveros, [1]Alvaro Padron, [2]Sladjana Skopelja-Gardner, [3]Kah Teong Soh, [3]Dhan Chand, [4]Tyler Curiel*. *[1]UT Health San Antonio, San Antonio, TX, United States; [2]Dartmouth, Lebanon, NH, United States; [3]Agenus, Lexington, MA, United States; [4]Dartmouth Health, Lebanon, NH, United States*

Background Immune checkpoint blockade (ICB) with αPD1, αPDL2, αCTLA4 and αLag3 is FDA-approved but agents fail to treat up to ~80% of all cancers. PDL2 is a second PD1 ligand[1] but little is reported on αPDL2 cancer immunotherapy.[2] Age is the biggest risk for cancer, yet little few age affects on ICB are reported.[3] We previously reported that αPD2 treats melanoma in aged but not young mice.[4] Here we provide mechanistic insights, outcomes in other cancers and human data.

Methods We tested αPDL2 ICB and mechanisms in WT, $IFN\gamma^{KO}$ and $IL17^{KO}$ mice in B16F10 (B16) and Nras mutated melanomas, ID8agg ovarian cancer and MB49 bladder cancer. We tested αPD-L2 in aged (18-33 months) and young (3-8 months) mice. Tumors were analyzed by flow cytometry plus UMAP. Human PBMC and tumor samples were from commercial and institutional sources. TCGA data were mined.

Results αPDL2 ICB was ineffective in young mice with transplanted SQ B16 or NRAS-mutated melanoma, but remarkably effective in both in aged. αPDL2 efficacy was host IFNγ-dependent as expected, but also unexpectedly host IL17-dependent, which induced IFNγ. αPDL2 promoted IFNγ production by $CD8^+$, $CD4^+$ and γδ T cells and induced Treg fragility[5] all in a host IL17-dependent manner. A cellular IL17 source for αPDL2 efficacy, mechanism for age-related IL17-driven IFNγ and contributions from Treg fragility are under study but not yet established. αPDL2 failed to treat transplanted orthotopic ovarian cancer in young or aged, but treated young mice bearing transplanted heterotopic, SQ bladder cancers, demonstrating αPDL2 is not efficacious only in aged or melanoma and that young skin is not necessarily hostile to αPDL2. TCGA data showed IL17 and PDL2 expression significantly increases by age in all cancers generally and specifically in melanomas. PDL2 protein increase by age was confirmed in human PBMC and primary tumors in $lin^-DR^+CD141^+$ cDC1 but not on cDC2, plasmacytoid DC or other myeloid cells, T cells or B cells by flow cytometry. Both TCGA and flow data sets corroborated mouse data.

Conclusions αPDL2 is effective in aged but not young melanoma-bearing hosts and requires IL17 for efficacy. IL-17 is necessary for improved IFNγ production which is a likely αPDL2 efficacy mechanism. αPDL2 is a promising ICB approach meriting additional studies of mechanisms and effects on distinct tumors and TME. As age effects were confirmed in humans, it could be especially useful in aged hosts, or selected ICB failures (*e.g.,* αPDL1) as we previously reported.[4]

502 TRANSPLANT ONCOLOGY: UTILIZATION OF IMMUNOTHERAPY IN THE PERI-TRANSPLANT SETTING

[1]Maen Abdelrahim*, [1]Abdullah Esmail, [2]Ala Abudayyeh, [3]Ashish Saharia, [3]R Mark Ghobrial. *[1]Houston Methodist Neal Cancer Center, Houston, TX, United States; [2]MD Anderson Cancer Center, Houston, TX, United States; [3]JC Walter Jr Center for Transplantation, Houston, TX, United States*

Background Transplant oncology is an emerging concept of cancer treatment with a promising prospective outcome. The application of oncology, transplant medicine, and surgery to improve patients' survival and quality of life is the core of transplant oncology. Hepatobiliary malignancies have been treated by liver transplantation (LT) with significantly improved outcomes. The indications of LT for hepatobiliary malignancies have been slowly expanded over the years in a stepwise manner; however, they have only been shown to improve patient survival in the setting of limited systemic therapy options. Recently, the use of anti-programmed cell death protein 1 and programmed cell death ligand 1 (PD-1 and PD-L1) checkpoint inhibitors in the treatment of cancers have evolved rapidly and these therapies have been approved for the treatment of HCC. Immune checkpoint inhibitors have resulted in good clinical outcomes in pre-and post-transplant HCC patients, although, some reports showed that certain recipients may face rejection and graft loss.

Methods In this abstract, we aim to illustrate and summarize the utilization of immune checkpoint inhibitor therapies in pre-and post-liver transplants for HCC patients and discuss the assessment of immune checkpoint inhibitor regulators that might determine liver transplant outcomes.

Results The ICPI therapies have tolerable side effects and excellent responses in the treatment of cancer patients as well as pre-transplant patients in the bridging therapy setting. In contrast, for post-transplant patients in the palliative setting, the existing data have eliminated the contraindication of using ICPIs in liver transplant patients. However, the main concerns about organ rejection in liver transplant patients who will be treated with ICPIs are still the same in both pre-and post-transplant setting.

Conclusions The decision to administer ICPI treatment in liver transplant patients should be made on a case-by-case basis according to the goal of care and the availability and efficacy of other treatment options. Biopsies of liver allografts might be used to predict rejection and decide the proper ICPI class to be used based on PD-1/PDL-1 expression, however, larger and prospective studies are missing to support this conclusion. The role and type of immunosuppression in the setting of peri-transplant use of ICPI are not defined yet whether one kind can be safer than others is yet to be decided. ICPI treatment is an evolving and promising therapeutic option in oncology. Further investigations of these agents in the pre-and post-transplant settings are highly needed.

503 CYTOTOXIC REVIVAL IS IMPLICATED IN RESPONSE TO NEOADJUVANT PD-1 BLOCKADE FOR HEAD AND NECK SQUAMOUS CELL CARCINOMA

[1]Alexander Afeyan*, [1]Giacomo Oliveira, [2]Ann Marie Egloff, [1]Zexiang Zeng, [3]Rebecca Chernock, [1]Liye Zhou, [1]Cameron Messier, [1]Patrick Lizotte, [1]Jacquelyn Wolff, [1]Kathleen Pfaff, [1]Kari Stromhaug, [2]Robert Haddad, [1]Glenn Hanna, [2]Jonathan Schoenfeld, [2]Laura Goguen, [2]Donald Annino, [2]Vickie Jo, [3]Peter Oppelt, [3]Patrik Pipkorn, [3]Ryan Jackson, [3]Sidharth Puram, [3]Randal Paniello, [3]Jason Rich, [1]Jason Webb, [1]Jose Zevallos, [3]Mena Mansour, [1]Jingxin Fu, [4]Gavin Dunn, [2]Scott Rodig, [3]Jessica Ley, [5]Luc Morris, [5]Lara Dunn, [1]Cloud Paweletz, [3]Dorina Kallogjeri, [3]Jay Piccirillo, [3]Douglas Adkins, [1]Catherine Wu, [1]Ravindra Uppaluri. *[1]Dana-Farber Cancer Institute, Boston, MA, United States; [2]Brigham and Women's Hospital, Boston, MA, United States; [3]Washington University School of Medicine, St. Louis, MO, United States; [4]Massachusetts General Hospital, Saint Louis, MO, United States; [5]Memorial Sloan Kettering Cancer Center, New York, NY, United States*

Background Pre-operative immunotherapy results in pathologic tumor responses (pTR) for some patients with head and neck squamous cell carcinoma (HNSCC), but response mechanisms remain poorly defined.[1,2] We evaluated T cell profiles and clonal dynamics associated with pTR in a phase II trial of two doses of neoadjuvant pembrolizumab.

