520 PD-1 INHIBITS BYSTANDER T CELL ACTIVATION AND PROTECTS FROM ACTIVATION INDUCED CELL DEATH

Michael Sheng*, Catherine Le, Cordelia Dunai, Lam Khuat, Logan Vick, Kevin Stoffel, Arta Monjazeb, Craig Collins, Robert Canter, William Murphy. *University of California Davis, School of Medicine, Happy Valley, OR, United States*

Background Immune checkpoint inhibition (ICI) targeting PD-1/PDL-1 is being increasingly applied and for longer periods of time. Aside from rapid response to antigen stimulation, memory T cells can also be directly activated and perform effector functions via cytokine signaling alone in the presence of high concentrations of inflammatory or immunostimulatory cytokines due to expression of CD132/CD122 receptor complexes.[1-3] These 'bystander-activated' T cells can therefore amplify T cell effector responses particularly in aged individuals where a higher proportion of memory T cells exists.[4] While the role of PD-1/PDL-1 on antigen-specific T cell responses has been extensively characterized, its role in bystander T cell responses is less clear.

Methods We examined the role of the PD-1/PD-L1 pathway during bystander activation using multiple mouse and human model systems. T cells from mice treated with high-dose (HD) rhIL-2 were evaluated for bystander activation using flow cytometry for NKG2D, CD69, granzyme B, CD25, Ki67, and PD-1 expression. Mouse T cells from control or TCR-transgenic OT-1 mice (which are specific for ovalbumin and thus not antigen-experienced) were stimulated in vitro with rhIL-2 or anti-CD3/28 to model bystander versus TCR-stimulated signaling. Activation, proliferative, and apoptotic responses (via annexin V staining) were assessed at various time-points. Effects of PD-1 blockade or loss was also assessed. We compared these results gating on PD1+ and PD1- T cell populations and subsequently repeated the same procedure using human T cells isolated from human PBMCs. We then assessed human T cells isolated from patients undergoing HD rhIL2 treatment for cancer, gating on PD1+ and PD-1- activated T populations.

Results Significantly reduced activation and proliferative responses were observed by activated PD-1+ bystander T cells compared to the PD-1- populations in both the mouse and human T cells following HD IL2 treatment in vitro or in vivo. PD-1- bystander-activated T cells also had increased apoptosis via activation induced cell death (AICD). Concurrent blockade or absence of PD-1 signaling in the mouse models resulted in greater activation responses comparable to PD-1- cells, but this also resulted in increased AICD and cell loss.

Conclusions The PD-1/PD-L1 pathway also inhibits antigen-nonspecific bystander-activated memory T cell responses and protects cells from AICD. While blockade of this pathway can result in increased bystander activation and effector functions, it also leads to increased AICD and T cell loss. These findings imply possible consequences of continuous PD-1 blockade application on the maintenance of the finite memory T-cell pool.

AK112, A TETRAVALENT BISPECIFIC ANTIBODY TARGETING PD-1 AND VEGF, ENHANCES BINDING AVIDITY AND FUNCTIONAL ACTIVITIES AND ELICITS POTENT ANTI-TUMOR EFFICACY IN PRE-CLINICAL STUDIES

Tingting Zhong, Zhaoliang Huang, Xinghua Pang, Chunshan Jin, Xinrong He, Yu Xia, Baiyong Li, Jing Min*,. *Akeso Biopharma Co., Ltd., Zhongshan, China*

Background PD-1/PD-L1 inhibition immunotherapy holds great promise in cancer treatment. Combination treatment using anti-PD-1/PD-L1 agents with other immunotherapeutics brings additional benefits, such as preventing refractory effects towards PD-1/PD-L1 antibodies, and improving anti-tumor activities. Vascular endothelial growth factor (VEGF) is found to be frequently overexpressed in various solid tumors, which not only promotes tumor angiogenesis but also functions to suppress anti-tumor immune response.[1, 2] Consequently, a novel anti-PD-1/VEGF bispecific antibody (AK112) was designed to inhibit PD-1-mediated immunosuppression and simultaneously block tumor angiogenesis in the tumor microenvironment (TME). The tetravalent structure of AK112 allows formation of large complexes with dimeric VEGF, resulting in improved avidity to PD-1 and functional activities, which elicits potent anti-tumor efficacy in pre-clinical studies.

Methods The antigen binding activity of AK112 with PD-1 and VEGF were assessed by ELISA, Fortebio and flow cytometry. The formation of AK112-VEGF complexes was detected by size-exclusion high-pressure liquid chromatography (SEC-HPLC). To determine if VEGF could enhance the avidity of AK112 to PD-1, the binding activity of AK112 with PD-1 was evaluated by Fortebio and flow cytometry in the presence of VEGF. The blockade of PD-1/PD-L1 signaling pathway was determined in luciferase reporter cell assay. The PD-1 internalization was determined by flow cytometry. In *in-vivo* pharmacology studies, the anti-tumor activity of AK112 was investigated in SCID/Beige mice implanted with HCC827 cells.

Results AK112 could specifically bind to human PD-1 and VEGF with high affinity (table 1). Intriguingly, AK112 was found to form soluble complexes with VEGF by SEC-HPLC assay (figure 1). Notably, VEGF efficiently enhanced the binding of AK112 to PD-1 (table 2, figure 2), which led to increased PD-1 internalization (figure 3) and better potency on blockade of PD-1/PD-L1 signaling (figure 4). Moreover, AK112 demonstrated greater anti-tumor efficacy compared to Bevacizumab in mice (figure 5).

Conclusions AK112, a dual-blocking anti-PD-1/VEGF bispecific antibody, shows improved avidity to PD-1 in the presence of VEGF, and displays great anti-tumor efficacy in a mouse tumor model, supporting its clinical development for the treatment of human cancers.

522 CLINICAL AND MOLECULAR FEATURES OF ACQUIRED RESISTANCE TO IMMUNOTHERAPY IN NON-SMALL CELL LUNG CANCER

[1]Danish Memon, [2]Matthew Hellmann, [2]Martin Miller*. [1]*University of Cambridge, Cambridge, UK*; [2]*AstraZeneca, New York, NY, United States*

Background Although cancer immunotherapy with PD-(L)1 blockade is now routine treatment for patients with lung cancer, remarkably little is known about the molecular and cellular features of acquired resistance. This is partially due to the difficulty in obtaining pre- and post-treatment samples from patients that initially respond to immunotherapy but relapse with time. Studies from smaller cohorts in lung cancer have identified antigen presentation defects, alterations in interferon (IFN) signalling and neoantigen loss as potential mechanisms of immunotherapy resistance.

Methods To address the clinical and molecular landscape of acquired resistance to PD-(L)1 blockade in patients with NSCLCs, we examined the largest clinical cohort (n = 1,201) of acquired resistance to PD-(L)1 blockade in lung cancer to date paired with a systematic genomic and transcriptomic analysis in a subset of patients (n = 29) with pre- and post-treatment tissue samples available. Post-treatment samples were obtained following radiographic progression to PD-1 blockade. We also examined syngeneic lung and colorectal cancer murine model of acquired resistance to PD-1 blockade to validate relationships identified in human samples.

Results Of 1,201 NSCLC patients treated with PD-1 blockade at MSKCC, 243 (20%) achieved initial response. Many responding patients ultimately developed acquired resistance, with an estimated cumulative acquired resistance rate of 61% (95% CI 36% – 85%) at 5 years of follow up using a competing risk model (figure 1a). Post-progression overall survival was significantly longer in acquired resistance compared to primary progression (median 18.9 months vs 4.4 months, Log-rank p< 0.0001, figure 1b), suggestive of persistent, partially effective anti-tumor immune responses that permits prolonged survival even after the initial onset of AR.

In a subset of NSCLC patients (n=29) with available pre- and post-treatment samples (figure 1c), systematic immunogenomic analysis revealed that tumors with acquired resistance generally associated with enriched signals of inflammation (including IFNg signaling and inferred CD8+ T cells) and could be separated into IFNg upregulated and stable subsets. IFNg upregulated tumors had putative routes of resistance with signatures of dysfunctional interferon signaling and mutations in antigen presentation genes (figure 1d).

Transcriptomic profiling of cancer cells from a murine model of acquired resistance to PD-1 blockade showed evidence of dysfunctional IFN signaling and acquired insensitivity to *in vitro* IFNg treatment (figure 1e,f).

Conclusions We find evidence of ongoing but dysfunctional IFN response associated with acquired resistance to PD1 blockade in preclinical and clinical lung cancer data.

523 SMALL CELL LUNG CANCER MOLECULAR SUBTYPES AND VULNERABILITY TO IMMUNE CHECKPOINT BLOCKADE

[1]Barzin Nabet*, [1]Habib Hamidi, [1]Romain Banchereau, [2]Stefanie Morris, [2]Leah Adler, [1]Minu Srivastava, [1]Namrata Patil, [3]Carl Gay, [4]John Minna, [3]John Heymach, [5]Joseph Chan, [5]Charles Rudin, [3]Lauren Byers, [6]Stephen Liu, [7]Martin Reck, [1]David Shames. *[1]Genentech, South San Francisco, CA, United States; [2]Roche, Basel, Switzerland; [3]MD Anderson Cancer Center, Houston, TX, United States; [4]UT Southwestern Medical Center, Dallas, TX, United States; [5]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [6]Lombardi Comprehensive Cancer Center, Washington, DC, United States; [7]German Center of Lung Research, Ahrensburg, Germany*

Background Extensive-stage (ES) small cell lung cancer (SCLC) disproportionately contributes to annual lung cancer-related deaths.[1,2,3] Following the pivotal Phase III IMpower133 study, the PD-L1 inhibitor atezolizumab, combined with carboplatin and etoposide (CE), was the first immune checkpoint inhibitor approved for first-line treatment of ES-SCLC and is now a standard-of-care.[4] In general, SCLC tumors are immunological deserts with limited tumor cell PD-L1 expression.[5,6] Previous subtyping define SCLC tumors as neuroendocrine (NE) (ASCL1 or NEUROD1-driven) and non-neuroendocrine (nonNE) (POU2F3 or an Inflamed subtype). [5,7,8,9] Subtyping approaches have been limited to small cohorts and cell lines, with associated clinical outcomes suggesting improved benefit of the inflamed subtype with immunotherapy.[5]

Methods We analyzed pre-treatment RNA-sequencing (RNA-seq) from 271 patient tumors from IMpower133. We applied nonnegative matrix factorization (NMF) to define SCLC classes within this dataset and correlated these new subtypes with clinical outcomes to atezolizumab+CE versus placebo +CE. We defined cell-intrinsic and –extrinsic hallmarks of each subtype with differential gene expression analyses.

Results We identify four subtypes that can be characterized by both cell-intrinsic and tumor microenvironmental features. The subtypes include NEUROD1-driven (NE-N, 31%), ASCL1-driven (NE-A, 33%), NE inflamed (NE-I, 14%), and nonNE inflamed (nonNE-I, 22%). Prior classification schema had one inflamed subgroup, whereas we identify two clusters with inflamed hallmarks. We observe both a NE-I and nonNE-I group with enrichment for T cells, B/plasma cells, antigen presentation machinery, and immune cell PD-L1 expression.

We find that while the NE-A and NE-N subtypes show similar atezolizumab+CE benefit compared to placebo, the inflamed subtypes have markedly distinct outcomes. The NE-I subtype shows a near doubling of median overall survival (OS) with atezolizumab+CE compared to placebo+CE (OS HR, 0.45 [0.22-0.89]), while the nonNE-I subtype shows no benefit despite hallmarks of lymphocyte inflammation and PD-L1 expression (OS HR, 1.02 [0.55-1.91]). The balance of T-effector to tumor-associated macrophage (TAM) signals distinguish these two inflamed subtypes (NE-I and nonNE-I). Tumors with high T-effector and high TAM signals have similar OS with atezolizumab+CE and placebo+CE (OS HR, 0.85 [0.53-1.37]), while tumors with high T-effector, but low TAM signals demonstrate markedly longer OS with atezolizumab +CE compared to placebo+CE (OS HR, 0.26 [0.12-0.57]).

Conclusions We further refine SCLC subtypes and describe a spectrum of heterogeneity. We identify two inflamed subtypes with distinct clinical outcomes to atezolizumab+CE therapy dependent on the balance of T-effector to TAM infiltration. These results demonstrate the potential for personalization of therapy for SCLC patients based on molecular subtypes.

524 SOLUBLE PROGRAMMED DEATH LIGAND 1 AS PROGNOSTIC BIOMARKER IN NON-SMALL CELL LUNG CANCER RECEIVING IMMUNE CHECK-POINT INHIBITORS – APPLICABILITY AND POTENTIAL CAVEATS

Line Nederby*, Sinne Brun, Torben Hansen, Christa Nyhus, Lisbeth Bertelsen, Rikke Andersen, Anders Jakobsen, Torben Hansen. *University Hospital of Southern Denmark, Vejle, Denmark*

Background Immune checkpoint inhibitors against programmed death protein 1 (PD-1) and programmed death ligand 1 (PD-L1) have improved the survival of non-small cell lung cancer (NSCLC) patients. A number of studies have analyzed the level of soluble PD-L1 (sPD-L1) as a prognostic marker, but the results are divergent and call for further investigations. We addressed this by looking at sPD-L1 in baseline samples of such patients. Moreover, we studied the dynamics of sPD-L1 in serum collected prior to the three subsequent cycles of treatment to determine if anti-PD-L1 therapy and anti-PD-1 treatments instigate changes in the level of sPD-L1.

Methods 79 patients with advanced or recurrent NSCLC were enrolled at the Department of Oncology, Vejle Hospital, Denmark. The patients were treated with pembrolizumab (n=73), nivolumab (n=3), and atezolizumab (n=3). Blood samples were collected at baseline and before the following three cycles of treatment. sPD-L1 was measured using the Simoa® PD-L1 Discovery Kit and the Simoa® HD-1 analyzer (Quanterix). The study was approved by the Regional Committee on Health Research Ethics for Southern Denmark, approval number S-20170063.

Results In baseline samples the median concentration of sPD-L1 was 52 pg/mL (95% CI=49-57). Based on baseline sPD-L1 level the cohort was divided in three groups: sPD-L1(low) (n=24, median 38 pg/mL), sPD-L1(medium) (n=31, median 53 pg/mL), and sPD-L1(high) (n=24, median 79 pg/mL). The median overall survival was 26 months in sPD-L1(low), 15 months in sPD-L1(medium), and 9 months in sPD-L1(high). The difference between these was statistically significant (p=0.04, logrank test). The dynamics of sPD-L1 differed between patients receiving anti-PD-1 and anti-PD-L1 treatment. In patients receiving anti-PD-1 therapy, the level of sPD-L1 remained stable from the baseline sample and over the course of three cycles. Notably, in patients treated with anti-PD-L1, sPD-L1 rose by 50-fold following the first cycle and the concentration remained at the same high level in the subsequent samples. However, spiking atezolizumab in serum from healthy donors and anti-PD-1 treated patients showed that atezolizumab did not result in assay interference, but caused lower levels of sPD-L1 as one would expect.

Conclusions sPD-L1 has potential as a prognostic marker in NSCLC receiving anti-PD-1 and anti-PD-L1 therapy. Moreover, the data imply that continuous measures of this antigen in patients in anti-PD-L1 therapy need to be interpreted with caution, as it is undecided whether the elevated levels observed are accurate. Currently, experiments are conducted in our lab to solve this issue.

Ethics Approval The study was approved by the Regional Committee on Health Research Ethics for Southern Denmark, approval number S-20170063. All participants provided written informed consent.

526 **MIR-15A AND MIR-15B MODULATE NATURAL KILLER AND CD8$^+$T-CELL ACTIVATION AND ANTI-TUMOR IMMUNE RESPONSE BY TARGETING PD-L1 IN NEUROBLASTOMA**

[1]Kishore Challagundla*, [1]Anup Pathania, [2]Philip Prathipati, [1]Srinivas Chava, [1]Omalla Olwenyi, [1]Oghenetejiri Smith, [3]Subash Gupta, [1]Nagendra Chaturvedi, [1]Siddappa Byrareddy, [1]Don Coulter. *[1]University of Nebraska Medical Center, Omaha, NE, United States*; *[2]NIBIOHN, Ibaraki City, Japan*; *[3]Banaras Hindu University, Varanasi, India*

Background Neuroblastoma (NB) is an enigmatic and deadliest pediatric cancer to treat. The major obstacles to effective immuno- therapy treatments in NB are defective immune cells and the immune evasion tactics deployed by the tumor cells and the stromal microenvironment. Nervous system development during embryonic and pediatric stages is critically mediated by non-coding RNAs such as micro RNAs (miR). However, how miRs influence T and NK cell function and anti-tumor immune response in NB remains poorly understood.[1-3]

Methods We explored the role of miRs in anti-tumor immune response via a range of data-driven workflows and in vitro & in vivo experiments. Using the TARGET, NB patient dataset (n=249), we applied the robust bioinformatic workflows incorporating differential expression, co-expression, survival, heatmaps, and box plots. We performed PD-L1 mRNA 3'-untranslated region sequence-specific luciferase activity and Ago2 RNA immunoprecipitation assays. NB cells expressing miR-15a/miR-15b were cocultured with CD8+T and NK cells and analyzed the activation and cytotoxicity against NB in vitro. Murine stable NB cells expressing miR-15a were subcutaneously injected into C57/BL6 mice and analyzed tumor size, tumor vasculature, and the activation and infiltration of tumoral CD8+T and NK cells. Further, surface PD- L1 was blocked using an anti-PD-L1 antibody and CD8+T, and NK cell-mediated anti-tumor responses were studied.

Results We initially demonstrated the role of miR-15a-5p (miR-15a) and miR-15b-5p (miR-15b) as tumor suppressors, followed by their negative association with stromal cell percentages and a statistically significant negative regulation of T and natural killer (NK) cell signature genes, especially CD274 (PD-L1) in stromal-low patient subsets. The NB phase-specific expression of the miR-15a/miR-15b-PD-L1 axis was further corroborated using the PDX (n=24) dataset. We demonstrated miR-15a/ miR-15b mediated degradation of PD-L1 mRNA through its interaction with the 3'-untranslated region and the RNA- induced silencing complex using sequence-specific luciferase activity and Ago2 RNA immunoprecipitation assays. In addition, we established miR-15a/miR-15b induced CD8+T and NK cell activation and cytotoxicity against NB in vitro. Moreover, the injection of murine cells expressing miR-15a reduced tumor size and tumor vasculature and enhanced the activation and infiltration of CD8+T and NK cells into the tumors in vivo. We further established that blocking the surface PD- L1 using an anti-PD-L1 antibody rescued miR-15a/ miR-15b induced CD8+T and NK cell-mediated anti-tumor responses.

Conclusions These findings demonstrate that miR-15a and miR-15b induce an anti-tumor immune response by targeting PD-L1 in NB.

527 SPATIAL PROTEOMIC AND TRANSCRIPTOMIC BIOMARKERS OF RESPONSE TO IMMUNE CHECKPOINT INHIBITORS IN OPERABLE LUNG CANCER

Jonathan Stauber, Corinne Ramos*, Adele Ponzoni, Amandine Gerstenberg. *ImaBiotech, Loos, France*

Background Non-small cell lung cancer (NSCLC) accounts for about 85% of all lung cancers. There is a strong rationale for incorporating immunotherapy into the treatment of early-stage NSCLC, given the breakthrough results with PD-1 checkpoint inhibitors in advanced-stage NSCLC. How immunotherapy should be implemented in patients who are operable is still unclear. Most of the efforts so far to identify clinically useful biomarkers do not preserve spatial information and leave us blind to the critical source of information revealed in the cell-to-cell biology of the tumor microenvironment (TME). In order to overcome these limitations, we used spatial biomarkers assays that preserve this critical information about which cells are influencing treatment response.

Methods Frozen sections from retrospectively collected surgically resected NSCLC (adenocarcinoma and squamous cell carcinoma) tumors treated with adjuvant pembrolizumab therapy were used. Patients were classified in two groups according to their Objective Response Rate (ORR): Complete Response (CR) and Progression Disease (PD) for spatial transcriptomic and proteomics assays. The statistical analysis was performed through the GeoMx® DSP analysis suite. Cell deconvolution using the SpatialDecon® algorithm (Nanostring®) was then used to estimate the cell-type abundance in the spatially-resolved region of interest. Results were validated with single cell proteomic spatial analysis using proprietary workflow to identify which cells are influencing the treatment response and how they are spatially distributed relative to each other.

Results A higher expression of the drug targets, PD1 (PDCD1) and PD-L1 (CD274), and genes related to T lymphocytes cytotoxicity (GZMB, CD8a) and activation (CD44, CD27, TNFRS9) were detected in the tumor microenvironment of the responder patient. The analysis of the non-responder patients highlighted the overexpression of inhibitory ligands CD86 and B7H3 (CD276). Interestingly, TIGIT, CTLA4 and TIM-3 were significantly overexpressed on the surface of the CD8a+ T cells. These results were validated by investigating the drug targets and immunosuppressive cells in the tumor microenvironment of patient samples that did not respond to immunotherapy.

Conclusions These findings highlight the relevance of considering a set of spatial biomarkers involved in immune suppression pathways to obtain a comprehensive portrait of the tumor microenvironment for personalized therapy selection. Our results suggest that for patients who did not respond to monotherapy, it would have been preferable to resort to a combined immune checkpoint inhibitors treatment strategy, aimed at the complete inhibition of all the immune-suppressive pathways.

528 ACQUIRED RESISTANCE TO PD-(L)1 BLOCKADE IN PATIENTS WITH NON-SMALL CELL LUNG CANCER (NSCLC)

[1]Biagio Ricciuti*, [1]Giuseppe Lamberti, [1]Joao Victor Alessi, [1]Federica Pecci, [1]Alessandro Di Federico, [2]Xinan Wang, [1]Adriana Barrichello, [1]Victor Vaz, [1]Andy Pangilinan, [1]Danielle Haradon, [1]Lee Elinton, [3]Mizuki Nishino, [3]Scott Rodig, [3]Lynette Sholl, [1]Mark Awad. *[1]Dana-Farber Cancer Institute, Boston, MA, United States; [2]Harvard TH Chan School of Public Health, Boston, MA, United States; [3]Brigham and Women's Hospital, Boston, MA, United States*

Background Although immune checkpoint inhibition (ICI) has improved survival in patients with non-small cell lung cancer (NSCLC), the majority of patients develop acquired resistance (AR) to ICI after an initial benefit.[1-2] However, the mechanisms underlying AR to ICI in NSCLC are largely unknown.

Methods Comprehensive genomic profiling and HLA-I immunohistochemistry (IHC, by blinded pathology assessment) were performed on samples from patients with NSCLC treated with PD-(L)1 blockade at the Dana-Farber Cancer Institute and matched pre and post ICI tumor biopsies (figure 1). Acquired resistance was defined as the development of disease progression after an initial objective response, or stable disease ≥3 months with PD-(L)1 blockade.

Results Among 1823 patients with advanced NSCLC who received ICI, 60 developed acquired resistance to treatment and had matched pre- and post-ICI tissue samples.

Putative mechanisms of AR to PD-(L)1 blockade were identified in 56.7% (34/60) of cases (figure 2). Acquired mutations in *STK11* were identified in 8.3% of cases (N=5) resulting in homozygous loss in 2, due to acquired copy deletion. Acquired mutations in *KEAP1* and *SMARCA4* were noted in one (1.7%) and 3 patients (5%), respectively. Four patients (6.7%) developed acquired deleterious mutations in the beta 2-microglobulin (*B2M*) gene. Of these, one exhibited bi-allelic loss due to concurrent *B2M* copy deletion. Other acquired alterations implicated in resistance to ICI included homozygous loss in *JAK1* (N=1, 1.7%) and *APC* (N=1, 1.7%), and acquired activating *PI3KCA* mutation (N=1, 1.7%). In examining acquired copy number variations (CNVs), we found bi-allelic deletions in *CDKN2A/CDKN2B* in four cases (6.7%), and acquired heterozygous deletion in *CD274* (PD-L1) and *PDCD1LG2* (PD-L2) genes in four cases (6.7%), while high level MDM2 and MYC amplifications were identified in 3 (5%) and 1 (1.7%) case, respectively. PD-L1 expression, tumor mutational burden, and total aneuploidy levels were not impacted by intervening ICI (figure 3). Among patients with tissue available for HLA-I IHC, we found a significant decrease in HLA-I expression by H-score at the moment of acquired resistance to ICI (median H-score decrease -10 [range: 0 to -220], P=0.03. figure 4).

In 2 independent control cohorts of patients with pre- and post-chemotherapy (N=41) or EGFR inhibitors (N=90) tumor genomic profiling, no acquired mutations in *STK11* or *B2M* were detected. Intervening chemotherapy and EGFR inhibition had no impact on HLA-I expression (figure 4).

Conclusions Mechanisms of AR to PD-(L)1 blockade are heterogenous, and new therapeutic strategies are required to delay and overcome ICI resistance in patients with NSCLC.

529 REDUCED DENDRITIC CELL INFILTRATION IN ANTI-PD-1 RESISTANT HEAD AND NECK SQUAMOUS CELL CARCINOMA

[1]Shin Saito*, [1]Hirofumi Shibata, [1]Liye Zhou, [2]Katie Campbell, [3]Ann Marie Egloff, [1]Ravindra Uppaluri. *[1]Dana Farber Cancer Institute, Boston, MA, United States; [2]University of California Los Angeles, Los Angeles, CA, United States; [3]Brigham and Women's Hospital, Boston, MA, United States*

Background Although immune checkpoint inhibitors have been approved for head and neck squamous cell carcinoma (HNSCC) patients, the majority do not respond, and further treatment optimization is required. Diverse anti-PD-1 resistance mechanisms have been proposed for this lack of benefit, which is inconsistent with the moderate tumor mutational burden and immune infiltration observed in HNSCC. Here we identified neoantigens and characterized dendritic cell (DC) infiltration in previously reported murine oral carcinoma (MOC) models with differential response to anti-PD-1, and we interrogated DC infiltration as a correlate of response in a neoadjuvant anti-PD-1 clinical trial.

Methods HNSCC MOC1 and its isogenic anti-PD-1 resistant MOC1-esc1 models were subjected to immunogenomic analysis. MOC1 and MOC1-esc1 expressed neoantigens that were defined using whole exome and RNA sequencing (RNASeq) data from cultured lines, and Class I presented neoantigens were predicted in silico (NetMHCpan4.0). MOC1 tumor infiltrating lymphocytes (TILs), following control, anti-PD-1 or anti-CTLA-4 treatment, were assayed for reactivity to synthesized predicted neoantigen peptides, and DC tumor infiltration was assessed by flow cytometry. Patient HNSCC tumor RNA-Seq data from our neoadjuvant pembrolizumab trial (NCT02296684) were interrogated, and response to neoadjuvant anti-PD-1 was classified based on pathological response in surgical specimens.

Results As we previously reported[1], MOC1 was anti-PD-1 responsive and MOC1-esc1 was resistant, while both lines were sensitive to anti-CTLA-4 therapy. Results from our immunogenomics pipeline identified 325 neoantigen candidates in MOC1 with a predicted Class I binding affinity (% rank) of less than 0.5. We tested 35 putative neoantigens for TIL immune reactivity to synthesized candidate neoepitope peptides using ELISPOT. MOC1 TIL had reactivity to mutant Yipf1 (mYipf1) neoepitope in addition to the endogenous retrovirus derived p15E antigen. Anti-PD-1 modestly increased while anti-CTLA-4 significantly increased MOC1 TIL reactivity to p15E and mYipf1 compared to control. Analysis of RNA-Seq data from MOC1 and MOC1esc1 showed a reduced conventional DC1 (cDC1) signature in MOC1esc1, and we confirmed this reduced infiltration by flow cytometry. Finally, in neoadjuvant anti-PD-1 HNSCC trial samples, a published DC signature [2] was found to be significantly higher in responder pretreatment biopsies compared to non-responders ($p=0.016$).

Conclusions We identified mYipf1 as a novel neoantigen in MOC1 and employed TIL response to mYipf1 or p15E peptides to measure MOC TIL anti-tumor activity. CTLA-4 directed antibodies enhanced TIL anti-tumor activity compared to anti-PD1 treatment. Reduced cDC1 infiltration and not lack of neoantigen expression may represent an anti-PD-1 resistance mechanism in HNSCC.

530 **B7-H3 IS A CHECKPOINT IMMUNOTHERAPY TARGET IN ADVANCED PROSTATE CANCER HARBORING PTEN AND TP53 DEFECTS**

Di Zhao*, Wei Shi, Yin Wang. *UT MD Anderson Cancer Center, Houston, TX, United States*

Background Prostate cancer is the most diagnosed cancer in men worldwide and the leading cause of cancer death in men worldwide. Genetic inactivation of *PTEN* and *TP53* are common in advanced prostate cancers. Checkpoint immunotherapy has yielded meaningful responses across many cancers but shown minimal activity in advanced prostate cancer. Prior studies showed that overexpression of immune checkpoint B7-H3 (CD276) correlates with the increased risks of clinical recurrence, disease spread, and poor outcomes in various cancer types, including prostate cancer. However, the roles of B7-H3 in prostate cancer development and its tumor microenvironment remain unclear, partially due to the lack of tissue-specific deletion mouse models. This gap in knowledge hinders the application of immunotherapy targeting B7-H3 in prostate cancers.

Methods To identify PTEN- and p53-associated immune checkpoints, we performed multi-omics analyses of expression patterns of 51 checkpoint molecules in human prostate cancer samples. Then, we generated a novel generated genetically engineered mouse model to elucidate the role of B7-H3 in tumor development and progression of PTEN/p53-deficient prostate cancer. We also performed unbiased immunoprofling using Mass Cytometry (CyTOF) and Immunofluorescence to visualize B7-H3's impact on immune components in prostate tumors.

Results Our multi-omics analyses in human samples revealed that B7-H3 is one of the most significantly overexpressed immune checkpoints in prostate tumors containing *PTEN* and *TP53* genetic inactivation. Mechanistically, we found that the PTEN-AKT pathway co-operates with the p53 pathway in modulating B7-H3 expression in cancer cells. In *Pten/Trp53* genetically engineered mouse (GEM) models, prostate-specific deletion of *Cd276* resulted in markedly delayed tumor progression. *Cd276* deletion also reversed the immunosuppression characterized by increased tumor-infiltrating lymphocytes.

Conclusions Our studies provide the genetic evidence for the tumor-promoting and immunosuppressive role of B7-H3 in prostate cancer and offer insights into combinatorial strategies for immunotherapy targeting B7-H3 in CRPC harboring PTEN and TP53 defects.

531 IDENTIFYING GENETIC FACTORS FOR RESISTANCE AND RESPONSE TO IMMUNE CHECKPOINT INHIBITORS (ICIS) IN ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS USING REAL-WORLD DATA

Neeraj Singh*, Smita Agrawal, Babu Narayanan. *ConcertAI, Bangalore, India*

Background ICIs are a promising class of drugs that have improved the treatment of a broad spectrum of cancers. Biomarkers such as high Tumor Mutation Burden (TMB), high PD-L1 expression, or high Microsatellite Instability (MSI) are predictive of improved response to ICIs.[1-3] However, not all patients with these biomarkers respond well to ICIs and some develop resistance over time. The underlying molecular mechanisms of resistance are poorly known. We leveraged our deeply curated real world clinico-genomics database (ConcertAI Genome360^{TM}) of NSCLC patients treated with ICIs to identify the drivers of resistance and response.

Methods This retrospective study used the ConcertAI Genome360^{TM} NSCLC dataset. The eligible patients had advanced NSCLC treated with ICIs (N=2532). A subset of these patients also had high TMB/PD-L1/MSI (TPM) status (N=986). The following analysis was performed for both the TPM unselected and high TPM populations. The patients were subdivided into responder and non-responder cohorts based on their response to ICIs. For each patient in both cohorts, genes with pathogenic mutations, fusions and copy number changes were identified and enrichment analysis was performed between cohorts. Biomarkers with p value less than 0.05 were further considered for pathway analysis along with the immune signaling network to identify pathways and genes responsible for response and resistance to ICIs in-spite of TPM high status.

Results We identified segments which predicted response or resistance to ICIs (table 1). TERT promoter mutations and loss of function (LOF) mutations in STAG2 promote high TMB and PD-L1 expression respectively.[4,5] We also see them enriched in our overall responder cohort, however, the effect of STAG2 LOF mutations towards response to ICIs is seen even in the TPM high population indicating the effect is due to more than just upregulation of PD-L1. LOF mutations in ATM/ATR genes were also enriched in the overall responder cohort in-line with previous observations in murine cells.[6,7] Gene amplifications in CDK12 and CEBPA genes were predictive of resistance to ICIs and interestingly, amplifications in CDK12 and RET were also highly predictive of resistance to ICIs in the TPM high cohort which was heavily biased towards response to therapy.

Pathway analysis on the combined results identified that genes in the cGAS-STING pathway are playing a vital role in determining response.

Conclusions Our analysis highlights some of the underlying mechanisms for response or resistance to ICIs which can provide clues for designing new combination trials for patients whose tumor progresses on ICIs.

Abstract 531 Table 1 Genomic segment of response towards ICIs treatment

Overall Cohort treated with ICI (N = 2532)			
Gene Name	**Status**	**Response**	**p value**
STAG2	LOF Mutations	Responder	0.001
NF1/2	LOF Mutations	Responder	0.015
ATM/ATR	LOF Mutations	Responder	0.031
RBM10	LOF Mutations	Responder	0.043
TERT	Promoter Mutation	Responder	0.048
CDK12	Amplification	Non-responder	0.011
CEBPA	Amplification	Non-responder	0.028
PDL1/MSI/TMB high cohort treated with ICI (N = 986)			
Gene Name	**Status**	**Response**	**p value**
STAG2	LOF Mutations	Responder	0.03
KRAS	GOF Mutations	Responder	0.041
CDK12	Amplification	Non-responder	0.003
RET	Amplification	Non-responder	0.017

532 ANTI-VISTA ANTIBODY HMBD-002 REPROGRAMS TUMOUR ASSOCIATED MACROPHAGES AND PROMOTES CYTOTOXIC T CELL RESPONSE

Bhushan Dharmadhikari*, Dipti Thakkar, Olga Zharkova, Debleena Ray, Jason Lai, Konrad Paszkiewicz, Piers Ingram, Jerome Boyd-Kirkup. *Hummingbird Bioscience, Singapore, Singapore*

Background VISTA is an emerging, predominantly myeloid, immune checkpoint, and its blockade has shown benefit in multiple preclinical models of cancer as both a monotherapy and in combination with other immune checkpoint inhibitors (ICI) such as anti-PD1 and anti-CTLA-4. In some murine models of cancers, such as non-small cell lung cancer, clear-renal cell carcinoma and colorectal carcinoma, VISTA is expressed on both T cells and macrophages. Understanding the cell subset specific immunomodulatory functions of VISTA is important to inform patient selection, develop effective combination strategies, and identify biomarkers of response to anti-VISTA therapy.

Methods The murine colon cancer model, CT26, exhibits robust infiltrations of multiple immune cells into tumors, and has been reported to respond to VISTA blockade. This allows simultaneous investigation of VISTA-mediated immune modulation in multiple cell subsets. Here, HMBD-002, an IgG4 anti-VISTA antibody which does not deplete VISTA-expressing cells, was used to assess the functional role of VISTA blockade in the absence of Fc-mediated effects. CT26 tumor-bearing mice were treated with HMBD-002 and/or anti-PD1. Tumors were harvested and profiled via multicolor flow cytometry to determine underlying changes in the polarization and functional status of immune infiltrates associated with anti-tumor responses.

Results In CT26 tumors, VISTA expression was highest on macrophages followed by MDSCs, DCs and T cells. VISTA blockade polarized macrophages to an activated pro-inflammatory anti-tumor phenotype with significant increases in TNFα and MHCII expressing macrophage subsets. VISTA blockade also resulted in significant increases in tumor antigen gp70-specific CD8 T cells. A concurrent increase in CD8 T cell activation was seen with an upregulation of several cytotoxicity associated markers, including Granzyme B. However, no change in T cell exhaustion levels was observed. The combination of VISTA blockade with anti-PD1 treatment led to further increases in tumor antigen-specific CD8 T cells, significant decreases in T cell exhaustion levels and enhanced anti-tumor efficacy when compared to monotherapy anti-VISTA or anti-PD1 arms.

Conclusions Reprograming of the tumor microenvironment by blockade of VISTA is associated with polarization of macrophages to an inflammatory phenotype and increases in both tumor antigen-specific CD8 T cells and their cytotoxic activity. Further, combining anti-VISTA with other immune checkpoint inhibitors that can reprogram exhausted T cells has the potential for synergistic activity.

Ethics Approval The study was approved by the Institutional Animal Care and Use Committee, approval number 2021/SHS/1660

533 A TUMOR-LUNG NLRP3-TLR4 DISTANT SIGNALING AXIS DRIVES IMMUNOTHERAPY RESISTANCE VIA G-CSF-DEPENDENT EXPANSION OF CIRCULATING PD1^{+} PMN-MDSCS

Balamayooran Theivanthiran*, Nagendra Yarla, Tarek Haykal, Michael Plebanek, Y-Van Nguyen, Nicholas DeVito Brent Hanks. *Duke University, Durham, NC, United States*

Background The majority of solid tumor cancer patients do not benefit from current immunotherapy options due to the development of either primary or secondary resistance. We recently determined that the tumor-intrinsic NLRP3 inflammasome drives the recruitment of granulocytic myeloid-derived suppressor cells (PMN-MDSCs) and adaptive resistance to anti-PD-1 immunotherapy via a HSP70-TLR4 signaling axis. Prior studies have associated *TLR4* gain-of-function mutations with inferior clinical outcomes while pulmonary inflammation has been correlated with anti-PD-1 resistance. How lung-expressed TLR4 and lung-derived factors influence tumor immunity at distant sites remains poorly understood

Methods We engineered an inducible lung epithelial-specific TLR4 knock-out transgenic mouse model (SPC-TLR4$^{-/-}$) to investigate the impact of lung TLR4 on anti-PD-1 immunotherapy responses in BRAF^{V600E}CDKN2A$^{-/-}$PTEN$^{-/-}$ (YUMM1) melanoma and EO771 breast cancer syngeneic tumor models. Genetic silencing of NLRP3 and HSP70 was performed in tumor models. Immunohistochemistry, qrt-PCR, Western blot analysis, and multi-parameter flow cytometry was used to characterize tumor NLRP3-lung TLR4 crosstalk and its impact on anti-tumor immunity. Baseline tumor specimens and plasma samples derived from 40 stage IV melanoma patients undergoing anti-PD-1 immunotherapy were interrogated for intrinsic NLRP3 inflammasome activation levels by NLRP3-ASC proximity ligation and HSP70 ELISA assays. Objective responses were assessed by computed tomography imaging at week 12 of therapy based on RECIST1.1 criteria

Results Anti-PD-1 immunotherapy expands circulating levels of PD-1+ PMN-MDSCs in mice harboring YUMM1 and E0771 breast cancer models. This was noted to correlate with elevated plasma levels of HSP70 and G-CSF. Both observations were ablated in mice harboring NLRP3$^{-/-}$ tumors as well as in SPC-TLR4$^{-/-}$ hosts. Further studies found lung epithelial HSP70-TLR4 signaling to induce G-CSF release in a Wnt5a-dependent manner. Pharmacologic inhibition of HSP70 suppresses lung epithelial Wnt5a and G-CSF expression and inhibits the accumulation of PD-1^{+} PMN-MDSCs in the circulation. Further studies demonstrate the distant lung TLR4-Wnt5a-G-CSF axis promotes PD-1^{+} PMN-MDSC accumulation and primary tumor progression. Baseline tumor NLRP3 inflammasome activity (P = 0.0014) and plasma HSP70 levels (P = 0.0008) in stage IV melanoma patients independently correlate with elevated circulating PMNs and disease progression during anti-PD-1 immunotherapy

Conclusions Together, these results describe a novel TLR4-Wnt5a-G-CSF signaling axis in the lung epithelium that induces the systemic expansion of PD-1^{+} PMN in response to activation of the tumor-intrinsic NLRP3 inflammasome. We conclude that this tumor-lung crosstalk supports primary tumor growth and contributes to anti-PD-1 immunotherapy resistance partially by serving as an anti-PD-1 antibody sink. Pharmacologic inhibition of NLRP3 and HSP70 represents promising strategies for overcoming anti-PD-1 resistance.

534 SEX-LINKED DIFFERENCES IN OBESITY MARKEDLY IMPACT THE ANTI-TUMOR EFFICACY OF PD-1 BLOCKADE

[1]Logan Vick*, [1]Ziming Wang, [1]Craig Collins, [1]Lam Khuat, [1]Cordelia Dunai, [1]Kevin Stoffel, [2]Sai Yendamuri, [2]Sarbajit Mukherjee, [2]Spencer Rosario, [1]Robert Canter, [1]Arta Monjazeb, [1]William Murphy. *[1]University of California, Davis, Sacramento, CA, United States*; *[2]Roswell Park Comprehensive Cancer Center, Buffalo, United States*

Background Immune checkpoint inhibitors (ICIs) particularly those targeting the PD-1/PD-L1 axis have markedly impacted cancer immunotherapy resulting in significant therapeutic responses across an increasingly wide variety of cancers. While obesity is often associated as a negative prognostic indicator in cancer and therapeutic outcomes, it has surprisingly been linked to greater anti-tumor efficacy and survival in multiple cancers following immune checkpoint blockade both in pre-clinical models and clinical outcomes. Clinical data have demonstrated that the increased clinical efficacy was only observed in high body mass index (BMI) males and not females, indicating that sex-linked differences of obesity as it pertains to immunotherapy may exist with regard to the "obesity paradox" in cancer immunotherapy.

Methods We assessed the effects of sex on obesity-associated immune checkpoint therapy responses using a diet induced obese (DIO) mouse model following placement on high fat diet (HFD) versus control diets for a period of several months. Mice then received tumors and the tumor-bearing male and female mice were treated by targeting PD-1/PDL-1 as a monotherapy. We then characterized the immune signature of the different cohorts before and after immunotherapy. To determine if hormonal pathways were indeed involved, we then assessed effects of anti-PD-1 therapy in ovariectomized DIO and lean tumor bearing mice. Stratification of immunotherapy outcomes in high versus low BMI male and female cancer patients was also assessed.

Results Tumor progression was observed greater in both male and female DIO mice compared to control diet recipients. Immunotherapy using anti-PD-1 resulted in significant anti-tumor effects in DIO male mice but not DIO female nor the lean male and female recipients. Ovariectomy of female mice resulted in markedly greater weight gain when placed on HFD as well as accelerated tumor growth but it also resulted in significant efficacy of anti-PD-1 monotherapy comparable to male DIO mice. Stratification of patient outcomes following checkpoint blockade for melanoma on both BMI and sex demonstrated that significant increases in survival and efficacy were only observed in high BMI male patients mirroring the effects observed in the mouse models.

Conclusions These data reveal potential implications in taking sex into account when using obesity as a predictive biomarker for effective use of ICI and provides potential insights on how to potentially improve immunotherapy efficacy by targeting hormonal pathways.

Ethics Approval All animal were housed in AAALAC-accredited animal facilities at University of California Davis and all animal protocols were approved by the University of California Davis Institutional Animal Care and Use Committee (IACUC). All studies maintained compliance with guidelines and regulation from the IACUC.