Methods 29 patients with stage III/IV HPV-unrelated HNSCC were enrolled in a multicenter phase 2 clinical trial of anti-PD-1 antibody pembrolizumab (2 doses, Q3 weeks) as neoadjuvant immunotherapy over 5 weeks prior to surgery. pTR to PD-1 blockade was assessed based on histologic reduction of tumor cell-fraction, as previously published, with responders defined as pTR of >10%.[1] We profiled tumor-infiltrating lymphocytes (TILs) from 14 tumor biopsies from 4 Responders (Rs) and 4 Non-Responders (NRs), collected either before or after PD-1 blockade through single-cell RNA (scRNA-seq) and T-cell receptor sequencing (scTCR-seq). Quality and quantity of TILs were assessed with multiplex immunofluorescence. Data were validated via comparison with a similar cohort of 36 HNSCC patients receiving single-dose neoadjuvant pembrolizumab.[1]

Results pTR was detected in surgical specimens from 15 patients (53%), with two-year overall survival (OS) and progression-free survival (PFS) rates of 92.2% (95% CI: 72.1-97.9) and 92.3% (95% CI: 72.6-98.0%), respectively. Single-cell analysis of CD8+ TILs identified 12 transcriptionally-defined clusters. The microenvironment of Rs compared to NRs showed higher pre-treatment frequencies of exhausted TILs (T_{Ex}-TILs) ($p<0.0001$, figure 1a), which were more clonally expanded and expressed a previously-defined gene signature associated with tumor-specificity.[3] R T_{Ex}-TILs were dominated by T_{TE}-CTX, a subpopulation with characteristics of cytotoxicity and high expression of *ZNF683*, suggesting a tissue-resident memory (TRM) program.[4,5] Multiplex immunofluorescence of pre-treatment biopsies confirmed that Rs were more highly infiltrated with CD3+ TILs with a TRM phenotype, identified through CD103 co-expression (figure 1b).[4 6 pTR following PD-1 blockade was associated with contraction of highly cytotoxic T_{TE}-CTX clones and likely unleashing of their antitumor activity (figure 1c). Within this timeframe, immunotherapy response was predominantly attributable to activity of pre-existing CD8+ TIL clones, while phenotypic revival of persisting clones and clonal replacement were modest. For NRs, the baseline microenvironment exhibited a relative absence of *ZNF683*+CTX+ TILs with post-therapy accumulation of extremely exhausted clones lacking evidence of post-therapy reinvigoration.

Conclusions A larger pre-treatment proportion of T_{Ex}-TILs retaining cytotoxic potential and a TRM signature are associated with pTR in HNSCC. Expanded T_{TE}-CTX clones were diminished in number after immunotherapy treatment, consistent with release of their anti-tumor activity and subsequent contraction due to antigen clearance.

504 **PVRIG, A NOVEL T CELL CHECKPOINT, IS PREFERENTIALLY EXPRESSED IN TLS ON STEM-LIKE MEMORY T CELLS, POTENTIALLY INHIBITING THEIR EXPANSION**

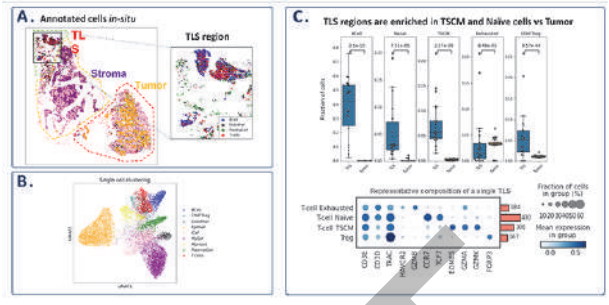
[1]Zoya Alteber, [1]Roy Granit, [1]Gady Cojocaru, [1]Amit Novik, [1]Niv Sabath, [1]Assaf Wool, [1]Yossef Kliger, [2]Yu Liang, [3]Natalia Petrenko, [3]Jiang He, [1]Pierre Ferre, [1]Yaron Turpaz, [1]Zurit Levin, [1]Eran Ophir*. *[1]Compugen Ltd., Holon, Israel; [2]Compugen USA Inc., South San Francisco, CA, United States; [3]Vizgen Inc., Cambridge, MA, United States*

Background Tertiary lymphoid structures (TLS) recently emerged as an intra-tumoral niches of immune-cell aggregates with a predictive value for cancer immunotherapy responses.[1] LAMP3$^+$DCs in the TLS were shown to interact and support the differentiation of stem-like CD8 T-cells into effector-like cells, that then expand in the tumor micro-environment (TME) and may exert anti-tumor responses.[2] We investigated the expression of DNAM-1 axis genes: PVRIG, TIGIT, DNAM-1 and their ligands PVRL2 and PVR in the TME.[3]

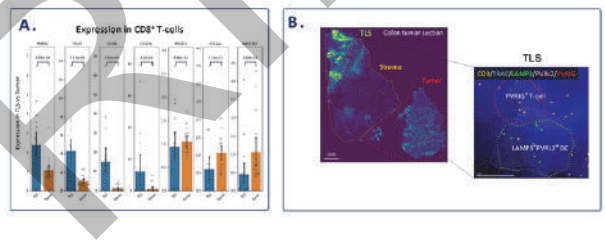
Methods MERFISH technology was employed to detect the expression of 350 distinct mRNA transcripts at sub-cellular resolution in CRC sections. Publicly available TME scRNA-seq datasets were analyzed for expression of PVRIG and PVRL2 across immune populations and validated by flow-cytometry. An extensive omics profiling was performed for patients with pre- and on-treatment biopsies from COM701 (anti-PVRIG antibody) and COM701+nivolumab Phase-1 study (NCT03667716).

Results Spatial distribution of gene transcripts allowed identifying localization of stem-like T-cells in TLS regions of two CRC patients (figure 1, $p<0.001$). While, CTLA-4, PD-1, and TIM3 were mainly expressed by tumor infiltrating T cells, PVRIG and other genes of DNAM-1 axis were also largely expressed in tumor bed, and even more intensely in TLS ($p<0.05$, figure 2). Furthermore, high resolution unsupervised scRNA gene co-expression analysis in the TME further validated that while PD-1 is strongly correlated with TIM3, CTLA-4, and other markers of exhausted T-cells, PVRIG uniquely clusters with markers of stem-like T-cells. The PVRIG protein expression was increased on CD28+ stem-like T-cells across indications (figure 3). RNA and protein expression data identified PVRL2, PVRIG ligand, preferentially expressed across DC-subtypes compared to PD-L1 and PVR (figure 4). PVRIG blockade could therefore enhance memory T-cell activation by DCs, resulting in their increased expansion and differentiation. Accordingly, COM701 monotherapy induced CD8 + T-cell numbers and immune activation in the TME of ovarian cancer patient (figure 5). Moreover, MSS-CRC patient with partial response to COM701+nivolumab, demonstrated an increase in TCR numbers, clonality, T-cell infiltration and activation in the TME (figure 6). Finally, preliminary analysis of serum from two patients clinically responding to COM701 +nivolumab (RECIST criteria), revealed induction of activated-DC markers, compared to non-responders (figure 7).

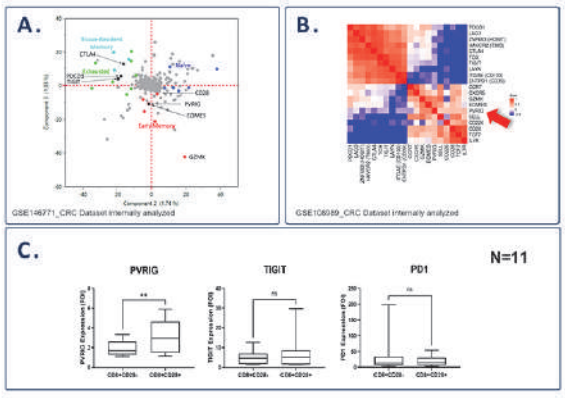
Conclusions By leveraging spatial and scRNA transcriptomics, we identified PVRIG$^+$CD8$^+$T-cells predominantly localized within TLS, interacting with PVRL2$^+$LAMP3$^+$DCs. PVRIG blockade could therefore enhance the differentiation and expansion of stem-like CD8$^+$ T-cells into effector cells (figure 8). Accordingly, early clinical data shows increased T-cells infiltration and immune activation in patients treated with COM701 or COM701+nivolumab.



Abstract 504 Figure 1 Analysis of CRC samples by Vizgen allowed identification of Tertiary Lymphoid Structures. A. TLS region harbored a unique co-localization of B-cells, T-cell, Plasma and endothelial cells that are unique to these structures. B. UMAP showing the clustering of cell populations into distinct cell types based on MRFISH mRNA readout. C. (Top) Boxplot demonstrating the cell composition in individual TLS structures or randomly sampled tumor regions. Tscm & naïve T cells localize to TLS while exhausted T cells localize to tumor region. (Bottom) Dotplot showing the gene expression of selected cell-state markers in a single TLS.

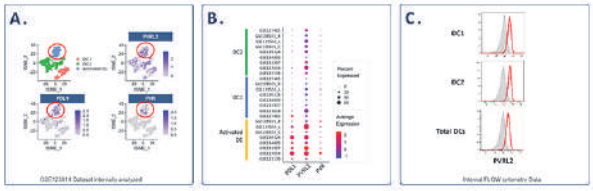


Abstract 504 Figure 2 DNAM-1 axis is dominantly expressed in TLS region. A. genes of the DNAM-1 axis, PVRIG, TIGIT, CD226, show dominant expression in TLS region, whereas other immune checkpoints, such as PD-1, CTLA4, TIM3 are expressed in the tumor bed. B. PVRIG expressing T cells intimately interacts with LAMP3+ PVRL2+ DC in the TLS of CRC patient.

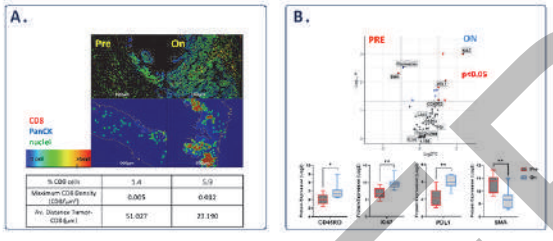


Abstract 504 Figure 3 PVRIG clusters with early differentiation/ memory genes in the TME, unlike other immune checkpoints that cluster with exhausted genes, in CD8+ T cells.
A. Unsupervised PCA analysis was performed on a scRNA expression matrix of TME CD8+ T cells, which includes all variable genes. Using cells as features and genes as entries, hierarchical co-expression pattern among genes known to be expressed on naïve, memory, and exhausted CD8+ T-cells was performed. B. scRNA-Seq datasets were analyzed for co-expression pattern among 19 genes, including genes known to be expressed on naïve (TCF7, IL7R, SELL), memory (GZMK, EOMES), and

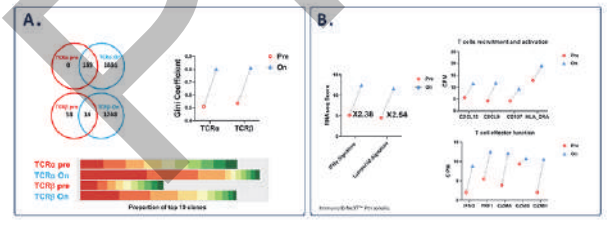
exhausted (PDCD1, LAG3, HAVCR2) CD8 T cells. Average gene-gene correlation over all datasets was calculated. Representative CRC dataset of n=13 (CRC, NSCLC, HNSCC, Melanoma, Liver cancer) is presented. C. Samples (n=11) of CRC, ovarian and bladder cancer were dissociated to single cell suspensions and analyzed for gene expression by flow-cytometry. Paired T-test was used to compare between PVRIG expression among cell populations.



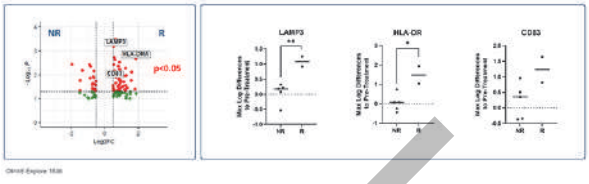
Abstract 504 Figure 4 PVRL2 is dominantly expressed on dendritic cells in the TME.
A. tSNE map depicting the expression profile of PVR/PVRL2/PDL1 in major dendritic cell subsets in Basal Cell Carcinoma patients. B. Dot plots showing the percent of cells and average level of expression of PVR/PVRL2/PD-L1 in major dendritic cell subsets across multiple scRNA-seq cancer datasets. C. PVRL2 protein expression across DC subsets in a representative ovarian cancer sample analyzed by flow-cytometry.



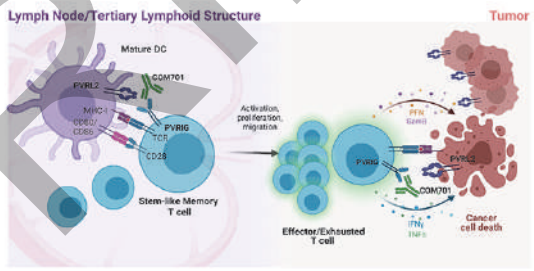
Abstract 504 Figure 5 COM701 Monotherapy induced immune activation in the TME of patient with ovarian cancer (radiologically defined as PD). Pre- and on-treatment biopsies from COM701 (anti-PVRIG antibody) treated patient with ovarian cancer were subjected to GeoMx® Immune Protein Assays, ROI selection was preformed using DAPI, and mAbs detecting PanCK, CD8 and CD68. A. CD8 distribution in the TME post COM701 monotherapy. B. Protein expression in CD8 regions as was detected with Nanostring, DSP in the TME post COM701 monotherapy.



Abstract 504 Figure 6 Increased TME immune activation and TCR clonality in patient with MSS CRC with PR to COM701+nivolumab combination therapy. Pre- and on-treatment biopsies from COM701 (anti-PVRIG antibody)+ nivolumab treated patient with MSS-CRC were subjected to Personalis®, ImmunoID NeXT analysis A. Increased number of clones and increased clonal expansion as was determined by Gini coefficient in the TME post COM701+nivolumab therapy. B. Increased immune infiltration and activation in the TME post COM701+nivolumab therapy



Abstract 504 Figure 7 Combination of COM701+nivolumab Induced Markers of Activated DCs in Serum of Two Responding Patients.
Serum of 7 patients from the nivolumab+COM701 dose escalation arm, were analyzed using Olink Explore 1536. For each patient, the maximal difference of log2 expression between all on-treatment time points and the pre-treatment value was calculated for each protein. Maximal log2 differences were compared by Student's t-test, with patients grouped based on response, RECIST criteria (responders (R): CR+PR vs. non responders (NR): SD+PD). Out of 10 proteins most significant for on-treatment up-regulation in responders, 3 are markers of activated DCs (LAMP3 ,HLA-DR and CD83).



Abstract 504 Figure 8 Summary. PVRIG-expressing stem-like memory T cells in LNs and TLS of cancer patients, are interacting PVRL2+DCs. PVRIG blockade could therefore enhance the differentiation and expansion of stem-like memory CD8 T-cells into effector cells that proliferate and infiltrate tumor. In the tumor bed, PVRIG blockade could further potentiate anti-tumor responses by breaking the interaction between PVRIG+T cells and PVRL2-expressing tumor cells.

505 **HIGH-DIMENSIONAL ANALYSES OF INTRATUMORAL MYELOID CELLS HIGHLIGHTS PRESENCE OF DISTINCT MYELOID CELL PHENOTYPES IN IMMUNE CHECKPOINT-SENSITIVE AND RESISTANT TUMORS**

Swetha Anandhan*, Sangeeta Goswami, Shelley Herbrich, Yulong Chen, Padmanee Sharma. *MD Anderson Cancer Center, Houston, TX, United States*

Background Immune checkpoint therapy (ICT) has revolutionized cancer treatment, however, has produced around 20% durable clinical response rates. [1] Multiple studies demonstrate myeloid cell abundance and function in the tumor microenvironment (TME) correlates with poor outcome in ICT resistant cancers. [2, 3] Despite the wealth of knowledge regarding the biology of these cells, our ability to distinguish immune-suppressive versus immune-stimulatory myeloid cells remains a major challenge and, thus, targeting myeloid cells has had limited clinical success. Our objective is to better understand the phenotype of these immunosuppressive myeloid cells to identify potential combination strategies to improve response to ICT.

Methods Comparative analyses of intratumoral myeloid cell subsets was performed in orthotopic murine models of ICT sensitive (B16F10 melanoma) and resistant (MT4 pancreatic) tumors at baseline and post ICT treatment (anti-PD-1 and/or anti-CTLA-4 antibodies) using single cell RNA sequencing (scRNAseq). To determine myeloid cell evolution with tumor progression, longitudinal scRNAseq was performed on MT4 tumors.