535 HYDROXYCHLOROQUINE SYNERGIZES WITH ANTI-PD-1 IMMUNE CHECKPOINT BLOCKADE IN SQUAMOUS CARCINOMA OF THE HEAD AND NECK

[1]Avani Vyas*, [1]Silvia Cruz-Rangel, [1]Nayel Khan, [1]Mikayla Bisignani, [1]Lidia Arantes, [2]Nicole Schmitt, [1]Kirill Kiselyov, [1]Robert Ferris, [1]Umamaheswar Duvvuri. [1]*University of Pittsburgh, Pittsburgh, PA, United States*; [2]*Emory Department of Otolaryngology, Atlanta, GA, United States*

Background The recent evidence shows that Programmed Death Ligand 1 (PD-L1) presentation on the plasma membrane is dynamically modulated by the delivery via the secretory pathway and withdrawal, recycling and degradation, which may involve endolysosomal pathway. PD-L1 is delivered to the plasma membrane via the secretory pathway which may involve lysosomal activity. Whereas the significance of this step is not completely understood, it provides a rationale for testing lysosomal inhibition as a means to regulate PD-L1. Limited, but intriguing, prior attempts yielded mixed results, suggesting that regulation of this process is complex. We hypothesized that inhibition of endolysosomal traffic would suppress PD-L1 plasma membrane presentation and synergize with anti-PD-1 immune checkpoint blockade.

Methods PD-L1 plasma membrane presentation was measured via flow cytometry using lysosomotropic drugs, apilimod or hydroxychloroquine (HCQ). Lysosomal exocytosis was measured using beta-hexosaminidase activity. PIKfyve knock down cells were created using CRISPR-Cas9 technique. We designed an *in vitro* assay to co-culture peripheral blood CD8+ T cells with human cancer cell lines. C57/Bl (4-week-old) mice were implanted subcutaneously with MOC-1 or UPCI: M4Tu lines on each flank and randomized. Treatments were administered two times a week intraperitoneally. The volume of the tumors was measured three times a week.

Results We find that *in vitro*, treatment with the PIKfyve inhibitor apilimod or suppresses plasma membrane presentation of PD-L1. Similarly, treatment with the lysosomal inhibitor hydroxychloroquine (HCQ) also reduced PD-L1 presentation, confirming endolysosomal involvement in PD-L1 handling. Using syngeneic mouse models of head and neck cancers, we find that HCQ synergizes with anti-PD-1 therapy, causing tumor growth inhibition of 80% and dramatically increased survival ($p<0.001$, log-rank test). Treatment with HCQ promoted *in vitro* cancer cell cytotoxicity, suggesting that HCQ may directly promote CD8+ T cell activity.

Conclusions HCQ is a potent adjuvant for anti-PD-1 therapy, by mediating PD-L1 plasma membrane presentation on cancer cells and possibly mediating CD8+ T cell activation.

Ethics Approval The animals were handled and euthanized in accordance with Institutional Animal Care and Use Committee (IACUC) guidelines. Human blood samples were obtained from the University of Pittsburgh Medical Center in accordance with established University of Pittsburgh IRB guidelines. Written informed consent was obtained from all the patients before inclusion in the study.

536 **DECOUPLING CYTOTOXIC T LYMPHOCYTE AND EXHAUSTED T LYMPHOCYTE TRANSCRIPTOMIC SIGNATURES ENHANCES IMMUNE CHECKPOINT INHIBITORS RESPONSE PREDICTION IN MELANOMA**

Binbin Wang, Kun Wang*, Eytan Ruppin, Peng Jiang. *National Cancer Institute, Rockville, MD, United States*

Background Cytotoxic T lymphocyte (CTL) plays a crucial role in anti-cancer immunity. Progression of CTL to exhausted T lymphocyte (ETL) cells that overexpress inhibitory receptors can substantially decrease effector cytokines production and diminish the cytolytic activity in tumor microenvironment (TME). However, while the activity levels of CTL and ETL are considered important determinants of Immune checkpoint inhibitor (ICI) response, it has been repeatedly observed that their predictive power of the latter is quite limited. Studying this conundrum on a large scale across the TCGA cohort, we find that ETL and CTL activity (estimated based on conventional gene signatures in the bulk tumor expression) is strongly positively correlated in most cancer types. We thus hypothesized that their limited predictive power may arise due to their high concordance in the bulk expression, such that their opposing associations with response effectively cancel each other.

Methods Aiming to better characterize these two CD8+ immune states as ICI response biomarkers, we analyzed several melanoma single cell expression datasets via an interaction linear regression model and identified 13 genes whose expression state decouples the CTLs and ETLs.

Results We further tested and validate this *decoupling signature* in several melanoma bulk expression ICI cohorts by first demonstrating that in high-decoupling-score patient groups, the correlation between ETL and CTL activities is indeed markedly lower than in the low-decoupling-score patient groups. Second, the performance of CTL activity in predicting ICI response is significantly better in the high-decoupling-score than that in the low one. Finally, importantly, in the high decoupling score, CTL activity is a better predictor of melanoma patients ICI response than state-of-art ICI prediction methods.

Conclusions These results demonstrate the utility of a new decoupling score for boosting the power of CTL activity in predicting ICI response in melanoma.

537 LOCAL IMMUNOTHERAPY WITH INTASYL™ SELF-DELIVERING RNAI TARGETING CTLA-4 PROVIDES ROBUST TUMOR CONTROL IN VIVO

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0537

Benjamin Cuiffo*, Melissa Maxwell, Dingxue Yan, Brianna Rivest, Andrew Boone, Shenghua Zhou, James Cardia, Simon Fricker. *Phio Pharmaceuticals, Marlborough, MA, United States*

Background Immune checkpoint inhibition (ICI) of CTLA-4 with ipilimumab has proven effective in improving clinical responses for patients with advanced melanoma or other approved indications in combination with nivolumab. However, systemic treatment with ipilimumab is associated with serious adverse events (SAEs) for many (>25%) patients that can be life-threatening and/or result in discontinuation of treatment. As such, balancing efficacy with associated toxicities remains a challenge in treating patients with ipilimumab.

Local intratumoral (IT) immunotherapy may enhance local activity and decrease systemic toxicity. Additionally, by using the tumor as its own vaccine, IT immunotherapy can ignite tumor-specific immune responses well beyond the local site of administration. While clinical testing of IT antibody therapies is underway, the high molecular weight properties of therapeutic antibodies may limit their local diffusion and retention time within tumors.

RNAi therapy is an emerging modality well-positioned to optimize local clinical application of ICI. We have previously demonstrated that self-delivering RNAi (INTASYL) therapeutic compounds built on proprietary INTASYL™ technology silence targets with high specificity and without need for specialized formulations or drug delivery systems and provide robust antitumor efficacy to both directly-treated and to non-directly treated distal tumors when delivered IT in vivo.

Here we present proof-of-concept (POC) in vivo data showing IT efficacy of a novel INTASYL targeting murine CTLA-4 (mCTLA-4; 27790) in two syngeneic mouse tumor models.

Methods CTLA4 mRNA silencing was validated in CHO K1 cells expressing murine CTLA-4 in vitro by RT-qPCR. For in vivo efficacy, Hepa1-6 or CT26 cells were implanted subcutaneously into the flanks of C57BL/6 or BALB/c mice, respectively. When tumors reached threshold volume (150 mm^3), animals were randomized into treatment groups; treatments were administered on Days 1, 4, 7, 10 and 13. Vehicle (PBS), a chemically identical non-targeting control (NTC) INTASYL, or INTASYL 27790 at two dose concentrations were administered IT; anti-CTLA-4 monoclonal antibody (mAb; clone 9D9) was administered intraperitoneally (IP). Tumor volumes and body weights were recorded longitudinally.

Results mCTLA-4-targeting INTASYL 27790 provided concentration-associated silencing of mCTLA-4 in vitro. When administered IT, mCTLA-4-targeting INTASYL 27790 elicited robust dose-associated antitumor efficacy in both in vivo tumor models compared with vehicle- or NTC-treated tumors, comparable to that observed under systemic IP treatment with anti-CTLA4 mAb.

Conclusions These data show IT INTASYL targeting mouse CTLA4 elicits robust on-target dose concentration-associated antitumor efficacy in two syngeneic tumor models in vivo and provide POC for targeting CTLA-4 IT with INTASYL.

Ethics Approval Animal studies were performed at Pharma Models LLC, Marlborough, MA 01752, under standard protocol approved by their IACUC.

Clinical Trials Completed

538 COMPREHENSIVE SINGLE CELL TRANSCRIPTOMIC PROFILING OF UNTREATED RESECTABLE LUNG CANCERS

Sydney Connor*, Jiajia Zhang, Justina Caushi, Boyang Zhang, Zhen Zeng, Khaled Sanber, Gavin Pereira, Valsamo Anagnostou, Ada Tam, Nicholas Ionta, Franck Housseau, Patrick Forde, Hongkai Ji, Andrew Pardoll, Kellie Smith. *Johns Hopkins School of Medicine, Baltimore, MD, United States*

Background Non-small cell lung cancer(NSCLC) is the leading cause of cancer-related deaths in men and women. The 5-year overall survival rate of metastatic NSCLC is an abysmal 21%, in part since >80% of lung cancers are diagnosed at an advanced stage.[1,2] Encouragingly, neoadjuvant immune checkpoint blockade(ICB) plus chemotherapy is now approved as standard of care for resectable lung cancer.[3,4] Because ICB success depends on an endogenous anti-tumor T cell response, it is critical that we understand the baseline functional biology of these T cells. To date, however, comprehensive studies of endogenous tumor-reactive TIL in operable NSCLC(Stage I-III) are lacking. Herein we present an integrated single cell immunogenomic profiling of 21 untreated tumor resections from patients who were surveilled for 1-5 years post-surgery.

Methods After acquiring written informed consent, PBMC and resected tissues were obtained from patients with Stage I-III NSCLC undergoing surgical resection. Tissues were enzymatically digested and viably frozen. Cryobanked tissues were thawed, T cells (CD3+CD45+) and non-T cells (CD3-) were sorted, and prepared for single cell RNA sequencing. Single Cell 5' V(D)J and 5' DGE kits (10X Genomics) were used to capture immune repertoire and gene expression information for the T cell fraction, DGE libraries were prepared for the non-T cell fraction.

Results Transcriptomic profiles were defined for CD3+ TIL from 21 untreated surgically-resected tumors (527,062 cells). Refined UMAP projection of CD8+ TIL (183,375 cells) uncovered 14 CD8+ T cell subsets. We observed four distinct tissue resident memory (TRM) clusters. This is notable, as our previous work defined the TRM subsets as being enriched in tumor-reactive TIL.[5,6] Apropos of this notion, two of these TRM clusters were significantly enriched in the tumor tissue compared to adjacent normal lung and lymph node (adj.p-value=$1.3x10^{-4}$ and $3.6x10^{-3}$), with one of these TRM clusters expressing high levels of markers previously shown to mark tumor-reactive TIL, including *HOBIT, CXCL13*, and *CD39* [5,7,8]. Further supporting our hypothesis that this cluster harbors tumor-reactive TIL, cross-reference with public TCR databases showed almost no overlap of the TCRs in this cluster with TCRs corresponding to virus-specific T cells, whereas 726 EBV- and 177 flu-specific TIL were readily detected within other TRM and T Effector clusters.

Conclusions This study is one of the first to evaluate the transcriptional programming of tumor-reactive TIL in treatment-naïve lung cancers. Understanding the baseline functional biology of these cells has significant implications for biomarker and novel therapy development for the treatment of lung cancers resistant to currently-approved therapies.

Trial Registration For the ICB treated NSCLC patients enrolled under NA_00092076 at JHU (NCT02259621), samples have already been collected, stored, and published.

541 MREGDC/T HELPER NICHES ENABLE LOCAL REACTIVATION OF CD8 T CELLS UPON PD-1 BLOCKADE

[1]Assaf Magen*, [1]Pauline Hamon, [2]Nathalie Fiaschi, [2]Raquel Deering, [1]Sacha Gnjatic, [3]Myron Schwartz, [1]Thomas Marron, [2]Gavin Thurston, [1]Alice Kamphorst, [1]Miriam Merad. *[1]Precision Immunology Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States; [2]Regeneron, Tarrytown, NY, United States; [3]Mount Sinai, New York, NY, United States*

Background While T cell accumulation in tumors is associated with response to immune checkpoint blockade (ICB), many T cell-rich tumors fail to respond to ICB.

Methods Here we leveraged a large neoadjuvant PD-1 blockade trial in hepatocellular carcinoma (HCC) to search for correlates of ICB response within T cell-rich tumors.

Results Paired single-cell RNA and TCR sequencing of nearly one million immune cells revealed that anti-tumor responses to ICB correlated with significant clonal expansion of intratumoral $CXCL13^{+}CH25H^{+}IL\text{-}21^{+}TCF7^{+}$ CD4 T helper cells ($CXCL13^{+}$ Th) and $GranzymeK^{+}PD\text{-}1^{+}$ CD8 effector-like T cells, whereas terminally exhausted $CD39^{hi}TOX^{hi}PD\text{-}1^{hi}$ CD8 T cells dominated in non-responders. Most T cell clonotypes that expanded post-treatment were found in pre-treatment biopsies, suggesting local reactivation of antigen-experienced T cells by PD-1 blockade. Notably, $PD\text{-}1^{+}TCF\text{-}1^{+}$ CD8 T cells with features of progenitor-exhausted cells were found in tumors of responders and non-responders. Strikingly, tumors from responders were highly enriched in mregDCs, a DC state triggered by capture of tumor debris, which formed physically interacting cellular triads with $CXCL13^{+}$ Th cells and $PD\text{-}1^{+}TCF1^{+}$ progenitor-like CD8 T cells. Receptor-ligand analysis revealed unique interactions within these triads that may promote the differentiation of progenitor-exhausted CD8 T cell into effector-like cells upon PD-1 blockade.

Conclusions These results suggest that discrete intratumoral niches that include mregDCs and $CXCL13^{+}$ Th cells control the differentiation of tumor-specific progenitor-exhausted CD8 T cell clones into effective anti-tumor T cells in patients treated with ICB.

Trial Registration NCT03916627

Ethics Approval Samples of lymph node, tumor and non-involved adjacent liver were obtained from surgical specimens of patients undergoing resection at Mount Sinai Hospital (New York, NY) after obtaining informed consent in accordance with a protocol reviewed and approved by the Institutional Review Board at the Icahn School of Medicine at Mount Sinai (IRB Human Subjects Electronic Research Applications 18-00407) and in collaboration with the Biorepository and Department of Pathology.

The single-arm, open-label, phase 2 trial of HCC patients with resectable tumors was registered on ClinicalTrials.gov (NCT03916627, Cohort B). 21 patients were enrolled and received two cycles of Cemiplimab before surgical resection as described in (Marron et al., 2022a).

542

B-CELL RECEPTOR (BCR) REPERTOIRE IS A DYNAMIC BIOMARKER OF SURVIVAL IN SARCOMA PATIENTS TREATED WITH NEOADJUVANT IMMUNE CHECKPOINT BLOCKADE (ICB)

Elise Nassif*, Bin Liu, Wei-Lien Wang, Alexander Lazar, Davis Ingram, Khalida Wani, Sheila Duncan, Taylor Tate, Grace Mathew, Shadarra Crosby, Kenna Shaw, Monika Zelazowska, Barry Feig, Keila Torres, Kelly Hunt, B Ashleigh Guadagnolo, Andrew Bishop, Phillip Andrew Futreal, Jennifer Wargo, Neeta Somaiah, Kevin McBride, Christina Roland, Emily Keung. *MD Anderson Cancer Center, Houston, TX, United States*

Background Intratumoral B-cells are associated with improved survival with ICB in sarcomas.[1] We investigated the dynamics of intratumoral and peripheral BCR repertoires and their association with survival in dedifferentiated liposarcoma (DDLPS, n=17) and undifferentiated pleomorphic sarcoma (UPS, n=10) patients treated in a neoadjuvant ICB trial of nivolumab +/- ipilimumab.[2-4]

Methods Tumor and peripheral blood mononuclear cells (PBMCs) were collected at baseline and surgery. Intratumoral and peripheral BCR heavy (IgH) and light (IgL) chain repertoires were evaluated using bulk RNA sequencing and the TRUST4 algorithm.[5] IgH and IgL repertoire diversity and clonality were assessed by inverse Simpson and Gini index, respectively. Comparisons of continuous variables were done using Wilcoxon Rank-Sum test. High and low categories were defined by median values. Comparisons of progression-free survival (PFS) and overall survival (OS) curves were performed by log-rank method. Correlations were assessed using Spearman's correlation.

Results Tumor transcriptomic data was available for 23 and 20 patients at baseline and surgery, respectively. PBMC transcriptomic data was available for 19 and 23 patients at baseline and surgery, respectively. BCR repertoire diversity increased with ICB, which was significant only in PBMCs (tumor: IgH p=0.077, IgL p=0.11; PBMC: IgH p=0.0065, IgL p=0.029; figures 1 and 2). Neither intratumoral nor peripheral BCR repertoire clonality was impacted by ICB treatment (figures 3 and 4). At baseline, patients with higher IgH BCR diversity had longer PFS (intratumoral: not reached [NR] vs 19 months, p=0.15; peripheral: NR vs 37 months, p=0.25). However, at surgery, patients with higher intratumoral IgH BCR diversity had shorter PFS (17 vs NR months, p=0.024), while peripheral BCR diversity was not associated with PFS (p=0.98). At baseline, patients with higher intratumoral IgH BCR clonality had longer PFS (p=0.19) and significantly longer OS (p=0.022) while neither intratumoral nor peripheral BCR clonality at surgery was associated with survival.

Conclusions ICB is associated with increases in intratumoral and peripheral BCR diversity but not with changes in clonality. Overall, neither the intratumoral IgL nor peripheral IgH and IgL BCR repertoires were associated with survival. Greater diversity of the intratumoral IgH repertoire was a favorable prognostic factor at baseline but a negative one after ICB. These findings warrant future investigations.

543 RESPONSE TO CHECKPOINT BLOCKADE IN HCC IS ASSOCIATED WITH IGG1 SKEWING

[1]Robert Sweeney*, [1]Edgar Gonzalez-Kozlova, [2]Alexandra Tabachnikova, [3]Christie Chang, [1]Laura Walker, [1]Assaf Magen, [1]Myron Schwartz, [1]Thomas Marron, [1]Miriam Merad, [1]Sacha Gnjatic. *[1]Icahn School of Medicine at Mount Sinai, New York, NY, United States; [2]Yale School of Medicine, New Haven, CT, United States; [3]Stanford University School of Medicine, Stanford, CA, United States*

Background Immune checkpoint blockade (ICB) is increasingly becoming the standard of care for many tumor types. Yet, useful predictive biomarkers for benefit from ICB are still lacking. Emerging literature has suggested the importance of intra-tumoral B cells in response to ICB; however, these studies fail to address the heterogeneity amongst B cells responses.[1-4] Here, we describe the largest single-cell RNA sequencing (scRNAseq) data set of B cells in treatment-naïve and ICB-treated hepatocellular carcinoma (HCC) patients and find specific B cell phenotypes that are highly associated with response to ICB.

Methods A cohort of 44 patients with early-stage HCC underwent surgical resection, of which, 26 patients received neoadjuvant anti-PD-1 treatment. Pre-and post-treatment blood and representative samples from resected tumor and adjacent uninvolved liver were collected fresh, and 10x scRNAseq was performed on the immune cell compartment. ELISA was performed on plasma from each patient to detect antibodies against a panel of 26 tumor antigens.

Results We identified three major subsets of B cells: naïve, memory (Bmems), and plasma cells (PCs), and identified different clusters within each subset with distinct transcriptional signatures. Bmem and PC clusters demonstrated differential expression of the immunoglobulin isotypes and subclasses, and we hypothesized that the B cell response in ICB responders might be skewed towards an IgG1 phenotype. Indeed, we observed that non-responders had a higher proportion of Bmems from clusters with the lowest IgG1 expression, while responders had an enrichment in Bmems originating from the cluster with the highest IgG1 expression. More strikingly, while we found an overall increase in PCs in responders compared to non-responders, there was a significantly higher enrichment of IgG1-high PC clusters in ICB responders compared to non-responders. Single-cell BCRseq on five patients (2 responders and 3 non-responders) revealed that the tumor-derived Bmems and PCs in responders were more clonally expanded than those from non-responders. Furthermore, we observed that while the clonally expanded B cells in non-responders were dominated by IgA or IgM isotypes, the clonally expanded B cells in responders were exclusively IgG1 or IgG3. Finally, we detected peripheral IgG antibodies against at least one tumor-antigen in our panel in 63% of the responders—which were mostly dominated by IgG1—whereas only 22% of non-responders had detectable IgG titers against any of the tumor antigens.

Conclusions HCC responders to ICB had B cell responses skewed towards an IgG1 phenotype, and the presence of anti-tumor IgG1 antibodies correlated with ICB response.

544 COMPANION DIAGNOSTIC ASSAYS FOR PEMBROLIZUMAB IN PATIENTS WITH MSI-H/DMMR TUMORS

[1]Aurelien Marabelle*, [2]Jeff Cesario, [2]Lixin Lang, [2]Deepti Aurora-Garg, [2]Siddhartha Krishan Mathur, [2]Diane Levitan, [2]Deb Card, [2]Fan Jin, [2]David Adelberg, [3]Thierry André, [2]Amy Wehn. [1]*Gustave Roussy, Villejuif, France*; [2]*Merck & Co., Inc., Rahway, NJ, United States*; [3]*Sorbonne University and Saint Antoine Ho, Paris, France*

Background Pembrolizumab is approved in the United States for unresectable or metastatic microsatellite instability-high (MSI-H)/mismatch repair–deficient (dMMR) solid tumors that progress after treatment. As part of a post-marketing commitment, we conducted a pan-tumor bridging study to determine MSI/MMR status for the purpose of developing 2 companion diagnostic assays. This bridging study was designed to evaluate clinical outcomes with second-line pembrolizumab and concordance with local enrollment assays. Concordance between the 2 companion diagnostic assays was also assessed.

Methods Patients with MSI-H/dMMR tumors, determined per local clinical trial assay (IHC, PCR, or NGS), who enrolled in the KEYNOTE-164 study (advanced colorectal cancer) or cohort K of the KEYNOTE-158 study (advanced non-colorectal cancer) were reevaluated for pembrolizumab efficacy (objective response rate [ORR] per RECIST v1.1) according to MSI/MMR status determined by companion diagnostic assays (Roche Tissue Diagnostics MMR RxDx Panel [RTD; IHC using MLH1, MSH2, MSH6, PMS2] and FoundationOne® CDx [NGS]). Agreement between the clinical trial assay and companion diagnostic assays was evaluated by overall percent agreement (OPA), positive percent agreement (PPA), and negative percent agreement (NPA) using the efficacy population; a supplemental population (KEYNOTE 158 cohorts A-J, KEYNOTE-177, and commercially procured tumor bank) was also used to assess NPA.

Results 444 patients with MSI-H/dMMR tumors per the clinical trial assay were analyzed for efficacy (n = 123, KEYNOTE-164; n = 321, KEYNOTE-158 cohort K). ORR is reported in table 1; responses were enriched in patients with MSI-H/dMMR tumors (RTD assay: 34.7%; FoundationOne CDx: 43.0%; clinical trial assay: 31.8%). When the clinical trial assay and RTD assay (n = 934) were compared, OPA was 90.9%, PPA was 72.0%, and NPA was 98.5%. When the clinical trial assay and FoundationOne CDx assay (n = 1174) were compared, OPA was 94.5%, PPA was 69.8%, and NPA was 99.3%. When the RTD and FoundationOne CDx assays (n = 662) were compared, OPA was 95.9%, PPA was 87.0%, and NPA was 97.1%.

Conclusions Although the RTD and FoundationOne CDx assays measure different analytes, they are comparable for the selection of patients with MSI-H/dMMR tumors likely to respond to pembrolizumab. Despite both companion diagnostic assays having lower concordance to the clinical trial assay, they demonstrated high concordance with each other and were able to better identify responders to pembrolizumab than the clinical trial assay.

545 A PHASE II RANDOMIZED WINDOW OF OPPORTUNITY TRIAL EVALUATING CYTOTOXIC AND IMMUNOMODULATORY EFFECTS OF INTRATUMORAL INT230-6 (CISPLATIN, VINBLASTINE) IN EARLY STAGE BREAST CANCER: THE INVINCIBLE TRIAL

[1]Angel Arnaout, [1]Susan Robertson, [1]Kianoosh Keyhanian, [1]Arif Awan, [2]Gregory Pond, [3]John Bartlett, [4]Megan Hopkins, [4]Linda Liao, [4]Vida Talebian, [4]Lazlo Radvyani, [5]Lewis Bender*, [5]Ian Walters, [1]Vanessa Lopez Ozuna, [4]Melanie Spears. *[1]Ottawa Hospital Research Institute, ottawa, Canada; [2]McMaster University, Hamilton, Canada; [3]University of Edinburgh, Edinburgh, UK; [4]Ontario Institute for Cancer Research, Toronto, Canada; [5]Intensity Therapeutics, Westport, CT, United States*

Background The majority of breast cancers are considered immunological quiescent and are therefore minimally responsive to immunotherapies. Local therapies that induce cell death and expose tumor antigens and potentially increase responsiveness to immunotherapies. We conducted a randomized, phase 2 presurgical window-of-opportunity trial with intratumoral (IT) INT230-6 (composed of a dispersion enhancer molecule (SHAO) in solution with drug agents vinblastine and cisplatin) designed to cause tumor necrosis by dispersion throughout the tumor and diffusion into cancer cells. The objective of the trial is to understand the effect of IT cytotoxic chemotherapy on the immune response within the tumor, microenvironment and blood in patients who are awaiting surgery for breast cancer.

Methods Women awaiting surgery for newly diagnosed intermediate or high-grade T1-T2 invasive breast cancers were recruited to the trial. Part I of the study randomized patients to 1-3 doses of INT230-6 injected weekly versus no treatment prior to surgery (2:1, open label) to evaluate safety, feasibility, and optimal drug dosing. Part II was a double-blinded randomized (2:1) trial where patients received one dose of INT230-6 versus saline injection. The primary objective was to assess the degree of tumor necrosis and to perform targeted sequencing and proteomic profiling in tumor samples from injected patients.

Results The study screened 95 patients, of which 87 enrolled. Mean age was 60 (range 40-77 yrs) and tumor size was 1.5-4.3 cm (mean = 2.4cm). The majority of the cancers were ductal histology (82%) and hormone (estrogen and/or progesterone) receptor positive (81%). The most common (>10%) AEs were injection site pain, injection site reaction and nausea/vomiting. INT230-6 induced up to 95% tumor necrosis in varying breast cancer subtypes and histologies, including invasive lobular carcinoma. Gene expression analysis showed significant differential gene expression between the baseline biopsy and surgical specimens. Pathway analysis identified genes associated with TCR signaling, B cells, T cells, chemokine signaling and NF-κB signaling were significantly changed in the post treatment samples. There was a relative increase in CD4 and CD8 T cells and B and NK cells within the tumor and in the tumor microenvironment.

Conclusions This window of opportunity clinical trial demonstrates that INT230-6 injection is a novel and simple method to convert traditionally immune quiescent breast cancers into immunogenic tumors with minimal adverse effects and good tolerability. The results indicate a future potential for INT230-6 as an immunotherapeutic option in early stage breast cancer.

Trial Registration Phase 2 presurgical Window-Of-Opportunity trial for intratumoral (IT) INT230-6 (comprising VINblastine (VIN) Cisplatin (VIN)) evaluating clinical and BioLogical Effects in patients with early-stage operable Breast Cancer (the INVINCIBLE trial- https://clinicaltrials.gov/ct2/show/NCT04781725).

Ethics Approval Ethics approval has been obtained at the Ottawa Hospital Research Institute 1.2 OHSN-REB Protocol Number: 20210002-01H.

546 A PHASE I DOSE ESCALATION STUDY OF STEMVAC, A MULTI-ANTIGEN, MULTI-EPITOPE TH1 SELECTIVE PLASMID-BASED VACCINE, TARGETING STEM CELL ASSOCIATED PROTEINS IN PATIENTS WITH ADVANCED BREAST CANCER

[1]Mary Disis*, [1]Ying Liu, [2]Sasha Stanton, [1]William Gwin, [1]Andrew Coveler, [1]John Liao, [1]Jennifer Childs, [1]Denise Cecil. *[1]UW Medicine Cancer Vaccine Institute, Seattle, WA, United States; [2]Providence, Portland, OR, United States*

Background Cancer stem cell or epithelial/mesenchymal transition antigens could have utility in vaccines for cancer treatment and prevention. We identified class II binding T-cell epitopes from non-mutated tumor antigens that selectively elicit a Th1 response. We constructed a 5 antigen (CD105-Yb-1-SOX2-CDH3-MDM2) multi-epitope plasmid-based vaccine; STEMVAC, and conducted a Phase I dose escalation study in patients with advanced breast cancer.

Methods Patients with advanced HER2 negative breast cancer previously treated and in remission were sequentially enrolled to 3 dose arms: 150, 300, or 600mcg of STEMVAC. Vaccines were given monthly intradermally for three doses with rhu-GM-CSF (100mcg) as adjuvant. Two booster immunizations (same dose) were given 3 and 6 months after the third vaccine. Primary endpoints were safety and immunogenicity. Secondary endpoints included persistence of the immune response after vaccination and assessment of potential stimulation of T-regulatory (Treg) cells or myeloid derived suppressor cells (MDSC) to the overexpressed non-mutated antigens expressed in STEMVAC. Antigen specific immunity was measured by IFN-gamma (g) and IL-10 ELISPOT. Immune cells were evaluated by flow cytometry.

Results Seventy-five percent of patients were hormone receptor positive and 25% triple negative (TNBC). Patient characteristics, including breast cancer subtype, did not vary significantly between doses (all $p>0.1$). The vast majority of adverse events (AE), 98%, were grades 1/2. The most common AE were injection site reactions, flu-like syndrome, and transient leukopenia and lymphopenia. Arm 1 (150mcg) generated transient low levels of IFN-g secreting T-cells to a median of 1 antigen per patient and considered the least immunogenic dose. Arm 2 (300mcg) resulted in a mean response (sum of all antigens) of 1 antigen specific T-cell per 2500 (1:2500) PBMC at week 16 ($p<0.05$ compared to baseline) which boosted to 1:1500 by week 60 ($p<0.001$ compared to baseline). Immune responses for Arm 3 (600mcg) were statistically similar to Arm 2 at 16 weeks, but did not persist and could not be boosted. In Arm 2, booster immunizations increased the incidence and breadth of the immune response, with patients showing significant IFN-g secretion to a median of 4/5 antigens. At 16 weeks, there was no increase in antigen specific IL-10 secreting T-cells, Treg, or MDSC at any dose.

Conclusions STEMVAC selectively elicits high level persistent Type I T-cell responses at the 300mcg dose. Two Phase II studies are enrolling; adjuvant setting for TNBC (NCT05455658) and maintenance therapy with pembrolizumab in metastatic non-small cell lung cancer (NCT05242965).

547 SAFETY AND EFFICACY OF DE-ESCALATED NEOADJUVANT CHEMOIMMUNOTHERAPY OF TRIPLE NEGATIVE BREAST CANCER (TNBC) USING CHEMOKINE-MODULATING REGIMEN (RINTATOLIMOD, IFN-α2B, CELECOXIB)

Shipra Gandhi*, Mateusz Opyrchal, Cayla Ford, Ronald Slomba, Marie Quinn, Tracey O'Connor, Ellis Levine, Pawel Kalinski. *Roswell Park Comprehensive Cancer Center, Buffalo, NY, United States*

Background Pathologic complete response (pCR) or microinvasive residual disease (ypTmic), following neoadjuvant chemotherapy (NAC) of triple negative breast cancer (TNBC) predicts improved relapse-free and overall survival. Combination of NAC with pembrolizumab, the new standard of care, increases pCR rate from 40% to 65% but is associated with significant immune-related permanent toxicities. Production of chemokines CCL5, CXCL9, CXCL10 and CXCL11 in the tumor microenvironment (TME) is critical for the infiltration with $CD8^+$ cytotoxic T-lymphocytes (CTLs), predicting higher probability of pCR.[1] Guided by our preclinical data that **C**hemo**k**ine-**m**odulating (**CKM**) regimen, combining rintatolimod (TLR3 agonist), interferon (IFN)-α2b and celecoxib (COX-2 inhibitor), selectively induces CTL-attractants but decreases Treg-attractants[2], we hypothesized that the combination of CKM with chemotherapy will promote CTL infiltration and result in higher pCR.

Methods In phase I study NCT04081389, 9 patients with stage I-III TNBC, median age 47 (37-55) years were treated with paclitaxel 80 mg/m^2 IV weekly for 12 weeks; CKM for first 3 weeks, days 1-3 (IV rintatolimod 200 mg daily and oral celecoxib 200 mg twice daily). IFN-α2b was administered in an accelerated dose-escalation at 0 or 5 million units (MU)/m^2 [dose levels (DL) 1,2 respectively] in first 2 patients; 10 MU/m^2 [DL 3] in 4 patients and 20 MU/ m^2 [DL 4] in 3 patients. CKM/Paclitaxel was followed by standard dose-dense doxorubicin and cyclophosphamide (AC) and surgery. Dose-limiting toxicity (DLT) was defined as grade 3 or higher toxicities within the first 3 weeks. Primary endpoint was safety and tolerability. Secondary endpoints included pCR rate. Tumor and blood biomarkers were analyzed in exploratory studies.

Results Treatment was well-tolerated with mostly grade 1 or 2 treatment-related adverse events (TRAEs) without DLTs or delayed or immune-related toxicities. Grade 3 TRAEs included neutropenia (3/9) attributed to CKM (1/9) or paclitaxel (3/9), pneumonia (1/9) and anemia (1/9) attributed to AC. Additional pneumonia and skin squamous cell carcinoma in situ were observed, unrelated to study treatment. Paclitaxel- or AC-related toxicities were not higher than expected. 5/9 (56%) patients attained pCR and 1 more patient attained ypTmic. CTL marker CD8α was selectively elevated in post-CKM tumor biopsies (5 patients at DL3 and 4) but decreased in the post-CKM blood.

Conclusions The treatment was well tolerated, with promising clinical activity of pCR + ypTmic at 66%, comparable to pembrolizumab/NAC. Upcoming phase II study in early stage TNBC is planned to determine if CKM can be used as an alternative to pembrolizumab or to overcome pembrolizumab/NAC resistance.

548 THE ONCOLYTIC VIRUS PELAREOREP IN COMBINATION WITH IMMUNE CHECKPOINT INHIBITOR ACTIVATES T-CELL FUNCTIONING IN EARLY BREAST CANCER PATIENTS – IMMUNOPHENOTYPE RESULTS FROM AWARE-1 STUDY

[1]Thomas C Heineman*, [1]Houra Loghmani, [1]Richard Trauger, [2]Fernando Salvador, [3]Luis Manso, [4]Tomás Pascual, [5]Manel Juan, [4,5]Aleix Prat, [6]Joaquín Gavilá, [1]Matt Coffey, [5]E Azucena González-Navarro. *[1]Oncolytics Biotech Inc., San Diego, United States; [2]SOLTI Breast Cancer Research Group, Barcelona, Spain; [3]Hospital 12 de Octubre, Madrid, Spain; [4]SOLTI/Hospital Clínic de Barcelona, Barcelona, Spain; [5]Hospital Clínic de Barcelona/IDIBAPS, Barcelona, Spain; [6]Instituto Valenciano de Oncología/SOLTI, Valencia, Spain*

Background Pelareorep (pela) is an intravenously delivered unmodified oncolytic reovirus demonstrating anti-tumor activity through innate and adaptive immune responses.[1] Previous data from the window of opportunity AWARE-1 study demonstrated that pela, alone or in combination with atezolizumab (atezo), establishes a favorable immunologic response in tumors from HR+/HER2- early breast cancer (BC) patients.[2] Here, we report additional translational flow cytometry results from peripheral blood of patients participating in the AWARE-1 trial.

Methods Treatment naïve HR+/HER2- early BC patients were enrolled in two cohorts: Cohort 1 (C1)– pela + letrozole (n=10); and Cohort 2 (C2)– pela + letrozole + atezo (n=10). Pela was administered on days 1, 2 and 8, 9, while atezo was administered on day 3. Blood samples were collected pre-treatment and on days 3 and 21. In this context, we investigated the immune cell composition of peripheral blood using a multicolor flow cytometry to describe different subsets of immune cells.

Results Flow cytometry analysis showed a significant increase in natural killer cells on day 21 in C2 compared to C1 (≈2-fold, p value=0.0166). No differences were observed in B cells, T cells, monocytes or neutrophils. Interestingly, a statistically significant decrease in CD4/CD8 ratio was observed when C2 was compared to C1 on day 21 after normalization with D3 (≈1.5-fold, p value= 0.0142). Moreover, an increase in HLA-DR expression in CD8 population was detected in C2 vs C1 on day 21 (≈1.5-fold, p value=0.0632). Regarding exhaustion markers, pela administration decreases CD39, LAG3 and TIM3 markers on day 3. However, low levels of these markers are only maintained at day 21 in patients who had received atezo on Day 3 (C2).

Conclusions These data suggest that combining pela with atezo may improve outcomes in HR+/HER2- BC by enhancing the cytotoxic and anti-tumor activity of T cells.

Trial Registration NCT04102618

549 BOOSTER VACCINATION OF A HER2 HELPER T-CELL VACCINE INCREASED HER2 IMMUNITY IN METASTATIC HER2 POSITIVE BREAST CANCER.

[1]Sasha Stanton*, [2]Jennifer Childs, [2]Doreen Higgins, [3]Angela Kask, [2]Yi Yang, [2]Mary Disis. *[1]Earle A. Chiles Research Institute, Portland, OR, United States; [2]University of Washington, Seattle, WA, United States; [3]Fred Hutchinson Cancer Research Center, Seattle, WA, United States*

Background NCT00194714 vaccinated women with HER2+ metastatic breast cancer after first line therapy with a 3 epitope HER2 T-cell helper peptide vaccine. Patients received six vaccines with concurrent trastuzumab with median progression free survival of 17.7 months at 3 years and median overall survival of 86% at 4 years. Ten years later, 10 of the 22 patients were still living. We therefore determined whether HER2 immunity persisted and whether adding two booster vaccinations could boost that HER2-specific immunity.

Methods Ten eligible patients were contacted about the vaccine booster and four participated. All four patients received the six vaccine series between 2004 and 2006 and the booster vaccine series between 2017 and 2018. Patients received two booster vaccinations of the HER2 T-cell helper tri-peptide vaccine 6 months apart. Peripheral blood was collected prior to booster, 48 hours after each booster, and six months after the second booster to evaluate HER2 immunity by IFN-g ELISPOT. Pre-existing immunity was defined as mean antigen specific spots per well significantly higher than mean no antigen wells.

Results At the time of enrollment, two of the patients had progressive disease and two had no evidence of disease. The boosters were well tolerated with 28 AEs, 39% (11/28) related to the booster vaccines. The majority of AEs were grade 1 including injection site reactions in all four patients and flu like syndromes. The grade 2 toxicities included hypotension and dizziness after the vaccine. Prior to the booster vaccinations, two of the patients had pre-existing immunity to the 3 epitopes included in the vaccine and all four patients had pre-existing immunity to HER2 intracelluar (ICD) and extracellular (ECD) peptide pools. After the boosters, all four patients had increased IFN-g T cell responses to the three pooled epitopes included in the vaccine with average precursor frequency prior to vaccination of 1:133,333 (range 0 to 61,539) increasing to 1:9381 after vaccination (range 1:53,333 to 1:4878, p=0.05). All four patients had augmented IFN-g immunity to the HER2 ICD peptide pool from baseline 1:2875 (range 1:400,000 to 1:1043) to 1:1851 (range 1:12,698 to 1:957, p=0.01). There was no significant augmentation in immunity to the HER2 ECD peptide pool from baseline (p=0.31).

Conclusions Patients receiving HER2 booster vaccines a decade after the initial vaccine series had augmented immune response to the immunizing epitopes and the HER2 ICD. Future studies will determine if boosters can improve long term disease control with vaccines.

551 INTRATUMORAL INFLUENZA VACCINE IN EARLY COLORECTAL CANCER

Mikail Gögenur*, Mustafa Bulut, Senior Resident, Lukas Balsevicius, Anne-Marie Kanstrup Fiehn, Marianne Bøgevang Jensen, Nesibe Özgur Colak, Tobias Freyberg Justesen, Paulo Cesar Martins Urbano, Lasse Bremholm Hansen, Chief Surgeon, Ismail Gögenur. *Zealand University Hospital, Køge, Denmark*

Background Recurrence is the leading cause of increased morbidity and mortality after colorectal cancer surgery, with up to one-third of patients undergoing curatively intended surgery having a recurrence. The degree of tumor-infiltrating immune cells is crucial for the risk of recurrence, which is why interventions targeting the tumor and the local microenvironment are in increased focus. Intratumoral injection of the vaccine has in experimental studies shown to increase the proportion of infiltrating immune cells and lead to tumor shrinkage in both treated and untreated tumors. The purpose of this combined phase 1 and 2 study was to determine the safety of intratumoral influenza vaccine injection and whether it induces local and systemic elicitation of anti-tumor immune response.

Methods All patients with non-metastatic sigmoid and rectal cancer were eligible for inclusion. The intratumoral influenza vaccine was administered by an additional sigmoidoscopy 7-14 days before the scheduled surgery. The primary outcome was safety. The clinical outcome was evaluated as Mandard tumor regression grade (TRG) assessed by two independent pathologists. Translational outcomes included local and systemic immunological changes, analyzed via immunohistochemistry, and local mRNA gene expression.

Results Ten patients were included in the study, four with sigmoid cancer and six with rectum cancer. No serious adverse reactions or events occurred. TRG was rated as five in all patients, except one rated as four by a single pathologist. A significant increase of $CD8^+$ but not $CD3^+$ T cell count was noted based upon immunohistochemical staining. mRNA gene expression showed several differentially expressed genes when comparing pre vs. post vaccination specimens. Functional enrichment analysis showed significant suppression of pro-tumor inflammatory related pathways. Spatial analysis of protein expression revealed an increased expression of PD-1 in areas of $CD8^+$ T cell infiltrated regions of the post-vaccination specimens compared with similar regions in pre-vaccination specimens.

Conclusions Intratumoral influenza vaccine is a safe intervention. The intervention did not lead to tumor regression, while immunohistochemistry and mRNA gene expression analyses revealed a significant increase in $CD8^+$ T cell count and suppression of pro-tumor inflammation, suggesting that intratumoral influenza vaccine induces an anti-tumor response in the tumor microenvironment.

552 **CHARACTERISTICS OF THE TUMOR MICROENVIRONMENT IN IDH1-MUTATED CHOLANGIOCARCINOMA PATIENTS FROM CLARIDHY TRIAL**

[1]H Duygu Saatcioglu, [2]Juan Valle, [3]Teresa Macarulla, [4]Milind Javle, [5]Do-Youn Oh, [6]Lipika Goyal, [7]Jake Conway, [7]Janani Iyer, [7]Fedaa Najdawi, [7]Chintan Shah, [1]Camelia Gliser, [1]Susan Pandya, [1]Scott Daigle, [8]Ghassan Abou-Alfa, [9]Robin Kelley*. *[1]Servier Pharmaceuticals, Boston, MA, United States; [2]University of Manchester and Department, Manchester, UK; [3]Hospital Universitario Vall d'Hebron, Barcelona, Spain; [4]MD Anderson Cancer Center, Houston, TX, United States; [5]Seoul National University College of Medicine, Seoul, Korea, Republic of; [6]Massachusetts General Hospital Cancer Center, Boston, MA, United States; [7]PathAI, Boston, MA, United States; [8]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [9]University of California San Francisco, San Francisco, CA, United States*

Background Somatic isocitrate dehydrogenase 1 mutations (*IDH1*m) convert α-ketoglutarate to the oncogenic metabolite R-2-hydroxyglutarate (2-HG). *IDH1*m are detected in approximately 13% of intrahepatic cholangiocarcinomas (CCAs).[1] Ivosidenib, an oral inhibitor of the IDH1m protein inhibits 2-HG and restores immune response in CCA.[2] We analyzed pre-treatment samples, using machine learning models to quantify histologic features of the CCA tumor microenvironment, enabling identification of correlates of *IDH1*m status, early disease progression (patients experienced progression or death within 1.54 months), and plasma 2-HG levels (median, 630 ng/ml).