Results We observed two-fold higher abundance of macrophages and neutrophils in baseline MT4 tumors as compared to B16F10 tumors from our scRNAseq analysis (figure 1A-C). Overall, we identified 4 distinct macrophage subsets and 1 neutrophil subset (figure 1B). Mac_1 and mac_2 (MT4_macrophages) were the dominant macrophage clusters in MT4 tumors and while mac_1 expressed *mmp14, axl and mafb*; mac_2 had high expression of *vegfa*, *arg1, ccl24* and *fn1*(figure 1D). In contrast, mac_3 (B16F10_macrophages), the most abundant macrophage cluster in B16F10 tumors, expresses antigen presenting genes (*cd72*) and interferon-induced genes (*cxcl10, isg15*) (figure 1D). MT4_macrophages were significantly enriched TGF beta signaling, angiogenesis, hypoxia, glycolysis and B16F10_macrophages which enriched in oxidative phosphorylation and interferon gamma and alpha response pathways (figure 1E). The neutrophil subset was present specifically in MT4 tumors and expressed *cd24a*, *cxcl2*, *il1b* and *cd274* (figure 1D); consistent with the suppressive tumor-associated neutrophil (TAN) phenotype. Overall, at baseline, MT4 myeloid cells possess characteristics associated with T cell inhibition whereas B16F10 myeloid cells show T cell activating phenotypes. Post ICT treatment, macrophage subsets decreased moderately, however, MT4 TAN abundance increased, indicating possible compensatory resistance mechanisms (figure 1F). Longitudinal analyses indicated that neutrophil and macrophage subsets were abundant in early stage tumors and persisted during MT4 tumor progression (figure 1G).

Conclusions Distinct myeloid subsets are present in ICT sensitive and ICT resistant tumors. Myeloid targeting prior ICT treatment might be necessary to generate an effective immune response in resistant tumors. This study provides the foundation to identify novel myeloid specific targets in resistant solid tumors.

506 FCγRIIB EXPRESSED ON CD8 T CELLS LIMITS RESPONSIVENESS TO PD-1 CHECKPOINT INHIBITION IN CANCER

Kelsey Bennion*, Marvi Tariq, Megan Wyatt, Kirsten Baecher, Chrystal Paulos, Ragini Kudchadkar, Michael Lowe, Mandy Ford. *Emory University, Atlanta, GA, United States*

Background Immune checkpoint inhibition (ICI) using Fc-containing monoclonal antibodies has emerged as a powerful therapeutic approach to augment anti-tumor immunity. While ICI has drastically improved patient outcomes in melanoma, there is still variability in patient response.[1, 2] We recently showed that FcγRIIB, the only inhibitory IgG-Fc receptor, is expressed on differentiated effector CD8 T cells in mice and humans [3, 4], raising the possibility that CD8 T cell responses may be directly modulated by checkpoint inhibitor binding to T cell-expressed FcγRIIB.

Methods Flow cytometric phenotyping was performed on PBMCs isolated from melanoma patients and healthy donors. For *in vitro* functional experiments, healthy human PBMCs were stimulated with CD3/28 Dynabeads and/or PMA/ionomycin. Effector function was assessed through intracellular cytokine staining. Anti-PD1 (clone J116) or anti-CTLA4 (clone BN13) were used where mentioned and the anti-PD1 F(ab) was generated from Nivolumab. *In vivo* experiments were performed in mice with B16-hgp100, B16-OVA, or LLC-OVA tumors. Where mentioned, WT OT-I, *Fcgr2b*$^{-/-}$ OT-I, or WT pmel-17 CD8 T cells were adoptively transferred into these mice. For treatment, 250 μg of anti-PD1 (clone RMP1-14) and anti-FcγRIIB (clone 2.4G2) or isotype antibodies were administered for blockade experiments.

Results Here, we show that despite exhibiting strong proliferative and cytokine responses at baseline, human FcγRIIB^{+} CD8 T cells exhibited reduced responsiveness to both PD-1 and CTLA-4 checkpoint inhibition compared to FcγRIIB^{-} CD8 T cells *in vitro* ($p<0.05$). Moreover, frequencies of FcγRIIB^{+} CD8 T cells were reduced following treatment of human melanoma patients with nivolumab *in vivo* ($p<0.05$). This reduced responsiveness was FcγRIIB-dependent, because conditional genetic deletion of FcγRIIB on tumor-specific CD8 T cells improved response to checkpoint blockade in a B16 mouse melanoma model ($p<0.01$). The limited responsiveness of FcγRIIB^{+} CD8 T cells was dependent on an intact Fc region of the checkpoint inhibitor, in that treatment with Fc-devoid anti-PD-1 F(ab) fragments resulted in a significant increase in proliferation of FcγRIIB^{+} CD8 T cells, without altering the response of FcγRIIB^{-} CD8 T cells($p<0.05$). Finally, blocking FcγRIIB in the context of PD-1 blockade significantly improved anti-tumor CD8 T cell responses in B16 melanoma and in Lewis lung cancer mouse models ($p<0.05$, $p<0.001$).

Conclusions These results illuminate an FcγRIIB-mediated, cell-autonomous mechanism of CD8 T-cell suppression which limits the efficacy of checkpoint inhibitors *in vivo*. The data presented here support the novel conclusion that CD8-expressed FcγRIIB is both a factor to consider in the development of therapeutic antibodies, and a new potential target for immunotherapeutic intervention.

507 HIGH ENDOTHELIAL VENULES CONTROL THE JOURNEY OF STEM-LIKE CD8+ T CELLS FROM LYMPH NODE TO TUMOR DURING CANCER IMMUNOTHERAPY WITH COMBINED ANTI-PD-1 PLUS ANTI-CTLA-4 ANTIBODIES

Lucas Blanchard student*, Estefania Vina, Dorian Tarroux, Emma Lefrançais, Nathalie Ortega, Jean-Philippe Girard. *CNRS-IPBS, University of Toulouse, Toulouse, France*

Background Recent reports revealed that $CD8^+$ T cell antitumor responses rely on a subset of stem-like $CD8^+$ T cells during cancer immunity and immunotherapy. However, the origin of stem-like $CD8^+$ T cells and the mechanisms controlling their trafficking are not well established. High endothelial venules (HEVs) are specialized blood vessels mediating lymphocyte trafficking in lymph nodes (LNs),[1,2] and HEV-like blood vessels defined as tumor-associated HEVs (TA-HEVs) are important regulators of lymphocyte entry into tumors.[3] Here, we investigated the role of LN-HEVs and TA-HEVs in the generation and migration of stem-like $CD8^+$ T cells during spontaneous antitumor immunity and cancer immunotherapy.

Methods In mouse syngeneic tumor models, we applied multidisciplinary approaches (immunofluorescence, flow cytometry, short-term homing assays and *in vivo* imaging) to identify the adhesion pathways used by LN-HEVs and TA-HEVs for $CD8^+$ T cell trafficking. Then, using *in vivo* function-blocking antibodies targeting LN-HEVs and/or TA-HEVs, we defined their respective roles in the recruitment of naive $CD44^-PD\text{-}1^-CD8^+$ T cells into tumor-draining lymph node and of $CD44^+PD\text{-}1^+TCF\text{-}1^{high}$ stem-like $CD8^+$ T cells into tumor. Lastly, we blocked the function of LN-HEVs and/or TA-HEVs during combined anti-PD-1 plus anti-CTLA-4 cancer immunotherapy to analyze their contributions in treatment-induced $CD8^+$ T cell responses.

Results We found that naive and stem-like $CD8^+$ T cells use distinct adhesion pathways to interact with LN-HEVs and TA-HEVs, respectively. Blocking naive $CD8^+$ T cell adhesion to LN-HEVs and their subsequent entry into tumor-draining lymph node abrogated the generation of stem-like $CD8^+$ T cells and prevented their accumulation in tumor, showing that peripheral and intratumoral responses are tightly related. In peripheral blood, circulating stem-like $CD8^+$ T cells expressed adhesion molecules and chemokine receptors enabling interaction with TA-HEVs that mediated their entry into tumor. Finally, we found that checkpoint blockade therapy increased the number and activity of stem-like $CD8^+$ T cells in tumor-draining lymph node and peripheral blood, suggesting that peripheral responses are involved during treatment. Accordingly, HEV-mediated trafficking in tumor, but also in tumor-draining lymph node, were required for expansion and differentiation of intratumoral stem-like $CD8^+$ T cells during checkpoint blockade therapy.

Conclusions In this study, we unveil the dual role of HEVs in tumor and periphery for $CD8^+$ T cell responses during cancer immunity and immunotherapy, and provide mechanistic insights on the importance of peripheral responses during checkpoint blockade therapy. Our findings also strongly support the use of combined anti-PD-1 plus anti-CTLA-4 cancer immunotherapy in the neoadjuvant setting.

Background Clinically actionable biomarkers of immune checkpoint inhibitor (ICI) response are currently limited to specific mutation profiling, immunohistochemistry staining for PD-L1, and tumor mutational burden. Use of the latter two are challenging, as they are incompletely predictive and lack accepted standards for measurement and interpretation. Transcriptomic associations with response have been reported and may add critical information to an integrated biomarker strategy. There is a need for better understanding of the performance of potential biomarkers across multiple datasets and tumor tissue types.

Methods RNA sequencing FASTQ data files from 12 ICI trials [1-13] and 29 solid tumors in The Cancer Genome Atlas (TCGA)[14] were processed using a standardized bioinformatics workflow for quality control, mapping, generation of gene expression matrices, and extraction of immunogenomics features. We evaluated 18 [2, 15-22] immunogenomics features that have been published or proposed to associate with clinical response to ICI therapy for correlation with response and survival across these datasets, estimating predictive information from the ICI trials and prognostic information from TCGA dataset results.

Results The MIRACLE score was associated with response and survival in most ICI studies, both overall and within melanoma trials (figures 1). Other immunogenomics features had both lower effect sizes of outcome associations and fewer cohorts in which their outcome associations were statistically significant. Features that were associated with outcome in the ICI studies were generally associated with survival in TCGA as well, whether evaluating all tumor tissue types (figure 2) or melanoma only (figure 3). In melanoma, the TIDE score was associated with response to ICIs, but not with overall survival in TCGA, though the effect size was small. Gene expression signatures built from responders versus non-responders in each trial did not yield generalizable associations with response across other trials. Harmonized gene expression data and immunogenomics features extracted in this project are available for review and further analysis in the CRI iAtlas platform (https://cri-iatlas.org/).

Conclusions The MIRACLE score performed best in both effect size and frequency of studies where its association with outcome was statistically significant. No features gave substantial predictive rather than prognostic information. We expect that integration of transcriptomic features with clinical features and DNA alterations will be required to provide predictive (rather than just prognostic) information. Methods that train models on prioritization of predictive information and generalizability across studies may be required for optimal biomarker development.

509 IMMUNE CHECKPOINT BLOCKADE BOOSTS ANTI-TUMOUR B CELL RESPONSES IN LUNG ADENOCARCINOMA

Jesse Boumelha*, Kevin Ng, Katey Enfield, Charles Swanton, George Kassiotis, Julian Downward. *The Francis Crick Institute, London, UK*

Background B cells are frequently found in the margins of solid tumours, where they are organized in tertiary lymphoid structures (TLS) that resemble antibody-producing germinal centres. The presence of TLS has been associated with improved patient outcome and response to immunotherapy, though the mechanisms underlying these associations remain unclear. Similarly, the contribution of B cells and TLS to anti-tumour immunity in non-small cell lung cancer (NSCLC) remains largely unexplored.

Methods We evaluated treatment-naive NSCLC cohorts to compare B cell and TLS gene signatures from human lung adenocarcinoma (LUAD) and squamous cell carcinoma (LUSC). Using a novel immunogenic mouse model of LUAD, we carried out lineage tracing, 3D immunofluorescence, and single-cell sequencing to characterise lung germinal centre and antibody responses during tumour progression and immunotherapy treatment.

Results B cell and TLS genes were significantly higher in LUAD compared to LUSC and correlated with improved survival. We therefore investigated the mechanistic basis of B cells in LUAD using a novel immunogenic KRAS-mutant lung cancer mouse model. Using serum transfer experiments, we demonstrated a highly protective role for tumour-binding class-switched antibodies. These germinal centre B cell responses and antibody quantity were increased after immunotherapy treatment or targeted KRAS inhibition. Interestingly, tumour-binding antibodies were demonstrated to be targeting re-expressed endogenous retroviral (ERV) antigens. Using single-cell BCR sequencing of immunotherapy-treated mice, we showed clonal expansion of B cells reactive to ERV antigens. Furthermore, ERVK-7 which encodes an endogenous retrovirus envelope glycoprotein was overexpressed in human LUAD and therefore may act as a relevant tumour antigen. Finally, we showed that combined treatment with CXCL13 and immune checkpoint blockade improved survival, suggesting that boosting local B cell responses can improve immunotherapy outcome.

Conclusions Our work describes a novel role for B cells in lung cancer and establishes that TLS directly contribute to anti-tumour immunity by producing class-switched protective antibodies. We demonstrate that selective boosting of anti-tumour B cells shows therapeutic potential in combination with immune checkpoint blockade.

Ethics Approval All animal experiments were approved by the ethics committee of the Francis Crick Institute and conducted according to local guidelines and UK Home Office regulations under the Animals Scientific Procedures Act 1986 (ASPA).

510 A PD-L1 REPORTER CELL LINE BASED ON THE IMMUNE CHECKPOINT PROTEIN PROFILING OF ATCC CELL LINES FACILITATES CANCER IMMUNOTHERAPY DRUG SCREENING

Hyeyoun Chang*, Brian Della Fera, Haiyun Liu, Arunajyothi Bandla, Kevin Tyo, John Foulke, Luping Chen, Zhizhan Gu, Fang Tian. *ATCC (American Type Culture Collection), Gaithersburg, MD, United States*

Background The success of immune checkpoint inhibitors in the treatment of various types of cancers and their continued growth in the market have driven burgeoning interests in developing more drugs in this category. However, the intrinsic complexity of the immunological models and the variable drug responses among different cancer types have become the most prominent challenges.

Methods To facilitate large scale research projects and drug discovery of immune checkpoint inhibitors, we conducted a comprehensive protein profiling of ATCC's vast portfolio of human tumor and immune cell lines for several established and novel immune checkpoint molecules. Based on this protein profiling data, we generated an immune checkpoint reporter cancer cell line with high expression of endogenous programmed death-ligand 1 (PD-L1), a highly validated target for immune checkpoint inhibitor therapeutics. The reporter system contains a gamma interferon activation site (GAS)-response element upstream of the luciferase gene, preventing luciferase expression when PD-L1 binds to programmed death-1 (PD-1) that suppresses T cell-mediated antitumor activity. In the presence of a PD-1/PD-L1 inhibitor, a luciferase expression based bioluminescent signal is produced, which can be readily detected and quantitated to evaluate the efficacy, potency, and dynamics of the inhibitor.

Results Our data showed that the bioluminescence in the reporter cancer cells increased ~ 250 folds in a dose-dependent manner in response to interferon gamma stimulation, which mimics the signaling from activated CD8+ cytotoxic T cells. The bioluminescence increased ~100 folds in response to CD8+ primary T cell-conditioned media stimulation, and up to 5 folds in response to co-culture with CD8+ primary T cells in the presence of an anti-PD-L1 blocking antibody in a dose-dependent manner. The luciferase expression and endogenous PD-L1 expression were well maintained after the cell line had reached >30 population doubling level. These results highlight the robustness and responsiveness of the reporter system for the assessment of T cell-mediated immune responses triggered by PD-1/PD-L1 checkpoint inhibitors.

Conclusions This PD-L1 immune checkpoint reporter cancer cell line yields exceptional in vitro and ex vivo assay sensitivity and reproducibility, while simplifies the complex immunological model by providing physiologically relevant expression of PD-L1, in comparison to similar assays on the market with an artificial PD-L1 overexpression system.

511 T CELL-INSTRUCTED INFLAMMATION DRIVES IMMUNE CHECKPOINT INHIBITOR THERAPY RESISTANCE

[1]Nam Woo Cho*, [1]Sophia Guldberg, [2]Eun Ji Kim, [1]Kamir Hiam-Galvez, [1]Katherine Wai, [1]Lauren Levine, [1]Rachel DeBarge, [1]Jacqueline Yee, [1]Naa Ashitey, [1]Matthew Spitzer. *[1]Helen Diller Family Comprehensive Cancer Center, Parker Institute for Cancer Immunotherapy, Chan Zuckerberg Biohub, University of California, San Francisco, San Francisco, CA, United States; [2]Unaffiliated, San Francisco, CA, United States*

Background Resistance to immune checkpoint inhibitors (ICIs) is a significant barrier to improving cancer immunotherapy.[1] To this end, we interrogated ICI-induced inflammation. One type of inflammation, driven by nuclear factor-kB (NF-kB) activation in the tumor microenvironment (TME), can power tumor-promoting mechanisms including immunosuppression to limit ICI efficacy.[2] Conversely, the current paradigm predicts that another type of inflammation, characterized by T cell infiltration, improves ICI responsiveness.[3,4] How these two units of inflammation can co-exist in the TME yet direct divergent responses to ICIs requires reconciliation. In particular, it is unknown whether conventional CD4 or CD8 T cells can themselves instruct NF-kB inflammation in the TME, shaping the immunologic setpoint and, unexpectedly, limiting ICI efficacy.