Methods A set of H&E images, including from ClarIDHy[3], a phase 3 placebo controlled clinical trial of ivosidenib in *IDH1*m CCA, were split into training/validation (n=200) and test sets for model development. Whole slide images were annotated by GI pathologists to identify and quantify more than 500 different human interpretable features (HIFs), including cell (cancer cell, lymphocyte, macrophage, plasma cell, fibroblast) and tissue (cancer epithelium, stroma, necrosis) features. Utilizing *IDH1*m and wild type (WT) screening samples, multivariate logistic regression models were trained to predict *IDH1*m status. P-values were calculated by univariate logistic regression and corrected for multiple comparisons via adjustment for FDR.

Results A HIF-based multivariate model discriminated between *IDH1m* and WT CCA (AUC, 0.83; 95% CI, 0.74-0.92). *IDH1*m was associated with a lower proportion of lymphocytes throughout the tumor (OR, 0.64; $P<0.01$; FDR $P=0.022$), and higher proportion of fibroblasts (OR, 1.8; $P<0.01$; FDR $P=0.023$) and lower proportion of plasma cells in the stroma (OR, 0.68; $P<0.01$; FDR $P=0.032$) (figure 1A). In a subset of samples, CD3 and CD8 staining showed reduced T-lymphocyte infiltration patterns in *IDH1*m (n=5) samples relative to *IDH1* WT (n=19) (figure 1B). Early disease progression of enrolled ClarIDHy patients (ivosidenib n=61, placebo n=38) was associated with a higher proportion of macrophages (OR, 1.70; $P<0.01$; FDR $P=0.08$) and a lower proportion of tumor infiltrating lymphocytes (OR, 0.63; $P<0.01$; FDR $P=0.08$), (figure 2A). When correcting for treatment effect, the proportion of lymphocytes in the tumor were still associated with improved PFS ($P=0.011$). Consistent with previously published data[2], high 2-HG levels were associated with lower numbers of tumor infiltrating lymphocytes (OR, 0.63; $P=0.011$; FDR $P=0.08$) (figure 2B).

Conclusions Quantitative histologic evaluation suggests that pre-treatment *IDH1*m CCA samples have a colder tumor microenvironment relative to *IDH1* WT CCA, with an immunosuppressive tumor microenvironment being associated with early progression. Results from this analysis support exploration of combination with immune checkpoint inhibitors.

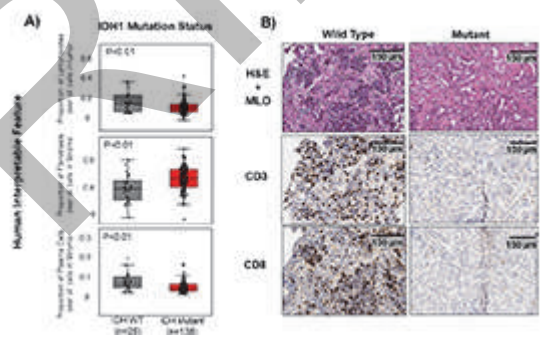
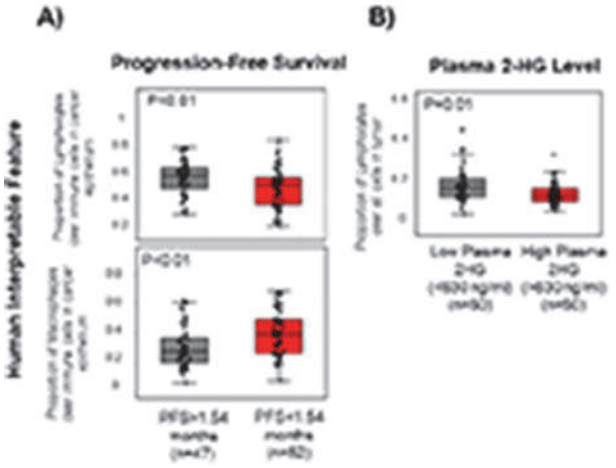
Approval from the institutional review board and international ethics committee was obtained at each study site. Patients provided written, informed consent before participating in the study.



Abstract 552 Figure 1 Tumor microenvironment of IDH1m vs IDH1 WT

Tumor microenvironment of IDH1m CCA compared to IDH1 WT at screening. (A) 163 screening samples, including IDH1m (n=138) and IDH1 WT (n=25) subjects were analyzed by machine learning of histological features. Samples deemed by a panel of GI pathologist to be extrahepatic as a best response were excluded from the analysis. IDH1m status in CCA was associated with lower proportions of lymphocytes in the tumor (Upper Row), higher proportions of fibroblasts in the stroma (Middle Row), and lower proportions of plasma cells in the stroma (Bottom Row). Tumor includes cancer epithelium and stroma tissues in the whole sections. Uncorrected P values are displayed on the Figures (B) Further analysis of a subset of screening samples (n=5 IDH1m, n=19 IDH1 WT) by CD3 and CD8 staining was performed. Representative whole slide biopsy H&E images indicating lower proportions of lymphocytes in the IDH1m CCA tumor via machine learning-derived predictions (Upper Row; Lymphocytes are indicated with dark green marker overlay. MLO=Machine Learning Overlay, representative image for CD3 immunohistochemistry (Middle Row), and representative image for CD8 immunohistochemistry (Bottom Row).



Abstract 552 Figure 2 Differences in CCA tumor microenvironment. Differences in CCA tumor microenvironment based on early disease progression and pre-treatment plasma 2-HG levels. (A) Pre-treatment screening samples from 99 (ivosidenib cohort n=61, placebo cohort n=38) patients treated on the ClarIDHy study were analyzed for association with early disease progression, defined as experiencing progression or death within 1.54 months (47 days) (PFS<1.54 months) Early disease progression was associated with lower proportions lymphocytes over immune cells in cancer epithelium (Upper Row) and higher proportions of macrophages (Bottom Row) over immune cells in cancer epithelium (B) Plasma 2-HG levels were available for 100 IDH1m patients, with sample groups separated based on the median plasma 2-HG level (630 ng/ml). Higher plasma 2-HG levels were associated with lower proportions of lymphocytes in CCA tumor. Uncorrected P values are displayed on the Figures (A and B)

Background Elevated tumoral DKK1 expression is seen in approximately one third of previously treated GEA and has been associated with more aggressive disease and shorter overall survival. DKN-01 (D) is a targeted anti-DKK1 mAb which has demonstrated improved clinical outcomes in previously treated GEA pts with elevated tumoral DKK1 expression when used in combination with an anti-PD1 antibody.

Methods DisTinGuish (NCT04363801) is a Phase 2a single arm 2-part trial; Part A is reported separately; Part B investigated two dosing cohorts of D (300 mg and 600 mg) + tislelizumab (TS) as 2L therapy for DKK1-high GEA pts. Primary objective was to examine safety and tolerability and secondary objectives evaluated multiple efficacy endpoints including overall response rate (ORR) and disease control rate (DCR) in a modified intent to treat (mITT) population (>1 dose D).

Results 52 pts enrolled between 27 Oct 2020 and 7 Jun 2022; (D-300 mg, 24 pts; D-600 mg 28 pts). Median age was 63 (29, 76); 41 males (79%). 18 pts (35%) had gastroesophageal junction (GEJ) adenocarcinoma; 34 pts (65%) had gastric cancer (GC). 22 pts from US, 30 pts from Republic of Korea. 49 pts have PD-L1 visually-estimated combined positive score (vCPS) results: <1 n=13 (27%); 1-<10 n=22 (45%); ≥10 n=14 (29%). 38 pts with genomic profiling: Wnt activating mutations in 12 pts, no MSI-H. 4 pts were IO experienced. Median number of cycles 2 (1, 19). 12 pts remain on therapy. 19 pts (37%) experienced D-related adverse events (AE); 74% were G1/2. Most common regimen related AEs: fatigue, nausea, AST increased. 3 pts (6%) had serious D-related AEs [vomiting, fatigue, dehydration]. No G5 TRAEs. No D-related AE led to D-dose reduction or discontinuation. Preliminary ORR in response evaluable IO naive mITT (n=36) was 25% and DCR 44%. mITT ORR by vCPS (figure 1): <1: [n=11; PR-3 (27%), SD-1, PD-7]; 1-<10: [n=12; PR-1 (8%), SD-3, PD-8 (1 PD pt -> irPR)]; ≥10: [n=11; PR-5 (45%), SD-3, PD-3]. 6 of 9 responders remain on therapy, median DoR not reached. Median PFS: 1.4 mos (vCPS <1: 1.4 mos, 1-<10: 1.4 mos, ≥10: 2.9 mos).

Conclusions The combination of D + TS represents a well-tolerated, active chemotherapy-free combination in previously treated DKK1-high IO naïve GEA pts. Encouraging durable activity was observed particularly in DKK1 high/vCPS≥10 cohort: ORR 45%, DCR 73%. Updated ORR, DoR, PFS and additional correlative biomarker evaluation will be reported.

554 **ARTIFICIAL INTELLIGENCE (AI)-POWERED IMMUNE PHENOTYPING OF ADVANCED OR METASTATIC UROTHELIAL CARCINOMA (AUC) CLINICAL TRIAL SAMPLES FROM HEMATOXYLIN AND EOSIN (H&E)-STAINED WHOLE SLIDE IMAGES (WSI)**

[1]Jake Conway*, [1]Limin Yu, [1]Yash Belhe, [1]Suyog Jain, [2]Hans Grote, [1]Mary Lin, [1]Benjamin Trotter, [1]Darpan Sanghavi, [2]Aslihan Gerhold-Ay, [3]XiaoZhe Wang, [1]Sergine Brutus, [2]Thomas Mrowiec. *[1]PathAI, Boston, MA, United States; [2]The Healthcare Business of Merck KGaA, Darmstadt, Germany; [3]EMD Serono, Billerica, MA, United States*

Background CD8 immune phenotype status is associated with response to anti–PD-L1 therapy in aUC. To assess the tumor microenvironment in aUC, we developed machine learning (ML)–based models to identify cell types and tissue regions in digitized H&E-stained WSI from the JAVELIN Bladder 100 trial, which showed that avelumab (anti–PD-L1) first-line maintenance plus best supportive care (BSC) significantly prolonged overall survival vs BSC alone in patients with aUC. ML-quantified features were used for subsequent slide-level immune phenotyping of these clinical trial samples.

Methods Models previously trained using samples from The Cancer Genome Atlas were refined using 25,926 tissue regions annotations and 183,259 cell type annotations on 704 formalin-fixed, paraffin-embedded, H&E-stained WSI scanned on MIRAX (40x) to identify artifacts, tissue regions (cancer, stroma, and necrosis), and cell types (cancer epithelial cells, lymphocytes, macrophages, fibroblasts, and granulocytes). Precision, recall, and F1 scores were calculated to evaluate model performance. Following pathologist guidelines, H&E slide-level digital immune phenotypes (excluded, inflamed, and desert) were determined using thresholds of lymphocyte area within stroma and proportion of lymphocytes vs all cells in cancer epithelium. The distribution of H&E slide-level digital immune phenotypes was calculated across samples in both trial arms, and the association between immune phenotype and CD8 score at the tumor core was determined using the Kruskal-Wallis and Mann-Whitney U tests.

Results Precision, recall, and F1 scores for model predictions were comparable to those of an average annotator across cell types. The model's concordance with consensus was also higher than that of an average human annotator (Cohen's kappa, 0.816 vs 0. 680). Calculation of the distribution of H&E slide-level digital immune phenotypes across trial arms showed that most samples in each arm had an excluded immune phenotype, and a slightly higher proportion of samples in the BSC-only arm had an inflamed phenotype. Association between immune phenotype and the gold-standard CD8 immunohistochemistry (IHC) score at the tumor core showed that samples with the inflamed immune phenotype had higher CD8 scores at the tumor core than samples with the excluded immune phenotype (Mann-Whitney, $p<0.026$).

Conclusions We show an AI-powered approach to determine slide-level immune phenotypes directly from digitized H&E-stained WSI of clinical aUC samples. An association between inflamed immune phenotypes and higher CD8 scores at the tumor core supports the potential use of this method as an alternative to CD8 IHC-based approaches to identify patients who may derive optimal benefit from anti–PD-L1 treatment.

Background Immune checkpoint therapy has failed to demonstrate a survival benefit for patients with metastatic castration resistant prostate cancer (mCRPC). New immunotherapy combination strategies are required to improve clinical outcomes in heavily-pretreated mCRPC patients.

Methods This open-label exploratory platform trial tested the safety and activity of immunotherapy combinations in patients with mCRPC. Three cohorts were enrolled A) bempegaldesleukin/nivolumab, B) stereotactic body radiation therapy (SBRT)/CDX-301 (FLT3L)/poly-ICLC/nivolumab, and C) CDX-301/INO-5151 (DNA vaccine encoding PSA/PSMA/IL-12)/nivolumab. Each cohort enrolled up to 15 participants who had progressed on androgen deprivation therapy with a subset being chemo- and/or radiation-exposed. Primary endpoint: safety. Secondary endpoints: composite response rate (CRR, defined as PR/CR per PCWG-3 modified RECIST v1.1, confirmed PSA reduction >50%, or CTC change from 5 to 4 cells/7.5 mL of blood), disease control rate (DCR; SD ≥6 mos), and time to radiographic PFS (rPFS). This study was not powered for comparison between cohorts.

Results Cohort A: CRR was 7% (1/14; 1 CTC response, no radiographic or PSA responses). DCR was 14% (2/14). Median rPFS was 2.8 months (95% CI: 2.0-7.3). Ten (71.4%) patients experienced a Grade 3-4 TRAE, including a Grade 5 TRAE of acute respiratory distress syndrome.

Cohort B: CRR was 33% (5/15; 1 PR, 1 CTC and 3 PSA responses, all in distinct patients). DCR was 27% (4/15). Median rPFS was 7.5 months (95% CI: 3.5-10.5). One (7%) patient experienced a Grade 3-4 TRAE.

Cohort C: CRR was 7% (1/14; 1 patient with both PR and PSA response). DCR was 14% (2/14). Median rPFS was 2.9 months (95% CI: 2.7-7.1). 2 (14%) patients experienced a Grade 3-4 TRAE.

Peripheral immune phenotyping analysis demonstrated distinct pharmacodynamic effects including increases in proliferating, activated T and NK cells following bempegaldesleukin treatment in cohort A. In cohorts B and C, the expansion of dendritic cells (DCs) and monocytes following FLT3L treatment was observed, as well as increases in serum proteins associated with DC activation/maturation. In cohort C, INO-5151 vaccination induced antigen-specific T cell responses. Elevated serum levels of PD-1 and IFN-gamma signaling-associated proteins were observed following nivolumab treatment in all cohorts.

Conclusions This platform study design demonstrated the feasibility and efficiency of iteratively testing distinct immunotherapy combinations with comprehensive biomarker assessment in patients with mCRPC. While neither cohort A nor C were expanded due to insufficient clinical activity, the clinical responses seen with SBRT/FLT3L/polyICLC/nivolumab suggest sufficient clinical benefit that may warrant additional investigation, particularly the contribution of radiation to the responses observed.

556 EXTRACELLULAR MATRIX (ECM) BIOMARKERS ARE ELEVATED IN ADVANCED RENAL CELL CARCINOMA (ARCC) AND PREDICTIVE OF RESPONSE TO NIVOLUMAB PLUS IPILIMUMAB (NIVO+IPI): ANALYSIS FROM CHECKMATE 214

[1]Saurabh Gupta*, [1]Celine Han, [1,2]Bhakti Dwivedi, [1]Jun Li, [3]Morten Karsdal, [4]Robert Motzer, [3]Nicholas Willumsen, [5]David McDermott, [6]Toni Choueiri. *[1]Bristol Myers Squibb, Princeton, NJ, United States; [2]Parexel, Princeton, NJ, United States; [3]Nordic Bioscience, Herlev, Denmark; [4]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [5]Beth Israel Deaconess Medical Center, Boston, MA, United States; [6]Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States*

Background Tumor fibrosis and cancer-associated fibroblast (CAF) activity is becoming a central aspect in cancer biology. The tumor microenvironment (TME) consists mainly of ECM, and biomarkers of tumor fibrosis activity can be quantified from small ECM fragments in serum. An unmet need exists to identify patients with aRCC who are most likely to benefit from treatment with NIVO+IPI.[1,2] Therefore, we explored the prognostic and predictive potential of circulating ECM-associated biomarkers for the first time in patients with aRCC, using samples from the CheckMate 214 trial.

Methods Pretreatment serum was collected, and levels of 17 biomarkers associated with ECM formation, ECM degradation, or immune response (table 1) were assessed using immunoassay-based methods. Biomarker levels were compared between healthy volunteers and patients with aRCC. Associations with International Metastatic RCC Database Consortium (IMDC) risk score, sarcomatoid status, and objective response rate were evaluated. Prognostic and predictive associations were determined retrospectively from patients' progression-free survival (PFS) and overall survival (OS) outcomes.

Results Clinical (5-year follow-up) and biomarker data were evaluable in 1006 of 1082 treated patients (93%). Statistically significant differences ($P < 0.0001$) in all 17 biomarkers were observed between healthy individuals and patients with aRCC (table 2). Higher levels of the majority of the biomarkers (all except PRO-C23) were positively correlated with increasing IMDC score ($P < 0.01$), and 9 biomarkers (including PRO-C3, C6M, and TGFβ-LAP) were increased in patients with sarcomatoid histology ($P < 0.05$). CPa9-HNE and TGFβ-LAP levels were higher in patients who responded to NIVO+IPI ($P < 0.05$). In the overall population, higher levels of biomarkers such as C4M, C6M, PRO-C19, TGFβ-LAP, and TUM were associated with shorter PFS and OS ($P < 0.05$). When comparing treatment arms, higher levels of PRO-C19, PRO-C22, C4M, C6M, CPa9-HNE, VICM, TGFβ-LAP, and TUM were associated with improved PFS with NIVO+IPI ($P < 0.05$), which is indicative of predictive potential.

Conclusions Biomarkers of ECM formation, degradation, and TGFβ signaling were significantly increased in patients with aRCC compared with healthy individuals, which is indicative of high CAF activity. In patient with aRCC, high levels of ECM biomarkers were associated with poor OS and PFS outcomes. Patients with high ECM remodeling activity responded better to NIVO+IPI than to sunitinib. ECM biomarkers could potentially guide patient selection and/or stratification in future clinical trials. The predictive value of these biomarkers needs to be investigated in prospective clinical trials.

Abstract 556 Table 1 Descriptions of biomarkers assessed in this study

Symbol	Name	Biological process
ECM formation		
PRO-C3	N-terminal pro-peptide of type III collagen	Fibrinogenesis
PRO-C4	Internal epitope in the 7S domain of type IV collagen	Basement membrane remodeling
PRO-C5	N-terminal pro-peptide of type V collagen	Fibrinogenesis
PRO-C6	C-terminal NC-domain of type VIa3 collagen (endotrophin)	Pro-fibrotic signaling
PRO-C19	C-terminal of type XIX collagen, NC1 domain	FACIT remodeling
PRO-C20	C-terminal of type XX collagen, NC1 domain	FACIT remodeling
PRO-C22	C-terminal of type XXII collagen, NC1 domain	FACIT remodeling
PRO-C23	C-terminal of type XXIII collagen	Membrane protein shedding
PRO-C28	C-terminal of type XXVIII collagen	Fibrogenesis
ECM degradation		
C3M	MMP-degraded type III collagen	Interstitial matrix degradation and remodeling
C4M	MMP-degraded type IV collagen	Basement membrane degradation and remodeling
C6M	MMP-degraded type VI collagen	Interface matrix degradation
Inflammation		
VICM	MMP-degraded and citrullinated vimentin	Macrophage activity
C4G	Granzyme B-degraded type IV collagen	T-cell activity
CPa9-HNE	Neutrophil elastase degraded fragment of calprotectin	Neutrophil activity and NETosis
TGFβ-LAP	PLK-cleaved LAP fragment	Active TGFβ
Vascular remodeling		
TUM	MMP-mediated release of tumstatin	Signaling peptide of the basement membrane

ECM, extracellular matrix; FACIT, fibril-associated collagens with interrupted triple helices; HNE, human neutrophil elastase; LAP, latency-associated protein; MMP, matrix metalloproteinase; PLK, plasma kallikrein; TGFβ, transforming growth factor beta.

557 THE EPITOPE-ENHANCED TARP PEPTIDE CAN INDUCE SPECIFIC T CELLS THAT CAN RECOGNIZE WILD-TYPE TARP TETRAMER BY EITHER PEPTIDE OR PEPTIDE-PULSED DC VACCINATION IN PATIENTS WITH PROSTATE CANCER

[1]Purevdorj Olkhanud , [2]Refika Turnier, [2]Kimberly Dunham, [1]Masaki Terabe, [1]Seth Steinberg, [1]Brenda Roberson, [1]Lauren Wood, [3]David Stroncek, [1]Ira Pastan, [1]Jay Berzofsky, [1]Hoyoung Maeng*. *[1]National Cancer Institute, Bethesda, MD, United States; [2]Frederick National Laboratory, Frederick, MD, United States; [3]NIH Clinical Center, Bethesda, MD, United States*

Background TARP is expressed in >90% of prostate cancer throughout Gleason score and stages. Two TARP-targeting vaccines were developed at the NCI (figure 1). HLA-A*0201-restricted epitopes Wild Type 27-35 (TARP27-35WT) and Epitope-Enhanced 29-37(9V) (TARP29-37(9V)EE) of TARP were injected with an adjuvant or on autologous dendritic cells (DCs). Previously, the first-in-human clinical trial studying TARP-targeting vaccines in biochemically recurrent prostate cancer was reported.[1, 2] This is a follow-up report focused on immunogenicity.

Methods TARP-specific T cell responses were assessed on study weeks 0, 12, 18, and 24 with vaccinations at weeks 3, 6, 9, 12, and 15 (Peptide vaccine=21, DC vaccine=20). PBMCs to assess the T cell response were collected and cryopreserved for batch testing. PSA was tested every 3 weeks. PSA-slope log was calculated using the MSKCC nomogram. Decreased PSA-slope log following vaccination at week 24 or week 48 was defined as the study-specific response as previously reported.

Thawed PBMCs were *in vitro* stimulated (IVS) with either TARP27-35WT, TARP29-37EE, or TARP29-37WT-pulsed monocytes in the presence of IL-7[1]. After 7 days of IVS, the cells were tested for tetramer-specific T cells by flow cytometry and for peptide-specific IFN-gamma response by ELISPOT.

Results Peptide-pulsed DC immunization induced tetramer-positive T cells at weeks 12, 18, and 24 post-immunization. The TARP29-37EE peptide performed as intended to induce specific T cells, the vast majority of which reacted equally well to the WT version of the EE sequence by 2-color flow cytometry. Only a small proportion reacted uniquely to EE, but not WT. This shows proof of the principle that EE-peptide can induce WT-specific T cells (figure 2).

In addition, all six patients who had the strongest IFN-gamma ELISPOT response to TARP27-35WT, TARP29-37EE, and TARP29-37WT peptides had decreased PSA-slope log at week 24 and/or 48 which corresponds to the study defined responses among 40 patients tested (figure 3). ELISPOT responses were more frequent in patients immunized with DC vaccines than in those with peptide/adjuvant vaccines.

Conclusions This first-in-human TARP vaccine study of peptide versus peptide-loaded DC platforms showed immunogenicity by peptide-HLA-tetramer assay and ELISPOT to detect IFN-gamma-producing cells. Importantly for proof-of-principle, the T cells recognizing the EE peptide immunogen recognized equally well the WT counterpart present in the tumor, as required for epitope-enhancement to be effective. The ability of high IFN-gamma ELISPOT response to the vaccine peptides to predict clinical responsiveness as measured by decreased PSA-slope log supports a protective role of antigen-specific T cells.

Acknowledgements The authors thank the patients and their families/caregivers for participating. This study was supported by the Center for Cancer Research/NCI intramural program. The authors appreciate the contributions of Dr. Anatoli Malyguine and Dr. Michael Davies who previously served at the Frederick National Laboratory for Cancer Research, and the members of NIH Clinical Center Pharmacy IDMRS (Investigational Drug Management and Research Section).

558 CTX130 ALLOGENEIC CRISPR-CAS9–ENGINEERED CHIMERIC ANTIGEN RECEPTOR (CAR) T CELLS IN PATIENTS WITH ADVANCED CLEAR CELL RENAL CELL CARCINOMA: RESULTS FROM THE PHASE 1 COBALT-RCC STUDY

[1]Sumanta Pal*, [2]Ben Tran, [3]John Haanen, [4]Michael Hurwitz, [5]Adrian Sacher, [6]Neeraj Agarwal, [7]Nizar Tannir, [1]Elizabeth Budde, [2]Simon Harrison, [3]Sebastian Klobuch, [6]Sagar Patel, [8]Mary Lee Dequeant, [9]Verena Karsten, [8]Kaitlyn Cohen, [8]Ellen Gurary, [8]Henia Dar, [8]Anna Ma, [8]Anjali Sharma, [7]Samer Srour. *[1]City of Hope Comprehensive Cancer Center, Duarte, CA, United States; [2]Peter MacCallum Cancer Centre, Melbourne, Australia; [3]Netherlands Cancer Institute, Amsterdam, Netherlands; [4]Yale School of Medicine, New Haven, CT, United States; [5]Princess Margaret Cancer Centre, Toronto, Canada; [6]University of Utah, Salt Lake City, UT, United States; [7]The University of Texas, Houston, TX, United States; [8]CRISPR Therapeutics, Boston, MA, United States; [9]Formerly CRISPR Therapeutics, Boston, MA, United States*

Background Clear cell renal cell carcinoma (ccRCC) is the most common subtype of renal tumors. Patients with ccRCC who fail checkpoint inhibitors (CPIs) and tyrosine kinase inhibitors (TKIs) have a poor prognosis. Preclinical studies identified substantial expression of CD70 in ccRCC tumor samples. Here, we report results from the Phase 1 dose-escalation study of CTX130™, a CD70-targeting allogeneic CAR T cell therapy in patients with ccRCC.

Methods COBALT-RCC (NCT04438083) is a Phase 1, open-label, multicenter, global study evaluating safety and efficacy of CTX130 in patients ≥18y with advanced (unresectable or metastatic), relapsed, or refractory (R/R) ccRCC and prior exposure to both CPIs and TKIs. Patients received standard lymphodepleting chemotherapy with fludarabine 30mg/m2 and cyclophosphamide 500mg/m2 for 3 days, followed by CTX130 infusion.

Results As of May 2, 2022, 14 patients with a median age of 64.5y (range, 54-77) were treated with CTX130. All patients had stage IV disease, and received a median of 3 (range, 1-6) prior treatments. Six patients had documented refractory disease at study entry. Median CD70 expression level on the tumors was 100% (range, 1-100%). Patients received CTX130 at dose levels (DLs) ranging from $3x10^7$ to $9x10^8$ CAR T cells. Overall, expansion occurred across all DLs. An emerging relationship between higher CAR T exposure and disease control was observed. CTX130 had an acceptable safety profile; there were no dose-limiting toxicities across all DLs. Seven (50%) patients experienced grade (Gr) 1-2 cytokine release syndrome (CRS); there was no Gr≥3 CRS. Three patients experienced serious adverse events (SAEs) related to CTX130; all were episodes of CRS. Three patients had SAEs of infections, all unrelated to CTX130, including a Gr5 pneumonia with Gr4 dyspnea resulting in death. No patients experienced immune effector cell associated neurotoxicity syndrome, graft versus host disease, or hemophagocytic lymphohistiocytosis. One patient (7.7%) had a durable complete remission (CR) maintained at 18+ months and 9 (69.2%) patients had stable disease (SD) with 4 patients (30.8%) in SD at 4 months. The disease control rate (CR + partial response + SD) was 76.9%.

Conclusions This first-in-human clinical trial exploring CD70 CAR T-cell therapy in ccRCC showed an excellent safety profile with no unexpected on-target off-tumor toxicities and encouraging antitumor activity. To our knowledge, this durable CR is the first to be achieved with allogeneic CAR T cell therapy in patients with R/R solid tumors and represents a proof-of-concept for further exploration of CD70-targeted CAR T cells in ccRCC and other CD70+ malignancies.

Background Immune checkpoint therapy has not provided meaningful clinical benefit in patients with metastatic castration resistant prostate cancer (mCRPC). Biomarker-rich clinical trials offer the opportunity to identify molecular targets of response and resistance to potentially inform patient selection and novel combinations in future trials that improve anti-tumor responses in patients with mCRPC.

Methods Two cohorts of the biomarker-rich PORTER platform trial tested a backbone combination of CDX-301 [FLT3L] and nivolumab. Cohort B added treatments to enhance endogenous immunity (stereotactic body radiation therapy/polyICLC). Cohort C included INO-5151, DNA vaccine expressing PSA/PSMA/IL-12 DNA plasmids. Matched blood and tumor samples were collected longitudinally for extensive immune biomarker analyses using flow/mass and full spectrum flow cytometry, serum proteomics, DNA/RNA sequencing, and high-dimensional multiplex imaging. Immune cell composition and cell:cell interactions are being explored in the tumor microenvironment by CODEX imaging and correlated with peripheral biomarker findings of response. Candidate biomarkers were prioritized based on those that were associated with outcomes.

Results There were 7 participants (5 cohort B, 2 cohort C) with clinical benefit/response (rPR, DCR $\geq$6 months, PSA and/or CTC response) and 22 non-responders.

Prior to treatment, responders had lower frequencies of both naïve CD4 Thelper and CD8 T cells in the periphery, but more proliferating PD-1+ CD4 Thelper cells and T cells with effector and/or memory phenotypes (Tbet+ CD8 and Eomes+ CD4 Thelper cells). Additionally, responders had lower peripheral naïve B cell percentages but higher percentages of Tbet+ and memory B cells.

Prior to and on treatment, higher levels of serum soluble proteins associated with cytotoxicity, inflammation, myeloid cell migration, cell adhesion, and immune response were observed in the responder group. LAMP3, a dendritic cell maturation marker, was elevated among patients with clinical benefit in cohort B.

Conclusions In this multi-cohort platform trial evaluating novel immunotherapy combination treatments in mCRPC, peripheral biomarkers associated with higher levels of proliferating, effector/memory B and T cells and inflammatory immune responses were found in patients with clinical benefit, both prior to and on-treatment. Higher levels of LAMP3 protein in patients with clinical benefit from one cohort suggests a role for baseline and on-treatment differences in dendritic cell phenotypes. Further work to integrate these findings with tumor imaging and genomic data is ongoing. Overall, the joint analysis of the two cohorts involving FLT3L + nivolumab highlights the power of a platform study to rapidly identify common biomarkers of clinical response and/or resistance and simultaneously interrogate treatment effects of cancer-specific immunotherapy combinations.

Acknowledgements We extend our gratitude to the patients, their families, the clinical investigators, and their site staff members who are making this trial possible. We would also like to thank Carri Browne, Christopher Perry, and Lancelote Leong at Parker Institute for Cancer Immunotherapy (PICI) for operations leadership of the trial. We thank Maria Jaimes and Quentin Low from Cytek Biosciences for spectral flow method development and sample analysis. We thank Jay Campbell (CRI), Samik Upadhaya (CRI), Andres Salazar (Oncovir) and Silvia Boffo (BMS) for their contributions. We thank Bristol Myers Squibb (BMS), Celldex, Oncovir and Inovio for collaboration and study drugs. The study was funded by Cancer Research Institute, BMS and PICI.

560 MOLECULAR AND IMMUNOGENOMICS FEATURES ASSOCIATED WITH COMPLETE RESPONSE AND SURVIVAL AFTER NEOADJUVANT CHEMO-IMMUNOTHERAPY FOR MUSCLE-INVASIVE BLADDER CANCER

AB Wolfgang Beckabir,*, Alec Wilkinson, Mark Woodcock, Mi Zhou, Hsing-Hui Wang, Karen McKinnon, Jonathan Serody, Tracy Rose, Matthew Milowsky, William Kim, Benjamin Vincent. *UNC-Chapel Hill, Chapel Hill, NC, United States*

Background Bladder cancer patients treated with immunotherapy have varied response and survival.[1–3] In the Phase II LCCC1520 trial, neoadjuvant chemo-immunotherapy (pembrolizumab with gemcitabine plus cisplatin) induced pathologic complete response (pCR) in 14 of 39 muscle-invasive bladder cancer patients.[4] In this correlative analysis, we identify molecular features associated with pCR and survival in patients with and without pCR.

Methods Associations of TMB, tumor neoantigens, antigen presentation, immune checkpoint gene expression, immune gene signature expression, and TCR repertoire diversity with response and survival were evaluated pre-and post-treatment. Predicted neoantigens were identified using the Landscape of Effective Neoantigens Software.[5] 25 patients with neoantigen data were divided into discovery (14 patients) and validation (11 patients) sets. Effective neoantigen count (ENC) was calculated by binning neoantigens by expression level score, binding affinity score, and normalized expression level, then identifying the subset in which neoantigen count was most strongly associated with pCR in the discovery set. Using elastic net modeling with 10-fold cross-validation, pCR was predicted from antigen presentation, immune checkpoint, and immune gene signature expression, TMB and ENC.

Results Pre-treatment features associated with pCR response included TMB (p=0.015) and PD-L1 expression (p=0.008); expression of antigen presentation genes TAP1 (p=0.009), TAP2 (p=0.013), B2M (p=0.018), and HLA-DRB1 (p=0.011); and signatures of T cell infiltration (p=0.005) and interferon gamma activation (p=0.001; figure 1). Pre-treatment TIGIT expression was associated with pCR (p=0.018), survival (p=0.026), and PD-1 expression (p=3.3E-5). Pre-treatment CD8+ TIGIT+ T cell percentage from flow cytometry was associated with complete response (p=0.048). ENC was calculated as the number of neoantigens with an expression level score above 90th percentile, a binding affinity below 90th percentile, and an upper quadrant normalized log2 TPM expression above 40th percentile. Pre-treatment ENC was positively associated with complete response in the discovery (p=0.036) and validation sets (p=0.042, ROC-AUC = 0.867, ROC-AUC p=0.021; figure 2). The final elastic net model—comprised of HLA-DRB1 expression, Ayers_IFNG signature, and ENC—predicted complete response in the validation set (p=0.017, ROC-AUC=0.933, ROC-AUC p=0.009). Post-treatment ENC (p=0.005) and TAP1 (p=0.003) and TAP2 (p=0.015) expression were negatively associated with survival among patients without complete response (figure 3).

Conclusions We identify pre-treatment and post-treatment features associated with response and survival in the LCCC1520 trial of pembrolizumab with gemcitabine plus cisplatin neoadjuvant therapy for muscle-invasive bladder cancer. Key features of a predictive model included neoantigen and antigen presentation estimates. We propose that tumor antigen presentation is a major driver of response and survival with neoadjuvant chemo-immunotherapy.

Acknowledgements Merck Sharp & Dohme, a subsidiary of Merck & Co, Kenilworth, NJ, USA (MSD) provided financial support for the LCCC1520 clinical trial as well as for correlative research in this study.

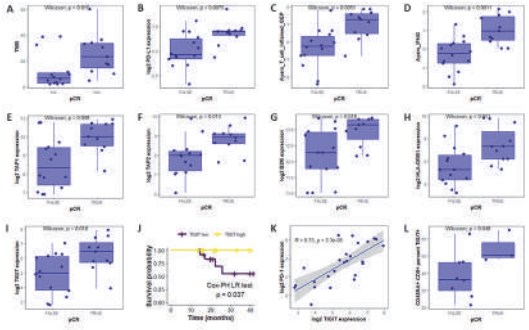
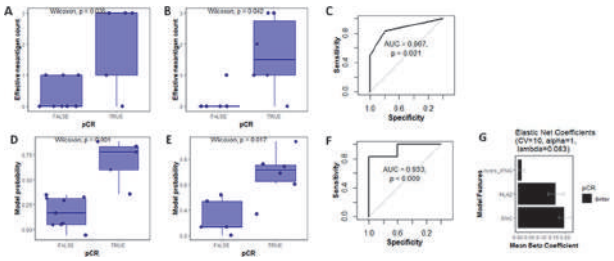
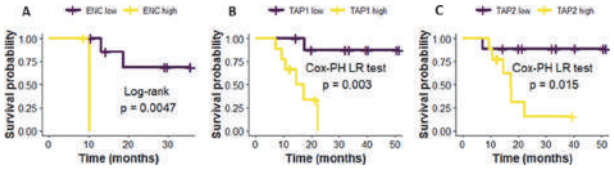
Ethics Approval The study was reviewed and approved by the institutional review boards at each participating institution and conducted in accordance with ethical principles per the Declaration of Helsinki.



Abstract 560 Figure 1 Pre-treatment features associated with complete response. Features associated with complete response include TMB (A) and PD-L1 expression (B); immunogenomic signatures Ayers_T_cell_inflamed_GEP (C) and Ayers_IFNG (D); and expression of antigen presentation genes TAP1 (E), TAP2 (F), B2M (G), and HLA-DRB1 (H). Pre-treatment TIGIT expression is associated with complete response (I), survival (J), and PD-1 expression (K). Pre-treatment CD8+ TIGIT+ T cell percentage from flow cytometry is associated with complete response (L).



Abstract 560 Figure 2 Effective neoantigen count predicts complete response. Pre-treatment effective neoantigen count is positively associated with complete response in the discovery (A) and validation sets (B,C). The final elastic net model predicts complete response in the discovery (D) and validation (E,F) sets. The final model features, which also have beta coefficient confidence intervals not spanning zero in 10-fold cross validation, are Ayers_IFNG, HLA2 (HLA-DRB1), and effective neoantigen count (G).



Abstract 560 Figure 3 Features associated with survival in patients without complete response. From post-treatment sequencing data, effective neoantigen count (A) and TAP1 (B) and TAP2 (C) expression are negatively associated with survival among patients without complete response.

561 **IMMUNE ACTIVATION AND CLINICAL RESPONSE FROM ENZALUTAMIDE (ENZA) ALONE OR WITH RADIUM223 (RA223) IN METASTATIC CASTRATION-RESISTANT PROSTATE CANCER (MCRPC)**

[1]Peter Zang*, [2]Tanya Dorff, [1]Zhang-Xu Liu, [1]Denice Tsao-Wei, [1]Susan Groshen, [1]Cheryl Kefauver, [2]Czarina Patricio, [1]Anishka D'Souza, [1]Sarah Chevalier, [2]Sumanta Pal, [1]Diane DaSilva, [1]Martin Kast, [1]David Quinn. *[1]University of Southern California, Los Angeles, CA, United States; [2]City of Hope, Duarte, CA, United States*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0561

Background We hypothesized that Ra223 in combination with enza would induce a higher degree of immune activation and clinical response than enzalutamide alone in patients with mCRPC.

Methods Patients were randomized 2:1 to Arm A (enza + Ra223) or Arm B (enza only). Blood was collected at start of treatment and evaluated by flow cytometry to measure immune activation or exhaustion after ≥3 months on study, and by Luminex for cytokines after 1 month on study. A Kaplan-Meier model was used to calculate survival data. Expression of immune correlatives were log-transformed and analyzed with the Wilcoxon Rank Sum test to detect differences between the two arms.

Results A total of 28 patients were enrolled, whose median age was 68 (57 – 87). 6 are Hispanic (21%) and 2 each are African American or Asian (7%). Median duration of follow up was 8.3 (1.8 – 29.9) months (mo). 9 pts (36%) had visceral metastases. Arm A showed significantly greater increase in PD-L2 expression after treatment compared to Arm B ($p = 0.0026$). There was otherwise no significant difference between the two arms for flow cytometry markers. Cytokines remained low generally, except for IL10 and TNFa, elevated in 5 and 2 patients, respectively. 9 of 21 (48%) in Arm A had SD or PR as best RECIST response compared to 3 of 9 (33%) in Arm B. PSA response was not different between the arms. Arm A had PFS of 8.8 (3.6 – 29.9+) mo while PFS was 5.3 (3.4 – 12.2+) mo in Arm B. 4 (27%) patients in Arm A and 3 (50%) patients in Arm B stopped treatment due to disease progression. No grade 3 adverse events were observed in either arm and no unexpected toxicities occurred.

Conclusions Although Ra223 with enza did not show increased PD-L1 expression as seen in pre-clinical mouse models treated with Ra223, the combination did significantly induce PDL-2 expression in this study and raise the potential of improved treatment efficacy with the addition of an immune checkpoint inhibitor as suggested in these pre-clinical models.[1] Despite the lack of augmentation of humoral response, combination treatment paradoxically showed better clinical response, consistent with prior studies involving Ra223 and Sipleucel-T immunotherapy.[2]

Acknowledgements The authors thank Bayer for providing funding to perform the clinical trial.

562 **TUMOR COLLECTION AND ESTABLISHMENT OF TUMOR-INITIATING CELL CULTURES TO SERVE AS THE ANTIGEN SOURCE FOR AV-OVA-1 DENDRITIC CELL VACCINES FOR PATIENTS WITH NEWLY DIAGNOSED ADVANCED OVARIAN CANCER**

[1]Ramez Eskander, [2]Lisa Abaid, [3]Bradley Corr, [4]James Mason, [5]Fabio Cappuccini, [6]Richard Friedman, [7]Rockelle Robles, [7]Katrina Lopez, [7]Gabriel Nistor, [7]Robert Dillman*. *[1]UC San Diego, San Diego, CA, United States; [2]Hoag Hospital, Newport Beach, CA, United States; [3]University of Colorado, Aurora, CO, United States; [4]Scripps MD Anderson Cancer Center, La Jolla, CA, United States; [5]UC Irvine, Irvine, CA, United States; [6]Providence-St. Joseph Medical Center, Burbank, CA, United States; [7]AIVITA Biomedical, Inc., Irvine, CA, United States*

Background With standard therapy, which includes chemotherapy and aggressive surgical debulking, relative 5-year survival for newly diagnosed advanced epithelial ovarian cancer is only 30%. AV-OVA-1 is a personal vaccine consisting of autologous dendritic cells (DC) loaded ex vivo with autologous tumor antigens (ATA) from a lysate of irradiated cells from a short-term cell culture. After completion of primary chemotherapy, immunization with DC-ATA may improve survival. A multicenter, 2:1 double-blind randomized phase 2 clinical trial was designed to compare treatment with AV-OVA-1 to autologous monocytes (MC). One objective was to determine the feasibility of collecting fresh ovary cancer and establishing cell cultures to serve as the ATA source.

Methods Tumor samples were obtained during surgical debulking of patients with stage 3 or 4 ovary epithelial cancer. Fresh tumor was placed in media and shipped via transport kit per overnight courier to AIVITA where a cell suspension was placed into culture and incubated in serum-free medium with factors that favor survival and proliferation of stem cells and early progenitor cells, i.e, tumor initiating cells (TICS). The objective was to harvest a minimum of 1 million cells within 28 days, and preferably 10 million cells or more.