Methods We generated new mouse syngeneic microsatellite instability-high (MSI-H) tumor models to study ICI response and resistance in the context of ample T cell inflammation. High-neoantigen-burden cell lines were implanted into syngeneic mice to assess responses to combination anti-PD-1 and -CTLA4 treatment.

Results Consistent with response in human tumors[5], 50% of mouse MSI-H tumors were resistant to combination ICIs. Analysis of the TME in the resistant AT3 breast cancer model and responsive B16F10 melanoma model by mass cytometry revealed that ICIs increased tumor T cell infiltration in each model, but CD8 T cells in AT3 tumors assumed a non-cytotoxic but early-activated phenotype characterized by CD69 expression. T cell expansion in AT3 MSI-H tumors was accompanied by recruitment of T cell-suppressive polymorphonuclear myeloid-derived suppressor cells requiring cytokines G-CSF and CXCL1, absent in B16F10 tumors. Inhibition of the inflammatory NF-kB circuit, which drives expression of these cytokines, via IL-1 receptor neutralization increased ICI efficacy against AT3 MSI-H tumors. Unexpectedly, in vivo depletion of T cells also abolished the NF-kB circuit in AT3 MSI-H tumors, and activated CD8 T cells were sufficient to instruct tumor cells to increase G-CSF and CXCL1 expression. We found that TNFa, increased in T cells and neutrophils upon ICIs, perpetuated the NF-kB circuit and contributed to ICI resistance in AT3 MSI-H tumors. Finally, analysis of single-cell RNA sequencing data from ICI-treated breast cancer patients revealed candidate human T cell correlates.

Conclusions We report a surprising, novel mechanism of ICI resistance whereby treatment-induced T cell infiltration and activation can paradoxically exacerbate a TNFa- and IL-1-dependent resistance circuit in tumors with active NF-kB inflammation. Our findings refine the current models of ICI response and resistance with important therapeutic implications.

512 TIME-OF-DAY OF PEMBROLIZUMAB INFUSION AND CLINICAL OUTCOMES OF PATIENTS WITH NSCLC: TOO SOON TO PROMOTE MORNING INFUSIONS

[1,2]Alessio Cortellini*, [3]Adriana Barrichello, [3]Joao Victor Alessi, [3]Biagio Ricciuti, [3]Victor Vatz, [4]Thomas Newsom-Davis, [1]Joanne Evans, [3]Giuseppe Lamberti, [3]Federica Pecci, [5]Patrizia Viola, [1]Antonio D'Alessio, [1]Claudia Fulgenzi, [3]Mark Awad, [1]David Pinato. [1]*Imperial College London, London, UK*; [2]*University of L'Aquila, London, UK*; [3]*Dana Farber Cancer Institute, Boston, MA, United States*; [4]*Chelsea and Westminster Hospital, London, UK*; [5]*Charing Cross Hospital, London, UK*

Background Circadian oscillations in T-cell function may influence outcome from cancer immunotherapy.[1] Evidence for an association between time-of-day of immune checkpoint inhibitors (ICI) infusion on outcomes in patients with non-small cell lung cancer (NSCLC) is scanty.

Methods In this multicenter study, we retrospectively evaluated the association between time-of-day patterns of pembrolizumab infusion and outcomes in a cohort of patients with treatment-naïve metastatic NSCLC with PD-L1 expression ≥50% treated from June 2016 to September 2021. Receipt of ≥20% vs <20% of infusions after the 16.30h cut off time ("late infusions") was set as threshold for analysis. In addition, we explored increasing thresholds for late infusions based on centre-specific distribution of cut-off times.

Results Overall 180/262 patients received ≥4 cycles and were eligible, 136 (75.5%) and 44 (24.5%) patients respectively received <20% and ≥20% of evening infusions. Evening infusions were associated with a lower number of cycles (median: 14 vs 8, p=0.0002). Following a propensity score matching (PSM) accounting for age, PD-L1-expression, ECOG-PS, bone metastases, smoking status and sex, 78 and 44 patients were matched from the <20% and the ≥20% evening infusions cohorts. Median OS and PFS of patients who received ≥20% and <20% of evening infusions were 27.8 vs 47.1 months (p=0.11) (figure 1A), and 6.6 vs 19.7 months (p=0.056) (figure 1B), respectively. Evening infusions did not affect the risk of death (HR 1.53, 95%CI: 0.88-2.76) or disease progression/death (HR 1.51, 95%CI: 0.95-2.42) at the multivariable analysis. When including the number of cycles in the PMS, patients who received <20% and ≥20% of evening infusions experienced similar OS and PFS estimates (figure 1C,D). The exploratory analyses of OS according to increasing quartiles using the 16.30h threshold and the centre-specific median time-of-day threshold across the entire population and the landmark population highlighted that both the receipt of 0% and 100% of evening and late infusions were associated with an increased risk of death (table 1), while after adjusting for the number of administered cycles, no proportion of late infusions was significantly associated to the risk of death.

Figure 2 provides a representation of the distribution of cycles across progressive thresholds for proportions of evening (16.30h threshold) and late (median time-of-day threshold) infusions according to incremental quartiles, highlighting duration of therapy as an inherent bias in retrospective analyses.

Conclusions Translational dynamic studies of peripheral T-cell immunity are warranted while prospective trials should be conducted before promoting morning infusion in clinic.

513 OVERCOMING HEDGEHOG MEDIATED ANTI-PD-1 RESISTANCE IN MELANOMA THROUGH PROSTAGLANDIN INHIBITION

Nicholas DeVito*, Y-Van Nguyen, Nagendra Yarla, Michael Plebanek, Balamayooran Theivanthiran, Michael Aksu, Vaibhav Jain, Brent Hanks. *Duke University, Durham, NC, United States*

Background Immunotherapy resistance correlates with mesenchymal transformation (MT),[1, 2] however we are unable to therapeutically target this immune evasive phenotype. We have shown that in anti-PD-1 resistant melanomas, the Hedgehog (Hh) transcription factor Gli2 drives the upregulation of Wnt and prostaglandin synthesis, which promotes the recruitment of granulocytic myeloid-derived suppressor cells (PMN-MDSCs) leading to immune evasion and immunotherapy failure.[3, 4] Hh activation has been described in immunotherapy resistance [5, 6], however targeting has focused on SMO inhibition, which is limited by noncanonical pathway activation.[7, 8] Here, we demonstrate the utility of a Gli2 signature to predict anti-PD-1 immunotherapy failure and determine whether selective prostaglandin receptor inhibition (EP2i/EP4i) can overcome this resistance pathway in melanoma.

Methods Gli2 was constitutively activated ($Gli2^{CA}$) in a $BRAF^{V600E}PTEN^{-/-}$ melanoma cell line by inducing an N-terminal truncating mutation. Multi-parameter flow cytometry, RNAseq, and scRNAseq were utilized to evaluate the impact of Gli2 activity and therapeutic treatments on the tumor immune microenvironment. Anti-PD-1, EP2i/EP4i, PORCNi (Wnt ligand inhibition), and PMN-MDSC ablation *in vivo* studies were performed in $Gli2^{CA}$ and control tumors. Nanostring analysis was performed on clinical melanoma tumor specimens and bioinformatics studies were conducted using the TCGA and Hugo et al databases.[2]

Results $Gli2^{CA}$ tumors display resistance to anti-PD-1, where flow cytometry revealed persistent exclusion of $CD103^+$ antigen-presenting DCs, activated T and NK cells, and greater numbers of PMN-MDSCs compared to control tumors. Gli2 upregulates genes involved in prostaglandin synthesis and PGE2 production, which is ablated in Gli2-knockout melanomas. Treatment with EP2i/EP4i suppresses tumor growth, increasing levels of $CD8^+$ T cells, NK cells, and cDC1s in $Gli2^{CA}$ but not in control tumors; and this is further potentiated by anti-PD-1. EP2i/EP4i markedly reduces PMN-MDSCs in $Gli2^{CA}$ tumors, and anti-Ly6G depletion of PMN-MDSCs had a similar impact on the immune microenvironment. scRNAseq showed enhanced NK cell activity with EP2i/EP4i over PORCNi in $Gli2^{CA}$ tumors, and while both therapies reduced PMN-MDSC numbers, EP2i/EP4i also diminished suppressive markers. Gli2 and prostaglandin signatures correlate in the melanoma and colorectal TCGA. Importantly, a Gli2 signature predicts for anti-PD-1 resistance in a subset of melanoma patients.