Results Patients were enrolled from five sites in California and one in Colorado. Tumors were collected between December 2017 and April 2021. 92 patients consented for tumor collection, but 12 were not malignant ovary, 4 withdrew consent, 3 had insufficient tissue to send, 1 had wrong stage; so, 72 malignant epithelial ovary tumors were placed into culture. 70/72 (97.2%) resulted in a successful cell culture; one could not be grown, one was contaminated. Of tumors submitted for patients who were subsequently randomized, 47/56 (84%) were in culture for 28 days or less, 4 (7%) were in culture for 29 to 35 days, and the remaining 5 were cultured 51, 52, 57, 62, and 67 days. All 56 cultures yielded at least 1 million cells; 48/56 (86%) yielded more than 10 million cells. The average number of irradiated cells per culture was 59.7 million (range 1.1 to 135 million); the median was 65.6 million (interquartile range 22.4 to 96.8 million).

Conclusions Self-renewing ovary TIC cultures were reliably and rapidly established for use as the antigen source for personal DC-ATA vaccines.

Trial Registration Clinicaltrials. gov NCT00331526

Ethics Approval This study was approved by the Western IRB, approval number 20171661; all participants gave written informed consent before taking part.

563 **A PHASE I CLINICAL TRIAL OF RADIATION THERAPY, DURVALUMAB AND TREMELIMUMAB IN RECURRENT GYNECOLOGIC CANCER**

[1]Larissa Lee, [2]Panagiotis Konstantinopoulos, [2]Ursula Matulonis, [2]Joyce Liu, [2]Neil Horowitz, [2]Elizabeth Lee, [1]Martin King, [1]Kelly Fitzgerald*. [1]*Brigham and Women's Hospital, Boston, MA, United States*; [2]*Dana Farber Cancer Institute, Boston, MA, United States*

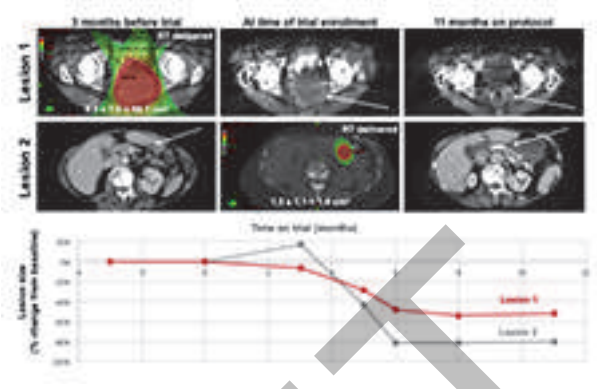
Background Dual immune checkpoint blockade (ICB) may synergize with palliative radiotherapy (RT) to improve response rates in patients with recurrent or metastatic gynecologic cancer. We conducted an open label prospective phase I trial to assess the safety and tolerability of ICB with RT to a single metastatic abdominopelvic site.

Methods Eligible patients included those with recurrent and/or metastatic gynecologic cancer of endometrial, ovarian, cervical, vaginal or vulvar origin without prior immunotherapy treatment. A safety lead-in cohort of patients (cohort A) was treated with durvalumab 1500 mg IV and palliative RT of 25 Gy in 5 fractions delivered to a single measurable lesion >1cm and <10cm in the abdomen or pelvis that was not previously irradiated. RT was initiated within 24 hours of immunotherapy. Durvalumab continued every 4 weeks up to one year or until disease progression. Following a toxicity assessment of cohort A, a second cohort (cohort B) received dual ICB with tremelimumab 75 mg IV given concurrently with the first 4 cycles of durvalumab. The primary endpoint was the rate of dose-limiting toxicities (DLT) in patients still on protocol 8 weeks after RT. Secondary endpoints included the overall response rate (ORR) in non-irradiated lesions.

Results 16 patients were enrolled, with 12 able to be assessed at the end of the 8-week DLT window, split evenly between the cohorts. There were 9 patients with ovarian, 2 with uterine, and 1 with cervical cancer. There were 0 DLTs in cohort A and 1 in cohort B (grade 3 pneumonitis possibly related to treatment). One patient with platinum resistant ovarian cancer in cohort B with two metastatic sites (a 8.3 x 7.0 cm pelvic lesion irradiated with 25 Gy/5 fractions 3 months prior to the study without initial shrinkage and a 1.3 x 1.1 cm peritoneal nodule irradiated on protocol) had a dramatic reduction in disease burden and no new lesions at 11 months of follow up (figure 1). No objective responses were observed in non-irradiated lesions in the remaining patients. The ORR for irradiated lesions was 50% for cohort A and 33% for cohort B.

Conclusions The combination of durvalumab, tremelimumab and RT to a single lesion had limited DLTs but no response in non-irradiated lesions in unselected patients with recurrent gynecologic malignancies. One patient with a previously irradiated lesion and another lesion irradiated on protocol experienced durable benefit in the setting of platinum resistant ovarian cancer.

Trial Registration Clinical trial information: NCT03277482



Abstract 563 Figure 1 Prolonged disease control in best responding patient. Patient 6B was initially diagnosed with FIGO Stage IIIC serous ovarian cancer in 2017 and underwent cytoreductive surgery plus neoadjuvant and adjuvant carboplatin/paclitaxel. She had no evidence of disease until 2020 when she recurred in the pelvis (lesion 1) and in a peritoneal implant on the lesser curvature of the stomach (lesion 2). She progressed in the pelvis on carboplatin and doxorubicin, then progressed again on paclitaxel. She received palliative RT of 25 Gy in 5 fractions to the large pelvic mass 3 months before trial enrollment. Lesion 1 remained stable, then she was enrolled on trial and received 25 Gy in 5 fractions to lesion 2 concurrently with durvalumab and tremelimumab. Both lesions shrank significantly and no new disease emerged.

564 SAFETY AND CLINICAL ACTIVITIES OF THE ACID PH-SENSITIVE ANTI-CTLA-4 MAB ONC-392 IN OVARIAN CANCER PATIENTS

[1]John Hays*, [2]Tianhong Li, [2]Hui Chen, [3]George Zahrah, [3]Richard Frank, [4]John Hamm, [5]Merry-Jennifer Markham, [5]Thomas George, [6]Eric Whitman, [7]Mark Goldstein, [1]Kai He, [8]Rohit Joshi, [9]Dan Chen, [9]Yang Liu, [9]Pan Zheng, [1]David O'Malley. *[1]The Ohio State University James Cancer Center, Columbus, OH, United States; [2]UC Davis Cancer Center, Sacramento, CA, United States; [3]Norwalk Health, Norwalk, CT, United States; [4]Norton Healthcare, Louisville, KY, United States; [5]University of Florida Cancer Center, Gainesville, FL, United States; [6]Atlantic Health, Morristown, NJ, United States; [7]Center for Cancer and Blood Disorders, Frederick, MD, United States; [8]Cancer Research SA, Adelaide, Australia; [9]OncoC4, Inc., Rockville, MD, United States*

Background Despite extensive effort, no immunotherapy has been approved for ovarian cancer patients. Ovarian cancer patients who fail more than two lines of systemic therapies have very poor prognosis. ONC-392 is an acid pH-sensitive anti-CTLA-4 antibody that preserves CTLA-4 recycling and avoids lysosomal degradation. ONC-392 is more effective for immunotherapy but largely devoid of immunotherapy-related adverse events (irAE) in preclinical studies. Our previous dose escalation study has established an RP2D for monotherapy at 10.0 mg/kg.[1] Here we report safety and clinical response of ovarian cancer patients to monotherapy of ONC-392 at 10.0 mg/kg in dose finding and dose expansion studies (NCT04140526, Part A and Part C Arm L).

Methods Thirty four patients with advanced/metastatic ovarian cancer, including primary peritoneal cancer and fallopian tube cancer, who have progressive disease after prior systemic treatments, including chemotherapy, targeted therapy or checkpoint inhibitors have been enrolled. Four patients were enrolled in Part A monotherapy dose finding with defined doses. Thirty patients in expansion cohort had ONC-392 administrated via IV infusion with starting two doses of 10.0 mg/kg, Q3W, followed by 6.0 mg/kg Q3W. The primary endpoints are safety and objective response rate (ORR) using RECIST 1.1 criteria.

Results Thirty-four patients have received 1-11 cycles of ONC-392 treatment. The safety data set consists of 32 patients. The median age is 67.5 (range 40-82), White/Asian/Black: 27/3/2, and 5 Hispanic. The median follow up is 17 weeks. Treatment related AEs (TRAEs) were observed in 26 (81%) patients. Grade 3 TRAEs were observed in 10 pts (31%): myocarditis (1), diarrhea (2), immune-mediated colitis or colitis (4), immune hepatitis (1). Grade 4 TRAE in 1 patient with hypotensive shock (3%). No grade 5 AE was observed. Among 26 evaluable patients, the CR/PR/SD/PD numbers are 1/3/15/7 (ORR=15%, DCR=73%) (figure 1).

Conclusions The safety profile of 10.0 mg/kg x 2, followed by 6.0 mg/kg Q3W is comparable to patients who received substantially lower doses other CTLA-4-targeting drug in the ovarian cancer patients. While the number of evaluable patients is small, the preliminary assessment suggests ONC-392 monotherapy has clinical activity among patients who has failed multiple lines of systemic therapy. The available data support continuous clinical testing of ONC-392 in ovarian cancer. A new Phase 2 study with combination of ONC-392 and pembrolizumab will initiated in Q32022 (ONC-392-004, MK3475-E24, GOG-3081).

565 **LEUKAPHERESIS TO OBTAIN MONOCYTES TO PRODUCE DENDRITIC CELLS FOR MANUFACTURING AV-OVA-1 PERSONAL VACCINES IN A RANDOMIZED PHASE II TRIAL IN PATIENTS WITH NEWLY DIAGNOSED ADVANCED OVARIAN CANCER**

[1]James Mason, [2]Lisa Abaid, [3]Bradley Corr, [4]Ramez Eskander, [5]Fabio Cappuccini, [6]Richard Friedman, [7]Rockelle Robles, [7]Katrina Lopez, [7]Gabriel Nistor, [7]Robert Dillman*. *[1]Scripps MD Anderson Cancer Center, La Jolla, CA, United States; [2]Hoag Hospital, Newport Beach, CA, United States; [3]University of Colorado, Aurora, CO, United States; [4]UC San Diego, San Diego, CA, United States; [5]UC Irvine, Irvine, CA, United States; [6]Providence-St. Joseph Medical Center, Burbank, CA, United States; [7]AIVITA Biomedical, Inc., Irvine, CA, United States*

Background Despite standard therapy, which includes chemotherapy and aggressive surgical debulking, relative 5-year survival for newly diagnosed advanced epithelial ovarian cancer is only 30%. AV-OVA-1 is a personal vaccine consisting of autologous dendritic cells (DC) loaded ex vivo with autologous tumor antigens (ATA) from a lysate of irradiated tumor cells from short-term cell culture. After completion of primary chemotherapy, immunization with DC-ATA may improve survival. A multi-center, 2:1 double-blind randomized phase 2 clinical trial was designed to compare treatment with AV-OVA-1 to autologous monocytes (MC). One objective was to determine the feasibility of collecting sufficient MC from which to generate DC for pulsing with ATA from ovarian cancer tumor-initiating cells (TIC) to produce DC-ATA.

Methods Peripheral blood mononuclear cells (PBMC) were collected by leukapheresis per local standard operating procedures, then shipped by overnight courier to the AIVITA laboratory in Irvine, CA. The product was enriched for MC using the Elutra® Cell Separation System (Terumo, Lakewood, CO.). If fewer than 450 million viable MC were available for cryopreservation, an additional leukapheresis was allowed. MC were cryopreserved in liquid nitrogen and subsequently thawed and incubated in media containing granulocyte-macrophage colony-stimulating factor and interleukin-4 to differentiate MC into DC. Batches of patient-specific AV-GBM-1 were produced by incubating autologous DC with a lysate of irradiated TICs, then aliquoted into individual doses.

Results Patients were enrolled from five sites in California and one in Colorado. PBMC were collected between December 2017 and April 2021. 47/50 patients (94%) had a successful PBMC collection, but four required a second procedure. An average of 1.90 billion monocytes (range 0.527 to 16.6 billion) were collected with an average of 1.55 billion monocytes cryopreserved (range 0.249 to 3.80), which subsequently could be thawed and differentiated into DC. For 29 patients treated with DC-ATA, an average of 648 million viable MC (range 336 to 1120) were differentiated into an average of 410 million DC (range 171 to 892) for incubation with ATA, which yielded an average of 78.6 million DC-ATA (range 16.0 to 270). This resulted in an average of 8.1 million DC-ATA cells per dose (range 2.0 to 27).

Conclusions Leukapheresis procedures reliably resulted in collection of sufficient numbers of monocytes to generate DC and large batches of personal AV-OVA-1 vaccines.

566 ENTPD1 AS PREDICTIVE MARKER OF TREATMENT RESPONSE TO GEMOGENOVATUCEL-T (VIGIL) IN NEWLY DIAGNOSED OVARIAN CANCER

[1]Rodney Rocconi*, [2]Laura Stanbery, [3]Min Tang, [2]Adam Walter, [4]Bradley Monk, [5]Thomas Herzog, [4]Robert Coleman, [2]Luisa Manning, [2]Gladice Wallraven, [2]Staci Horvath, [2]Ernest Bognar, [6]Neil Senzer, [7]Scott Brun, [2]John Nemunaitis. [1]*University of Alabama at Birmingham; Infirmary Cancer Care, Mobile, AL, United States*; [2]*Gradalis, Inc, Carrolton, TX, United States*; [3]*Statbeyond, Carrolton, TX, United States*; [4]*US Oncology, Phoenix, AZ, United States*; [5]*University of Cincinnati, Cincinnati, OH, United States*; [6]*Mary Crowley, Dallas, TX, United States*; [7]*Gold Mast Consulting, Carrolton, TX, United States*

Background Clinical cancer management with precision therapeutics is generally optimized with predictive molecular and phenotypic profiling. However, in ovarian cancer (OC) there has been limited clinical benefit demonstrated. Vigil (Gradalis, Dallas, TX) is a novel plasmid engineered autologous tumor cell immunotherapy designed to achieve a trifecta of immune anticancer activity using a unique bi-shRNA DNA based technology. The trifecta of systemic activity involves knock down of TGFβ1 and TGFβ2 which function as tumor suppressor cytokines, increased GMCSF expression to enhance local immune function and presentation of personal clonal neoantigen epitopes via use of autologous cancer tissue. Phase 2b randomized double blind controlled study (VITAL) of Vigil involving newly diagnosed stage IIIB/IV OC patients undergoing frontline maintenance therapy revealed significant improvement in relapse free and overall survival (RFS/OS) in *BRCA1*/2wt, HRP patient subgroups. We explored molecular biomarker relationship to clinical benefit with NanoString assessment and comparison to RFS and OS.

Methods All patients enrolled on the VITAL study had RNA isolated from tumor tissue at time of procurement and submitted for NanoString® PanCancer Immuno-Oncology 360™ CodeSet using the nCounter® SPRINT platform. All 750 genes underwent a predefined statistical NanoString algorithm (NSA) to assess correlation with RFS and OS. First, a univariate Cox model was used to determine the gene Z-score for RFS and OS in Vigil treated patients at 1% significance. Next, a Cox proportional hazards model with interaction term was utilized to identify genes predictive of Vigil response in both Vigil and placebo treated patients. Patients were then dichotomized into high and low expression based on median gene expression and Kaplan Meier curves were generated. Finally, the my.stepwise.coxph function was used to select genes associated with RFS and OS in Vigil treated patients.

Results Using NSA, high expression of *ENTPD1/CD39* (the rate limiting enzyme in the adenosine pathway) was identified as a predictor of RFS (n=23 vs n=23; median not achieved vs 8.1 months, p=0.00007) and OS (n=23 vs n=23; median not achieved vs 41.4 months, p=0.013) benefit to Vigil irrespective of HRP status. Results further suggested additional benefit in HRP subset but were limited by small number of patients.

Conclusions NSA was successfully implemented and identified ENTPD1/CD39 high expression correlated with RFS and OS benefit in OC treatment population to Vigil. Further consideration of NSA utilization to identify populations that would benefit from investigational targeted therapies is warranted. ENTPD1 high may predict a more sensitive OC population to Vigil.

568 PHASE 2 TRIAL OF INDUCTION AND CONCOMITANT CTLA4 (IPILIMUMAB) AND PD-1 (NIVOLUMAB) IMMUNE CHECKPOINT BLOCKADE AND INTENSITY MODULATED RADIATION THERAPY (IMRT) IN HPV-POSITIVE OROPHARYNGEAL SQUAMOUS CELL CARCINOMA (HPV-OPSCC)

Maura Gillison*, Michelle Williams, Jason Johnson, Cheuk Leung, Jay Reddy, Adam Garden, Renata Ferrarotto, Frank Mott, Xiuning Le, Gary Gunn, Anna Lee, Clifton Fuller, Charles Lu, Amy Moreno, Katherine Hutcheson, Neil Gross, Miriam Lango, Ryan Goepfert, Jeffrey Myers, Ehab Hanna, Weihong Xiao, Bo Jiang, Nils-Petter Rudqvist, Jack Lee, Jack Phan. *The University of Texas MD Anderson Cancer Center, Houston, TX, United States*

Background PD-1 immune checkpoint blockade (ICB) improves survival versus chemotherapy in PD-L1 CPS≥1 recurrent or metastatic head and neck cancer. We evaluated the safety and efficacy of induction and concurrent CTLA4 and PD-1 ICB and IMRT in newly diagnosed HPV-OPSCC.

Methods PD-L1 CPS≥1, p16-positive + HPV RNA-Scope-positive, AJCC 8th edition T1-3N1-2 M0 or T3N0M0 OPSCC patients irrespective of smoking status received two, six-week cycles of ipilimumab (1 mg/kg) day 1 and nivolumab (3 mg/kg) on days 1, 15, and 29, and IMRT concurrent with cycle 2. IMRT was delivered in 4 weeks to pre-induction tumor volume (40-44 Gy) and one adjacent uninvolved nodal level (36 Gy). Post-induction volume was boosted to 50-66 Gy in 2 weeks. Response was evaluated by RECIST 1.1. Principal outcomes were FDG-PET complete response (PET-CR) at 6 months per Hopkins Criteria[1] and progression-free survival (PFS) at 2-years. Correlatives included histological (% tumor viability)[2] and molecular (plasma cfHPV clearance) responses after induction ICB.

Results Treated patients (35) were male (97%), median age 64 (49-78) years with stage T1(14), T2(16), T3(5) and N0(1), N1(33), N2(1) base of tongue (18) or tonsil (17) SCC. 66% had acute grade≥3 AEs (table 1). Five discontinued ICB due to toxicity (n=3), progression (n=1), or physician decision (n=1) and received concurrent platinum (n=3) or IMRT alone (n=2). PET-CR was 90% (29 of 32 evaluable). One of 3 patients without PET-CR progressed. After median follow-up of 14.9 months, 3 patients had local progression and were treated with surgery or SBRT. All patients are alive without cancer at last follow-up. Response to induction ICB was 14% (figure 1). Among 27 evaluable patients, histological response was 0% viability in 37% and <10% viability in 48% (figure 2). 96% had pathological treatment effect ≥20% [2]. At baseline, 97% were positive and 74% quantifiable (≥16 copies/ml) by cfHPV. cfHPV clearance was 30% after induction ICB and 100% 4 weeks after IMRT. Compared to standard planning, RT volume to ≥66 Gy and ≥50 Gy was reduced by 21% (+/- 3%) and 36% (+/- 4%), and dose to ipsilateral parotid, spinal cord, larynx and esophagus was reduced by up to 50%.

Conclusions Patients with HPV-OPSCC treated with induction and concurrent CTLA4 and PD-1 ICB with dose-volume-adapted IMRT experienced a 6-month PET-CR of 90%, a 2-year PFS of 86%, and acute grade≥3 toxicity rate of 66%. Efficacy of induction ICB was supported by <10% tumor viability in 48% and cfHPV clearance in 30%.

569 A CIVO INTRATUMOR MICRODOSE PHASE 0 TRIAL OF SUBASUMSTAT (TAK-981) IN COMBINATION WITH CETUXIMAB OR AVELUMAB REVEALS TYPE 1 INTERFERON INDUCTION AND IMMUNE ACTIVATION IN HEAD AND NECK CANCER PATIENTS

[1]Jeffrey Houlton, [2]Daniel Clayburgh, [2]Ryan Li, [3]Nathan Schauer, [3]Marc Grenley, [3]Connor Burns, [3]Angela Merrell, [3]Jason Frazier, [3]Jonathan Derry, [3]Emily Beirne, [3]Wendy Jenkins, [4]Allison Berger, [3]Richard Klinghoffer*. [1]*University of Washington, Seattle, United States*; [2]*Oregon Health and Sciences University, Portland, OR, United States*; [3]*Presage Biosciences, Seattle, WA, United States*; [4]*Takeda Development Center Americas, Inc., Cambridge, MA, United States*

Background Subasumstat (TAK-981) is an investigational drug designed to induce type I interferon (IFN) signaling via inhibition of the SUMO activating enzyme (SAE). In parallel to Phase I trials of intravenous (IV) dosing, we completed a Phase 0 intratumoral (IT) microdosing trial in head and neck cancer (HNC) using the Comparative In Vivo Oncology (CIVO) platform in order to understand effects of subasumstat within the native tumor microenvironment (TME). A major advantage of the CIVO platform is the ability to compare responses to up to 8 different drugs and combinations in the same human tumor. Here we present data from a Phase 0 trial evaluating TME responses to subasumstat alone or in combination with cetuximab or avelumab.

Methods We enrolled 12 patients with a confirmed diagnosis of HNC and planned surgical resection. Patients' surface accessible and $\geq$2 cm diameter tumors (either primary sites or metastatic to cervical lymph nodes or parotid) were injected with a 3, 5, or 8-needle CIVO device containing vehicle, subasumstat, cetuximab, avelumab, and combinations thereof co-formulated with a fluorescent tracking marker for injection site identification and visualization. Tumors were resected 24 to 96 hours after injection, processed, and analyzed at a central site using multiplex ISH / IHC and molecular profiling via GeoMx Digital Spatial Profiling (DSP). In each tumor, biomarker responses were resolved to individual injection sites, quantified, and compared by injection contents.

Results Consistent with our reports from the interim analysis of this study, subasumstat IT microdoses induced IFN signaling and activation of both innate immune cells and CD8+ T cells in the TME.[1]

Combinations of subasumstat with avelumab or cetuximab led to enhanced and prolonged IFN signaling and increased expression of CD86 and granzyme B within the TME. GeoMx DSP revealed key similarities and differences between cetuximab and avelumab combination sites, including inflammatory markers, chemokines, and stromal markers.

Conclusions IT microdosing with CIVO provides early insights into investigational agents that can only be obtained in the native, intact TME. This is the first reported trial we know of where side-by-side evaluation of an investigational agent, two different biologics, and combinations thereof all in the same patient tumor was achieved. Results provide the first evidence in human tumors that subasumstat combinations can enhance immune cell activation in the TME. They also provide mechanistic rationale for further evaluating combinations of subasumstat with anti-EGFR antibodies and/or checkpoint blockade in human tumors.

570 CABOZANTINIB PLUS ATEZOLIZUMAB IN ADVANCED HEAD AND NECK CANCER PREVIOUSLY TREATED WITH PLATINUM-CONTAINING CHEMOTHERAPY: RESULTS FROM COHORT 17 OF THE COSMIC-021 STUDY

[1]Sylvie Rottey*, [2]Armando Santoro, [3]Suzanne Arnold, [4]Saad Khan, [5]Allen Cohn, [6]Bruno Fang, [7]Svetlana Andrianova, [7]Ramu Sudhagoni, [7]Leleesha Samaraweera, [8]Maria Gonzalez-Cao. *[1]Ghent University Hospital, Gent, Belgium; [2]Humanitas Cancer Center, Rozzano-Milan, Italy; [3]University of Kentucky, Lexington, KY, United States; [4]University of Texas, Dallas, TX, United States; [5]Rocky Mountain Cancer Center, Denver, CO, United States; [6]Regional Cancer Care Associates, East Brunswick, NJ, United States; [7]Exelixis, Inc., Alameda, CA, United States; [8]Dexeus University Hospital, Barcelona, Spain*

Background Cabozantinib, a multiple receptor tyrosine kinase inhibitor, promotes an immune-permissive environment which might enhance activity of immune checkpoint inhibitors (ICI). COSMIC-021 (NCT03170960), a multicenter phase 1b study, is evaluating cabozantinib plus atezolizumab in advanced solid tumors; here we present outcomes in patients with platinum-pretreated advanced head and neck cancer (cohort 17).

Methods Patients with head and neck squamous cell carcinoma who had progressed during or following prior platinum-containing chemotherapy for advanced or metastatic disease were enrolled. Primary tumors in the oropharynx, oral cavity, hypopharynx, or larynx were allowed (nasopharynx was excluded). Up to two prior lines of systemic therapy were allowed. Prior ICI, EGFR-targeted therapy, and radiotherapy were permitted. Patients received cabozantinib, 40 mg PO QD, plus atezolizumab, 1200 mg IV Q3W. The primary endpoint was ORR per RECIST 1.1 as assessed by the investigator. Other endpoints included safety, DOR, PFS, and OS.

Results As of May 31, 2022, 30 patients were enrolled. Baseline characteristics were, median age, 62 y (range, 44-78); male, 83%; ECOG PS 0 and 1, 33% and 67%; HPV positive, negative, and unknown, 17%, 33%, and 50%; primary tumor in oropharynx, oral cavity, hypopharynx, and larynx, 40%, 33%, 10%, and 7%; lung, lymph node, and bone metastasis, 60%, 53%, and 10%; ≥3 metastatic sites, 43%; two lines of therapy for locally advanced or metastatic disease, 40%; median (range) number of prior lines of systemic therapy, 2.5 (1-10); prior ICI, 30%; prior radiation, 97%. The median follow-up was 25.9 mo. Clinical activity was observed with cabozantinib plus atezolizumab (table 1). Most common treatment-related adverse events (TRAEs) of any grade included fatigue (30%), stomatitis (30%), hypertension (27%), hypothyroidism (23%), nausea (23%), diarrhea (20%), decreased appetite (20%), and aspartate aminotransferase increased (20%); grade 3/4 TRAEs occurred in 47%. There were no grade 5 TRAEs.

Conclusions Cabozantinib plus atezolizumab demonstrated moderate clinical activity with manageable toxicity in patients with platinum-pretreated advanced head and neck cancer.

Trial Registration This study is registered with ClinicalTrials.gov (NCT03170960).

Ethics Approval The study Protocol (online only) was reviewed and approved by the institutional review board or ethics committee at participating sites. The study was conducted in accordance with the International Conference on Harmonisation Good Clinical Practice guidelines, the principles of the Declaration of Helsinki, and any local regulations.

Consent All patients provided written informed consent.

Abstract 570 Table 1

	Platinum-pretreated advanced head and neck cancer (N=30)
ORR, % (95% CI)	17 (6, 35)

Background Nearly all anti-PD-1 antibodies are of the IgG4 isotype which may possess residual crystallizable fragment (Fc) gamma receptor (FcγR) effector functions and are also associated with immune tolerance and escape due to instability of the CH3 domain and Fc-Fc interaction. Penpulimab is a novel IgG1 anti-PD-1 antibody that has a good stability and reduced host cell protein residue. Penpulimab was engineered to eliminate Fc-mediated effector function that compromises anti-tumor immune cell function. Penpulimab also showed numerous contacts with N58 glycosylation on the BC loop of PD-1 which may contribute to slower binding off-rate. In this trial, we examined the efficacy and safety of penpulimab in patients (pts) with R/R cHL. Here we report results from up to 30 months follow-up.

Methods AK105-201 (NCT03722147) is a multicenter, single-arm, open-label study of penpulimab in R/R cHL. Adult pts (≥18 years of age) received penpulimab 200 mg once biweekly until progression or unacceptable toxicities. Eligible pts had prior autologous stem cell transplant (ASCT) or at least 2 lines of prior chemotherapy. The primary endpoint was ORR based on the Lugano 2014 criteria as assessed by an independent review committee (IRC). Key secondary endpoints included complete response (CR) rate, progression-free survival (PFS), overall survival (OS), treatment-related adverse events (TRAEs) and immune-related adverse events (irAEs).

Results A total of 94 patients were enrolled. As of the data cutoff date (Dec 31, 2021), the median follow-up was 29.5 months. Median number of treatment cycles was 26.1 (range 2–36). 85 patients meted the definition of primary efficacy population-IRC. Efficacy data is presented in (table 1). TRAEs (with unlikely related events included) occurred in 98.9% of pts (≥ G3 in 28.7% [27/94], treatment discontinuation in 6.4% [6/94]). Treatment related serious adverse event (SAEs) occurred in 12.8%. Most frequent TRAEs were hypothyroidism (33.0%), upper respiratory tract infection (26.6%), fever (24.5%), and ALT elevations (24.5%). Grade ≥3 TRAEs reported in ≥3 pts were platelet count decreased (3.2%), hyperlipemia (3.2%), rash (3.2%). In addition, 52 (55.3%) patients experienced an irAEs. The most frequent irAE was hypothyroidism (51.1%), and 4 (4.3%) patients developed grade 3 irAEs. No grade 4 or 5 irAEs were reported. No new safety signals were observed.

Conclusions Penpulimab was well tolerated, with a good safety profile in long-term use in R/R cHL pts. It demonstrated promising therapeutic activity and continued PFS and OS benefit.

Trial Registration NCT03722147

Ethics Approval The study was approved by relevant ethic committees and institutional review boards.

Consent Written informed consent was obtained from the patient for publication of this abstract and any accompanying images. A copy of the written consent is available for review by the Editor of this journal.

Abstract 571 Table 1 Efficacy data evaluated by IRC based on 2014 Lugano classification in the full analysis set (FAS; n=85)

572 GUT MICROBIOTA TUNING PROMOTES TUMOR-ASSOCIATED ANTIGEN CROSS-PRESENTATION AND ENHANCES CAR T ANTITUMOR EFFECTS

Andrea Facciabene, Mireia Uribe-Herranz , Silvia Beghi, Marco Ruella, Kalpana Parvathaneni, Guido Ghilrardi, Yung Gu Lee, Noelle Frey, John Scholler, Khatuna Gabunia, Research Specialist, Gary Wu, Elise Chong, David Porter, Carl June, Stephen Schuster, Vijay Bhoj*. *UPENN, Philadelphia, PA, United States*

Background CAR T cell therapy has shown impressive clinical responses in B cell lymphoma and leukemia, and to date, four CAR T therapies targeting CD19 have been approved by the Food and Drug Administration for the treatment of CD19-positive hematologic malignancies. Notwithstanding the encouraging results, a significant proportion of patients experience a lack of response or disease relapse. Recently several studies have shown the influence of commensal microbes on T cell function, specifically in the setting of checkpoint immunotherapy. We previously reported that gut microbiota perturbation by oral vancomycin, affects dendritic cell antigen presentation and cytokine secretion profile and affects the outcome of radiation and CAR-T therapies. Based on these data, in the present study we explore how modulation of the gut microbiota by vancomycin would influence the outcome of CART-19 therapy.

Methods We employed two murine tumor models, the hematopoietic CD19+ A20 lymphoma and the CD19+ B16 melanoma. We injected BALB/c or C57/black6 mice subcutaneously with $2x10^6$ A20 or $1x10^5$ CD19 positive B16 tumor cells. The same day we started treatment with oral vancomycin. Nineteen days after A20 inoculation or eleven days after CD19+ B16, mice were lymphodepletion with total body radiation (TBI). Two days later, CART-19 cells containing second generation fully murine CAR with a 4-1BB costimulatory domain were infused by tail vein. To validate the data in humans, we proceeded by: a. generating "human gut microbiota avatars", antibiotics preconditioned recipient mice were engrafted with human gut microbiota and enrolled in similar experiments mentioned before, and b. evaluating CART-19 peak expansion on lymphoblastic leukemia patients receiving vancomycin.

Results In both models, mice receiving vancomycin in combination with CD19 directed CAR T cell therapy displayed increased tumor-associated antigens (TAAs) presentation and tumor control compared to CART-19 alone. Fecal microbiota transplant from human healthy donors to pre-conditioned mice recapitulated the results obtained in naïve gut microbiota mice. Lastly, B-cell acute lymphoblastic leukemia patients treated with CART-19 and exposed to oral vancomycin showed higher CART-19 peak expansion compared with matched unexposed patients.

Conclusions These results highlight the role of the gut microbiota on immunotherapy and suggest that the modulation of the gut microbiota using vancomycin affects the outcome of CAR T cell therapy.

574 BLOOD-BASED EXTRACELLULAR MATRIX BIOMARKERS ARE CORRELATED WITH PROGNOSTIC AND FIBROTIC-RELATED CLINICAL CHARACTERISTICS AND LIVER FUNCTION MARKERS IN PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA

[1]Jaclyn Neely*, [1]Jin Yao, [2]Christina Jensen, [2]Morten Karsdal, [2]Nicholas Willumsen. [1]*Bristol Myers Squibb, Lawrenceville, NJ, United States*; [2]*Nordic Bioscience, Herlev, Denmark*

Background Immune checkpoint inhibitors (ICI) have demonstrated clinical benefit in advanced hepatocellular carcinoma (aHCC). However, many patients do not respond to these therapies indicating a need for novel non-invasive biomarkers to monitor disease progression and predict treatment outcomes. HCC is a highly fibrotic disease with excessive extracellular matrix (ECM) and collagen remodeling and a reactive stroma that can affect T-cell infiltration and influence response to ICI. Fibrotic processes cause ECM remodeling, during which unique collagen fragments, like PRO-C3, are released into the blood and could be used as a non-invasive measure of the tumor fibrotic activity. Here we investigated if circulating ECM fragments are correlated with prognosis, fibrotic characteristics, and liver function in patients with aHCC.

Methods We performed the analysis on 602 patient sera specimens collected before treatment in the CheckMate 040 study (NCT01658878) of patients with advanced HCC. ELISA assays were used to measure ECM fragments related to fibroblast activity and collagen synthesis including pro-peptides of type III, IV, V, VI, XXVIII collagens (PRO-C3, PRO-C4, PRO-C5, PRO-C6, PRO-C28), cross-linked pro-peptide of type III collagen (PRO-C3X), alpha smooth muscle actin (αSMA) and ECM degradation fragments such as MMP-degraded type I, III, IV, V, VI collagens (reC1M, C3M, C4M, C5M, C6M, TUM), granzyme B-degraded type IV collagen (C4GzB), and citrullinated and MMP-degraded vimentin (VICM). ECM fragments were evaluated for their association with each other, liver function markers (Spearman's correlation, rho) and clinical characteristics (Kruskal-Wallis test).

Results Of the 15 ECM markers assessed, C3M and C4M (rho=0.82), C6M and TUM (rho=0.82), and PRO-C4 and PRO-C5 (rho=0.78) showed the highest correlation. Higher levels of the circulating collagens including PRO-C3 were associated with poor prognostic factors such as macrovascular invasion (p=4.8e-06) and ascites (p=4.1e-04), as well as poor overall survival. Similarly, PRO-C3 was also associated with fibrosis-related characteristics such as Child-Pugh score and class (p=5.4e-10 and p=5e-06 respectively) and OKUDA stage (p=4.3e-08). Circulating collagen fragments were positively correlated with C-reactive protein, alfa-fetoprotein, aspartate aminotransferase and negatively correlated with albumin levels. Collagen levels were distributed differentially based on viral etiology suggesting underlying biological differences in the TME.

Conclusions Quantifying circulating ECM fragments could enable non-invasive profiling of tumor stroma dynamics during the course of aHCC. Tumor stroma may influence response to ICI; therefore, these biomarkers may have prognostic and/or predictive potential. Further analysis is needed to determine the clinical utility of circulating ECM fragments and their impact on treatment outcomes in aHCC.

Acknowledgements We acknowledge CheckMate 040 investigators for providing patient samples for these correlative analyses.

576 COMPREHENSIVE SINGLE CELL SEQUENCING ANALYSIS OF PAIRED TISSUE AND BLOOD SAMPLES FROM HCC PATIENTS TREATED WITH NEOADJUVANT ANTI-PD-1 THERAPY REVEALS TREATMENT-INDUCED CLONAL T CELL DYNAMICS

[1]Wei Wang, [1]Peter Hawkins, [1]Lianjie Li, [1]Nathalie Fiaschi, [2]Assaf Magen, [1]Se Jeong, [1]Lauren Boucher, [1]Christina Adler, [1]Min Ni, [1]Nicola James, [2]Myron Schwartz, [2]Thomas Marron, [1]Elizabeth Miller, [1]Israel Lowy, [1]Yi Wei, [2]Alice Kamphorst, [2]Miriam Merad, [1]Gurinder Atwal, [1]Gavin Thurston, [1]Namita Gupta, [1]Raquel Deering*. *[1]Regeneron Pharmaceuticals, Tarrytown, NY, United States; [2]Mount Sinai School of Medicine, New York, NY, United States*

Background While immune checkpoint blockade (ICB) therapy has provided benefit to many cancer patients, the characteristics of anti-tumor T cell responses in non-tumor tissues and in circulation are not fully understood. Neoadjuvant ICB therapy provides a unique opportunity to deeply characterize pre- and post-therapy biomarker samples and identify features of drug activity across matched patient tissues. In a single-arm, open label phase 2 study, 21 patients with resectable (stage Ib, II, and IIIb) hepatocellular carcinoma (HCC) were treated with anti-PD-1 antibody, cemiplimab, in the neoadjuvant setting.[1]Patients were treated with two cycles of cemiplimab (350 mg Q3W) prior to resection (median time to resection = 29 days), and 6/21 patients experienced pathologic response to therapy at the time of resection (Responders).

Methods Single cell RNA (scRNA) and T cell receptor (TCR) sequencing were performed on tumor, normal adjacent tissues (NAT), tumor draining lymph node (tdLN), and blood from 20/21 patients at the time of resection. Additionally, blood samples from all patients were analyzed by scRNA- and TCR-sequencing at baseline, during neoadjuvant therapy, at resection, and during adjuvant therapy. The characteristics of all tumor-expanded T cells were compared across tissues and longitudinally in the periphery.

Results We identified several populations of PD-1+ T cells that were enriched in patient tumors compared to other tissues. Responder tumors contained significantly more PD-1+ Effector T cells than Non-responders, and TCR clonality was greater in tumors of Responders. Using TCR sequence as a fingerprint, we tracked tumor TCR clones across tissues, including longitudinal blood samples. Interestingly, NAT and tdLN had more shared T cell clones with the tumors of Responders relative to Non-responders. The most clonally-expanded TCRs identified in Responders' resection tumors were present in baseline tumor biopsies. Additionally, tumor-expanded TCRs were found to be expanded in the circulation of Responders at baseline and multiple treatment timepoints, including just one week following initiation of anti-PD-1 therapy.

Conclusions Our analyses revealed significant tumor-expanded TCR sharing across the tdLN and NAT at the time of resection in patients who responded to neoadjuvant anti-PD-1 therapy. These clones were present in tumors at baseline, indicating that pre-existing T cell clones expanded in response to treatment and were also more expanded in circulation of Responders as early as one week into therapy. Our study suggests that tumor-expanded T cells are frequently found in the periphery, and peripheral expansion might correlate with response to neoadjuvant anti-PD-1 therapy.

Trial Registration NCT03916627

577 THE VARIATION OF T-CELL RECEPTORS (TCR) DIVERSITY AND GENOMIC HUMAN LEUKOCYTE ANTIGEN (HLA-I) AMONG NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS EXPRESSING HIGH PDL-1 (≥50%) VERSUS THOSE WITH LOW OR NO PDL1 (<50%)

[1]Aaron Beasley, [1]Anna Reid, [1]Leslie Calapre, [2]Michael Millward, [1]Elin Gray, [1]Afaf Abed*. *[1]Edith Cowan University, Joondalup, Australia*; *[2]University of Western Australia, Perth, Australia*

Background NSCLC patients with PDL1≥50% are more likely to respond to single agent anti-PD1 comparing to those who are expressing PDL1 in less than 50% of their cancer cells. This suggest that there might be biological differences among high PDL1 (≥50%) NSCLC comparing to low PDL1 (<50%) NSCLC. We aim to investigating the presence of differences between those two groups in terms of pre-treatment T-Cell Receptor (TCR) repertoire and genomic Human Leukocyte Antigen-I (HLA-I).

Methods We prospectively collected baseline blood from 90 NSCLC; 50 patients with high PDL1 and 40 patients with low PDL1. High quality DNA was extracted. Genomic HLA-I typing and TCR sequencing was performed. TCR diversity variables were represented by number of unique clones, evenness, Shannon diversity, clonality and convergence. TCR gene usage has been compared between both groups as well. Mann-Whitney test was used to perform the comparison analysis. HLA-I homozygosity at one or more loci versus maximal heterozygisty was compared between the two groups using Fisher's exact test to calculate relative risk. HLA-A and -B supertypes was compared between the two groups as well. All analysis was conducted using GraphPad Prism version 9.3.1.

Results We had TCR results for 84 patients (47 high PDL1 and 37 low PDL1). We had to repeat the analysis for 6 patients. We found that patients with high PDL1 NSCLC are mole likely to have higher TCR evenness and lower clonality comparing to those with low or no PDL1 (median = 0.887 vs 0.845, P=0.013) and (median = 0.110 vs 0.155, P=0.008) respectively. No statistically significant results were found with other TCR variables. Moreover, certain TCR-genes are found more frequent among patients with high PDL1 comparing to those with low PDL1 like: TRBV3-1 (P=0.012), TRBV5-3 (P=0.029), TRBV9 (P=0.029), TRBV18 (P=0.019). Other TCR genes are found less frequent among patients with high PDL1 comparing to those with low PDL1 like: TRBV6-2 (P=0.040), TRBJ1-5 (P=0.032) and TRBJ2-7 (P=0.049). HLA typing was available for the 90 patients. No statistically significant result was found among both groups in terms of homozygosity versus heterozygosity. However, patients with high PDL1 are less likely to express HLA-A24 (RR=0.47, 95%CI 0.19-0.94, P=0.027) and more likely to express HLA-A03 (RR=1.87, 95%CI 1.24-2.98, P=0.002) on their cell surfaces.

Conclusions High PDL1 NSCLC is biologically differ from low or no PDL1 expressing NSCLC. This is reflected by their different response to immunotherapy treatment and confirmed by different pre-treatment TCR repertoire and HLA-I supertypes.

Ethics Approval Patients were recruited from two major teaching hos- pitals in Western Australia. All procedures were approved by the Human Research Ethics Committees at Edith Cowan University (ECU) (No. 18957) and Sir Charles Gairdner Hospital (No. 2013-246 and RGS0000003289) in compliance with the Declaration of Helsinki.

Consent All participants signed a consent form which is saved at ECU research database.

578 FEASIBILITY OF EFTILAGIMOD ALPHA (SOLUBLE LAG-3 PROTEIN) COMBINED WITH STANDARD-OF-CARE-THERAPY IN ADVANCED NON-SMALL-CELL LUNG CANCER (NSCLC) ADENOCARCINOMAS. INITIAL RESULTS FROM INSIGHT–003

[1]Akin Atmaca, [2]Daniel W Mueller, [1]Timursah Habibzade, [2]Marina Schaaf, [2]Jorge Klagges, [2]Regina Eickhoff, [1]Elke Jaeger, [2]Salah-Eddin Al-Batran, [1]Thorsten O Goetze*. [1]*Krankenhaus Nordwest, Frankfurt a.M., Germany*; [2]*Institut für Klinische Krebsforschung IKF am Krankenhaus Nordwest, Frankfurt a.M., Germany*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0578

Background Eftilagimod alpha (efti; IMP321) is a MHC II class agonist (soluble LAG-3 protein) which activates antigen-presenting cells followed by T-cell (CD4/CD8) activation. Data from the TACTI-002–trial (NCT03625323) and INSIGHT–004 of the current multiple-strata INSIGHT phase-I platform-study revealed that the combination of 30 mg efti subcutaneous (s.c.) with anti-PD-(L)1–checkpoint–inhibitor is well tolerated with encouraging efficacy especially in NSCLC. Stratum–C (INSIGHT-003) of the INSIGHT–study aims to evaluate the feasibility and tolerability of s.c. injections with efti combined with Standard-of-Care (SOC) chemo- and immuno-therapy in 1st-line NSCLC-patients (pts).

Methods In Stratum–C, pts with metastatic NSCLC adenocarcinomas are treated with: SOC–chemotherapy (carboplatin AUC5 / pemetrexed 500 mg/m^2 q3w for 4 cycles + 500 mg/m^2 q3w for maintenance) plus pembrolizumab 200 mg q3w combined with s.c. injections of efti (30 mg) (q2w for 24 weeks; thereafter q3w till week 52). Imaging is performed every 8 weeks and assessed locally. The primary endpoint is feasibility (defined by safety & tolerability) while secondary endpoints include objective response acc. to RECIST 1.1 and other efficacy parameters. In total 20 pts will be enrolled.

Results From 02Aug2021 till 22Jul2022, 14 pts have been enrolled. Median age is 66 years and 71.4% are male. Eleven (78.6 %) pts had PD-L1 TPS <50%. No occurrence of unacceptable toxicities (i.e., causally related to efti AND resulting in permanent discontinuation of combination-treatment before administration of two complete cycles). Two serious adverse events (1 thromboembolic event, grade 3; 1 bronchial infection grade, 3) were reported, both unrelated to efti. In total, 69 adverse events (grade 1-2: 29; grade 3: 38; grade 4: 2) were documented. The most frequent AEs were platelet-count decreased in three pts (21.4%, grade 1-3) and anemia (grade 2-3), white-blood-cell decreased (grade 3), and neutrophil-count decreased (grade 3-4) in four pts (28.6%). One grade 3 AE was considered related to efti (insomnia). 10/14 pts are currently evaluable for efficacy (four did not yet have any on-treatment tumor-staging): Seven (70 %) partial responses, two (20%) stable diseases, one (10%) progressive disease as best overall response acc to RECIST 1.1.

Conclusions To date, 30 mg efti combined with SOC appears to be feasible and safe with first promising signals of efficacy.

Acknowledgements We thank all the participating patients & their families.

We thank the dedicated clinical trial investigators & their team members.

Immutep, Berlin, Germany provided eftilagimod alpha and funding support for the study.

Ethics Approval The study was approved by 'Ethik-Kommission bei der Landesärztekammer Hessen' institution's Ethics Board, approval number 2019-1267-fAM. Participants gave informed consent before taking part.

579 **NOVEL DIGITAL IMAGE APPROACH OF MULTIPLEX IMMUNOFLUORESCENCE BASED PD-L1 EXPRESSION ENABLES THE STRATIFICATION OF ADVANCED NSCLC PATIENTS TREATED WITH DURVALUMAB**

Nicolas Brieu*, Felix Segerer, Harald Hessel, Ashok Gupta, Ikbel Achour, Guenter Schmidt. *AstraZeneca, Munich, Germany*

Background Pathologist-based scoring of PD-L1 expression on tumor cells using IHC[1] has shown clinical utility in predicting favorable overall survival in advanced non-small cell lung cancer (NSCLC) patients treated with anti-PD-(L)1 therapies including durvalumab.[2-3]Quantitative Continuous Scoring (QCS)[4] enables the continuous measurement of the PD-L1 expression on single cells and the selection of the PD-L1 expression cutoff that best stratifies anti-PD-L1-treated patients with respect to prevalence and log-rank test p-value.[5] We present here the extension of QCS to PD-L1 measured by multiplex immunofluorescence (mIF)[6] to evaluate its ability to optimize patient stratification.

Methods Pre-treatment tumor samples from advanced NSCLC patients enrolled in durvalumab nonrandomized phase 1/2 trial (CP1108/NCT01693562) [2], were stained by mIF panel containing PD-L1. [6] Similarly to IHC PD-L1 QCS, mIF PD-L1 QCS consists of two deep-learning models, first to segment epithelium regions and second to detect membrane, cytoplasm and nuclei of each epithelium cell, transferring for the second model annotations from IHC to mIF domain. [7] The mIF images are normalized based on batch statistics prior to image analysis. PD-L1 expression is measured for each epithelium cell as the average of the PD-L1 signal in the segmented membrane. Cells with expression higher than an expression threshold (T_{PDL1}) are considered positive. A slide is considered QCS-positive if it comprises a greater percentage of PD-L1 positive cells (QCS-score) than a cutoff value (CoV).

Results The QCS-scores are computed on 119 NSCLC patients treated with durvalumab. As a first proof of concept that QCS-scoring can replicate tumor proportion scoring (TPS), we optimize T_{PDL1} as to maximize the correlation between QCS and TPS scores (figure 1). Second, we estimate for different combinations of (T_{PDL1}, CoV) the log rank p-value associated with the stratification between patients with low and high QCS scores. A subregion of the parameter space was identified for which the stratification is significant ($p<0.01$) with more than 50% prevalence in the positive subgroup (figure 2). The p-value is minimized ($p=7.2\ 10^{-5}$) for ($T_{PD\text{-}L1}=37$, $CoV=0.75\%$), yielding a median OS of 5.58 months and 13.44 months in the QCS negative and positive subgroups respectively, similar to those of IHC PD-L1 manual scoring with 25% cutoff.

Conclusions The extension of QCS to mIF imaging provides opportunities to evaluate continuous PD-L1 expression of single tumor cells in relation to spatial distribution of other cells (e.g. PD1+ CD8+ T cells) and identify predictive biomarkers of tumor-immune cell interactions of anti-PD-(L)1 therapies.

580 HOST IMMUNE PROFILING IN FIRST-LINE IMMUNOTHERAPY TREATED ADVANCED STAGE NON-SMALL CELL LUNG CANCER: RESULTS FROM THE INSIGHT REGISTRY STUDY

[1]Hefez Halawani, [2]Eric Schaefer, [3]Ray Page, [4]Bassam Ghabach, [5]Wallace Akerley*. *[1]Christus St. Frances Cabrini, Alexandria, LA, United States; [2]Highlands Oncology, Fayetteville, AR, United States; [3]The Center For Cancer and Blood Disorder, Fort Worth, TX, United States; [4]JPS Oncology and Infusion Center, Ft. Worth, TX, United States; [5]Huntsman Cancer Institute, Salt Lake City, UT, United States*

Background Immune checkpoint inhibitor therapies (ICI) have revolutionized the treatment of advanced stage non-small cell lung cancer (NSCLC) yielding 5 year-survival in ~30% for ICI treated patients and PD-L1 expression (≥50%) with median survival of 26.3 months (m).[1] New treatment biomarkers have the potential to improve these results. Here we report the updated interim analysis results from the INSIGHT study, evaluating the extensively validated blood-based proteomic test, the Host Immune Classifier (HIC).[2]

Methods INSIGHT (NCT03289780) is a prospectively designed multicenter observational clinical study, having enrolled over 4,500 patients with NSCLC, across all stages and histologies. Pre-treatment blood samples were evaluated with the HIC test, which classifies patients as either HIC-Hot (HIC-H) or HIC-Cold (HIC-C). An interim analysis of exploratory endpoints was performed once patients had at least 12 months of follow up in the first 3,035 patients enrolled.

Results In the analysis population, 564 advanced stage (Stages IIIB & IV) patients were treated with a 1st line ICI containing regimen (ICI monotherapy [ICI-m] n=204 and ICI+Platinum based Chemotherapy [ICI+PC] n=360). Real-world median Overall Survival (mOS) for the ICI-m and ICI+PC cohorts was 12.9m and 13.0m, respectively. mOS for the ICI-m cohort stratified by the HIC test was 17.5m (HIC-H) vs. 5.6m (HIC-C), Hazard Ratio (HR): 0.49 (95% Confidence Interval [CI] 0.34-0.71), p-value=0.0001. Similarly, stratification of the ICI+PC cohort indicated that patients classified as HIC-H had a mOS of 17.1m vs. 8.2m in HIC-C (HR 0.53 [0.40-0.70]), p-value=<0.0001. Evaluation of the ICI-m treated patients with PD-L1 expression ≥50% demonstrated a similar survival stratification, 16.4m vs 5.3m (HR 0.49 [0.32-0.76, p-value=0.001, Figure 1A) for HIC-H and HIC-C, respectively. However, in the ICI+PC PD-L1 high cohort, OS did not significantly differ between patients classified as HIC-H and HIC-C (Not Reached vs. 14.3, HR 0.49 [0.23-1.03], p value=0.06). Furthermore, the HIC test classifications were independent of PD-L1 expression (p-value=0.196) and remained an independent predictor of OS in ICI-treated patients, when covariates such PS and PD-L1 expression were adjusted for in a multivariate analysis (HR 0.54 [0.45-0.64], p-value=<0.0001).

Conclusions HIC-C patients with PD-L1 expression ≥50% treated with ICI+PC had better survival than those treated with ICI-m (mOS 14.3m vs 5.3m) suggesting that a blood-based HIC test provides clinically meaningful information that may aid in selecting 1st line immunotherapy containing regimens. Additionally, in the real-world setting mOS of patients treated with ICI-m was reduced as compared to survival reported in registrational clinical trials (i.e. 26.3m). [1]

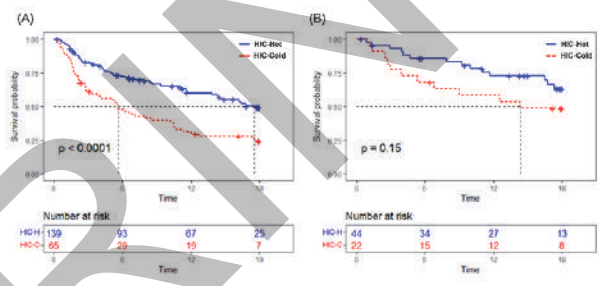
Ethics Approval INSIGHT (NCT03289780) is an ongoing registry study involving over 30 academic and community oncology practices across the United States of America. The study has been reviewed and approved by an accredited central IRB (Advarra; formerly Quorum), as well as multiple local institutional review boards and conducted in accordance with the International Conference on Harmonization guidelines for Good Clinical Practice and the Declaration of Helsinki. All patients have provided written informed consent for participation.



Abstract 580 Figure 1 Overall survival stratification of patients with PD-L1 ≥50% expression treated with either ICI-m (A) or ICI+PC (B). In patients treated with ICI-m, mOS differed significantly between HIC-H and HIC-C, HR 0.49 (CI 0.32-0.76), p-value = 0.001. Conversely, in patients with PD-L1 ≥50% expression treated with ICI+PC, overall survival did not significantly differ between HIC-H and HIC-C, HR 0.49 (0.23-1.0), P-value = 0.06.

581 MATCHING-ADJUSTED INDIRECT TREATMENT COMPARISON OF TREMELIMUMAB + DURVALUMAB + CHEMOTHERAPY VS PEMBROLIZUMAB + CHEMOTHERAPY AND NIVOLUMAB + IPILIMUMAB + CHEMOTHERAPY FOR FIRST-LINE METASTATIC NSCLC

[1]Sukhvinder Johal*, [1]Miguel Miranda, [1]Tina Sarbajna, [1]Xiaojin Shi, [2]Alastair Greystoke, [3]Melissa Johnson. *[1]AstraZeneca, Cambridge, UK; [2]The Newcastle Hospitals NHS Foundation Trust, Newcastle, UK; [3]Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN, United States*

Background Tremelimumab plus durvalumab and chemotherapy (T+D+CT), for first-line treatment of metastatic NSCLC, has been evaluated vs CT in a randomized phase III trial, POSEIDON (NCT03164616). In the absence of head-to-head studies, indirect treatment comparisons (ITCs) can be used to compare the efficacy of T+D+CT vs other currently approved agents including pembrolizumab plus CT (P+CT) and nivolumab plus ipilimumab plus CT (N+I+CT). However, given the potential differences in baseline characteristics between patient populations across studies, a standard ITC may be subject to bias and is therefore not necessarily the most appropriate method to derive comparative efficacy estimates. An anchored matching-adjusted indirect comparison (MAIC) is an alternative ITC method which attempts to adjust for cross-trial heterogeneity in patient populations using CT as the common comparator or anchor.

Methods Patient-level data from POSEIDON was weighted to match the baseline covariate distribution from the CheckMate 9LA trial, for both intention-to-treat (mixed histology) and non-squamous histology (NSQ) cohorts, and matched to the KEYNOTE-189 trial for the NSQ cohort. Overall survival (OS) was compared. Patient baseline characteristics and endpoints in POSEIDON were statistically tested to identify potential treatment effect modifiers (TEMs) which were subsequently clinically validated. Reweighting for POSEIDON was conducted in a pairwise manner against each comparator trial in turn using a propensity score weighting approach for the covariates that were identified as TEMs and were imbalanced across the trials. Hazard ratios (HRs) for OS were then re-estimated for POSEIDON using weighted Cox regression models and indirectly compared with those of CheckMate 9LA and KEYNOTE-189 using an ITC approach.

Results Covariates identified as TEMs through a series of interaction tests with treatment were race, histology and smoking status. For the mixed histology cohort, the estimated OS HR (95% CI) of T+D+CT vs N+I+CT after weighting was 0.89 (0.68, 1.16). For the NSQ cohort, the estimated OS HRs (95% CI) of T+D+CT vs P+CT and vs N+I+CT, were 0.96 (0.69, 1.35) and 0.76 (0.55, 1.07), respectively.

Conclusions The MAIC approach provides a method to generate comparative effectiveness estimates by accounting for heterogeneity in the baseline distribution of TEMs across trials. After adjusting for these differences between the considered trials, the OS HR point estimates were numerically in favour of treatment with T+D+CT vs N+I+CT in the mixed histology and NSQ populations and indicated similar OS with T+D+CT and P+CT in the NSQ population. This comparison supports T+D+CT as a potential new first-line treatment option for metastatic NSCLC.

582 PATIENT-REPORTED OUTCOMES WITH CEMIPLIMAB VERSUS CHEMOTHERAPY IN ADVANCED NON-SMALL CELL LUNG CANCER (ANSCLC): EASTERN COOPERATIVE ONCOLOGY GROUP (ECOG) PERFORMANCE STATUS SUBGROUPS IN EMPOWER-LUNG 1

[1]Saadettin Kilickap*, [2]Ahmet Sezer, [3]Mahmut Gümüş, [4]Igor Bondarenko, [5]Mustafa Ozguroglu, [6]Miranda Gogishvili, [7]Xuanyao He, [7]Giuseppe Gullo, [7]Petra Rietschel, [7]Ruben Quek. *[1]Istinye University Faculty of Medicine, Istanbul, Turkey; [2]Başkent University, Adana, Turkey; [3]Istanbul Medeniyet University, Istanbul, Turkey; [4]Dnipropetrovsk Medical Academy, Dnipro, Ukraine; [5]Istanbul University-Cerrahpaşa, Istanbul, Turkey; [6]University Clinic Ltd, Tbilisi, Georgia; [7]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, United States*

Background Subgroup analysis of EMPOWER-Lung 1, a 1:1 randomized, open-label Phase 3 study, showed improvements in overall survival (OS) and progression-free survival with cemiplimab monotherapy (CEMI, n=283) versus platinum-doublet chemotherapy (CHEMO, n=280) in patients with an ECOG performance status (PS) score 0 and 1 (OS: PS 0: hazard ratio [HR] 0.77, 95% confidence interval [CI] 0.41, 1.44; PS 1: HR 0.54, 95% CI 0.38, 0.76) in patients with aNSCLC with programmed cell death-ligand 1 $\geq$50%.[1] Post-hoc analyses evaluated patient-reported outcomes (PROs) in both ECOG PS subgroups.

Methods PROs were assessed at baseline and Day 1 of each treatment cycle for the first 6 cycles, and then on Day 1 of every third cycle using the European Organization for Research and Treatment of Cancer Quality of Life-Core 30 (QLQ-C30) and Lung Cancer Module (QLQ-LC13) questionnaires. Higher scores indicate better functioning and global health status (GHS)/quality of life (QoL), or worse symptom severity. Mixed-model repeated-measures analyses were performed to compare overall change from baseline scores between the two treatment arms while controlling for baseline characteristics. Time to definitive clinically meaningful deterioration (TTD) per 10-point threshold was analyzed using a stratified log-rank test and proportional hazards model.[2]

Results Baseline PRO scores were broadly similar between treatment arms. Statistically significant difference in overall change from baseline in GHS/QoL favoring CEMI versus CHEMO occurred in the ECOG PS score 1 subgroup (mean treatment difference 5.03, 95% CI 1.90, 8.15, P=0.0017). CEMI also resulted in statistically significant favorable differences in both ECOG subgroups in overall change from baseline in physical and social functioning; fatigue, nausea/vomiting, and constipation symptoms per QLQ-C30; and peripheral neuropathy and alopecia symptoms per QLQ-LC13. There was a statistically significant delay in TTD in physical functioning in the ECOG PS score 1 subgroup, favoring CEMI (HR 0.59, 95% CI 0.37, 0.95, P=0.028). Statistically significant delays in TTD favoring CEMI occurred in both ECOG subgroups in social functioning, fatigue and nausea/vomiting symptoms per QLQ-C30; peripheral neuropathy and alopecia symptoms per QLQ-LC13. When comparing between arms, no analyses yielded statistically significant PRO results favoring CHEMO for any QLQ-C30 or QLQ-LC13 scale.

Conclusions In this post-hoc analysis of patients with aNSCLC across both ECOG PS subgroups, CEMI resulted in significant overall improvement and delayed TTD relative to CHEMO in multiple patient-reported cancer-related and lung cancer–specific functions and symptoms. Positive PRO results further support the favorable benefit-risk profile of CEMI versus CHEMO in aNSCLC in both PS subgroups.

583 QUANTITATIVE COMPUTATIONAL ASSESSMENT OF PD-L1 ENABLES ROBUST PATIENT SELECTION FOR BIOMARKER-INFORMED ANTI-PD-L1 TREATMENT OF NSCLC PATIENTS

[1]Jan Lesniak*, [1]Markus Schick, [1]Thomas Kunzke, [1]Pallavi Sontakke, [1]Thomas Padel, [1]Anatoliy Shumilov, [1]Farzad Sekhavati, [1]Christian Sachs, [1]Federico Pollastri, Ansh Kapil, [1]Masters of Informatics, [1]Nicolas Brieu, [2]Carl Barrett, [1]Hadassah Sade, [1]Guenter Schmidt, [2]Ross Stewart. *[1]AstraZeneca Computational Pathology GmbH, Munich, Germany; [2]AstraZeneca Early Oncology, Gaithersburg, MD, United States*

Background Immune checkpoint inhibitors (ICIs) targeting PD-1 or its ligand PD-L1 have shown clinical activity in patients with metastatic non-small cell lung cancer (mNSCLC). However, only subgroups of mNSCLC patients respond to ICI, while their robust and accurate identification using PD-L1 as a biomarker remains challenging. Typically, PD-L1 expression is assessed by pathologist scoring of immunohistochemically (IHC) stained tissue, e.g. using the tumor proportion score (TPS). However, this manual process is subjective and semi-quantitative. To this end, we aim to develop robust quantitative continuous scoring of PD-L1 expression via IHC (PD-L1 QCS), relying on digitized image analysis, with the aim of improving robustness of patient selection.

Methods QCS of PD-L1 (Ventana SP263) on digitized whole slide images (WSI) is approached by segmenting the tumor epithelium within a given region of interest. Here, a deep learning (DL) region segmentation model is applied which was enriched with additional training data; expanding previous work.[1,2] A second DL model segments individual tumor cells and their membranes. By applying color deconvolution, the resulting Optical Density (OD) provides a continuous measurement of PD-L1 intensity on each cell membrane. The percentage of positive cells is derived by thresholding the OD, whereas the specific cut-point for stratification was obtained by optimizing on an exploratory cohort (samples from 163 mNSCLC patients treated with anti-PD-L1; NCT01693562) and validated for its robustness using an independent cohort (samples from 252 patients treated with anti-PD-L1; NCT02453282), for which IHC staining and WSI scanning were completed at a contract research organization (CRO).[3,4]

Results On the exploratory cohort, pathologist TPS correlated favorably against PD-L1 QCS (Spearman R=0.86), confirming the validity of image analysis. PD-L1 QCS yielded a group of responders to anti-PD-L1 treatment with a significantly increased median overall survival (mOS) by 9.2 months (log-rank p=0.0017, HR=0.54, prevalence=46%). On the independent validation cohort, this finding was confirmed with an mOS increase of 9.9 months (log-rank p=0.0001, HR=0.55, prevalence=40%), although IHC for the second cohort was completed in a different laboratory and slides digitized with a different scanner.

Conclusions We describe a computational pathology approach for precise quantification of PD-L1 expression and selection of mNSCLC patients for anti-PD-L1 treatment using the Ventana SP263 assay. Importantly, we successfully validated the performance of our PD-L1 QCS solution in two independent clinical trial datasets, which were processed by different CROs using different scanners revealing broad applicability and thereby underscoring the potential of PD-L1 QCS to transform pathology.

584 EVALUATION OF A COMPOSITE IMMUNOTHERAPY SIGNATURE IN NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH ATEZOLIZUMAB

[1]Khaled Tolba, [2]David Gandara, [1]Meagan Montesion, [3]Barzin Nabet, [3]Minu Srivastava, [1]Lee Albacker, [4]Mary Redman, [5]David Kozono, [3]Craig Cummings, [6]Roy Herbst, [3]David Shames, [1]David Fabrizio*. *[1]Foundation Medicine, Cambridge, MA, United States; [2]UC Davis, Sacramento, CA, United States; [3]Genentech, South San Francisco, CA, United States; [4]Fred Hutchinson Cancer Research Center, Seattle, WA, United States; [5]Brigham and Women Hospital, Harvard, Boston, MA, United States; [6]Yale University, New Haven, CT, United States*

Background Immune checkpoint inhibitors have transformed the care of NSCLC, however many patients do not respond and current biomarkers have limited predictive value. While current guidelines recommend that patients with advanced NSCLC undergo large panel NGS to guide treatment selection, most of the genomic data generated are rarely utilized for therapeutic decision making in the absence of an actionable driver mutation. In this work, we validated a composite IO biomarker that integrates multiple genomic features readily available on large-panel NGS to predict response to ICI in NSCLC patients.

Methods OAK is a phase III trial that randomized 1250 patients with advanced stage NSCLC who progressed on initial platinum therapy to receive atezolizumab (Atezo) or docetaxel until disease progression (1). 239 participants with Foundation Medicine tissue NGS were included and 180 were WT for EGFR, ALK, ROS1, BRAF, MET and RET, of whom 86 received Atezo while 94 received docetaxel. We tested the predictive value of 7 biomarkers that had been trained previously on a subset of squamous lung patients treated with immunotherapy and were part of the Lung-MAP clinical trial, including TMB < 10, 10-19 and ≥ 20 Mut/Mb; PD-L1 IHC <1%, 1-49% and ≥ 50%; mutations or loss of ARID1A, KEAP1, STK11, CDKN2A; and altered DDR defined as functional loss of one or more of these 7 genes: ATM, BRCA2, BRIP1, MRE11, POLE, MSH2 and PARP1. A nominal system included binning scores based on individual biomarker positivity of 0-2, 3-4 or 5-8 (IO signature low, medium, high). We used a Cox proportional hazards regression model to investigate the effect of individual covariates and three composite bins on OS of the two treatment arms.

Results Individual biomarker analysis showed that TMB ≥ 20 exerted the greatest effect on OS in Atezo-treated patients (HR= 0.4, P = 0.07). Altered DDR, PD-L1 >50% and STK11 loss numerically impacted OS but did not reach statistical significance due to small sample size. High IO signature correlated with improved OS within the Atezo-treated patients, yielding a median OS of 23 months vs. 7 months (HR=0.38; 95% CI, 0.18-0.81) between high vs. low, as well as a median OS of 23 months vs. 10 months between Atezo and docetaxel treated patients within the high IO signature subpopulations (HR=0.68; 95% CI, 0.34-1.3).

Conclusions Our data suggest that Composite IO signature might be more accurate and informative than a single biomarker in guiding ICI treatment selection in NSCLC.

585

PHASE 1 DOSE ESCALATION TRIAL OF THE SELECTIVE A2B ADENOSINE RECEPTOR ANTAGONIST PBF-1129 IN PATIENTS WITH METASTATIC NON-SMALL CELL LUNG CANCER (MNSCLC)

[1]Dwight Owen*, [1]Lai Wei, [1]Mikhail Dikov, [1]Shankar Suman, [1]Ruohan Wu, [1]Joseph Amann, [1]Catherine Schweitzer, [1]Sarah Ferguson, [1]Michael Smith, [2]Julio Castro, [1]Erin Bertino, [1]Peter Shields, [1]Kai He, [1]Carolyn Presley, [1]Gregory Otterson, [1]David Carbone. *[1]The Ohio State University, Columbus, OH, United States; [2]Palobiofarma S.L., Barcelona, Spain*

Background Adenosinergic signaling has recently emerged as a powerful regulator within the tumor microenvironment (TME). Preclinical studies on interference with adenosine generation or signaling through A2A and A2B adenosine receptors (A2BAR) have been shown to relieve immunosuppression by reducing stress in the TME by decreasing expression of key adenosine-generating enzymes. A2BAR blockade enhances anti-tumor immunity through a reduction in myeloid-derived suppressor cell differentiation and an enhancement of the capacity of dendritic cells to evoke anti-tumor T cell responses. We conducted a phase 1 dose escalation trial of PBF-1129, a first in class selective A2BAR inhibitor in patients with mNSCLC who progressed on chemotherapy and immune checkpoint inhibitors (ICI).

Methods NCT03274479 was a single site dose escalation phase 1 trial. Patients received escalating doses of PBF-1129 orally daily (80 mg, 160 mg, 240 mg, 360 mg) until disease progression or intolerability. Primary objective was safety and tolerability as define by occurrence of dose limiting toxicities (DLT) and to determine maximum tolerated dose (MTD). PK, ORR, PFS, OS were secondary endpoints.

Results 21 patients (9 female), median age 61 years (range 49-75) were enrolled. 12 patients with adenocarcinoma, 7 with squamous, 1 with adenosquamous and 1 NOS. Median line of therapy was 4th (range 3-6). All patients received prior PD-1/L1 therapy and chemotherapy; 4 pts received prior anti-CTLA-4. PD-L1 expression negative in 6 pts, positive in 12 and unknown in 3 pts. No DLTs were observed at any dose level. No MTD was identified. Grade≥3 treatment-related adverse events (TRAEs) occurred in 3 patients including lymphocytopenia (n=2), hyponatremia (n=1), hypertension (n=1), and encephalopathy (n=1). Most frequent TRAEs of any grade were lymphocytopenia (n=8, 38%), vomiting (n=8, 38%), anorexia (n=6, 29%), and fatigue (n=6, 29%). 18 patients were evaluable for response, best response of stable disease was observed in 3 pts; median PFS 1.5 months (95% CI 1.0, 1.9), median OS 4.6 months (95% CI: 2.1, 5.2). PK analysis revealed a dose-dependent exposure increase, with median C(max) ranging from 150ng/ml at the 40mg dose to 800ng/ml at the 320mg dose, together with a moderate half-life above 10h (figure 1) . The 320mg is able to maintain PBF-1129 free concentrations above the IC(50) against the adenosine A2b receptor for 24h.

Conclusions PBF-1129 was safe and tolerable in patients with heavily pretreated mNSCLC although limited single agent activity was observed. RP2D was identified as 360 mg orally daily. A trial of PBF-1129 given in combination with ICI is planned (NCT05234307).

Trial Registration NCT03274479

Ethics Approval The study was approved by the OSU institution's Ethics Board (#2018C0019)

Consent All study participants granted a written informed consent prior to treatment initiation.

586 **DURVALUMAB (D) ± TREMELIMUMAB (T) + PLATINUM-ETOPOSIDE (EP) IN EXTENSIVE-STAGE SMALL-CELL LUNG CANCER (ES–SCLC): RNA SEQUENCING ANALYSIS TO EXPLORE CANONICAL MARKERS OF IO ACTIVITY IN CASPIAN**

[1]Mingchao Xie, [1]Priti Chugh, [1]Cathy O'Brien, [1]Zhongwu Lai, [1]Ross Stewart, [2]Luis Paz-Ares, [3]Jonathan Goldman, [4]Marina Garassino, [5]Charles Rudin, [1]J Carl Barrett, [1]Yashaswi Shrestha*. *[1]AstraZeneca, Waltham, United States; [2]Hospital Universitario 12 de Octubre, Madrid, Spain; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA, United States; [4]Istituto Nazionale dei Tumori, Milan, Italy; [5]Memorial Sloan Kettering Cancer Center, New York, NY, United States*

Background In the Phase 3 CASPIAN study, first-line D+EP significantly improved overall survival (OS) vs EP in patients with ES-SCLC, and OS benefit was sustained at >3 years of median follow-up (HR 0.71 [95% CI 0.60–0.86]; nominal p=0.0003; median OS [mOS] 12.9 vs 10.5 months). Although not statistically significant, a numerical improvement in OS was observed with D+T+EP vs EP, which continued at >3 years of median follow-up (HR 0.81 [95% CI 0.67–0.97]; nominal p=0.0200; mOS 10.4 vs 10.5 months). Various biomarkers of immune checkpoint inhibitor activity have been identified previously, including *CD8A*, *CD4*, *CTLA-4*, and *FOXP3* (a regulatory T-cell marker), although such biomarkers are not well characterized in SCLC. In this exploratory analysis using RNA sequencing (RNAseq) data from CASPIAN, we explored the association of these canonical biomarkers with OS in patients with ES-SCLC.

Methods In CASPIAN, treatment-naïve patients with ES-SCLC received 4 cycles of D+EP or D+T+EP followed by maintenance D; or up to 6 cycles of EP. RNAseq data were generated from FFPE tumor samples collected at screening. Data cutoff: Mar 22, 2021.

Results 57/268 (21.3%) patients in the D+EP arm, 60/268 (22.4%) patients in the D+T+EP arm, and 47/269 (17.5%) patients in the EP arm had RNAseq data (biomarker-evaluable population; BEP). In the BEP, mOS was 11.8 months in the D+EP arm, 11.9 months in the D+T+EP arm, and 9.1 months in the EP arm (HR for D+EP vs EP: 0.61 [95% CI 0.40–0.92]; HR for D+T+EP vs EP: 0.53 [95% CI 0.35–0.81]). In both the D+EP and D+T+EP arms, mOS was higher in the *CD8A*-high vs -low expression group (table 1). In the D+T+EP arm only, mOS was higher in the *CD4*-, *CTLA-4*-, or *FOXP3*-high vs -low expression groups (table 1).

Conclusions These exploratory data on the association of *CD8A*, *CD4*, *CTLA-4*, and *FOXP3* with outcomes in CASPIAN provide insights into the mechanism and biology of IO in ES-SCLC and support their further exploration as biomarkers in this setting. Pre-existing cytotoxic T cells may be an important factor for durvalumab to extend anti-tumor activity, and tremelimumab may enhance T-cell activation by overcoming sequestration of CD28 ligands by regulatory T cells. The RNAseq BEP was ~20% of the CASPIAN intention-to-treat population, so these findings should be regarded as hypothesis generating.

Background Although immune checkpoint inhibitors (ICI) are efficacious in some patients with cancer, many do not benefit. Identifying pre- and on-treatment biomarkers correlating with clinical outcomes is essential for better treatment strategies. High pre- and on-treatment recruitment of CD8+ T cells into the tumor are associated with improved outcomes following ICI therapy. We report orthogonal biomarker results from the AMADEUS study, an all-comer solid tumors trial, in which patients were treated with nivolumab (NIVO) with or without ipilimumab (IPI) based on the proportion of pretreatment tumoral CD8+ T cells.

Methods AMADEUS is a prospective, non-randomized, multicenter study that enrolled 79 patients with various metastatic solid tumors. The frequency of pretreatment tumoral CD8+ T cells was measured by a CLIA-certified immunohistochemistry (IHC) assay. Patients with ≥15% tumoral CD8 received NIVO monotherapy (CD8 high) and those with <15% tumoral CD8 received NIVO+IPI (CD8 low). Pre- and on-treatment tumor and blood samples were collected for longitudinal multi-omic biomarker analysis. Bulk RNA/DNA sequencing and high dimensional imaging technologies were used to analyze the tumor biopsies. Peripheral blood analyses included mass cytometry time of flight (CyTOF) for broad immune profiling, and a high parameter flow cytometry panel for T cell specific phenotypic evaluation.

Results In the CD8 low arm, on-treatment conversion from CD8 low to high (≥15%) was associated with a trend towards improved clinical benefit (p = 0.0582), whereas pretreatment tumoral CD8 T cell frequency was not correlated with clinical benefit. Analysis of tumor bulk mRNA sequencing yielded pan-tumor gene signatures of response and resistance to NIVO +IPI. Responders had elevated expression of genes relating to IFNg and JAK/STAT signaling, whereas glycolysis pathway genes and MYC targets dominated in the non-responders. Analysis of pretreatment peripheral blood immune cell populations demonstrated a significantly higher frequency of T cells with a stem cell progenitor-like phenotype (TCF1+) (p = 0.0179) in the non-responders compared to the responders. On-treatment, elevated frequencies of circulating gdT cells, NK cells, as well as enhanced activation and proliferation of effector and central memory conventional T cells were associated with response to ICI therapy.

Conclusions In this study, increased tumoral infiltration of CD8+ T cells on-treatment (≥15%) was associated with a trend towards improved clinical benefit (p = 0.0582). Using multi-omic analysis of pre- and on-treatment tissue and blood samples, we identified additional composite tumor agnostic biomarkers correlating with response. These biomarkers warrant further investigation for patient stratification and identification of novel drug targets to overcome ICI resistance.

588 PHASE IB STUDY OF THE P38 INHIBITOR ARRY-614 WITH NIVOLUMAB, IPILIMUMAB OR NIVOLUMAB +IPILIMUMAB IN ADVANCED SOLID TUMORS

[1]Ryan Augustin*, [2]Andrew Poklepovic, [3]Xin Gao, [1]William Gooding, [1]Sarah Brodeur, [1]Julie Urban, [1]Amy Rose, [1]Amy Goodman, [1]Darcy Ploucha, [1]Roby Thomas, [1]Dan Zandberg, [1]John Kirkwood, [1]Yana Najjar, [1]Diwakar Davar, [1]Liza Villaruz, [1]Jan Beumer, [1]Riyue Bao, [1]Jason Luke. *[1]UPMC Hillman Cancer Center, Pittsburgh, PA, United States; [2]VCU Massey Cancer Center, Richmond, VA, United States; [3]MGH Cancer Center, Boston, MA, United States*

Background The p38 mitogen-activated protein kinase (MAPK) pathway limits dendritic cell priming and we have discovered a novel tumor-intrinsic immune-exclusion role for p38 MAPK across multiple tumor types. ARRY-614 (pexmetinib) is a p38 MAPK inhibitor that enhances immune-checkpoint blockade (ICB) in murine models. Here we report on the safety and anti-tumor activity of ARRY-614 with nivolumab (N), ipilimumab (I), or N+I in human subjects with advanced solid tumors.

Methods Subjects received daily, oral ARRY-614 (de-escalated from 800 to 200mg) with N (480 mg), I (3 mg/kg), or N+I (1 mg/kg) on either 28- or 21-day cycles. The primary objective was safety and tolerability of ARRY-614 with N, I, or N +I and selection of the recommended phase II dose (RP2D) using a Bayesian dose-finding strategy. Preliminary anti-tumor activity per RECISTv1.1 or irRECIST were secondary objectives.

Results Twenty-eight subjects were recruited (n=15 with N; including NSCLC, GEJ, RCC and mesothelioma; n=13 with I or N+I; all melanoma). Most were male (71.4%) with median age 67, three prior therapy lines, and 93% previously exposed to PD(L)1 (all meeting SITC PD(L)1 resistance definition)[1]. Treatment-related adverse events (TRAEs) were documented in all 28 subjects with 17.2% TRAEs reported as clinically significant, 9.2% grade 3, and 7.0% deemed immune-related adverse events (irAE). Eight subjects experienced dose-limiting toxicities (DLT) including rash, colitis, atrial fibrillation, hypotension, dyspnea, anaphylaxis, and visual disturbances; all in patients receiving a starting dose ≥400mg ARRY-614 and equally distributed in N vs N+I cohorts. The RP2D is 200 mg ARRY-614 with ICB and preliminary ARRY-614 PK assessment suggesting a dose-exposure relationship with DLT via area under the curve. Response was evaluable in 20 subjects (eight were nonevaluable due to toxicity or early progression) with three confirmed PRs and nine SD/irSD (figure 1). Median duration of response is not reached with two PR ongoing more than 1.5 years (NSCLC: PDL1 0%, TMB 5.4 muts/Mb, prior chemotherapy + anti-PD1 / RCC: prior TKI, IL2, multiple PD(L)1 combinations). Six-month progression-free survival was achieved in six subjects including two patients with SD/irSD reaching >12 months (and three with continued benefit despite early drug cessation due to irAE; figure 2). Length of prior treatment time on most recent anti-PD(L)1 therapy did not associate with outcome. Immune monitoring and pharmacodynamic assessments are in progress.

Conclusions Inhibition of the p38 MAPK pathway with ARRY-614 is well tolerated at 200mg in combination with ICB, eliciting durable responses and disease control in poor risk and PD(L)1-refractory subjects.

589 **XEVINAPANT PLUS NIVOLUMAB IN PATIENTS WITH ADVANCED SOLID TUMORS WHO PROGRESSED ON PRIOR ANTI–PD-1/PD-L1 TREATMENT: RESULTS OF A DOSE-OPTIMIZATION, EXPLORATORY PHASE 1B/2 TRIAL**

[1]Emiliano Calvo Aller, [2]Glenn Hanna*, [3]Maria Vieito Villar, [4]Caroline Even, [5]Victor Moreno, [6]Chul Kim, [7]Shuchi Gulati, [8]Daniel Morgensztern, [9]Ana Acuna-Villaorduna, [10]Philippe Cassier, [11]Dennie Jones, [12]Florilene Bouisset, [12]Daniela Sahlender, [12]Elisabeth Rouits, [12]Dany Spaggiari, [12]Lars Damstrup, [13]Carlos-Alberto Gomez-Roca. *[1]START Madrid-CIOCC, Centro Integral Oncológico Clara Campal, Madrid, Spain; [2]Dana-Farber Cancer Institute, BOSTON, MA, United States; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [4]Institut Gustave Roussy, Villejuif, Val de Marne, France; [5]Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; [6]Georgetown University – Lombardi Comprehensive Cancer Center, Washington, DC, DC, United States; [7]University of Cincinnati, Cincinnati, OH, United States; [8]Washington University, School of Medicine, St. Louis, MO, United States; [9]Montefiore Medical Center PRIME, Bronx, NY, United States; [10]Centre Léon Bérard, Lyon, Rhone, France; [11]University of Florida, Gainesville, FL, United States; [12]Debiopharm International SA, Lausanne, Switzerland; [13]Institut Claudius Regaud, Toulouse, Haute Garonne, France*

Background Anticancer agents that render cancer cells susceptible to apoptosis and increase antitumor immunity may enhance clinical responses to immune checkpoint inhibitors. In this phase 1b/2 trial, we investigated the antitumor activity and safety of xevinapant, a first-in-class, potent, oral, small-molecule inhibitor of apoptosis proteins inhibitor which restores cancer cell sensitivity to apoptosis, in combination with the anti-PD-1 antibody nivolumab.

Methods Eligible patients had histologically confirmed advanced or metastatic solid tumors that progressed on prior anti–PD-1/PD-L1 treatment, including small cell lung cancer (cohort 1), squamous cell carcinoma of the head and neck (cohort 2), gastrointestinal cancers with known microsatellite-high (MSI-H)/mismatch repair deficiency (MMRd) or other DNA-damage response (DDR) abnormalities (cohort 3), or platinum-resistant epithelial ovarian, endometrial, primary peritoneal or cervical cancer (with known MSI-H/MMRd, *BRCA1/2* mutations, or other DDR abnormalities; cohort 4). In the dose-escalation part of the trial (part A), patients received xevinapant 150 or 200 mg/day on days 1-10 and days 15-24 plus nivolumab 240 mg on days 1 and 15 of a 28-day cycle. The primary objective of part A was to determine the recommended phase 2 dose (RP2D). In the phase 2 basket trial (part B), patients received xevinapant plus nivolumab at the RP2D; the primary endpoint was objective response rate (ORR).

Results Eleven patients were enrolled in part A; 3 patients received xevinapant 150 mg/day and 8 received 200 mg/day. No dose-limiting toxicities during the observation period (28 days) or grade ≥3 treatment-related adverse events (TRAEs) were reported. The RP2D was established as xevinapant 200 mg/day (days 1-10 and 15-24) plus nivolumab 240 mg (days 1 and 15) per 28-day cycle.[1] In part B, 35 patients (n=8 cohorts 1-3, n=11 cohort 4) received xevinapant plus nivolumab at the RP2D. Most patients (60.0%) had stage IV disease and all patients had received prior chemotherapy treatment. At data cutoff (April 6, 2022), the ORR was 2.9%, with 1 partial response (cohort 4; endometrial cancer); 15 patients (42.9%) had stable disease. Thirty-four patients (97.1%) had discontinued treatment; the most common reason was disease progression (26 patients; 74.3%). Median PFS across cohorts was 1.9 months (95% CI, 1.7-2.7); median OS was 11.7 months (95% CI, 6.0-15.9). TRAEs occurred in 30 patients (85.7%); grade ≥3 TRAEs in 9 patients (25.7%). No treatment-related deaths were reported.

Conclusions Xevinapant plus nivolumab had a tolerable safety profile in patients with heavily pretreated solid tumors but limited clinical activity in this immunotherapy-refractory population.

590 **METAGENOMIC SEQUENCING REVEALS UNIQUE GUT MICROBIAL FEATURES ASSOCIATED WITH TERTIARY LYMPHOID STRUCTURES IN RESPONSE TO IMMUNE CHECKPOINT BLOCKADE IN SOLID CANCERS**

[1]Manoj Chelvanambi*, [1]Nathaniel Deboever, [1]Elise Nassif, [1]Ashish Damania, [1]Lili Chen, [1]Cheuk Leung, [1]Emily Keung, [1]Chia-Chin Wu, [1]Russell Witt, [1]Michael White, [1]Sarah Johnson, [1]Matthew Wong, [1]Aditya Mishra, [1]Matthew Lastrapes, [1]Neeta Somaiah, [1]Humam Kadara, [1]Sreyashi Basu, [1]James Allison, [1]Padmanee Sharma, [1]Kevin McBride, [2]Wolf Fridman, [1]John Heymach, [1]Boris Sepesi, [1]Nadim Ajami, [1]Christina Roland, [1]Jennifer Wargo, [1]Tina Cascone. *[1]UT MD Anderson Cancer Center, Houston, TX, United States; [2]Centre de Recherche des Cordeliers, Paris, France*

Background Immune checkpoint blockade (ICB) therapy has significantly improved clinical outcomes; however, a significant proportion of patients fail to develop durable responses.[1] Therefore, novel targetable biomarkers are needed. Our group has previously shown that the composition of the gut microbiome and presence of intratumoral tertiary lymphoid structures (TLS) can influence response to ICB.[2-4] Here, we study three randomized phase II neoadjuvant ICB trials [melanoma (MEL; NCT02519322; n=23), non-small-cell lung cancer (NSCLC; NCT03158129; n=31)[5] and sarcoma (SARC; NCT02301039; n=17)] to investigate the relationship and interplay between these two established determinants of response.