Conclusions Gli2 drives the development of a tolerogenic tumor microenvironment during MT via Wnt and prostaglandin signaling, leading to anti-PD-1 failure through enhanced PMN-MDSC recruitment and activity. This state can be reversed with EP2i/EP4i in mouse models. These results suggest that a Gli2 signature may predict for EP2i/EP4i sensitivity in a subset of anti-PD-1 resistant melanomas.

514 TUMOR CONTEXT DICTATES RELIANCE ON TCF1 FOR RESPONSE TO IMMUNOTHERAPY

[1]Giulia Escobar*, [1]Katherine Tooley, [1]Joan Pagès Oliveras, [1]Cheng Hanning, [1]Xue Chang, [1]Davide Mangani, [1]Hazel Natanael, [1]Carola Rutigliani, [2]Luca Biasco, [1]Ana Carrizosa Anderson. *[1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States; [2]UCL Great Ormond Street Institute of Chi, London, UK*

Background Stem-like CD8 T cells that are regulated by the transcription factor TCF1 are key players in the response to immune checkpoint blockers (ICB). Recent findings indicate that the dependance on $TCF1^+$ stem-like T cells for ICB efficacy may not be equal across patients and in different tumor contexts.

Methods Here we leveraged TCF1 conditional knock-out (TCF1-cKO) mice to investigate how TCF1 instructs the early fate and functions of CD8 cells upon ICB therapy in tumors that differ for immunogenicity and levels of tumor antigens expression.

Results Strikingly, we discovered that TCF1 expression in CD8 T cells is required for ICB efficacy in poorly immunogenic B16OVA melanomas but is dispensable in highly immunogenic MC38OVA colorectal tumors. Single-cell-RNA sequencing and immunophenotyping revealed defective priming and expansion of tumor-specific TCF1-cKO T cells in the tumor draining lymph-node (TDLN) of B16OVA- but not MC38OVA-bearing mice treated with ICB. In vitro, we found defective proliferation, reduced PD-1 and CD28 up-regulation and reduced phosphorylation of key molecules downstream the T cell receptor pathway when TCF1 cKO T cells were stimulated with low doses of antigens but not when stimulated with strong TCR signals. These data indicate that TCF1 poises T cells for optimal activation. Furthermore, transcriptional profiling of T cells in the TDLN further revealed the accumulation of a subset of tumor-specific naïve T cells poised to give rise to short-lived effectors in TCF1 cKO mice and thus is less suited to sustain anti-tumor responses in poorly immunogenic tumors where expansion of T cells retaining stem-like potential is required for durable anti-tumor responses. In tumors, single-cell-RNA sequencing and immunophenotyping showed that in MC38OVA tumors both WT and TCF1-cKO mice expanded a CD8 subset sharing a signature with transitory effector cells that mediate ICB efficacy in chronic viral infection models. Conversely, B16-OVA tumors retained a higher frequency of stem-like cells, failed to expand transitory effectors and accumulated Tox+ CD8 T cells, sharing a signature with CD8 cells expanded in non-responders to ICB. Importantly, loss of TCF1 was associated with reduced maintenance and proliferation of stem-like precursors and reduced expression of the Tox gene which was required for the survival of late effectors, altogether contributing to the failure of TCF1-cKO mice to sustain effective ICB responses.

Conclusions Our study highlights a role for TCF1 in the early stages of the CD8 T cell response with important implications for guiding the choice of optimal therapeutic interventions in tumors expressing low neoantigen levels.

515 ASSESSING THE EFFECT OF POST-TRAUMATIC OSTEOARTHRITIS ON MURINE TUMOR GROWTH AND RESPONSIVENESS TO IMMUNE CHECKPOINT BLOCKADE

Elise Gray-Gaillard*, Younghwan Choi, Jin Han, Helen Nguyen, Katlin Stivers, Anna Ruta, Andrew Pardoll, Jennifer Elisseeff. *The Johns Hopkins University, Baltimore, MD, United States*

Background Immune checkpoint blockade (ICB) has revolutionized cancer treatment. The mechanisms of heterogeneous ICB responses (responder/non-responder), however, are poorly understood. Because of the increasing application of (neo)adjuvant ICB with tumor resection, the role of tissue injury caused by surgical procedures is a potential and usually overlooked factor in the generation of systemic anti-tumor immunity. Prior tissue injury has been shown to advance breast cancer progression.[1,2] Whereas, the induction of senescent tumor cells and their senescence-associated secretory phenotype (SASP) within pancreatic cancer has been shown to remodel tumor vasculature, increasing ICB responsiveness.[3] Thus, here we explore the role of cellular senescence induced by distant tissue damage on tumor growth. Anterior cruciate ligament (ACL) transection, a model of post-traumatic osteoarthritis, leads to senescent cell (SnC) accumulation in the joint and systemic SASP-mediated effects.[4] We investigate the immunological and stromal changes arising with ACL injury and ICB within B16F10 murine melanoma, a classical non-responding model.

Methods ACL transection was performed prior to subcutaneous B16F10 inoculation. ICB treatment consisted of 4x intraperitoneal-injected 5mg/kg anti-PD1 monotherapy or anti-PD1/anti-CTLA4 combination therapy. Tumor growth was monitored via caliper measurements. Serum was collected after ICB treatment for cytokine array. Tumors were collected at termination for histological assessment. To elucidate changes in vascularization and senescence within tumors due to injury and/or treatment, we performed histological (H&E) and immunofluorescent staining of CD31 and p16, respectively. We quantified the change in tumor vessel number and size using QuPath and used HALO image analysis to quantify $p16^+$ and $CD31^+$ cells and their proximity.

Results ACL injury either 1- or 7-weeks prior to tumor injection significantly increased B16F10 responsiveness to ICB and survival. In tumors from ACL-injured mice treated with ICB, immunofluorescent staining showed significantly more $p16^+$ SnCs and $CD31^+$ cells, with a greater number of $p16^+$ SnCs within 10μm of vasculature compared to controls. QuPath analysis of immunofluorescent-stained tumors from ACL-injured+ICB-treated mice uncovered a significantly higher frequency of large blood vessels (surface area $>10000\mu m^2$) and H&E staining showed vessels had larger lumen. Cytokine array revealed increased serum-levels of pro-inflammatory cytokines and angiogenic factors in ACL-injured+ICB-treated mice.

Conclusions Our data demonstrate that ACL injury significantly increases ICB responsiveness in a classically non-responsive tumor model. ACL injury ameliorates tumor vascularization and increases the frequency of $p16^+$ SnCs surrounding vasculature within ICB-treated tumors. The mechanism causing this effect is being elucidated. This study aims to develop predictive understanding of ICB responsiveness and provide mechanisms to sensitize non-responders.

516 CLINICAL TIER GRADING OF CANCER STEM CELLS ACCORDING TO CLINICAL CHARACTERISTICS FOR IMMUNE CHECKPOINT INHIBITORS GUIDED BY MRNA STEMNESS INDEX

Priya Hays*. *Hays Documentation Specialists, LLC, San Mateo, CA, United States*

Background Cancer stems cells are cells in tumors that have self-renewing capabilities and proliferation, and are partly responsible for tumor growth, metastasis and drug resistance, and have been associated with multidrug resistance and epithelial-mesenchymal transition. Recent studies have shown that cancer stemness is capable of being targeted by immunotherapies.[1]

mRNAsi, or mRNA stemness index, is a tool that has been developed to analyze prognostic significance for immunotherapy response for cancer stemness in lung adenocarcinoma, adrenocortical carcinoma and gastric cancer, among other carcinomas[2,3,4] This abstract proposes to apply the prognostic signatures as determined by mRNAsi to create a clinical tier grading system that categorizes cancer stemness presenting characteristics based on studies by for ICI (nivolumab, (anti-PD-1) ipilumumab (anti-CTLA-4), pembrolizumab (anti-PD-L1), atezolizumab (anti-PD-L1)) treatment. [5]

Methods A literature search will be conducted using the keywords "cancer stem cells" OR "cancer stemness" AND "immunotherapies" AND "mRNAsi" AND "immune checkpoint inhibitors efficacy". Additional keywords include "prognostic signatures" AND "metastasis" AND "clinical features" AND "clinical presentation."