Methods Patients were defined as responders (R) or non-responders (NR) based on major pathologic response (MPR; MEL and NSCLC-viable ≤ 10%; SARC-hyalinization ≥ 30%). Transcriptional profiles of tumor specimen collected pre-ICB (MEL and SARC) and post-ICB (MEL, SARC and NSCLC) were used to score and dichotomize patients (by median) based on a TLS gene signature (*LTA, LTB, TNFSF14, CXCL13, CCL18, CCL19, CCL21, CD79B, CR2, PAX54A1, MZB1*). Paired baseline stool samples were profiled via metagenomic sequencing to characterize the composition and the molecular and metabolic function using MetaPhlAn 3.0 and HUMAnN 3.0, respectively.

Results There were 21 R overall (NSCLC n=9; MEL n=9; SARC n=3). TLS signature was significantly higher in R vs NR on-treatment with ICB (p=0.032; unpaired t-test). Longitudinal evaluation of transcriptional profiles showed increased expression of the TLS signature with treatment in R (p=0.032; paired t-test) but not in NR (p>0.99; paired t-test). Following patient dichotomization by TLS score, analysis of baseline microbiome profiles revealed the presence of unique TLS-associated gut microbiome signatures, including enrichment of specific taxa such as *Holdemanella* and *Lactococcus* (ANCOM-BC; p<0.0001). Further analysis of Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways in baseline stool metagenomes suggested enhanced function of membrane transport proteins (q=0.006) in TLS^{high}patients and increased carbohydrate metabolism (q=0.04) in TLS^{low}patients.

Conclusions Our data suggest that unique gut microbiome features are associated with TLS in the context of treatment with ICB in solid cancers. Future mechanistic and translational studies will seek to validate and parlay these novel findings into microbiome-based treatments to induce TLS and/or augment the efficacy of ICB in solid tumors.

591 IMMUNOGENICITY OF DURVALUMAB: ANALYSIS OF POOLED PAN-TUMOR DATA

[1]Anthony El-Khoueiry*, [2]Diansong Zhou, [3]Mustafa Ozguroglu, [4]Melissa Johnson, [5]Ghassan Abou-Alfa, [2]Mallory Makowsky, [2]Lee Krug, [2]Ashok Gupta, [2]Cecil Chen. *[1]University of Southern California, Los Angeles, CA, United States; [2]AstraZeneca, Waltham, MA, United States; [3]Istanbul University-Cerrahpasa, Istanbul, Türkiye; [4]Sarah Cannon Research Institute, Nashville, TN, United States; [5]Memorial Sloan Kettering Cancer Center, New York, NY, United States*

Background Durvalumab, an immune checkpoint inhibitor (ICI) targeting PD-L1, has demonstrated clinical activity with or without tremelimumab, a CTLA-4 inhibitor, in Phase 3 studies in multiple tumor types.[1-3] The occurrence of anti-drug antibodies (ADA) could potentially negatively impact ICI safety and efficacy.[4] This analysis assessed the immunogenicity of durvalumab using pooled pan-tumor data.

Methods Durvalumab immunogenicity was assessed using pooled data from 18 clinical studies of 7826 participants with lung cancer (MYSTIC, ATLANTIC, NEPTUNE, Study 6, ARCTIC, PACIFIC), hepatocellular carcinoma (HIMALAYA, Study 22), bladder cancer (DANUBE, Study 10), head and neck cancer (KESTREL, HAWK, CONDOR, EAGLE, Study 11), gastric or gastroesophageal junction adenocarcinoma (Study 21) or advanced solid tumors (Study 1108, Japan Study 2). ADA and neutralizing ADA (nAb) to durvalumab were detected using validated solution-phase bridging electrochemiluminescence immunoassays. Impact of durvalumab ADA on safety was assessed using pan-tumor data from the pool of 18 studies. Impact of ADA on durvalumab pharmacokinetics was assessed using a pooled dataset from Study 1108, PACIFIC, ATLANTIC, CASPIAN, POSEIDON, HIMALAYA, and Study 22. Due to differences in cancer settings of the studies, the impact of durvalumab ADA on efficacy was not assessed.

Results The proportion of durvalumab ADA-positive participants at any visit (ADA prevalence) was 6.2% with durvalumab monotherapy (D), 6.8% with T75+D, and 7.3% with T300+D (STRIDE) (table 1). The proportion of treatment-emergent ADA–positive participants (ADA incidence) was low and similar across data pools: 2.7% with D, 3.4% with T75+D, and 2.8% with T300+D (table 1). Median ADA titers were ≤16 across all ADA categories in all pools (table 1). The proportion of transiently ADA-positive participants out of those with ADA prevalence was 32/191 with D, 22/146 with T75+D, and 3/26 with T300+D. The proportion of participants who tested positive for durvalumab nAb at any visit was 0.5% with D, 0.6% with T75+D, and 1.4% with T300+D (table 1). Incidence of infusion-related reactions was low in ADA-positive participants across treatment regimens (1% with D, and 0% with T75+D and T300+D); there was no marked impact of durvalumab ADA presence on categorical AE data (table 2). Durvalumab ADA presence did not have a clinically meaningful impact on durvalumab exposure metrics.

Conclusions Although incidences of ADA vary greatly among ICI [4], analysis of this large, multi-study, pooled pan-tumor dataset demonstrates that durvalumab has a low-risk immunogenicity profile as monotherapy or in combination with tremelimumab. Immunogenicity of durvalumab appeared to have no marked impact on safety or exposure.

Pascale, Milan, Italy; [6]START Madrid-CIOCC. Centro Integral Oncológico Clara Campal, Madrid, Spain; [7]University of Pennsylvania, Philadelphia, PA, United States; [8]Sanford Cancer Center, Sioux Falls, SD, United States; [9]Sheba Medical Center, Ramat Gan, Israel; [10]Vall d'Hebron University Hospital, Barcelona, Spain; [11]BC Cancer, The University of British Columbia, Vancouver, Canada; [12]Rambam Health Care Campus, Technion – Israel Institute of Technology, Haifa, Israel; [13]Bristol Myers Squibb, Princeton, NJ, United States; [14]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, United States*

Background BMS–986218 is a nonfucosylated human IgG1 anti-cytotoxic T-lymphocyte antigen (CTLA)-4 monoclonal antibody with optimized CD16 FcγR binding that enhances T-cell priming and mitigates T-regulatory cell–mediated suppression in the tumor microenvironment. In preclinical models, BMS-986218 increased the proportion of antigen-specific CD8 + effector T cells vs ipilimumab in peripheral blood.[1] We present safety, efficacy, and pharmacodynamic data from the dose-escalation part of the first-in-human study of BMS-986218 ± nivolumab in patients with advanced solid tumors (NCT03110107).

Methods Patients with advanced solid tumors, disease progression on ≥ 2 lines of therapy (≥ 1 line for patients with melanoma), and Eastern Cooperative Oncology Group performance status 0–1 were included. Patients received BMS-986218 as monotherapy (2–200 mg Q4W or 20–50 mg Q2W) or as combination therapy (BMS-986218 20–70 mg Q4W plus nivolumab 480 mg Q4W). The primary endpoint was safety and tolerability. Secondary endpoints included preliminary efficacy and characterization of BMS-986218 ± nivolumab pharmacokinetics and immunogenicity.

Results In total, 155 patients were treated on dose escalation; 107 with monotherapy and 48 with combination (table 1). Any-grade and grade 3/4 treatment-related adverse events (TRAEs) were reported in 58% and 18% of monotherapy patients, respectively. The most common grade 3/4 TRAE was diarrhea (5%). Any-grade and grade 3/4 TRAEs were reported in 60% and 27% of combination patients, respectively. The most common 3/4 TRAEs were colitis (6%) and increased amylase (6%). TRAEs leading to treatment discontinuation were reported in 11% of monotherapy patients and 15% of combination patients. A grade 5 TRAE of pneumonitis was reported in the monotherapy group at the 7-mg Q4W dose level. Partial responses with durations of 1.9–10.3 months were observed with monotherapy and combination therapy in patients with microsatellite-stable colorectal, pancreatic, gastric, and breast cancer. Analysis of peripheral cytokine levels (interferon-γ, CXCL9, and CXCL10) showed increases with increasing BMS–986218 dose in the monotherapy and combination groups (figure 1). Additional preclinical and clinical results will be presented.

Conclusions BMS-986218 demonstrated a tolerable safety profile and preliminary antitumor activity as monotherapy and in combination with nivolumab across various tumor types, including tumors with high unmet need or that are traditionally immune checkpoint inhibitor-insensitive. These results support further investigation of nonfucosylated anti-CTLA-4 therapies. The dose expansion part of the BMS-986218 ± nivolumab study and a phase 1/2 study evaluating anti–CTLA-4 nonfucosylated probody (BMS-986288; NCT03994601) ± nivolumab are ongoing.

594 DOSE ESCALATION OF NEXT GENERATION ANTI-CTLA-4 ANTIBODY ONC-392 IN COMBINATION WITH FIXED DOSE OF PEMBROLIZUMAB IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Siwen Hu-Lieskovan*, [2]Kai He, [3]Mei Tang, [4]Dan Chen, [4]Yang Liu, [4]Pan Zheng, [5]Tianhong Li. *[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, United States; [2]The Ohio State University Cancer Center, Columbus, OH, United States; [3]Greater Baltimore Medical Center, Baltimore, MD, United States; [4]OncoC4, Inc., Rockville, MD, United States; [5]University of California at Davis, Sacramento, CA, United States*

Background Combination of CTLA-4 and PD-1/PD-L1 targeting antibodies are effective cancer immunotherapy with great potential, but the high risk of severe toxicity limits clinical development. Our preclinical studies suggest that acid pH-sensitive anti-CTLA-4 antibodies that preserve CTLA-4 recycling by avoiding lysosomal degradation are more effective for immunotherapy while largely devoid of immunotherapy-related adverse events (irAE) when used in combination with anti-PD-1 antibodies. We previously showed the recommended phase II dose (RP2D) of ONC-392 monotherapy is 10mg/kg IV Q3W.[1] In the current study, we evaluated the safety and tolerability of ONC-392 in combination with pembrolizumab.

Methods ONC-392-001 (NCT04140526) Part B is a dose finding study of ONC 392 at 3 mg/kg (cohort 1) or 6 mg/kg (cohort 2) in combination with a fixed dose of pembrolizumab 200 mg, IV, Q3W. We enrolled patients with advanced/metastatic solid tumors whose disease had progressed on standard of care (SOC) therapies and pembrolizumab was approved as SOC. The primary endpoints are safety, tolerability and RP2D of ONC-392 in combination with pembrolizumab (RP2D-C).

Results Cohort 1 enrolled 7 patients and cohort 2 enrolled 6 patients, including 4 NSCLC, 5 melanoma, 1 each with cervical, TNBC, HCC and CuSCC. Patient characteristics are listed in table 1. Eleven patients had prior anti-PD-1/PD-L1 and 5 melanoma patients had prior ipilimumab. The mean cycles of treatment are 5.7 cycles (1-13) in 5.2 months and 4.5 cycles (1-9) in 4.1 months in cohort 1 and 2, respectively. None of the 13 pts experienced dose limiting toxicity (DLT) in the DLT period. Treatment related AEs (TRAEs) were observed in 11 (85%) patients without Grade 4 or 5 TRAEs. Grade 3 TRAEs were observed in 5 pts (38.5%) (3/7 in cohort 1 and 2/6 in cohort 2): infusion reaction (2) and immune-mediated colitis (3). Three patients (23%) had Gr 3 irAEs in the form of immune colitis or colitis. The RP2D-C is determined to be 6.0 mg/kg ONC-392+ 200 mg of pembrolizumab Q3W. Two confirmed PR (TNBC and cervical cancer, ORR=29%, DOR>6 months) and 4 SD in cohort 1, and 3 SD and 1 PD in cohort 2 were observed (figure 1).

Conclusions ONC-392 combination with pembrolizumab is safe and clinically active. The rate of irAE is low relative to drugs of the same class. These results support the feasibility to significantly increase drug exposure for full immunotherapeutic potential of anti-CTLA-4 and anti-PD-1 combination therapy.

FLT3L-PRIMED *IN SITU* VACCINATION AND PEMBROLIZUMAB INDUCE SYSTEMIC TUMOR REGRESSIONS OF BULKY TUMORS IN PATIENTS WITH LYMPHOMAS AND ER/PR+ BREAST CANCER

[1]Thomas Marron*, [1]Julie Fasano, [1]Deborah Doroshow, [1]Dana Ostrowski, [1]Joan Sorich, [1]Martine Van-Voorthuysen, [1]Jennifer Coffey, [1]Erin Moshier, [2]Andres Salazar, [3]Michael Yellin, [1]Marshall Posner, [1]Joseph Sparano, [1]Jonah Shulman, [1]Paula Klein, [1]Hanna Irie, [1]Seunghee Kim-Schulze, [1]Sacha Gnjatic, [1]Miriam Merad, [1]Joshua Brody, [1]Haley Labo. *[1]Icahn School of Medicine at Mount Sinai, New York, NY, United States; [2]Oncovir, Washington DC, United States; [3]Celldex, Hampton, NJ, United States*

Background Most patients fail to respond to checkpoint blockade, partly due to a lack of preexisting anti-tumor immunity. Cancer vaccines aim to induce *de novo* anti-tumor immune responses against tumor neoantigens. We previously described an *in situ* vaccine approach combining intratumoral (IT) Flt3L, low dose irradiation (XRT), and IT polyICLC to, respectively, mobilize, antigen-load, and activate IT DC1 in patients with advanced stage indolent non-Hodgkin's lymphoma (iNHL), yielding partial and complete remissions lasting months to years. Pre-clinical modeling revealed this combination induced tumoral PD-L1 expression, potentially explaining resistance, and addition of PD-1 blockade to the vaccine improved cure rates.[1]

Methods In this Phase 1/2 trial, patients with iNHL, metastatic breast cancer (MBC) or head and neck squamous cell carcinoma (HNSCC) received local XRT on Days 1-2, IT Flt3L to the same tumor for 9 days, followed by 8 IT injections of poly-ICLC over 6 weeks. On Day 23 patients received their first of 8 doses of intravenous (IV) pembrolizumab q3wk (figure 1).

Phase 1 enrolled 6 patients to assess safety. In Phase 2, tumor-specific cohorts are enrolling, each with a Simon's Two-Stage design (figure 2). Here, we report interim results from the first 10 patients.

Results Between April 2019 and July 2022, 10 patients were enrolled; 6 with MBC, 3 with iNHL and one patient with HNSCC have completed their first disease response assessment. All patients experienced TRAEs, mostly low-grade injection-site reactions and flu-like symptoms related to poly-ICLC. Two patients experienced Grade 3 TRAE, one experienced self-resolving grade 3 fever after poly-ICLC, another experienced grade 3 pembrolizumab-related colitis. Of ten evaluable patients, 1 patient had a CR, 2 achieved partial response, one had SD, and six had PD. One patient with ER/PR$^+$ breast cancer had received 12 prior lines of therapy with non-response to two prior chemotherapies, achieved PR—with all residual hypermetabolism likely related to scar tissue—without evidence of new or recurrent disease at 6 months, including regression of (distant) bulky left adrenal metastasis (figure 3) and other metastatic sites.

Conclusions *In situ* vaccination with Flt3L, XRT, poly-ICLC and pembrolizumab is well tolerated, with early signs of efficacy in patients with relapsed/refractory NHL and MBC, warranting expansion of this approach. Analysis of biopsies and blood from patients to define determinants of response to this *in situ* vaccine approach is ongoing.

Trial Registration NCT03789097

Chiles Research Institute, Providence Cancer Institute, Portland, OR, United States; [2]Gabrail Cancer Center, Canton, OH, United States; [3]Legorreta Cancer Center at Brown University, Lifespan Cancer Institute, Providence, RI, United States; [4]Hospital of the University of Pennsylvania, Philadelphia, PA, United States; [5]Georgia Cancer Specialists, Marietta, GA, United States; [6]HonorHealth Research Institute, Scottsdale, AZ, United States; [7]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [8]Nebraska Cancer Specialists, Omaha, NE, United States; [9]Celldex Therapeutics, Inc., Hampton, NJ, United States

Background CD40 agonist mAbs can enhance the efficacy of checkpoint blockade in preclinical models and can functionally revive PD-1^{hi} exhausted T cells. This Phase 1 study examined safety, clinical activity, and pharmacodynamics of CDX-1140 as monotherapy or in combination with other agents (NCT03329950). We now report the completed results from Part 3 of the study, combination with anti-PD-1 mAb pembrolizumab.

Methods Patients with advanced solid tumors and documented disease progression on a single prior anti-PD-1/L1 based regimen were enrolled. In dose-escalation (DE) cohorts, CDX-1140 was administered at 0.72 mg/kg and 1.5 mg/kg. Expansion cohorts (EX) in non-small cell lung cancer (NSCLC) and squamous cell carcinoma of head and neck (SCCHN) evaluated CDX-1140 1.5 mg/kg. Treatment was q3w co-administered with pembrolizumab 200 mg in both DE and EX.

Results 10 patients were treated in DE (renal cell carcinoma n=2, SSCHN n=2, n=1 for NSCLC, endometrial cancer, MSI^{hi}-CRC, ocular melanoma, esophageal adenocarcinoma, MSI^{hi}-cholangiocarcinoma) and 15 patients treated in EX; NSCLC (n=9) and SCCHN (n=6). The median number of prior regimens was 3. Treatment was generally well tolerated, with most treatment-related AEs (TRAE) being grade 1 or 2. The most frequent TRAE at the CDX-1140 1.5 mg/kg dose level (n=21) were arthralgia (62%), fatigue (62%), nausea (48%), diarrhea (48%), vomiting (43%), myalgia (43%), fever (38%), chills (38%), AST increase (38%), bilirubin increase (24%), ALT increase (19%), and cytokine release syndrome (CRS) (19%). Across Part 3, there was 1 complete response (CR) in a patient with oropharyngeal cancer (HPV^{+} and PD-L1 status unknown); 9 additional patients had stable disease (SD), including 4 with SCCHN and 4 with NSCLC. The patient achieving CR received 4 prior regimens (including chemotherapy, pembrolizumab, and cetuximab), discontinued study therapy after 2 doses due to arthralgia (grade 3) and CRS (grade 2), and initially demonstrated a partial response that evolved into CR, with the response ongoing at 12+ months without further anti-tumor treatment. Of the 4 SCCHN with SD, 2 had target lesions shrinkage (-15% and -18%) and 2 had no change. One NSCLC patient has SD for 10+ months with a nadir in target lesions of -15%. Part 3 biomarker data will be presented.

Conclusions CDX-1140 in combination with pembrolizumab had an acceptable safety profile. Evidence of clinical benefit was most evident in patients with SCCHN, all of whom had progressive disease on prior anti-PD-1/L1 based therapies. Further studies are warranted.

597 PRELIMINARY SAFETY, EFFICACY AND PHARMACOKINETIC RESULTS OF THE EP4 ANTAGONIST INV-1120 FROM A FIRST-IN-HUMAN STUDY IN SUBJECTS WITH ADVANCED SOLID TUMORS

[1]John Sarantopoulos, [2]Amita Patnaik, [3]Zhaopie Zeng, [3]Johannes Nippgen, [3]Yongkui Sun, [3]Yi Zhu*. *[1]Mays Cancer Center, San Antonio, TX, United States; [2]South Texas Accelerated Research Therape, San Antonio, TX, United States; [3]Shenzhen Ionova Life Science Co., Ltd, Shenzhen, China*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0597

Background INV-1120 is a highly selective, small-molecule antagonist of the E-type prostanoid receptor 4 (EP4) for prostaglandin E2 (PGE2), an immunosuppressive mediator of tumor immune microenvironment. Objectives of this first in human study were to assess safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), maximum tolerated dose (MTD) and recommended phase 2 dose of INV-1120.

Methods Dose-escalation was based on the traditional "3+3" dose-escalation design in sequential escalating dose cohorts (15, 30, 60, 100, 150, 200 , 250, 300 mg). Dose limiting toxicity (DLT) evaluation period was 28 days. Efficacy evaluation was performed every 8 weeks by RECIST 1.1. Blood samples were collected for pharmacokinetic characterization of the treatment.

Results Twenty-four patients were enrolled and treated with single-agent INV-1120 in 6 dose cohorts (15 mg, n=3; 30 mg, n=3; 60 mg, n=6; 100 mg, n=3; 150mg, n=3; 200 mg, n=6). The median age is 58.0 with the range from 20 to 80. 10 patients are male and 14 are female. Tumor types include colorectal cancer (8), lung cancer (4), parotid adenocarcinoma (2), sarcoma (2) and others (8). 7 patients had received prior CPI therapy.

There were two DLTs, one at 60 mg (grade 2 duodenal ulcer) and one at 200 mg (grade 2 duodenitis).

At least 1 TEAE was reported in 24 patients (100%). The most common TEAEs (all grades) were diarrhea (6 subjects, 25.0%), nausea (6, 25.0%), anemia (6, 25.0%), and fatigue (5, 20.8%). Drug-related TEAEs occurred in 13 patients (54.2%) and grade $\geq$3 treatment related TEAEs occurred in one patient (4.2%). Five patients (20.8%) were discontinued or interrupted for treatment due to TEAEs, and two of them due to TEAEs that were unrelated to study drug treatment.

Twenty-one patients were evaluable for efficacy as of the cut-off date of May 30, 2022. Stable disease was observed in 9 of 21(42.9%) patients. Among the 9 patients with stable disease, 5 had treatment duration $\geq$18 weeks.

INV-1120 was rapidly absorbed across all doses, and time to maximum drug concentration was observed at ~2 hours postdose. The exposure of INV-1120 appeared to increase with dose from 15 mg to 100/150 mg and plateaued thereafter. There is no PD markers data available currently.

Conclusions Single agent INV-1120 was generally well tolerated and showed prolonged stable disease. Preclinical data showing the efficacy synergy when INV-1120 combining with anti PD-1 support phase Ib protocol amendment about INV-1120 in combination with anti PD-1, and the dose escalation of the combination study will explore INV 1120 at 60, 100 and 150mg QD.

Trial Registration Clinical trial registry number: NCT04443088.

598 FIRST IN HUMAN STUDY OF S-488210/S-488211, A CANCER PEPTIDE VACCINE, IN PATIENTS WITH ADVANCED SOLID TUMOURS

[1]Mark Linch*, [1]Paramivir Sawhney, [1]Jasmin Waterhouse, [1]Kayani Mahaz, [1]Anuradha Jayaram, [1]Dionysis Papadatos-Pastos, [2]Takahiro Hasegawa, [2]Ide Nobuyuki, [2]Takayuki Kanazawa, [2]Tomohiko Harada. [1]*University College London Hospital, London, UK*; [2]*Shionogi & Co., Ltd, Osaka, Japan*

Background S-488210/S-488211 is a cancer peptide vaccine composed of 5 human leukocyte antigen (HLA)-A*02:01-restricted epitope peptides derived from 5 cancer-testis antigens: DEPDC1, MPHOSPH1, URLC10, CDCA1 and KOC1. These antigens were shown to be highly and differentially expressed in a range of solid tumours. A vaccine composed of HLA-A*24:02 restricted epitopes of the same antigens previously demonstrated safety and immunogenicity. This study aimed to evaluate the safety and immunological responses of S-488210/S-488211 in patients with HLA-A*02:01, the most prevalent HLA subtype in Europe and the US.

Methods An open-label, single centre, first-in-human phase I study (NCT04316689) was conducted. Eligible patients had unresectable recurrent or metastatic malignancies of the lung, oesophagus, mesothelium, head and neck or urinary tract and had exhausted conventional treatment options. Patients who were HLA-A*02:01 positive, performance status 0-1 and had a lymphocyte count ^{3}10% received S-488210/S-488211 (1 mg of each of 5 peptides mixed with Montanide ISA 51 VG) subcutaneously weekly for 4 weeks, then every 2 weeks for up to 8 weeks. The primary objective was to evaluate the safety and tolerability with adverse events classified by CTCAE version 4.03. The secondary objective was to evaluate cytotoxic T lymphocyte (CTL) induction rate during treatment, defined as the proportion of patients who showed increased CTL activity for $\geq$1 peptide. An exploratory objective was to assess disease control rate (DCR; CR+PR+SD) at 12 weeks.

Results 7 patients were enrolled between 30/7/19 and 9/7/21. One patient did not receive treatment due to a decline in performance status and was excluded from the safety analysis. Median age was 57, 5/6 patients were male and 5/6 were white. All patients experienced at least 1 adverse event (AE), most commonly a Grade 1 injection site reaction. There were 2 Grade 3 treatment-related AEs (hypertension and injection site reaction), neither of which met the dose-limiting toxicity criteria. There were no treatment-related serious AEs. 3/6 patients received the full planned treatment (9 doses) and 3/6 patients were withdrawn due to disease progression or death. The CTL induction rate was 100% in the 5 evaluable patients and was highest for the DEPDC1 (100%), MPHOSPH1 (60%) and URLC10 (40%) peptides. The DCR at 12 weeks was 16.7% (1/6 patients with SD).

Conclusions S-488210/S-488211 was generally well tolerated and led to a robust CTL response in a range of solid tumours. S-488210/S-488211 is being taken forward in a phase 2 study in combination with PD-L1 blockade.

599 MECHANISM OF ACTION FOR OT-101 TGF-ß IMMUNOTHERAPY

Vuong Trieu*, Osmond D'Cruz. *Oncotelic, Agoura Hills, CA, United States*

Background OT-101 is being developed as immunotherapy for a broad range of cancers. Cancers overexpress TGF-β, which suppresses host innate immune response to the cancers. Treatment with OT-101 lifts the TGF-β cloaking effect and allows innate or therapeutic immunity to attack and eliminate the cancers. OT-101 completed phase 2 for pancreatic cancer and melanoma and phase 2 in glioblastoma with robust efficacy and safety.

Methods Pharmacokinetic analysis of OT-101/trabedersen for P001 study was assessed over the first two cycles of 7- or 4-day intravenous infusions, separated by 7- or 10-day treatment-free interval, respectively, at doses of 40, 80, 140, 160, 190, 240, 250, and 330 mg/m^2/day to demonstrated dose exposure response. Xenograft studies were performed across immunocompetent mice (C57Bl6), humanized immune mice (SCID), and T-cell deficient immune mice (nude) to demonstrate immune cell responses.

Results The median AUC_{last} was 232 ug*h/mL (29.7-834) across the three tumor types (pancreatic cancer (PC), melanoma (Mel), and colorectal cancer (CRC)). OT-101 PK is dose proportional ($p<0.0001$). The PK is highly variable between patients with the AUC_{last} of 140 mg/m^2 spanning the range of observed values for the four dose levels examined for 4 days on 10 days off schedule (140, 190, 250, 330). Patients with AUC > median exhibited improved PFS for Mel and CRC but not for PC with median PFS of 67 vs. 49 days, $p=0.005$, 84 vs. 40 days, p=ns, and 55 vs. 56 days, p= ns, respectively. More than half of the OT-101 treated PC patients went into long term disease control (21 of 37 pts, 55%) allowing them to enter into subsequent chemotherapy which has an unexpected benefit of more than doubling their median OS, 9.3 vs. 2.6 mos, $p<0.0001$. Among those who underwent subsequent chemotherapy, high AUC was associated with improved OS, 9.6 vs. 2.4 mos, $p=0.0006$. Animal xenograft studies demonstrated robust immune cell infiltration of the tumors. Synergy demonstrated when OT-101 combined with immunotherapy or chemotherapy.

Conclusions Suppression of the TGF-β resulted in conversion of cold to hot tumors with dose dependent relationship. The synergy between OT-101 chemotherapy is similar to OT-101 immunotherapy suggesting that chemotherapy is inducing immune responds amplified with prior treatment of OT-101. OT-101 is currently being combined with IL2, PD-1, and PDL-1 agents in multiple phase 2 trials.

Trial Registration NCT00844064- Safety and Tolerability of AP 12009, Administered I.V. in Patients With Advanced Tumors Known to Overproduce TGF-beta-2

600 **POST-HOC ANALYSIS FROM TWO PHASE I/II NY-ESO-1-TCR T-CELL THERAPY CLINICAL TRIALS IN PATIENTS WITH ADVANCED SARCOMA (SS OR MRCLS) DEMONSTRATES RESPONSE ACROSS A RANGE OF NY-ESO-1 EXPRESSION**

[1]Erika Klohe, [1]Sunil Suchindran, [1]Gurpreet Kapoor, [1]Jimson D'Souza, [1]Ellie Corigleano, [2]Dejka Araujo, [3]Sandra D'Angelo*. *[1]GlaxoSmithKline, Collegeville, PA, United States; [2]Univerity of Texas MD Anderson Cancer Center, Houston, TX, United States; [3]Memorial Sloan Kettering Cancer Center, New York, NY, United States*

Background An investigational use only immunohistochemical (IHC) clinical trial assay was used to prospectively identify NY-ESO-1-positive patients for eligibility in two phase I/II pilot clinical trials. NY-ESO-1 T-cell receptor (TCR) T-cell therapy was investigated in NY-ESO-1 expressing HLA-A*02:01, 05, or 06 positive patients with either metastatic or locally advanced synovial sarcoma (SS) (NCT01343043)[1], or advanced myxoid round cell liposarcoma (MRCLS) (NCT02992743).[2] Post-hoc analyses on both studies investigated the relationship of NY-ESO-1 expression levels in patients with response and no response as per RECIST1.1 (investigator assessed) to NY-ESO-1 TCR T-cell therapy.

Methods NY-ESO-1 expression was determined by total tumor percent staining at stain intensities 0, 1+, 2+, 3+ (TP-score) as assessed by a board-certified pathologist. Eligible SS patients were enrolled into study cohorts with differing cut-off criteria for NY-ESO-1 expression levels (table 1). MRCLS patients were enrolled into study cohorts using a single cut-off for NY-ESO-1 expression levels (≥2+, TP ≥30%). SS and MRCLS eligible patients received different dose lymphodepleting regimens (LDR) of fludarabine and cyclophosphamide depending on trial and cohort (table 1).[3,4] For the present NY-ESO-1 expression analysis, the distribution of the NY-ESO-1 TP-score is displayed as boxplots allowing simultaneous visual comparisons of the range of expression across response, indication, and LDR. In addition, an exploratory cut-off of ≥50% was used to evaluate responses. All analyses are exploratory and descriptive.

Results All MRCLS patients and most SS patients expressed NY-ESO-1 as predominately moderate/strong (2+/3+) in ≥50% tumor cells.[5] A pooled ORR assessment at ≥ 50% threshold was 33%. Responders and non-responders were observed across a range of NY-ESO-1 TP-scores in SS from ≥1% to 100% and in MRCLS ≥50% to 100% (figure 1). Of the six patients with threshold ≤30%; there were two SS responders expressing TP-score at 30% and one at 10% (figure 1, table 1).

Conclusions NY-ESO-1 expression as a biomarker of patient selection is a relevant approach for use with NY-ESO-1 TCR T-cell therapy. Observed range of response may be supportive of a cut-off in SS of less than 50% TP-score given that three patient responders had low to moderate (<50% TP-score) NY-ESO-1 expression, and that MRCLS cut-off was set at ≥30%. Further exploration of TP-score is underway in a current phase II trial of NY-ESO-1 TCR T-cell therapy (NCT03967223).

601 BIOMARKER CORRELATES OF LETETRESGENE AUTOLEUCEL (LETE-CEL; GSK3377794) RESPONSE IN PATIENTS WITH ADVANCED MYXOID/ROUND CELL LIPOSARCOMA (MRCLS)

[1]Gurpreet Kapoor*, [1]Stefan Zajic, [1]Sunil Suchindran, [1]Jaegil Kim, [1]Uma Saxena, [1]Aishwarya Bhaskar, [1]Heather Kaczynski, [1]Michael Nathenson, [1]Jimson D'Souza, [1]Benjamin Rich, [2]Sandra D'Angelo, [3]Mihaela Druta, [4]Brian Van Tine, [5]Neeta Somaiah, [6]David Liebner, [7]Scott Schuetze, [1]Ioanna Eleftheriadou. *[1]GlaxoSmithKline, Collegeville, PA, United States; [2]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [3]H. Lee Moffitt Cancer Center, Tampa, FL, United States; [4]Washington University in St. Louis, MO, United States; [5]University of Texas MD Anderson Cancer Center, Houston, TX, United States; [6]The Ohio State University, Columbus, OH, United States; [7]University of Michigan, Ann Arbor, MI, United States*

Background NCT02992743 is an open-label pilot study of lete-cel, a New York esophageal squamous cell carcinoma 1 (NY-ESO-1)-specific autologous T-cell therapy, expressing a high-affinity T-cell receptor (TCR) that recognizes the NY-ESO-1 antigen epitope in complex with specific human leukocyte antigen (HLA) alleles of group A*02. Lete-cel exhibited anti-tumor activity and an acceptable safety profile in patients with advanced MRCLS[1] Previously, the association of T-cell kinetics with response and elevated inflammatory cytokines levels has been shown in responders.[2] This abstract presents additional data on potential biomarkers of response and non-response to lete-cel in patients with advanced MRCLS.

Methods Twenty patients with advanced MRCLS received either reduced-dose (Cohort 1 [C1]; n=10; 30 mg/m^2 fludarabine for 3 days + 600 mg/m^2 cyclophosphamide for 3 days) or standard-dose (Cohort 2 [C2]; n=10; 30 mg/m^2 fludarabine for 4 days + 900 mg/m^2 cyclophosphamide for 3 days) lymphodepletion prior to lete-cel infusion (median transduced T-cell dose = 4.6 × 10^9). Key eligibility criteria were: ≥18 years of age; HLA-A*02:01 and/or 05 and/or 06; advanced or metastatic NY-ESO-1-positive MRCLS (≥30% of cells 2+/3+ by immunohistochemistry); prior anthracycline treatment; and measurable disease. Investigator-assessed objective response rate by Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 was the primary efficacy endpoint. For T-cell kinetics, a quantitative polymerase chain reaction assay was used to assess transgene vector copies in DNA from peripheral blood mononuclear cells collected longitudinally during the trial. Serum cytokines were measured by Meso Scale Discovery platform. Whole-transcriptome sequencing was performed on pre- and post-infusion tumor samples. Statistical methods specific to data modalities were used for post-hoc correlative analyses.

Results T-cell persistence at Week 4 was significantly higher (P=0.0067) in responders (n=5) than in non-responders (n=13). Lete-cel peak cell expansion was associated with maximum levels of interferon-γ (IFN-γ; r=0.56, P=0.03) and interleukin-15 (IL-15; r=0.55, P=0.02) post-infusion. Preliminary gene expression data from the tumors collected at baseline showed enrichment of metabolic pathways in responders and epithelial–mesenchymal transition and fibroblast activation in non-responders.

Conclusions These data suggest that higher lete-cel persistence and the association of lete-cel expansion with cytokine upregulation post-infusion, as well as tumor-intrinsic transcriptional features, may have a role in lete-cel response in patients with advanced MRCLS.

602 MASS SPECTROMETRY-BASED PROTEIN BIOMARKER ANALYSIS IN CHEMOIMMUNOTHERAPY COMBINATIONS IDENTIFIES UNIQUE IMMUNE SIGNATURES IN PANCREATIC CANCER

Marco Tognetti, Nigel Beaton*, Kamil Sklodowski, Roland Bruderer, Lukas Reiter. *Biognosys, Schlieren, Switzerland*

Background Although the combination of chemotherapy with immunotherapy has led to significant improvements in the treatment of some solid tumors, metastatic pancreatic ductal adenocarcinoma (mPDAC) prognosis has remained largely unaffected by such approaches. Recently, PRINCE, a randomized phase 2 clinical study, reported significantly improved 1-year overall survival (OS) for mPDAC patients treated with nivolumab (nivo)/chemo compared to historical control[1] but not for sotigalimab (sotiga)/chemo or the sotiga/nivo/chemo combination. However, the study identified potential improvement to treatment outcome with patient stratification.[2] Here, we report an unbiased mass spectrometry (MS)-based proteomics profiling of a subset of plasma samples from the PRINCE trial.

Methods Plasma proteomic profiling was conducted on PRINCE nivo/chemo and sotiga/chemo longitudinal samples (n = 211, 62 individuals) using Biognosys ultradeep plasma workflow. Briefly, plasma samples were depleted, digested to tryptic peptides, measured by MS/MS and quantified using Spectronaut (Biognosys). Data was investigated for both protein and peptide biomarker with an emphasis on baseline biomarkers associated with clinical outcomes.

Results Plasma profiling identified 1,662 proteins and 17,451 modified peptides across the cohorts. First, we developed a model that identified the pharmacodynamic effects of treatment in individual patients. In accordance with the PRINCE study and among the major model contributors, sotiga/chemo increased proteins associated with innate immunity and chemokines (including CCL15) while proteins aiding in T cell activation and immune cell migration increased with nivo/chemo (including CXCL7 and CD115). Second, we looked for markers in the pretreatment plasma samples that could predict OS. Overall, we found 25 predictive markers ($p < 0.05$), with only six shared among the two arms, including Attractin and CD58. Among the seven predictive biomarkers specific to nivo/chemo, we found MEGF10 and GALNT1, which are suggested to play a role in neoantigen generation.[3] For sotiga/chemo, we found 12 predictive biomarkers including IGF2, CD304, and periostin (known to support immune responses). Third, we expanded our predictive biomarker search to the identified peptides, an analysis that is currently only possible using an unbiased mass spectrometry-based approach. Using such an approach we were able to identify predictive peptides, likely cleavage products, as well as predictive post-translational modifications.

Conclusions Herein we demonstrate the value of both an unbiased approach, as well as the use of peptide level data for novel biomarker identification. We identify numerous proteins and peptides that have the potential to be used for better patient treatment stratification in the case of mPDAC and immunotherapy.

603 **A RANDOMIZED, PLACEBO-CONTROLLED, FIRST IN HUMAN PHASE I SINGLE ASCENDING DOSE (SAD) AND MULTIPLE ASCENDING DOSE (MAD) STUDY IN HEALTHY MALE VOLUNTEERS OF THE IMMUNOSTIMULANT 7HP349**

[1]Lionel Lewis*, [2]William Schary, [2]Siddhartha De, [2]Peter Vanderslice, [3]Ronald Biediger, [4]Yared Hailemichael, [3]Darren Woodside, [5]William Overwijk, [6]Frank Lee, [2]Upendra Marathi. *[1]7 Hills Pharma & The Geisel School of Medicine at Dartmouth, Lebanon, NH, United States; [2]7 Hills Pharma LLC Texas Heart Institute, Houston, TX, United States; [3]Texas Heart Institute, Houston, TX, United States; [4]MD Anderson Cancer Center, Houston, TX, United States; [5]Nextar, Houston, TX, United States; [6]Frontage Clinical Services, Sacaucus, NJ, United States*

Background 7HP349 is a first in class allosteric agonist of integrins α4β1 and αLβ2 which promotes both T-cell extravascular trafficking and antigen priming. In B16 and CT26 syngeneic models 7HP349 monotherapy has anti-tumor efficacy and enhanced anti-CTLA-4 and anti-PD-1 tumoricidal effects. 7HP349 has a very safe acute and chronic preclinical toxicity profile. We undertook a placebo-controlled Phase I SAD and MAD study with the objectives of determining (i) the safety and tolerability of oral 7HP349 (ii) the optimal pharmacokinetic dose (OPD).

Methods Four cohorts (1-4) of healthy male volunteers (n=8; 6 active;2 placebo) received single oral 7HP349/placebo doses of 50, 100, 200 or 300 mg after a standard breakfast. Two further cohorts [5&6 (n=8)] received 100 or 300 mg 7HP349/placebo daily for five days. Subjects were monitored for clinical and laboratory adverse events (AEs) during and up to 7 days post single dose and during and up to 10 days post multiple dosing and graded using 5.0 CTCAE criteria. Pharmacokinetic samples were collected pre-treatment and up to 96h post single and the last multiple dose. 7HP349 plasma concentrations were measured by LC-MS/MS, PK data was analyzed non-compartmentally.

Results Forty-eight healthy male volunteers median age 32 (range 21-44 y) were enrolled in the study, 36 received 7HP349 and 12 placebo. No 7HP349 related SAEs or clinical AEs were noted. Treatment emergent, reversible, non-clinically significant safety lab abnormalities were: SAD cohort 100 mg Gr 1. amylase/lipase n= 1/6; SAD Cohort 200 mg Gr 1 isolated ALT n=1/6 and Gr 1 amylase/lipase n=1/6; SAD Cohort 300 mg isolated Gr 1 ALT =1/6; MAD cohort 100 mg Gr 1 isolated ALT n=1/8 ; MAD cohort 300 mg Gr 1 AST/ALT & Gr 1 amylase/lipase n=1/8 and Gr 1 AST/ALT n=1/6. Similar out of range lab values were seen in a minority of placebo-treated subjects (1-2/12). 7HP349 mean PK parameters [(n=6; (±SD)] are detailed in table 1.

Conclusions Oral 7HP349 at single and multiple doses (daily x 5) up to 300 mg was safe and very well tolerated. 7HP349 mean terminal $T_{1/2}$ ranged from 20.6-34.6 h, with no accumulation and non-linear PK at the highest doses. Planned studies combining 7HP349 dosed at 100 mg and 300 mg/day x 5 (at a monotherapy safety margin of >10x) have the potential to augment immune checkpoint blockade without additional toxicity.

Background Prior to the approval of immune checkpoint inhibitors, patients with metastatic Merkel cell carcinoma (mMCC), a rare and aggressive neuroendocrine skin carcinoma, had a poor prognosis (5-year overall survival [OS] rate of approximately 17%). Avelumab, an anti–PD-L1 antibody, has been approved in multiple countries for the treatment of mMCC based on the results of the phase 2 JAVELIN Merkel 200 trial (NCT02155647). In the primary analysis of part B of the trial, which investigated avelumab as first-line (1L) treatment for mMCC and was reported after 15 months of follow-up in all patients, the objective response rate was 39.7%, the durable (≥6 months) response rate was 30.2%, and median OS was 20.3 months. Here, we report findings after 4 years of follow-up.

Methods Eligible patients had histologically confirmed stage IV mMCC and had received no prior systemic therapy. Patients received avelumab 10 mg/kg intravenously every 2 weeks as monotherapy until confirmed disease progression, unacceptable toxicity, or withdrawal of consent. Here, patient disposition and long-term OS were analyzed.

Results A total of 116 patients received 1L avelumab treatment. At data cutoff (February 2, 2022), median follow-up was 54.3 months (range, 48.0-69.7 months) and 72 patients (62.1%) had died. At last follow-up, 7 patients (6.0%) remained on treatment and were progression-free, 22 patients (19.0%) had discontinued treatment but remained in follow-up, and 87 patients (75.0%) had discontinued from the trial. Reasons for treatment discontinuation were disease progression in 54 (46.6%), adverse event in 27 (23.3%), withdrawal of consent in 6 (5.2%), death in 5 (4.3%), loss to follow-up in 1 (0.9%), and other reasons in 16 (13.8%). Median OS was 20.3 months (95% CI, 12.4-42.0 months) and OS rates (95% CIs) after 2, 3, and 4 years were 49% (40%-58%), 44% (34%-53%), and 38% (29%-47%), respectively. Median OS was 38.7 months (95% CI, 11.3 months to not estimable) in patients with PD-L1+ tumors (n=21) and 16.1 months (95% CI, 9.6-42.0 months) in patients with PD-L1− tumors (n=87). Overall, 48 patients (41.4%) had received ≥1 subsequent anticancer drug therapy, most commonly etoposide (20 [17.2%]), carboplatin (18 [15.5%]), and avelumab (post-trial; 14 [12.1%]).

Conclusions Avelumab 1L monotherapy in patients with mMCC resulted in a 4-year OS rate of 38%. OS rates were numerically higher than those seen in historical studies of 1L chemotherapy. These results further support the use of avelumab as a standard-of-care treatment for patients with mMCC.

605 NEOADJUVANT VIDUTOLIMOD (VIDU) AND NIVOLUMAB (NIVO) RESULTS IN MPR AND IMMUNE ACTIVATION IN HIGH-RISK RESECTABLE MELANOMA (MEL): FINAL PHASE II CLINICAL TRIAL RESULTS

[1]Arivarasan Karunamurthy, [1]Joe-Marc Chauvin, [1]Robert Morrison, [1]Yulong Bai, [1]Jie Sun, [1]Hong Wang, [1]Douglas Hartman, [2]Julie Stein, [1]Christopher Deitrick, [1]Riyue Bao, [1]Jagjit Singh, [1]Quanquan Ding, [1]Wentao Gao, [1]Drew Hurd, [1]Ornella Pagliano, [1]Amy Rose, [1]Yana Najjar, [1]Jason Luke, [3]David Mauro, [3]Arthur Krieg, [3]James Wooldridge, [3]Dmitri Bobilev, [1]John Kirkwood, [2]Janis Taube, [1]Hyun Jung Park, [1]Hassane Zarour, [1]Diwakar Davar*. *[1]University of Pittsburgh Medical Center Hillman Cancer Center, Pittsburgh, PA, United States; [2]Johns Hopkins University, Baltimore, MD, United States; [3]Checkmate Pharmaceuticals, Cambridge, MA, United States*

Background Neoadjuvant PD-1 blockade produces major pathological responses (MPR) in ~30% of patients (pts) with high-risk resectable MEL with durable relapse-free benefit, and increased circulating activated CD8+ T cells.[1,2] Vidutolimod (vidu) comprises a CpG-A oligodeoxynucleotide packaged within a virus-like particle (VLP) and is designed to activate tumor-associated plasmacytoid dendritic cells (pDC) via TLR9, inducing an IFN-rich tumor microenvironment and anti-tumor CD8+ T cell responses. Vidu/anti-PD-1 resulted in durable tumor responses in PD-1 refractory MEL.[3] This phase II study evaluated the pathological, clinical and immunological activities of neoadjuvant vidu/nivo in high-risk stage III B/C/D resectable MEL.

Methods Vidu/nivo was administered over 7 weeks (vidu 10mg IT Q1W x7, nivo 240mg Q2W x3) pre-surgery. Post-surgery, vidu/nivo (vidu SC 5mg, nivo 480mg Q4W) was continued for 48 weeks. Primary endpoints included MPR rate, and incidence of DLT. Secondary endpoints were radiographic response, relapse-free survival (RFS), distant metastasis-free survival (DMFS) and overall survival (OS). Pathological response assessment was performed to evaluate % residual volume of tumor (RVT) per consensus criteria[4-6] by 3 blinded dermatopathologists: 0% (pCR); 0%50% (pNR). Radiographic response assessed using RECIST v1.1. Serial blood, tumor and stool were collected for correlative analyses.

Results 31 pts were enrolled, of whom 30 evaluable for per-protocol (PP) analyses as 1 pt progressed pre-surgery. No DLTs were observed. 8 Gr3 TRAE, including hypertension (7/8) and colitis (1/8) were observed; no delays in surgery occurred. ORR by BICR was 45% (all) and 47% (PP). In PP population, MPR was observed in 57% (17/30) including 47% pCR (14/30) and 10% pMR (3/30). With median follow-up of 26.5 months, median RFS was not reached (table 1). Post-treatment, MPR was associated with increased CD8+ tumor infiltrating lymphocytes ($p<0.0001$), and peripheral immune activation and pDC activation by multiparameter flow cytometry ($p < 0.001$). Spatial investigation of immune cell infiltrates by mIHC revealed significantly immune cell infiltrates ($p<0.05$) and higher pDC ($p=0.053$) within tumor (but not stroma) of MPRs post-treatment (figure 1a,b). Deconvoluted RNAseq confirmed these findings compared to a control cohort of PD-1 treated MEL.

Conclusions Neoadjuvant vidu/nivo has minimal tox and demonstrated promising activity with 47% pCR rate and 57% MPR rate. MPR was associated with improved 1-/2- year RFS (94%/88%), and 1-/2- year DMFS (94%/94%) and 2-year OS (100%). MPR is associated with pDC and immune infiltrate (figure 1c). Further evaluation of this combination is ongoing in an ongoing randomized phase II trial (EA6194, NCT04708418).

606 **BIOMARKER ANALYSES OF BASELINE TUMOR SPECIMENS AND ON-TREATMENT CHANGES IN SERA SAMPLES OF PATIENTS ENROLLED IN THE RELATIVITY-047 TRIAL TO CHARACTERIZE LAG-3 BIOLOGY**

[1]Sonia Dolfi*, [1]Tracy Tang, [2]Georgina Long AO, [3]Paolo Ascierto, [4]F Stephen Hodi, [5]Evan Lipson, [6]Dirk Schadendorf, [1]John Wojcik, [1]Jennifer Postelnek, [1]Yu Wang, [1]Anne Marie Sobiesk, [1]Kaushal Mishra, [1]Sarah Keidel, [1]Karen Miller-Moslin, [7]Hussein Tawbi, [1]Charlie Garnett-Benson. *[1]Bristol Myers Squibb, Princeton, NJ, United States; [2]Melanoma Institute Australia, The University of Sydney; Royal North Shore Hospital; Mater Hospital, Wollstonecraft, Australia; [3]Istituto Nazionale Tumori IRCCS Fondazione G. Pascale, Milan, Italy; [4]Dana-Farber Cancer Institute, Boston, MA, United States; [5]Bloomberg-Kimmel Institute for Cancer Immunotherapy, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, United States; [6]University Hospital Essen, and German Cancer Consortium, Essen, Germany; [7]University of Texas MD Anderson Cancer Center, Houston, TX, United States*

Background The phase 2/3 RELATIVITY-047 clinical trial (NCT03470922) in patients with previously untreated metastatic or unresectable melanoma met its primary endpoint of improved progression-free survival with a combination of nivolumab plus relatlimab (NIVO+RELA) compared with NIVO monotherapy.[1] To better understand the biology underlying combined programmed death-1 (PD-1) and lymphocyte-activation gene 3 (LAG-3) inhibition, a series of exploratory biomarker analyses was performed. Analyses included longitudinal changes in immunomodulatory cytokines, free soluble LAG-3 (sLAG-3), and selected immune-cell markers within tumor biopsies collected at baseline.

Methods Peripheral blood serum samples collected prior to treatment, and prior to study drug during week 4 and week 8 of treatment, were evaluated for changes in inflammatory cytokines including interferon gamma (IFNγ) and sLAG-3. Baseline tumor samples were collected prior to treatment and were analyzed by immunohistochemistry for LAG-3 (17B4), CD8 (C8/144B), and tumor cell programmed death-ligand 1 (PD-L1) expression (Agilent/Dako PD-L1 28-8 IHC pharmDx).[1–3] Correlative analyses were performed.

Results Four weeks after treatment initiation, IFNγ levels increased over baseline in both treatment arms (table 1), but increases were significantly larger with NIVO+RELA than with NIVO (fold change 2.17 and 1.54, respectively; P <0.0001). Eight weeks after treatment initiation, sLAG-3 levels were modestly increased with NIVO (fold change 1.12; P <0.001), and significantly decreased with NIVO+RELA (fold change 0.60; P <0.001) (table 2), suggesting RELA-specific target engagement in the combination arm. No significant correlation was observed between baseline sLAG-3 and tissue-based LAG-3 expression in pretreatment tumors (Spearman's r=0.21). In baseline tumor biopsies, LAG-3 showed moderate correlation with PD-L1 expression (r=0.53) (figure 1). The majority of LAG-3–negative tumors (<1%) were also PD-L1 negative (<1%). PD-L1 expression varied among LAG-3–expressing tumors, with differences observed in the range of PD-L1 expression (high vs low) across LAG-3 subgroups. CD8 levels correlated more strongly with LAG-3 than with PD-L1. Furthermore, patients whose tumors had higher LAG-3 expression (≥1% and ≥5%) had numerically higher median progression-free survival and objective response rates in both the NIVO+RELA and NIVO arms.

Conclusions These exploratory analyses support the hypothesis that NIVO+RELA enhances immune activation compared with NIVO alone, and that LAG-3 may be a promising biomarker of tumor inflammation. Although LAG-3 alone may not be a useful predictive biomarker for selection of patients with melanoma for NIVO+RELA vs NIVO regimens, further work is required to assess the clinical utility of LAG-3, likely as part of a composite biomarker of immunotherapy susceptibility.

607 MCGRAW TRIAL: EVALUATION OF THE SAFETY AND EFFICACY OF AN ORAL MICROBIOME INTERVENTION (SER-401) IN COMBINATION WITH NIVOLUMAB IN FIRST LINE METASTATIC MELANOMA PATIENTS

[1]Isabella Glitza Oliva*, [2]Omid Hamid, [3]Patrick Ott, [4]Genevieve Boland, [4]Ryan Sullivan, [5]Kenneth Grossmann, [6]Christopher Desjardins, [6]Nathan Hicks, [6]Brian Weiner, [7]Farah Alayli, [7]Farah Alayli, [7]Christine Spencer, [7]Shikha Guatam, [7]Christopher Loo, [7]Benjamin Kamphaus, [7]Julie Densmore, [7]Christopher Cabanski, [7]Diane Da Silva, [1]Jennifer Wargo, [7]Justin Fairchild, [7]Marko Spasic, [6]John Aunins, [6]Kelly Brady, [1]Elizabeth Burton, [6]Jennifer Wortman, [7]Theresa LaVallee, [6]Mathew Henn, [1]Hussein Tawbi. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX, United States; [2]Angeles Clinic and Research Institute, Los Angeles, CA, United States; [3]Dana-Farber Cancer Institute, Boston, MA, United States; [4]Mass General Cancer Center, Boston, MA, United States; [5]Huntsman Cancer Institute, Salt Lake City, UT United States; [6]Seres Therapeutics, Cambridge, MA, United States; [7]Parker Institute for Cancer Immunotherapy, San Francisco, CA, United States*

Background While anti-PD-based therapy is an approved first-line treatment for patients with advanced, surgically unresectable metastatic melanoma (MM), many do not benefit. Abundance of *Ruminococcaceae* and other microbes in cancer patients' gut microbiome has been associated with improved anti-PD1 efficacy. Thus, combination approaches to overcome anti-PD1 primary resistance with gut microbiome modulation are being explored. In this trial, SER-401, an investigational microbiome therapeutic enriched in *Ruminococcaceae* and other spore-forming microbes, was evaluated in combination with nivolumab in first line MM patients.

Methods MCGRAW is a multi-center, randomized, blinded, and placebo-controlled phase 1b study in patients with advanced melanoma. Patients were randomized 2:1 to the SER-401 active or placebo arm, respectively, and stratified by baseline stool *Ruminococcaceae* abundance. Patients received an oral vancomycin preparative regimen+SER-401 (active arm), versus no antibiotics+placebo (placebo arm). One week later, all patients received nivolumab 480 mg Q4W. The primary endpoint was safety. Secondary endpoints were SER-401 microbiome engraftment, ORR, DCR, PFS, and change in frequency of tumoral CD8+ T cells on-treatment. The study was not powered for comparison between arms. Baseline and on-treatment stool samples were collected for microbiome analysis, tumor and blood samples were collected for exploratory biomarker analysis.

Results Fourteen patients were randomized (N=8 active, N=6 placebo). Grade 3-4 TRAEs were observed in 0 and 1 (17%) participants in the SER-401/nivolumab and placebo/nivolumab arms, respectively. In the vancomycin+SER-401/nivolumab arm, ORR was 25.0% (95% CI: 3-65) and DCR was 37.5% (95% CI: 9-76). In the no antibiotics+placebo/nivolumab arm, ORR was 66.7% (95% CI: 22-96) and DCR was 83.3% (95% CI: 36-99). Overall, microbiome engraftment was observed in the active arm but did not reach optimal kinetics or magnitude in many patients. Differences in the fecal microbial and metabolic profiles of responders and non-responders were observed to be prior to initial nivolumab administration. Additional orthogonal biomarker analyses revealed further differences between the responders and non-responders, with the CR patient in the active arm having a distinct profile both at screening and on-treatment.

Conclusions This study demonstrated that SER-401 and anti-PD1 are a safe combination in MM patients, however DCR was lower in the active arm versus control, perhaps related to the antibiotic preparative regimen. Enrollment challenges and sub-optimal SER-401 engraftment resulted in early termination of the study. Despite these limitations, our integrative clinical and biomarker analysis provides information regarding the link between the gut microbiome, peripheral immune cell populations, and the tumor microenvironment during nivolumab therapy with or without SER-401.

Acknowledgements We extend our gratitude to the patients, their families, the clinical investigators, and their site staff members who made this trial possible. We would also like to thank Sultan Nawabi at Parker Institute for Cancer Immunotherapy (PICI) for operations leadership of the trial. The study was funded by Seres Therapeutics.

Trial Registration ClinicalTrials. gov (NCT03817125)

Ethics Approval The MCGRAW study was approved by WCG IRB (previously known as WIRB) protocol # 20182747

Consent All participants provided written informed consent before enrollment

608 PREDICTING PRIMARY RESISTANCE AND EXPLORING MECHANISMS IN PATIENTS WITH ADVANCED MELANOMA TREATED WITH IMMUNE CHECKPOINT INHIBITORS (ICIS)

[1]Georgina Long AO*, [2]Tracy Tang, [2]Abraham Apfel, [2]David Paulucci, [2]Scott Chasalow, [2]Daniel Tenney, [2]Gina Fusaro, [3]Dirk Schadendorf, [4]Hussein Tawbi, [5]F Stephen Hodi, [2]Pratik Thakkar, [6]James Larkin, [7]Jedd Wolchok, [2]Megan Wind-Rotolo, [2]Shu-Pang Huang, [8]Peter Mohr, [9]Caroline Robert, [10]Christoph Hoeller, [11]Jean-Jacque Grob, [12]Helen Gogas, [13]Jeffrey Weber, [2]Han Chang, [2]Rebecca Moss. *[1]Melanoma Institute Australia, The University of Sydney; Royal North Shore Hospital; Mater Hospital, Wollstonecraft, Australia; [2]Bristol Myers Squibb, Princeton, NJ, United States; [3]University Hospital Essen, Essen, Germany; [4]University of Texas MD Anderson Cancer Center, Houston, United States; [5]Dana-Farber Cancer Institute, Boston, MA, United States; [6]Royal Marsden Hospital, London, UK; [7]Memorial Sloan Kettering Cancer Center; Weill Cornell Medicine; Parker Institute for Cancer Immunotherapy, New York, NY, United States; [8]Elbekliniken Buxtehude, Buxtehude, Germany; [9]Institut Gustave-Roussy, Villejuif-Paris, France; [10]Medical University of Vienna, Vienna, Austria; [11]APHM and Aix-Marseille University, Marseille, France; [12]National and Kapodistrian University of Athens, Athens, Greece; [13]NYU Langone Health, New York, NY, United States*

Background Despite significant improvements in treatment outcomes with ICIs, deeper understanding is needed to improve outcomes for patients with melanoma who experience no clinical benefit from ICI therapy and exhibit early disease progression (primary resistance).[1] We analyzed clinical and translational factors using data from 9 BMS-sponsored clinical trials of nivolumab (NIVO), ipilimumab (IPI) and their combination in patients with advanced cutaneous melanoma (CheckMate 003, 037, 038, 064, 066, 067, 069, 511, 742) to predict resistance to ICIs and explore underlying mechanisms.

Methods Analyses of pre-treatment clinical covariates and biomarkers (determined by tumor immunohistochemistry, whole exome DNA sequencing, RNA sequencing, and serum cytokine analysis) were performed in patients with melanoma who received NIVO, IPI or NIVO+IPI and were evaluable for resistance. Several methods were used to develop and test models predicting ICI primary resistance, defined as death due to disease or best overall response of progressive disease (excluding pseudoprogression) before the first radiographic scan (≤13 weeks of treatment). Model performance was assessed using cross-validated area under the receiver operating characteristic curve (AUROC) and bootstrap bias-adjusted calibration metrics. Additionally, we evaluated individual biomarker associations with primary resistance.

Results Across 1803 patients from 9 clinical trials, 1638 were evaluable for cutaneous melanoma primary resistance and 585 (36%) met the criteria. A multivariable logistic regression model for predicting primary resistance yielded an AUROC of 0.78 (R^2=0.29) and included 17 commonly available clinical factors and PD-L1 (table 1). External validation using data from an independent study yielded an AUROC of 0.70 (R^2=0.17). Higher levels of acute phase cytokines and expression of genes associated with suppressive tumor microenvironment or stromal factors, including epithelial-mesenchymal transition, cancer-associated fibroblasts, transforming growth factor beta, and angiogenesis, were associated with increased risk of primary resistance. In contrast, higher levels of tumor mutational burden, PD-L1, CD8, mutations in MAPK-pathway genes, and immune gene signature scores were associated with decreased risk (figure 1, table 2).

Conclusions This exploratory analysis of clinical and translational factors in patients with advanced cutaneous melanoma identified associations with primary resistance to NIVO, IPI, or NIVO+IPI, with the best model yielding an AUROC of 0.78. Factors associated with primary resistance included higher levels of prognostic cytokines, gene expression indicating an immune suppressive tumor microenvironment, lower levels of anti-tumor immunity, and lack of MAPK-pathway mutations. These findings are supportive of future clinical trial stratification of patients and mechanistic studies targeting the biology of primary resistance to ICI therapy.

609 NITRIC OXIDE DEPENDENT IMPROVED RELAPSE FREE SURVIVAL TO IPILIMUMAB THERAPY IN MELANOMA PATIENTS

[1]Joseph Markowitz*, [1]Saurabh Garg, [2]James Sun, [1]Youngchul Kim, [1]Junmin Whiting, [1]Jose Conejo-Garcia, [3]Mitch Phelps, [4]Jeffrey Weber, [1]James Mule. *[1]Moffitt Cancer Center & Research Institute, Tampa, FL, United States; [2]Case Western Reserve University, Cleveland, OH, United States; [3]The Ohio State University, Columbus, OH, United States; [4]Perlmutter Cancer Center, New York University Langone Health, New York, NY, United States*

Background Though FDA-approved for use after surgery for stage III/IV melanoma in the adjuvant setting, ipilimumab (anti–CTLA-4) and interferon-α are not typically used because of the improved toxicity profile and relapse-free survival (RFS) benefits seen with anti–PD-1–based regimens in this patient population. However, it is important to study samples derived from anti-CTLA-4 treated patients from the mechanistic perspective to understand its contribution to ipilimumab/nivolumab therapy and to study single agent CTLA4 therapy in the adjuvant cases of BRAF wild-type patients who were re-resected and previously received anti-PD-1 therapy. Recently published data from our group indicated that nitric oxide (NO) increased in immune effector cells among patients treated with longer RFS, whereas NO also increased in immune suppressor cells among patients with shorter RFS. Given this unexpected dichotomy, we measured the posttranslational modification in the immune cells that is a direct result of increased NO levels on the interferon response protein STAT1 important for response to anti-CTLA-4 therapy/interferon responsiveness. Nitration is a stable post-translational modification of NO metabolism and STAT1 is nitrated at the same position (Y701) as it is phosphorylated.

Methods Peripheral blood mononuclear cells (PBMCs) collected from 35 patients at day 0 and day 155 of ipilimumab therapy were analyzed for phosphorylated STAT1 (pSTAT1; using flow cytometry) and nitrated STAT1 at position 701 (nSTAT1; using liquid chromatography with tandem mass spectrometry). Patients were divided into groups based on RFS post ipilimumab therapy.

Results Pre- and post-therapy PBMCs were available from 35 patients with stage IIIC/IV melanoma. The median patient age was 58 years (range, 21-78 years), and 63% of patients were male. pSTAT1 levels had the least variability in the tercile of patients with the longest RFS ($P=0.002$). Higher pSTAT1 levels in PBMCs were associated with worse RFS before ($P = 0.007$) and after therapy ($P = 0.036$) with ipilimumab. Expectedly, pSTAT1 levels in PBMCs increased following ipilimumab therapy. Patients whose STAT1 remained nitrated had decreased RFS, but intriguingly, increases in nitration of STAT1 following ipilimumab therapy was associated with favorable outcomes ($P=0.01$).

Conclusions These data suggest that interferon responsiveness is regulated by changes in nitration of STAT1. Nitration of Y701 on STAT1 may regulate excessive interferon responses by limiting pSTAT1 phosphorylation for successful ipilimumab-based therapy in melanoma and deserves further study in the adjuvant and metastatic settings.

610 IMMUNE BIOMARKER ANALYSIS OF RP1 IN COMBINATION WITH NIVOLUMAB IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Kevin Harrington*, [2]Pablo Nenclares, [1]Isla Leslie, [3]Ari VanderWalde, [4]Tawnya Bowles, [5]Joseph Sacco, [5]Anna Olsson-Brown, [6]Jiaxin Niu, [7]Katy Tsai, [8]Jason Chesney, [9]Bartosz Chmielowski, [10]Adel Samson, [4]Terence Rhodes, [11]Gino In, [12]Anna Pavlick, [13]Trisha Wise-Draper, [14]Miguel Sanmamed, [15]Laxminarasimha Donthireddy, [15]Yawei Zhang, [15]Jeannie Hou, [15]Praveen Bommareddy, [15]Robert Coffin, [16]Mark Middleton, [17]Mohammed Milhem. *[1]Royal Marsden NHS Foundation Trust & ICR, Sutton, UK; [2]The Institute of Cancer Research, London, UK; [3]West Cancer Center and Research Institute, Germantown, TN, United States; [4]Intermountain Medical Center, Murray, UT, United States; [5]Clatterbridge Cancer Centre, Liverpool, UK; [6]Banner MD Anderson Cancer Center, Gilbert, AZ, United States; [7]Helen Diller Family Comprehensive Cancer, San Francisco, CA, United States; [8]James Graham Brown Cancer Center, Louisville, KY, United States; [9]University of California Los Angeles, Los Angeles, CA, United States; [10]University of Leeds, Leeds, UK; [11]Norris Comprehensive Cancer Center, Los Angeles, CA, United States; [12]Weill Cornell Medical College, New York, NY, United States; [13]University of Cincinnati, Cincinnati, OH, United States; [14]Clínica Universidad de Navarra, New Haven, CT, United States; [15]Replimune Inc, Woburn, MA, United States; [16]Churchill Hospital, Oxford, UK; [17]Holden Comprehensive Cancer Center, Iowa City, IA, United States*

Background RP1 is a novel, enhanced potency, oncolytic version of HSV-1 engineered to express human GM-CSF and GALV-GP R-.[1] RP1 + anti-PD1 therapy combination has resulted in deep and durable responses, including in melanoma patients who have previously failed prior anti-PD1 therapy.[2] Here we present biomarker data from the ongoing clinical trial of RP1 + nivolumab (nivo).

Methods Tumor biopsies were taken pre-treatment and at 43 days after the first dose of RP1. The tumor immune microenvironment (TIME) was analyzed IHC for CD8 (SP57 clone, Ventana) and PD-L1 (PD-L1 IHC 28-8 pharmDx by Agilent) and by gene expression analysis using the NanoString IO360 panel. The tumor inflammation signature score (TIS) was also calculated using an 18 gene signature.[3] Systemic anti-tumor immunity was assessed using PBMCs by sequencing the CDR3 regions of human TCRβ chains using the immunoSEQ assay. Correlation analysis of baseline tumor PD-L1 and CD8 status versus clinical response was also performed.

Results A consistent increase in CD8 and PD-L1 expression in the tumor was observed in most of the tested biopsies (30/44), which generally appeared to be co-located. These increases were observed both in superficial lesions and visceral tumors, including in the liver. A notable reversal of CD8 T cell exclusion was observed in a melanoma patient who failed prior ipilimumab and nivo treatment. Clinical responses were independent of baseline CD8 T cell infiltration, PD-L1 expression levels, and prior anti-PD-1 therapy. Gene expression analyses of tumor biopsies (n=11) demonstrated significant increases in the expression levels of genes associated with innate and adaptive immune activation and genes previously reported to be associated with responsiveness to anti-PD1 therapy, particularly CD8, CXCL9, CD27, and TIGIT, as well as consistent increases in TIS. TCR sequencing of PBMCs revealed expansion of pre-existing T cell clones and the appearance of new clones with 20-80% of these changes being newly detected clones. Expansion of new clones (n=170) was observed in a melanoma patient who had a complete response.

Conclusions The biomarker data indicate broad immune activation by RP1 + nivo. Clinical responses are independent of baseline PD-L1 expression and associated with increases in gene signatures associated with cytotoxic T, NK, and Th1 cells. The data indicate the potential for broad utility of RP1 in a range of tumor types, including in patients with primary or acquired resistance to immune checkpoint blockade.

Background RP1 is HSV1-based oncolytic immunotherapy expressing GM-CSF and the fusogenic GALV-GP R- protein. We present biodistribution and shedding data from the melanoma (n=30) and NMSC patients (n=31) of an ongoing clinical trial of RP1 + nivolumab (nivo).

Methods RP1 was injected into lesions (10^6 PFU/mL, then 10^7 PFU/mL Q2W) for up to 8 cycles. Injected lesions were covered with occlusive dressings. Blood, urine and swabs from dressing exteriors, tumor surface, oral mucosa, and areas of suspected herpetic origin were collected. RP1 DNA presence was assessed using qPCR and infectivity by TCID50.

Results RP1 DNA was detected in blood from 32.1% patients and 11.0% of blood samples. Highest levels were detected at 6 hrs. A sub-set of patients showed continued DNA until the next injection, with kinetics indicating RP1 replication. RP1 DNA was undetectable in all urine samples. Additionally, 50.9% of patients and 22.7% of swabs were positive from injection sites, with approximately 20% of patients positive at the next injection, also indicating RP1 replication. 20.5% of patients and 6.2% of samples tested positive for RP1 DNA on the dressing exterior between 24 hrs and the next dose, at low levels compared to injection sites. RP1 DNA was detected at low levels on the oral mucosa (15.1% of patients or 1.9% of samples). During the safety follow-up period, RP1 DNA was only detected on the injected lesion surface and not other sites, with 5.5% and 3.8% of patients positive at 30 and 60 days after the last RP1 dose respectively. Swabs positive for RP1 DNA were assessed for infectious virus by TCID50, and all were negative. No RP1 DNA was detected in swabs from potentially herpetic lesions, with no reports of herpetic infection in patient's caregivers.

Conclusions All positive samples showed only residual RP1 DNA rather than RP1 itself. RP1 DNA was detected on injected tumor surfaces at higher levels compared to other sites for up to 15 days (time of next dose), and then at diminishing levels up to 60 days from last dose. DNA levels at other sites were much lower and transient. In blood, RP1 DNA was detected in a quantity and with kinetics indicative of virus replication in a sub-set of patients, as expected based on the mechanism of action of RP1. Overall, the data suggest that the possibility of RP1 transmission to contacts is minimal, with no evidence of transmission reported.

Trial Registration NCT03767348

Ethics Approval The study was approved by the institutional review board or the local ethics committee at each participating site. Informed consent was obtained from patients before participating in the trial.

612 PERIPHERAL IMMUNE SIGNATURE OF RESPONSIVENESS TO ADOPTIVE CELL THERAPY WITH EX VIVO EXPANDED TILS USING HIGH DIMENSIONAL SINGLE CELL ANALYSIS

Cecilie Oelvang Madsen*, Marta Velasco Santiago, Troels Holz Borch, Inge Marie Svane, Morten Hansen. *The National Center of Cancer Immune Therapy (CCIT-DK), Herlev, Denmark*

Background Adoptive cell therapy (ACT) with *ex-vivo* expanded tumor infiltrating lymphocytes (TILs) has shown remarkable results in patients with metastatic melanoma (MM).[1, 2] There is a crucial need for noninvasive biomarkers for screening patients which could improve the selection of patients responsive to therapy. Most studies have until now investigated phenotype, numbers, and persistence of infused TILs, while the role of peripheral immune cell in this process is still poorly understood. Here, we sought to elucidate potential peripheral immune signatures before and early on-treatment to predict patients with clinical outcome of ACT-TIL therapy, as well as characterize its impact on circulating immune cells.

Methods Here we retrospectively analyzed peripheral blood mononuclear cells (PBMCs) and serum on-treatment changes from 45 patients with MM treated at our cancer center in one of three clinical trials: Study I (NCT00937625),[3] Study II (NCT02379195),[4] and Study III (NCT02354690).[5] Three multicolor flow cytometry panels were developed, two focused on T cells and one designed to measure all major mononuclear subsets and their characteristics. Data were evaluated by algorithm-based clustering and manual gate-setting of major immune cell subsets. Multiplex Luminex and ELISA was used to analyze serum samples to further reveal specific cytokine profiles of responsiveness to TIL therapy.

Results Higher frequency of $CD8^+$effector memory (EM) T cells was the only subset characterizing a peripheral immune signature of responsiveness pre-TIL. However, post-TIL therapy multiple immune subsets were associated with clinical outcome. Non-responders were characterized by mobilization of monocytic and NK subsets at the expense of $CD4^+$ T cells and several subsets of dendritic cells (DCs). While major pro-inflammatory cytokines, IL-6 and IL-8, decreased post-TIL in responding patients they persisted in non-responding patients. In contrast, responders post-TIL therapy was characterized by higher frequency of both cDC2s and pDCs, $CD4^+$ T cells and a subpopulation of $CD4^+$ EM T cells expressing CD28, CD29, CD95, and PD-1.

Conclusions While TIL therapy encompasses adoptive transfer of *ex-vivo* expanded preexisting TILs such therapy seems to modify both lymphoid and myeloid cell populations in peripheral blood. This indicates that early on-treatment peripheral immune signature of responsiveness to TIL therapy is characterized by higher frequency of $CD4^+$ T cells and subsets of DCs, and a decrease in inflammatory cells and their mediators.

613 NEOADJUVANT SEMA4D BLOCKADE WITH NIVOLUMAB ALTERS SUPPRESSIVE MYELOID CELLS WHILE ELEVATING B CELL AND CD26^{HI} T CELL INFILTRATION IN THE TUMORS OF PATIENTS WITH RESECTABLE STAGE III MELANOMA

[1]Brian Olson*, [2]Crystal Mallow, [2]Christine Reilly, [1]Jacklyn Hammons, [1]Jayden Kim, [1]Brian Burns, [1]Agnes Harutyunyan, [2]Elizabeth Evans, [2]Terrence Fisher, [2]Maurice Zauderer, [1]Keith Delman, [1]Melinda Yushak, [1]Ali Mokhtari, [1]Douglas Parker, [1]Chrystal Paulos, [1]Gregory Lesinski, [1]Michael Lowe. *[1]Emory University, Atlanta, GA, United States; [2]Vaccinex, Inc., Rochester, NY, United States*

Background Semaphorin 4D (SEMA4D) modulates suppressive myeloid cells to promote infiltration of effector immune populations into the tumor microenvironment (TME). When combined with immune checkpoint blockade (ICB), SEMA4D blockade limits tumor progression in preclinical models. We have shown that pepinemab (a SEM4D-blocking Ab) can be safely combined with ICB in the neoadjuvant setting, and we hypothesize it will enhance immune infiltration in TME and benefit patients with resectable stage III melanoma.

Methods Patients with resectable stage III melanoma received neoadjuvant nivolumab alone, pepinemab/nivolumab, pepinemab/ipilimumab, or pepinemab/nivolumab/ipilimumab for six weeks followed by surgical resection (NCT03769155). A control cohort underwent surgery without neoadjuvant therapy. Full clinical data from this trial will be presented at ESMO 2022. Peripheral blood was drawn at three time points: a) pre-treatment, b) two weeks into treatment, and c) at time of surgery. High dimensional immune analysis was performed on tissue and blood using 32-color flow cytometry. Pretreatment archival tissue was also used in conjunction with on study surgical resection tissue to evaluate spatial distribution of immune populations using multiplex immunohistochemistry. Finally, pharmacodynamics of SEMA4D blockade by pepinemab was tested using flow-based saturation assays.

Results Pepinemab treatment significantly increased tumor-infiltrating B cells (CD19+) and CD4+ T cells in surgical tissue of patients also given nivolumab (alone or with ipilimumab). A striking increase in a sub-population of proliferating (Ki67+) CD4+ T cells expressing the costimulatory molecule CD26 was also detected in patients receiving pepinemab-containing regimens (as compared to those receiving nivolumab alone). Intriguingly, tertiary lymphoid structures (TLS) comprised of a rich density of B and T cells were found in the tumor bed of patients given the tripartite therapy, as illuminated by spatial distribution of these immune populations using multiplex IHC. Patients experiencing a major pathologic response to pepinemab and nivolumab (with or without ipilimumab) had increased frequencies of tumor-infiltrating B cells and CD4+CD26^{hi} T cells and elevated M1/M2 macrophage ratio. Multiplex IHC results, biomarker analysis, and peripheral blood analysis will be updated at presentation.

Conclusions Neoadjuvant pepinemab with nivolumab (alone or with ipilimumab) modulates immune responses in tumors from patients with resectable melanoma, particularly those with major pathologic responses. Mechanistically, this therapy may act in part by fostering interactions between B and T cell populations within TLS in tumors, with concurrent modulation of myeloid cells. Given the encouraging clinical activity and tolerability of these regimens, the addition of pepinemab has the potential to augment the activity of ICB in advanced melanoma.

614 **MICROBIOME MODIFICATION WITH FECAL MICROBIOTA TRANSPLANT FROM HEALTHY DONORS BEFORE ANTI-PD1 THERAPY REDUCES PRIMARY RESISTANCE TO IMMUNOTHERAPY IN ADVANCED AND METASTATIC MELANOMA PATIENTS**

[1]Bertrand Routy, [2]John Lenehan, [2]Brendan Daisley, [1]Meriem Messaoudene, [2]Kait Al, [1]Corentin Richard, [3]Wilson Miller, [1]Rahima Jamal, [2]Scott Ernst, [2]Diane Logan, [1]Karl Belanger, [4]Luara Martinez- Gili, [4]Benjamin Mullish, [4]Panteleimon Takis, [5]Cecilia Hermosilla Samayoa, [2]Marina Ninkov, [6]Seema Nair Parvathy, [3]Caroline Lambert, [1]Arielle Elkrief, [1]Rejean Lapointe, [2]Mansour Haeryfar, [2]Jeremy Burton, [6]Michael Silverman, [2]Saman Maleki*. *[1]CRCHUM, Montreal, Canada; [2]Western University, London, Canada; [3]McGill University, Montreal, Canada; [4]Imperial College London, London, UK; [5]McGill, Montreal, Canada; [6]St. Joseph's Hospital, London, Canada*

Background Microbiome-based interventions with fecal microbiota transplant (FMT) from treatment responders (R) have shown promising results in re-sensitizing anti-PD-1-refractory melanoma patients to anti-PD1 therapy. However, it is not currently known whether FMT can be used to prevent primary resistance. Here, we report results from the first phase I clinical trial (NCT03772899) that combines FMT with anti-PD1 therapy in anti-PD1-naïve melanoma patients.

Methods Twenty patients with advanced disease were treated with FMT with capsules from healthy donors one week before the standard of care anti-PD-1. A total of three donors were used. Fecal microbiota was profiled with 16S rRNA and metagenomics sequencing. ^{1}H-NMR/SMolESY was used to measure plasma metabolites, and flow cytometry was performed on PBMCs. Additionally, FMT in avatar murine models was performed.

Results The median age was 75.5 years, and eight were female. The median follow-up time was 12.2 months. No unexpected toxicities or grade 3/4 toxicities were observed with FMT. Grade 3 immune-related adverse events included nephritis, pneumonitis, and vasculitis. ORR was 65% (13/20), of which 3 were CR. Clinical benefit rate (includes SD lasting > 6 months) was 75% (15/20). There was no correlation between outcomes/toxicities and donors. Microbiome profiling revealed positive engraftment of all patients one week after FMT; however, sustainable engraftment was only observed in R at one month and maintained at three months. At the taxa level, R had enrichment of *Eubacterium rectale*, *Eubacterium ramuleus*, and *Firmicutes* while a loss of *Hungatella*. Metabolomics analysis uncovered that succinate levels were lower in R at baseline. A significant fold change increase in plasma propionate between pre- and post-FMT was observed in R but not non-responders (NR). Immune profiling showed an increase in conventional effector $CD8^+$ T-cells and an increase in $CD38^+CD8^+$ Mucosa-associated invariant T (MAIT) cells in R compared to NR post-FMT. Avatar mouse models in germ-free and antibiotic-treated mice confirmed our clinical observations in that pre-FMT stool from both NR and R patients did not induce a response to anti-PD1 therapy. However, the post-FMT stool from R or FMT using donor feces sensitized B16-OVA and MCA-205 tumors to anti-PD1. Post FMT alpha diversity in responder mice correlated with increased intratumor memory $CD8^+$ T-cells, $TIM3^+$ T-cells, and stronger anti-PD-1 response.

Conclusions Our findings show that combining FMT from healthy donors with anti-PD1 potentially reduces primary resistance to immunotherapy. Successful engraftment of donor microbiota in patients correlated with better outcomes, and this was corroborated by translational experiments.

615 **REPEAT DOSING OF ONCOLYTIC ADENOVIRUS ONCOS-102 IS ASSOCIATED WITH ENHANCED AND PERSISTENT IMMUNE RESPONSES AND IMPROVED SYSTEMIC ACTIVITY IN ANTI-PD-1 RESISTANT/REFRACTORY (R/R) MELANOMA**

[1]Alexander Shoushtari*, [2]Lone Ottesen, [2]Victor Levitsky, [2]Thomas Birkballe Hansen, [3]Thomas Hornyak, [4]Anthony Olszanski, [5]Martha Nyakas, [6]Jedd Wolchok. *[1]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [2]Targovax Asa, Lysaker, Norway; [3]University of Maryland Cancer Center, Baltimore, MD, United States; [4]Fox Chase Cancer Center, Philadelphia, PA, United States; [5]Oslo University Hospital, Oslo, Norway*

Background Defining the optimal dosing-schedule is critical for the development of novel immunotherapeutic combinations. We recently completed phase 1/2 testing of ONCOS-102, a GM-CSF-encoding oncolytic adenovirus (Ad5/3-D24-GMCSF) in two different dosing schedules in combination with pembrolizumab (pem) in patients (pts) with unresectable, stage III-IV, anti-PD-1 resistant/refractory melanoma (NCT03003676). Here, we report tumor viral exposure, comparative, longitudinal gene expression analysis of tumor samples, safety, and detailed analysis of local and systemic effects on tumor lesions according to dosing schedule.

Methods In study Part 1, pts (n=9) received sequential treatment comprising three priming injections of ONCOS-102 (3x1011 VP/injection, intra-tumoral) at every 3 days during the first week of treatment followed by i.v. pem administration (10 mg/kg) every 3 weeks from day 22 for 6 months. In study part 2, pts (n=12) received concomitant treatment with three priming injections of ONCOS-102 during the first week and at day 15 and then ONCOS-102+pem every 3 weeks from day 22. Injected and non-injected target lesion response was assessed, and tumor biopsies were collected at baseline, day 22 and 64. Total RNA sequencing with differential gene expression analysis was conducted on samples from 17 pts. AEs were assessed according to CTCAE.

Results 35% (7 of 20) of evaluable patients achieved RECIST v1.1 objective response. ORR was similar in the two cohorts: 38% (3 of 8 patients) in Part 1 and 33% (4 of 12 patients) in Part 2, despite evidence of more advanced disease in Part 2. Fifty-two individual target lesions (TL) were assessed for response; 16 injected (I)-TL and 36 non-injected (NI)-TL. In I-TL, 25% completely regressed. In NI-TL, $\geq$ 30% shrinkage was observed in 1 of 8 (12.5%) in Part 1 vs 7 of 28 (25%) in Part 2.

Greater persistence of ONCOS-102 DNA in the tumor through day 64 was observed in Part 2. This correlated with an increased expression of immune-related genes particularly at day 64.

The most frequently reported TEAEs were pyrexia (48%), chills (43%), hypertension (43%), nausea (33%), and alanine aminotransferase increase (33%) with similar incidence, and severity in both parts.

Conclusions Repeat dosing concomitantly with pembrolizumab demonstrated greater viral persistence in the tumor and a trend for upregulation of immune-related genes at Day 64, with no added toxicity concerns beyond pyrexia and local injection site events. Persisting immune activation and substantial tumor shrinkage in non-injected lesions supports the extended (Part 2) dosing regimen for further clinical development.

616 UNDERSTANDING MOLECULAR CONSEQUENCES OF IMMUNOTHERAPY ON THE GERMINAL CENTER AXIS

[1]Sabrina Solis*, [1]Tomoaki Muramatsu, [1]Sophie Gray-Gaillard, [1]Ramin Herati. *[1]NYU Langone Health, New York, NY, United States*

Background Checkpoint inhibitor (CPI) antibodies induce blockade of CTLA-4 and PD-1 to reinvigorate the immune system to induce tumor cell clearance. Despite the success of CPI in cancer treatment, CPIs often result in toxicity due to immune related adverse events (irAEs).[1] Both mechanistic understanding and predictive biomarkers for irAEs is lacking. It is necessary to characterize the effect of CPI on the immune system to reduce therapeutic toxicity and improve patient outcomes.

CD4 T follicular helper cells (Tfh) strongly express PD-1 and CTLA-4, yet little is known about the effects of CPI on these cells. Tfh provide help to antibody producing B cells within germinal centers in lymphoid tissue.[2] Although this is an essential mechanism of adaptive immunity, several groups have shown hyperactivity in Tfh drives germinal center activity, resulting in increased help to autoreactive B cells and the generation of disease-causing autoantibodies.[3, 4, 5] In the context of CPI, Tfh dysfunction may also drive the induction of autoantibodies and associated irAEs.

Methods Using flow cytometry and scRNAseq, we are analyzing PBMC samples from the Checkmate-238 clinical trial in which patients with resected stage III or IV melanoma received either αPD-1 or αCTLA-4 monotherapy.[6]Patients had blood drawn on the same day as the first immunotherapy infusion (baseline) and two weeks post-baseline.