Results mRNAsi-guided tools determined differentially expressed genes in tumors and generated prognostic signatures which in turn reflected clinical characteristics that could be grouped into a tiered list, creating grading categories for ICI treatment efficacy (table 1). Low-risk and high-risk survival groups, tumor mutational burden, TNM pathological stages, overall survival were generated from prognostic gene signatures through mRNAsi. They also could predict 1-year, 3-year, and 5-year overall survival in certain cancers. Based on this clinical presentation, guidance for ICI therapy could be developed.

Conclusions A clinical tier grading list may be an effective way to guide oncologists in applying mRNAsi tools to cancer stemness for treatment through ICIs. Future studies could focus on stratifying patients through the prognostic signatures generated by these tools.

Abstract 516 Table 1 Clinical Tier Grading List According to Prognostic Signatures as Determined by mRNAsi (adapted from Shi 2021, Li 2021, Mao 2021, Santoro 2022)

Table 1 Clinical Tier Grading List According to Prognostic Signatures as Determined by mRNAsi (adapted from Shi 2021, Li 2021, Mao 2021, Santoro 2022)

Tier 1		
Signature	Clinical Characteristics	ICI Efficacy
High-mRNAsi	High risk	Low
Low PD-L1	Low OS	
Low PD-1	High TMB	
Low CTLA-4		

Tier 2		
Signature	Clinical Characteristics	ICI Efficacy
Low-mRNAsi	Low to moderate risk	High
High PD-L1	High OS	
High PD-1		
High CTLA-4

517 SPLENIC TUMOR-REACTIVE CD8+ T CELLS ARE ENDOWED WITH A UNIQUE POTENTIAL FOR EXPANSION AND ARE THE DOMINANT SOURCE OF SYSTEMIC ANTI-TUMOR IMMUNITY AFTER ICB THERAPY

Brendan Horton*, Duncan Morgan, J Love, Stefani Spranger. *Massachusetts Institute of Technology, Cambridge, MA, United States*

Background Expansion of systemic tumor-reactive T cells after immune checkpoint blockade (ICB) has been linked to successful tumor control, but regulators of systemic T cell expansion remain unknown. Using a murine lung cancer model, we previously demonstrated that flank tumors respond to ICB, while lung tumors do not. ICB-mediated control of flank tumors correlated with stronger expansion of systemic anti-tumor T cell responses, and the spleen, not tumor-draining lymph nodes (TdLNs), appeared to be the source of ICB-expanded tumor-reactive T cells.

Methods The murine KP lung cancer cell line was engineered to express the $CD8^+$ T cell antigen SIY (KP.SIY). Mice were inoculated subcutaneously to generate flank tumors or intravenously to generate lung tumors. For single cell sequencing experiments, endogenous SIY-reactive $CD8^+$ T cells were isolated using fluorescence activated cell sorting (FACS) and RNA sequencing was performed using SeqWell. Mice expressing the transgenic 2C T cell receptor, specific for SIY, were used as T cell donors in adoptive transfer experiments.

Results KP.SIY flank tumors generated higher numbers of splenic SIY-reactive $CD8^+$ T cells than KP.SIY lung tumors, and the spleen was the major site of SIY-reactive $CD8^+$ T cell accumulation after ICB. Paired single cell RNA and TCR sequencing revealed extensive clonal expansion of SIY-reactive $CD8^+$ T cells in flank tumor-bearing mice, including multiple recurrent TCR sequences shared between mice, that was significantly reduced in the lung tumor setting. To determine the influence of anatomic site on the response to ICB, we adoptively transferred naive 2C TCR-transgenic T cells to mice bearing KP.SIY flank tumors. In vivo primed 2C T cells were FACS isolated from TdLNs or spleens and transferred into secondary tumor-bearing hosts prior to ICB treatment. Surprisingly, only 2C T cells isolated from spleens of primary tumor-bearing mice expanded in secondary hosts following ICB. Single cell sequencing of endogenous SIY-reactive $CD8^+$ T cells confirmed distinct gene expression profiles between SIY-reactive T cells from TdLNs and spleens, and that tumor-infiltrating clonotypes were more prevalent in spleens of tumor-bearing mice than in TdLNs.

Conclusions The major source of systemic tumor-reactive $CD8^+$ T cells after ICB in mice is the spleen, not the TdLN. The enhanced ability of splenic $CD8^+$ T cells to expand after ICB therapy was driven by T cell-intrinsic differences which govern ICB responsiveness.

Ethics Approval The experiments in this abstract were approved by the Massachusetts Institute of Technology Committee on Animal Care, protocol number 0220-006-23, NIH assurance ID D16-00078.

META-ANALYSIS ON IMMUNOTHERAPY-RELATED HYPERPROGRESSIVE DISEASE (HPD) INCIDENCE ACROSS TUMOR TYPES AND HPD DEFINITIONS

[1]Min Jeong Kim*, [1]Seung Pyo Hong, [1]Yeonggyeong Park, [2]Allison Belette, [3]Chiwoo Song, [1]Youjin Oh, [4]Sukjoo Cho, [1]Ilene Hong, [1]Young Kwang Chae. *[1]Northwestern University Feinberg School of Medicine, Chicago, IL, United States; [2]University of Texas Health Science Center, Houston, TX, United States; [3]Nowon Eulji Medical Center, Eulji University, Seoul, Korea, Republic of; [4]South Florida Morsani College of Medicine, Tampa, FL, United States*

Background While reported in other types of systemic therapy as well, evidence for hyperprogressive disease (HPD) following onset of immunotherapy has increased in the past decade. Despite such growing evidence, the lack of a consensual definition precludes a better understanding of this phenomenon.

Methods A systematic literature search was done on PubMed, Embase, Web of Science, and Cochrane Database of Systematic Reviews based on a search algorithm that included key terms including immune checkpoint inhibitor, immunotherapy, and hyperprogress. Studies published until June 21, 2022 which used a definition based on tumor kinetics were included. All studies were categorized according to one of three definitions of HPD: A) RECIST-defined progressive disease (PD) and tumor growth rate(TGR) ratio $< u >> 2^1$ B) RECIST-based tumor growth kinetics(TGK) ratio $< u >> 2^2$, and C) RECIST-defined PD and $\Delta TGR > 50\%$.[3] A generalized linear mixed-effects model was used, and multivariable analysis was conducted to explore differences in the incidence across tumor types and HPD definitions.

Results A total of 34 studies comprising 4117 patients and 5 different tumor types (renal cell carcinoma(RCC), mixed or other, hepatocelluar carcinoma(HCC), non-small cell lung cancer(NSCLC), and advanced gastric cancer(AGC)) were included in the meta-analysis.[4-36] The overall pooled incidence of HPD was 12.40% (95% CI, 10.28 – 14.89%) and ranged from 0.0% to 36.73% (figure 1 and 2). Statistical heterogeneity was significant (I2 = 72.3%; P < 0.01). Patients diagnosed with AGC (odds ratio (OR), 10.83; 95% CI, 2.15-66.02; P <.001), HCC (OR, 7.99; 95% CI, 1.68-38.10; P =.003), NSCLC (OR, 7.14; 95% CI, 1.58-32.27; P =.004), and mixed or other (OR, 5.09; 95% CI, 1.12-23.12; P =.03) were more likely to experience HPD than patients with RCC. Across definitions, differences in the HPD incidence was significantly higher for definition B (OR, 1.81; 95% CI, 0.58-1.80; P =.025) compared to definition C.

Conclusions Significant differences in HPD incidence are observed across tumor types and HPD definitions. To better characterize these differences, further studies — as well as efforts to agree on a consensual definition — are warranted.