Tfh may be key to understanding irAE, but the study of Tfh in humans is challenging as these cells are commonly found in germinal centers of lymph nodes. To overcome this, our group has shown that circulating Tfh cells (cTfh) are recent emigrants from the lymph node and can be used to study cellular dynamics.[7]

Results In this study, αCTLA-4-treated patients developed irAE at higher rates than αPD1-treated patients, with 46% of αCTLA-4 patients developing Grade 3 or 4 irAE compared to 14% of αPD-1 patients.[6] We are interested in determining if the higher rate of irAE associated with αCTLA-4 was correlated to cTfh responses. Indeed, in flow cytometry studies, our lab identified a dramatic induction of activated cTfh following αCTLA-4 but not αPD-1 therapy, with a median fold-change of 7.5 within two weeks after baseline in αCTLA-4 patients but no difference in αPD-1 patients (figure 1).

Conclusions The greater influx of cTfh and higher incidence of severe irAEs suggest that αCTLA-4 therapy may predispose patients to dysregulated Tfh proliferation and induction of autoantibody responses.

617 **NEOADJUVANT INTRATUMORAL TAVO-EP (PLASMID IL-12 ELECTRO GENE TRANSFER) IN COMBINATION WITH NIVOLUMAB; PRELIMINARY CLINICAL AND BIOMARKER DATA IN PATIENTS WITH OPERABLE LOCOREGIONALLY ADVANCED MELANOMA**

[1]Ahmad Tarhini*, [1]Zeynep Eroglu, [1]Amod Sarnaik, [1]Jonathan Zager, [1]Ricardo Gonzalez, [1]Deanryan De Aquino, [1]Edith Abraham, [1]Justin Martin, [1]Allison Richards, [1]Yian Ann Chen, [1]Denise Kalos, [2]Jessica Lloyd, [2]Jonathan Hanna, [2]Erica Browning, [2]David Canton, [1]Kenneth Tsai, [1]Jane Messina, [1]Pei-Ling Chen, [1]Vernon Sondak. *[1]Moffitt Cancer Center & Research Inst., Tampa, FL, United State; [2]OncoSec, San Diego, CA, United States*

Background Intratumoral (IT) treatment with TAVO-EP (tavokinogene telseplasmid delivered by electroporation) results in localized expression of IL-12 in the tumor microenvironment. This study (NCT04526730) was designed to evaluate neoadjuvant TAVO-EP in combination with nivolumab followed by surgery and adjuvant nivolumab in patients with operable, locoregionally advanced melanoma.

Methods The neoadjuvant phase comprised up to 3 x4-week cycles of TAVO-EP on days 1, 8 and 15 (optional) concurrently with 480 mg nivolumab I.V. on day 8 of each cycle. Surgery followed and adjuvant nivolumab was initiated after recovery from surgery for up to one year. Longitudinal samples of tumor biopsies, PBMCs, serum, PAXgene© blood DNA/RNA, and fecal material were collected at screening, C1D8, C2D1, pre-surgery and during adjuvant phase. Patients provided an IRB-approved (Advarra-IRB Pro00041794) informed consent and were treated at Moffitt Cancer Center.

Results Ten patients (6 female, 4 male, 1 black, 9 white, 10 cutaneous primary including 1 acral), age 58–88, were treated. Five had Stage IIIB (4N1c, 1N2b), 3 IIIC (1N3b, 1N3c, 1N1c) and 2 IV (M1a). Treatment was well tolerated. Highest-grade treatment-related events to date were limited to one Gr3 hyponatremia possibly related to nivolumab. One patient is currently in the neoadjuvant phase. Among the nine patients who completed the neoadjuvant phase, median number of neoadjuvant cycles was 3; 2 patients received 2 cycles due to near complete clinical response. Preoperative response rate (RECIST, unconfirmed) was 7/9 (77.8%; 95%CI 40.0-97.2); 1PD, 1SD, 4CR, 3 PR. One patient with PR declined surgery. Among 8 patients who had surgery to date, 1 pathologic non-response (Surgery at 4 weeks after initiating treatment due to clinical progression), 1 pathologic major response (pMR; ≤10% viable tumor), 6 pathologic complete response (pCR). The overall pMR rate was 7/8 (87.5%; 95%CI 47.4–99.7), all with no disease recurrence to date, at a median follow up from the date of surgery of 7.08 months (range 0.2–17.5).

Transient on-treatment changes in systemic peripheral immune subsets were identified. At C2D1 (week 5), peripheral proliferating CD8+PD-1+ T cells were significantly increased. In addition, memory precursor effector cells (mPECs; CD8+KLRG1-CD127+) were transiently upregulated at same timepoint, while short-lived effector cells (SLECs; CD8+KLRG1+CD127-) were significantly reduced. These peripheral T cell changes coincided with increased intratumoral CD8+ TIL.

Conclusions Neoadjuvant IT TAVO-EP in combination with nivolumab exhibited promising clinical activity and a favorable safety profile. There was evidence of significantly enhanced immune activation supporting the proposed immune mechanisms. Analyses of additional biomaterials are underway.

618 DIETARY FIBER INTAKE IS ASSOCIATED WITH INCREASED TERTIARY LYMPHOID STRUCTURES IN DEDIFFERENTIATED LIPOSARCOMA FOLLOWING IMMUNE CHECKPOINT BLOCKADE

Raymond Traweek*, Russell Witt, Elise Nassif, Nadim Ajami, Aditya Mishra, Ashish Damania, Manoj Chelvanambi, Wei-Lien Wang, Alexander Lazar, Emily Keung, Keila Torres, Christopher Scally, Xiaotao Zhang, Carrie Daniel-MacDougall, Jennifer Wargo, Neeta Somaiah, Christina Roland. *MD Anderson Cancer Center, Houston, TX, United States*

Background Recent evidence suggests that dietary fiber intake is associated with improved clinical and pathologic response to anti-PD-1 therapy,[1] though this relationship is unclear in soft-tissue sarcoma. We evaluated the impact of dietary fiber intake on survival and the immune microenvironment in patients with surgically resectable dedifferentiated liposarcoma (DDLPS) and extremity/truncal undifferentiated pleomorphic sarcomas (UPS) treated with neoadjuvant immune checkpoint blockade (ICB) (NCT03307616).[2]

Methods Adult patients with treatment-naïve or locally recurrent resectable retroperitoneal DDLPS (n=17) or UPS (n=10) were randomized to receive either neoadjuvant nivolumab or nivolumab/ipilimumab, with UPS patients receiving concurrent radiation. Fecal and tumor samples were collected at baseline, after 1 cycle of ICB, and at surgery; dietary habits (NCI Dietary Screener Questionnaire [NCI-DSQ]) were collected at baseline. Fiber intake was derived from responses to the NCI-DSQ. Tumor infiltration by immune cells was assessed by multiplex immunofluorescence and presence of tertiary lymphoid structures (TLS) was assessed by immunohistochemistry of CD20 and CD21. Fecal microbiomes were profiled via metagenomic sequencing, MetaPhlAn 3 and differential abundance analysis was performed using Analysis of Compositions of Microbiomes with Bias Correction (ANCOM-BC).[3] Log-rank tests were used to compare survival curves. Wilcoxon rank sum tests were used to compare continuous variables between groups.

Results Median fiber intake was 16 g/day (IQR 13.6-18.4) and similar between the two histologic subtypes (p=0.27). Patients who consumed more (≥16 g/day) fiber had significantly improved overall survival when compared to patients who consumed less (p=0.025, Figure 1). Dietary fiber intake was significantly greater in DDLPS patients with a higher density of intratumoral cytotoxic T cells (CD3+CD8+/CD3+) at baseline (p=0.0088, Figure 2a). The presence of TLS at surgery was significantly associated with improved overall survival in DDLPS patients (p=0.031, Figure 2b), and fiber intake was significantly greater in patients with intratumoral TLS following ICB (p=0.0012, Figure 2c). Fiber intake was significantly higher in DDLPS patients who either gained or retained the TLS signature over their treatment course (p=0.0047). Multiple Firmicutes spp. were observed to be significantly associated with fiber intake and the presence of TLS at surgery (q<0.05) over the treatment duration.

Conclusions This study demonstrates that dietary fiber is associated with increased cytotoxic T cell infiltration and TLS formation in DDLPS treated with neoadjuvant ICB. Dietary fiber intake may represent a modifiable factor to improve response to ICB, and the stability of certain fecal microbial taxa may be clinically beneficial.

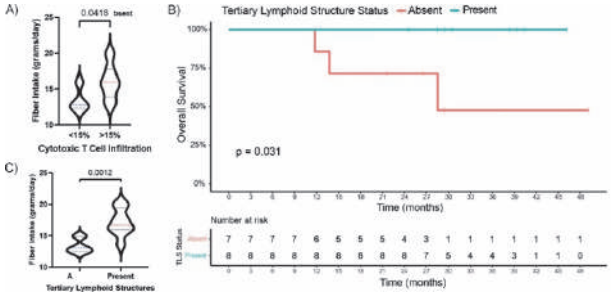
Abstract 618 Figure 1 Impact of dietary fiber on survival in resectable retroperitoneal dedifferentiated liposarcoma (DDLPS) and undifferentiated pleomorphic sarcomas (UPS). A) Kaplan-Meier curves of overall survival (OS) in DDLPS and UPS patients who had higher (=16g/day, n = 17) and lower (<16g/day, n = 8) fiber intake from date of first dose to death. B) Kaplan-Meier curves of OS in DDLPS patients who had higher (=16g/day, n = 8) and lower (<16g/day, n = 8) fiber intake from date of first dose to death. C) Kaplan-Meier curves of OS in UPS patients who had higher (=16g/day, n =5) and lower (<16g/day, n = 4) fiber intake from date of first dose to death
Abbreviations: OS, overall survival; DDLPS, dedifferentiated liposarcoma; UPS, undifferentiated pleomorphic sarcoma



Abstract 618 Figure 2 Association of fiber with the immune microenvironment in retroperitoneal dedifferentiated liposarcoma. A) Fiber intake (g/day) of samples with higher (>15%) density of intratumoral cytotoxic T cells (n = 12) and lower (<15%) density of intratumoral cytotoxic T cells (n = 3) at baseline as assessed by multiplex immunofluorescence. B) Kaplan-Meier curves of OS in DDLPS patients who had TLS (n = 8) and those who did not have TLS (n = 7) at surgery from date of first dose to death. C) Fiber intake (g/day) of samples with TLS (n = 8) and those without TLS (n = 7) at surgery
Abbreviations: OS, overall survival; DDLPS, dedifferentiated liposarcoma; TLS, tertiary lymphoid structure.

619 TEBENTAFUSP INDUCED T AND B CELL EPITOPE SPREAD IN PATIENTS WITH ADVANCED MELANOMA

Alexander Greenshields Watson, Camille Britton-Rivet, Sarah Stanhope, Laura Collins, Koustubh Ranade, Adel Benlahrech*. *Immunocore Ltd, Abingdon, UK*

Background ImmTAC® molecules are TCR-CD3 bispecific fusion proteins that can redirect and activate polyclonal T cells to kill tumors. Tebentafusp, which targets gp100 (gp100 × CD3), is the first ImmTAC to demonstrate overall survival benefit and is approved for the treatment of metastatic uveal melanoma[1] in HLA-A*02:01+ patients. We explored whether tebentafusp can induce new T and B cell responses to tumor antigens other than gp100, a phenomenon termed epitope spread.

Methods TCRseq was performed on pre- and post-treatment PBMC samples from tebentafusp-treated patients with advanced malignant melanoma (N=10 from NCT01211262). T cell repertoire breadth was assessed using Simpson clonality index (SCI). A proteome array with 22,976 human proteins was used to assess changes in serum antibody profiles on tebentafusp treatment (N=29 from NCT02570308). Immunohistochemistry (N=36) and RNAseq (N=35) were used to analyze paired baseline and on-treatment tumor biopsies.

Results Substantial T cell clonal expansion and diversification were observed upon treatment with tebentafusp. A median of 56 (range 11-216) T cell clones per patient were expanded after 5-8 doses of tebentafusp, of which 25 (range 0-46) were new clones undetected at baseline. Patients with greater than 1 year overall survival (OS, N = 4) exhibited a focused T cell repertoire at baseline (median SCI=0.08) compared to patients with shorter than 6 months OS (N = 6, median SCI=0.02, p=0.009), which increased in diversity on tebentafusp in patients with long OS but not short OS (median 44% on-treatment decrease in SCI from baseline in patients with long OS compared to a median of 15% on-treatment increase in SCI in patients with short OS, p=0.038).

B cell responses were also induced upon treatment with tebentafusp. B cells were recruited to the tumor microenvironment after 3 doses of tebentafusp, with evidence of new tertiary lymphoid structures. On-treatment B cell levels in biopsies correlated with better OS (hazard ratio HR=0.3, p=0.016) and tumor shrinkage (odds ratio OR=0.06, p=0.007). Serum IgG repertoire profiling showed a median of 42 auto-antibody specificities (range 16-114) per patient at baseline, which increased to 106 (range 32-261) after 4 doses of tebentafusp. Tebentafusp induced antibodies against multiple proteins including p53, the uveal melanoma driver CYSLTR2 and numerous cancer testis antigens. Antibodies were also induced against novel somatic mutants in 2 patients.

Conclusions By inducing T cell repertoire expansion and diversification and antibodies against multiple tumor antigens, tebentafusp is the first TCR-CD3 bispecific to demonstrate T and B cell epitope spread.

Trial Registration A Study of the Intra-Patient Escalation Dosing Regimen With IMCgp100 in Patients With Advanced Uveal Melanoma

ClinicalTrials.gov Identifier: NCT02570308

Study to Assess the Tolerability of a Bispecific Targeted Biologic IMCgp100 in Malignant Melanoma

IMCgp100-01 study: NCT01211262

Ethics Approval The study was approved by each site's Institutional Review Board. An independent data monitoring committee (IDMC) was also established to provide oversight of safety and efficacy considerations and give advice and recommendations regarding steps to ensure both patient safety and the ethical integrity of the study.

Consent Written informed consent was provided by all study participants.

620 MOLECULAR FEATURES IN TUMORS AT TIME OF PROGRESSION ON TEBENTAFUSP ASSOCIATED WITH OVERALL SURVIVAL (OS)

Laura Collins, Alexander Greenshields Watson, Shaad Abdullah, Sarah Stanhope, Koustubh Ranade, Emma Leach, Emma Leach*. *Immunocore Ltd, Abingdon, UK*

Background Tebentafusp, a TCR bispecific (gp100xCD3) fusion protein (ImmTAC) that targets gp100 in the context of HLA-A*02:01 and activates T cells to kill tumor cells, was approved for the treatment of unresectable or metastatic uveal melanoma (mUM), with many patients demonstrating OS benefit despite radiographic progression.[1,2] We explored molecular features of the tumor and its micro-environment at clinically confirmed progression, and their association with OS on tebentafusp.

Methods NCT02570308 was conducted in HLA-A*02:01 2L+ patients with advanced mUM. Tumor biopsies (N=14) collected soon after progression on tebentafusp were analyzed by immunohistochemistry (IHC) and RNAseq. Presence of HLA-A and B2M on tumor cells was analyzed by IHC with expression at any intensity quantified. Presence of necrosis was determined by hematoxylin and eosin staining, and CD163+ melanophages by IHC. K-M analysis landmarked to 90 days from initiation of treatment was used for OS.

Results Median OS in the 14 pts with biopsies collected at the time of progression was 22 months, and patients were treated with tebentafusp for 1 day-22 months beyond progression.

Expression of PMEL (gp100) was high at the time of progression and not associated with OS. The degree of necrosis or presence of melanophages in the tumor microenvironment was also not associated with OS.

RNAseq analysis revealed that higher levels of the antigen presentation machinery, presence of PRDM1 expressing effector CD3 T cells, expression of genes required in the necroptosis and apoptosis pathways, and the IFN-inducible transcription factor IRF1 were associated with long OS. In contrast, higher expression of the cell cycle gene CDC45 and the tumor metabolism gene HPDL were associated with short OS. (table 1).

Membrane bound HLA-A was strongly correlated with B2M expression on tumor cells (R-squared = 0.68, p = 2.8e-9), consistent with the requirement of B2M for stability of cell surface HLA. Lack of membrane-bound HLA-A and B2M was associated with short OS, consistent with the requirement of cell surface HLA for antigen presentation.

Conclusions Tebentafusp has demonstrated OS benefit even in patients with progressive disease. Based on tumor biopsies at time of progression, long OS was associated with higher levels of antigen presentation machinery, expression of apoptosis and necroptosis pathways, presence of effector memory T cells and activation of the interferon pathway. These observations provide mechanistic insight into how some patients can derive benefit from tebentafusp despite radiographic progression.

Trial Registration NCT02570308

Clinical Trials In Progress

621 ATEZOLIZUMAB AND BEVACIZUMAB PRE-LIVER TRANSPLANTATION FOR PATIENTS WITH HEPATOCELLULAR CARCINOMA BEYOND MILAN CRITERIA: TRIAL IN PROGRESS

[1]Maen Abdelrahim*, [1]Abdullah Esmail, [2]Ashish Saharia, [3]Gonzalo Sapisochin, [3]Grainne Kane, [2]Sudha Kodali, [2]David Victor, [1]Kirk Heyne, [2]Rafik Ghobrial. *[1]Houston Methodist Neal Cancer Center, Houston, TX, USA; [2]JC Walter Jr Center for Transplantation, Houston, TX, USA; [3]University Health Network, Toronto, Canada*

Background Hepatocellular carcinoma (HCC) represents the second most common cause of cancer-related death and accounts for over 80% of primary liver cancers worldwide. However, in 90% of patients, HCC occurs in the setting of cirrhosis where optimal management remains liver transplantation (LT) with 5-year survival rates of approximately 80%. Therapeutic blockade of PD-L1 binding by atezolizumab has been shown to enhance the magnitude and quality of tumor-specific T cell responses, resulting in improved anti-tumor activity. Bevacizumab is a recombinant humanized monoclonal IgG1 antibody that binds to and inhibits the biologic activity of human vascular endothelial growth factor (VEGF) in vitro and in vivo assay systems. We hypothesize that atezolizumab and bevacizumab can appropriately bridge patients with HCC beyond MC to transplantation and not increase the risk of 1-year post-transplant rejection. To test this hypothesis, patients with HCC beyond Milan Criteria (in brief, 5 – 10 cm), who are transplant-eligible will be treated with 6 months of neoadjuvant/downstaging atezolizumab plus bevacizumab while receiving standard of care transarterial chemoembolization (TACE). The proposed clinical trial will evaluate the feasibility of using a combination of the chemotherapeutic interventions atezolizumab and bevacizumab in a group of patients with HCC who have tumors beyond the Milan Criteria in order to bridge them to liver transplantation.

Methods This is a Phase II multi-site study, a site in the US and a site in Canada. Combined enrollment from these sites will be up to 30 patients. Atezolizumab will be administered as a 1200mg intravenous infusion followed by bevacizumab 15mg/kg on the same day. The regimen will be administered every three weeks for up to 8 cycles (or 6 months) in pre-Liver Transplantation patients with HCC. The primary objective of this study is to assess the feasibility and safety of transplantation post atezolizumab/bevacizumab for patients with HCC beyond Milan criteria. The secondary endpoints include ORR of participants who enroll in the study, DFS at 1-year in participants who undergo a liver transplant, defined as time to disease recurrence or death, whichever is earlier, from time of liver transplant, and OS in patients from the time of study enrollment to death from any cause as well as from the time of transplant to death from any cause. An interim analysis will be performed is to assess the feasibility and safety after 20 patients become evaluable. The study is open with 30 patients enrolled at the time of submission. Clinical trial information: NCT05185505.

622 A PHASE 1 STUDY EXPLORING THE SAFETY AND TOLERABILITY OF THE SMALL-MOLECULE PD-L1 INHIBITOR, INCB099318, IN PATIENTS WITH SELECT ADVANCED SOLID TUMORS

[1]David Pinato*, [2]Ruth Plummer, [3]Martin Gutierrez, [4]Jeffrey Yachnin, [5]Aglaia Schiza, [6]Martin Hojgaard, [7]Knut Smeland, [8]William Edenfield, [9]Hans Prenen, [10]Lars Ny, [11]Alan Anthoney, [12]Nuria Kotecki, [13]Stefan Symeonides, [14]Louis Viviers, [14]Jeannie Daniel, [14]Jennifer Pulini, [15]Udai Banerji. *[1]Imperial College Healthcare NHS Trust, London, UK; [2]Newcastle Hospital NHS Foundation Trust, Newcastle-upon-Tyne, UK; [3]Hackensack University Medical Center, Hackensack, NJ, USA; [4]Karolinska University Hospital, Solna, Sweden; [5]Uppsala Universitet, Uppsala, Sweden; [6]Rigshopitalet Copenhagen University Hosp, Copenhagen, Denmark; [7]Oslo University Hospital, Oslo, Norway; [8]Prisma Health Cancer Institute, Greenville, SC, USA; [9]University Hospital Antwerp, Antwerp, Belgium; [10]Sahlgrenska University Hospital, Gothenburg, Sweden; [11]St. James University Hospital, Leeds, UK; [12]Intitut Jules Bordet, Brussels, Belgium; [13]University of Edinburgh, Edinburgh, UK; [14]Incyte Corporation, Wilmington, DE, USA; [15]The Royal Marsden Hospital NHS Trust, London, UK*

Background INCB099318 is an orally administered small-molecule inhibitor of programmed cell death ligand 1 (PD-L1). This is an ongoing phase 1, open-label, multicenter study.

Methods Eligible patients are aged ≥18 years with advanced solid tumors and Eastern Cooperative Oncology Group performance status of 0–1. Patients had disease progression after treatment with available therapies or were ineligible for or without access to standard treatment. The study is conducted in 2 parts: in part 1, a Bayesian optimal interval design is being used to identify the maximum tolerated dose (MTD) of INCB099318. In part 2, selected doses will be expanded for patients who are immunotherapy-naive with various tumor types. The primary endpoints are safety and tolerability measured by monitoring frequency and severity of adverse events (AEs) and to determine a pharmacologically active dose and/or MTD. Antitumor activity is assessed using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1.

Results As of April 22, 2022, 32 patients received INCB099318 in part 1 in 6 dose-escalation cohorts ranging from 100 mg twice daily (bid) to 600 mg bid; median age was 60 years (range, 34–78), 56.3% were women, 81.3% were white, 56.3% had ≥2 lines of previous therapy, and 15.6% had prior exposure to immunotherapy. Eleven patients (34.4%) discontinued treatment, 10 of whom discontinued for disease progression. Treatment-emergent AEs (TEAEs) occurring in >20% of patients were fatigue and nausea. Seven serious TEAEs (SAEs) occurred in 5 patients (15.6%) and consisted of abdominal pain, cerebrovascular accident, migraine, neck pain, pleural infection, pneumonia, and sepsis (n=1 each). Three grade ≥3 treatment-related TEAEs occurred in one patient (abdominal pain, fatigue, and insomnia). No dose-limiting toxicities occurred. Several responses have been observed, and updated results will be presented.

Conclusions INCB099318 was generally well tolerated at total daily doses up to 600 mg bid. Unlike with the first-generation oral PD-L1 inhibitor, INCB086550, no dose-limiting immune-mediated peripheral neuropathy has occurred with INCB099318 to date. Preliminary safety warrants continued investigation and further development. Dose escalation is ongoing, and dose expansion is planned to further characterize the safety, tolerability, pharmacokinetics, pharmacodynamics, and antitumor activity of INCB099318.

623 **TRIAL IN PROGRESS: A PHASE 1 FIRST-IN-HUMAN STUDY OF HMBD-002, AN IGG4 MONOCLONAL ANTIBODY TARGETING VISTA, AS A MONOTHERAPY AND COMBINED WITH PEMBROLIZUMAB IN PATIENTS WITH ADVANCED SOLID MALIGNANCIES**

[1]Tom Haber*, [1]Jessica Symons, [1]Bhushan Dharmadhikari, [1]Thomas Müller, [1]Dipti Thakkar, [2]Jordi Ahnert Rodon, [3]Joshua Gruber, [4]Melinda Telli, [5]Monica Mita, [5]Alain Mita, [6]Meera Patel, [6]Daniel Wang, [7]Joseph Kim, [2]Shalini Yadav, [2]Padmanee Sharma, [1]Leah DiMascio, [1]Eric Rowinsky, [1]Piers Ingram, [1]Jerome Boyd-Kirkup. *[1]Hummingbird Bioscience, Houston, TX, USA; [2]The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]UT Southwestern Medical Center, Dallas, TX, USA; [4]Stanford University School of Medicine, Stanford, CA, USA; [5]Cedars-Sinai Medical Center, Los Angeles, CA, USA; [6]Baylor College of Medicine, Houston, TX, USA; [7]Yale School of Medicine, New Haven, CT, USA*

Background V-domain Ig Suppressor of T-cell Activation (VISTA) is an immune-checkpoint regulator predominantly expressed on myeloid cells. The presence of VISTA has been shown to promote tumorigenesis and induce an immunosuppressive environment within the tumor microenvironment (TME). Moreover, VISTA's upregulation has been associated with acquired resistance to anti-CTLA-4 and anti-PD-1/PD-L1 therapies. Therefore, VISTA represents a promising therapeutic target. HMBD-002 has been designed as a non-depleting, IgG4 monoclonal-antibody with high affinity and specificity to VISTA across species (human, cynomolgus monkey, and rodent). In preclinical studies, HMBD-002 significantly inhibited tumor growth, both as a monotherapy and in combination with pembrolizumab, while decreasing infiltration of suppressive-myeloid cells within the TME and thus increasing T-cell activity. In addition to VISTA expression on pro-inflammatory immune cells, examination of VISTA expression across cancer types has revealed that several malignancies, particularly triple-negative breast cancer (TNBC) and non-small cell lung cancer (NSCLC), express high levels of VISTA, thereby providing a rationale for exploring these indications in early clinical studies.

Methods This phase 1/2, open-label, multi-center, first-in-human trial is evaluating HMBD-002 as a monotherapy and in combination with pembrolizumab in patients with advanced solid tumors and is conducted in two parts. The dose-escalation cohorts (Part 1), follow a standard 3 + 3 study design, with adaptive dose-escalation increments, and weekly dosing for HMBD-002, to identify the maximum tolerated (or tested) dose (MTD) of HMBD-002 as a monotherapy, and in combination with pembrolizumab (pembrolizumab to be dosed Q3W), and to recommend doses for subsequent disease-directed studies (i.e. RP2D) as well as to determine safety, PK, and ADA. In the dose-expansion stage at the RP2D (Part 2), the antitumor activity of HMBD-002 alone or combined with pembrolizumab will be evaluated in patients with TNBC and NSCLC. Combination therapy will also be evaluated in additional VISTA-expressing malignancies. Biomarker analyses are exploratory endpoints in this clinical study and are assessed for treatment-induced immunological changes both systemically and within the TME. Longitudinal blood samples and pre and on-treatment tumor tissue samples will be assessed using CyTOF, multiplex-cytokine analysis, VISTA & PD-L1 IHC, and gene-expression profiling. Identification of immunological parameters associated with HMBD-002 monotherapy and combination therapy may provide insight into markers associated with the biological activity of HMBD-002. Exploratory correlative analyses with clinical outcomes may lead to the identification of predictive biomarkers of clinical benefit with HMBD-002.

624 A PHASE I/II STUDY EVALUATING THE SAFETY AND EFFICACY OF A NOVEL LONG-ACTING INTERLEUKIN-7, NT-I7, FOR PATIENTS WITH NEWLY DIAGNOSED HIGH-GRADE GLIOMAS AFTER CHEMORADIOTHERAPY

[1]Omar Butt*, [1]Yu Tao, [1]Jiayi Huang, [1]Jingquin Luo, [1]Alice Zhou, [1]Christopher Abraham, [1]Ruth Katumba, [2]Se Hwan Yang, [2]Byung Lee, [1]Michael Rettig, [1]George Ansstas, [1]Tanner Johanns, [1]Milan Chheda, [3]Jian Campian. *[1]Washington University, Saint Louis, MO, USA; [2]NeoImmuneTech, Rockville, MD, USA; [3]Mayo Clinic, Rochester, MN, USA*

Background Standard of care after surgery for high-grade gliomas (HGG), including glioblastoma (GBM) and anaplastic astrocytoma, is radiation therapy (RT) and temozolomide (TMZ). Unfortunately, lymphopenia commonly occurs after treatment, leading to decreased survival.[1,2] Concentrations of interleukin-7 (IL-7), a T-cell homeostatic cytokine, are inappropriately low in patients with HGG.[3] Our previous work, using murine glioma models, demonstrated that NT-I7 (efineptakin alfa), a long-acting recombinant human IL-7, corrects lymphopenia and improves survival.[4] Here we examine survival, safety, and change in absolute lymphocyte counts (ALCs) following administration of NT-I7 after concurrent RT/TMZ in patients with newly diagnosed HGG.

Methods Key inclusion criteria for this Phase I/II study included ALC $\geq$ 600 cells/mm^3. NT-I7 was administered intramuscularly within 2 weeks after completion of concurrent RT/TMZ and then every 12 weeks for up to 4 doses. The primary objective of the Phase I portion was to determine safety and the maximum tolerated dose (MTD) of NT-I7 using a 2-dose accelerated phase, followed by a 3+3 design. The Phase II portion (ongoing) is a double-blind, randomized study of 20 HGG patients (10 per arm) to compare ALC changes after administration of either NT-I7 at the MTD or placebo. Exploratory objectives include immune profiling and survival analysis.

Results Phase I completed accrual with results as follows: 19 patients enrolled (17 GBM, median age 58.0 years [25-78], median baseline ALC 1000 cells/mm^3 [400-2,000], median baseline dexamethasone use 0 mg/day [0-12], cut-off date 7/15/22). Twelve patients (63%) were MGMT promotor unmethylated, as unmethylation is associated with worse survival. The median number of NT-I7 doses administered was 2 [2-4]. NT-I7 was well-tolerated with grade 1/2 injection site reactions (42%) the most common treatment-related adverse event (TRAE). The MTD was 720 mcg/kg due to two grade 3 dose-limiting toxicities at 960 mcg/kg (elevated alanine aminotransferase and back pain). Dose-dependent increases in ALC were observed at 4 weeks (1.3-4.1 times of baseline level), persisting up to 12 weeks. Median progression-free survival (mPFS) was 19.1 months (95%CI: 15.1-NA) and median overall survival (mOS) was 22 months (95%CI: 20.7-NA) in methylated GBM. For the harder-to-treat unmethylated GBM patients, mPFS was 11.2 months (95%CI: 5.4-22.4) and mOS was 16 months (95%CI: 12.3-24.3). Immune profiling of peripheral blood is ongoing.

Conclusions NT-I7 is well tolerated and is associated with an increase in ALC in HGG patients after chemoradiotherapy. Phase II accrual and immune profiling are ongoing.

625 **A PHASE 1 SINGLE ASCENDING DOSE STUDY EVALUATING THE SAFETY, TOLERABILITY, AND PHARMACODYNAMIC EFFECTS OF MDK-703, AN IL-7 MIMETIC WITH EXTENDED HALF-LIFE**

[1]Richard Friend, [2]Bryan Baxter, [2]Inkyung Angie Park, [2]Steven Cwirla, [2]Ronald Barrett*.
[1]Nucleus Network Pty Ltd, Herston, QLD, Australia; *[2]Medikine, Menlo Park, CA, USA*

Background There has been historical interest in applying IL-7 as an immunotherapeutic in oncology. Efforts to develop derivatives of IL-7 have been hampered by short half-life and immunogenicity, which has the potential to neutralize native IL-7. MDK-703 is an IL-7 mimetic peptide fused to an immunoglobulin Fc-domain. MDK-703 behaves like IL-7 in human immune cells *in vitro* and in humanized mice and non-human primates studies. In addition to increasing the total number of CD8+ and CD4+ T cells, MDK-703 increases the number of memory T cells, particularly the T stem cell memory (Tscm) subpopulation. In addition, MDK-703 had a negligible-to-no impact on the expansion of CD4+ T regulatory and natural killer (NK) cells. Because the IL-7 mimetic peptide in MDK-703 is structurally unrelated to IL-7, it is unlikely to generate anti-drug antibodies (ADAs) that neutralize native IL-7.

Methods This Phase 1, randomized, placebo-controlled, single-blind, single ascending dose study evaluates the safety, tolerability, pharmacokinetics, and pharmacodynamics of MDK-703 in healthy adult volunteers. Three sequential cohorts of 10 subjects (8 MDK-703; 2 Placebo) will be studied. The primary outcome measure is the assessment of adverse events after a single injection of MDK-703 over 8 weeks. Pharmacodynamic measures include assessment of blood cells by complete blood counts, including lymphocytes, and immunophenotyping of T-cells, including memory cell subpopulations. Blood cytokine/chemokines and T-cell receptor repertoire will also be measured, along with the presence of ADAs and NAbs against MDK-703 and IL-7.

Results As of July 28, 2022, the first cohort of subjects has been dosed. It is expected that preliminary data for three ascending dose cohorts will be available in November 2022 (Clinical trial information: NCT05366634)

626 **TRIAL IN PROGRESS: AN INTRAVENOUSLY ADMINISTERED SECOND-GENERATION STING AGONIST, BI 1703880 WITH A NOVEL LEAD-IN DESIGN IN COMBINATION WITH EZABENLIMAB**

[1]Kevin Harrington*, [2]Elizabeth Dowling, [3]Robert Latek, [3]Michael Schmohl, [4]Patricia Lorusso. *[1]The Royal Marsden NHS Foundation Trust, Sutton, UK; [2]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT, USA; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]Yale Cancer Center, New Haven, CT, USA*

Background The prognosis for cancer patients diagnosed with advanced-stage disease or who have experienced disease progression is poor. STING (stimulator of interferon genes) is an intracellular nucleic acid sensor, which has a key role in innate immunity and detects the presence of cytosolic cyclic dinucleotides indicative of pathogen invasion and cellular disruption. BI 1703880 is a synthetic second-generation STING agonist, which induces a type 1 interferon response and transient secretion of interferon β and proinflammatory cytokines. Interferon receptor signaling upregulates PD-L1 expression, which reduces T-cell functionality and facilitates immune evasion through interaction with PD-1, suggesting that the combination of BI 1703880 with an anti-PD-1 antibody, such as ezabenlimab, may synergize to overcome tumor resistance.

Methods The 1480-0001 study is a first-in-human Phase Ia, open-label, dose-escalation trial of BI 1703880 monotherapy and in combination with ezabenlimab. In this innovative trial design, all patients will receive intravenous BI 1703880 as monotherapy followed by BI 1703880 in combination with ezabenlimab. The primary objective is to characterize the dose–toxicity curve for escalating doses of BI 1703880 in combination with ezabenlimab. Secondary objectives are to determine the safety profile of escalating doses of BI 1703880 (dose-limiting toxicities), to characterize its pharmacokinetics and pharmacodynamics, and to assess efficacy.

The lead-in dose escalation of BI 1703880 will be tested through six consecutive cohorts (figure 1) guided by a Bayesian 5-parameter logistic regression model with fitted overdose control. This will determine the maximum tolerated dose estimate. BI 1703880 will be administered intravenously for up to 18 cycles, or unacceptable toxicity or disease progression, at increasing dose levels (figure 2). Patients can continue to receive treatment if there is clinical benefit. Ezabenlimab 240 mg will be administered intravenously from Cycle 2 (figure 2). Approximately 36 patients will be enrolled.

Key eligibility criteria include an advanced, unresectable and/or metastatic malignant solid tumor, Eastern Cooperative Oncology Group performance score of 0–1, exhausted established treatment options and at least one lesion amenable to pre- and on-treatment biopsy.

Peripheral and tumor biomarkers will be analyzed to assess the BI 1703880 mode of action. Peripheral cytokine analysis will supplement clinical safety profiles for informing dose escalation decisions, since cytokine release syndrome is a potential risk for STING agonists.

627 ORAL ADMINISTRATION OF MRX0518 IN TREATMENT-NAÏVE CANCER PATIENTS IS ASSOCIATED WITH COMPOSITIONAL TAXONOMIC AND METABOLOMIC CHANGES INDICATIVE OF ANTI-TUMORIGENIC EFFICACY

[1]Mark Lythgoe*, [1]Benjamin Mullish, [2]Adam Frampton, [3]Paola Dama, [1]Emily Pickford, [1]Laura Tookman, [1]Paula Cunnea, [1]Christina Fotopoulou, [4]Ian Jeffery, [4]Gayle Fyvie, [4]Alexander Stevenson, [1]Jonathan Krell. *[1]Imperial College London, London, UK; [2]University of Surrey, Guildford, UK; [3]University of Sussex, Brighton, UK; [4]4D Pharma, Leeds, UK*

Background Live biotherapeutic products (LBPs) are promising novel anti-cancer therapies. Their mechanism of action has not yet been fully elucidated but is thought to be partly due to compositional changes in the gut microbiome and metabolomic profile. There is particular interest in the anti-cancer efficacy of microbial fermentation products, including short chain fatty acids (SCFAs), including butyrate and propionate.

MRx0518 is a novel, gut microbiome-derived LBP, consisting of a single strain of *Enterococcus gallinarum*, which has demonstrated potent anti-tumorigenic efficacy preclinically.[1] We have previously shown MRx0518 therapy is associated with significant anti-tumorigenic genomic, cytokine and immune modulatory changes in treatment-naïve cancer patients.[2,3] Here, we report compositional taxonomic and metabolomic changes following MRx0518 treatment.

Methods NCT03934827 is a Phase 1B single-centre study in patients with histologically confirmed cancer undergoing surgical resection. Patients receive 1 capsule of MRx0518 ($1x10^{10}$-$1x10^{11}$CFU) BID from inclusion until surgery (maximum 28 days therapy). Exploratory outcomes included microbiome analysis of longitudinal faecal samples, with 16S rRNA gene sequencing, and investigation of metabolomic changes in SCFAs in plasma samples, by liquid chromatography-mass spectrometry.

Results 17 patients received 7-28 days of MRx0518 therapy. Significantly ($P=0.0001$) increased levels of MRx0518 16S rRNA levels were detected in all faecal samples at time of therapy cessation (Visit 6). 30-days after treatment stoppage (Visit 8), levels of MRx0518 16S rRNA were undetectable. MRx0518 therapy was associated with a small but significant increase in beta-diversity. Post-therapy samples showed significant microbiota changes, with a visual trend (non-statistical) back towards baseline profile at 6-month follow-up (Visit 9). Significant ($P<0.05$) taxa changes in *Bacteroides* at Visit 6, and Lachnospiraceae, Clostridium sensu, Enterocloster, *Ruminococcacea,* and*Anaerobutyricum* at Visit 8, were identified.

Analysis of plasma metabolomics on paired pre- and post-treatment samples, at 30-days, demonstrated a significant reduction ($P<0.05$) in levels of acetic acid, with positive trends (non-significant) identified in 2-methyl butyric acid, butyrate and propionate. Sub-analysis of subjects ($n=11$) who received MRx0518 for >15 days showed significant ($P<0.05$) post-treatment increases in 2-methyl butyrate, butyrate, propionate and valerate, with a concordant significant reduction in acetic acid levels.

Conclusions MRx0518 therapy is associated with significant compositional taxonomic changes and alterations in SCFA, indicative of anti-cancer efficacy. This effect is more pronounced in patients who receive treatment for longer periods. Changes in SCFAs, such as butyrate and propionate, may contribute to the anti-cancer efficacy of MRx0518. Further investigation is required to link post-treatment metabolomic changes to taxonomic changes in the gut microbiome.

628 TRIAL IN PROGRESS: PHASE I DOSE-ESCALATION STUDY OF VSV-GP (BI 1831169) MONOTHERAPY AND WITH EZABENLIMAB (BI 754091) IN PATIENTS WITH LOCALLY ADVANCED OR METASTATIC SOLID TUMORS

[1]Mercedes Porosnicu*, [2]Anne-Marie Quinson, [3]Abi MacKay, [4]Stephan Luecke, [5]Ulrich M Lauer. *[1]Wake Forest School of Medicine, Winston Salem, NC, USA; [2]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT, USA; [3]Boehringer Ingelheim Ltd, Bracknell, UK; [4]Boehringer Ingelheim Pharma GmbH and Co.KG, Biberach, Germany; [5]University Hospital Tübingen, Tübingen, Germany*

Background Patients with locally advanced or metastatic cancer have poor prognosis despite treatment advancements. VSV-GP (BI 1831169) is a chimeric vesicular stomatitis virus (VSV) with its neurotropic glycoprotein (G) replaced by the non-neurotropic glycoprotein (GP) of the lymphocytic choriomeningitis virus. This live, recombinant oncolytic virus has demonstrated preclinical efficacy as a viral-based immunotherapy due to its interferon-dependent tumor specificity and stimulation of anti-tumor immune activity. Co-administration of ezabenlimab (BI 754091), a PD-1 targeting checkpoint inhibitor, may enhance antitumor efficacy. The potential synergism of VSV-GP and ezabenlimab will be explored in this first-in-human trial.

Methods This Phase I, open-label, dose-escalation trial will assess the safety, tolerability and early efficacy of VSV-GP given intratumorally (IT), intravenously (IV) or both, as a monotherapy (Part 1) and in combination with ezabenlimab (Part 2) in patients with locally advanced, metastatic or relapsed/refractory solid tumors who previously received or are not candidates for available standard treatment. Key objectives are to determine the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D).

Part 1 is a dose-escalation and expansion study of VSV-GP monotherapy administered in four 21-day cycles starting at 5 x 10^7 median tissue culture infectious dose ($TCID_{50}$) in Arm A (IT) and at the next tolerated dose level in Arm B (IV) and Arm C (IT + IV). Part 2 is a dose-escalation study of VSV-GP in combination with ezabenlimab. The starting dose of VSV-GP will be one dose level less than the monotherapy RP2D in the corresponding Part 1 arm (IT [Arm D], IV [Arm E], IT + IV [Arm F]) (figure 1). Dose finding will be guided by the Bayesian Optimal Interval design (BOIN).

Primary endpoints include the number of patients experiencing dose-limiting toxicities (DLTs [Part 1/2]) and objective response according to Intratumoral RECIST (itRECIST; Part 1). Secondary endpoints are safety-based (on-treatment DLTs and adverse events). Patients are being recruited. Updates will be provided at the time of presentation.[1]

629 NEOADJUVANT NIVOLUMAB COMBINED WITH CCR2/5 INHIBITOR OR ANTI-IL-8 ANTIBODY IN NON-SMALL CELL LUNG CANCER AND HEPATOCELLULAR CARCINOMA

[1]Nicholas Venturini*, [1]Thomas Marron, [2]Maria Casanova-Acebes, [1]John Mandeli, [1]Deborah Doroshow, [1]Natalie Lucas, [1]Kathy Wu, [1]Olivia Hapanowicz, [1]Paula King, [1]Pauline Hamon, [1]Jessica Le Berichel, [1]Diane Del Valle, [1]Clotilde Hennequin, [1]Seunghee Kim-Schulze, [1]Sacha Gnjatic, [1]Miriam Merad, [1]Zhen Zhao, [1]Stephen Ward, [1]Maria Isabel Fiel, [1]Mary Beasley, [1]Edward Kim, [1]Kirema Garcia-Reyes, [1]Udit Chaddha, [1]Timothy Harkin, [1]David Yankelevitz, [1]Ganesh Gunasekaran, [1]Parissa Tabrizian, [1]Myron Schwartz, [1]Andrew Kaufman, [1]Daniel Nicastri, [1]Andrew Wolf, [1]Raja Flores. *[1]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [2]Centro Nacional de Investigaciones Oncológicas, Madrid, Spain*

Background Immune checkpoint blockade (ICB) has revolutionized cancer treatment; however, most patients fail to achieve the full clinical benefit of ICB. Although anti-PD-1 agents are FDA-approved for non-small cell lung cancer (NSCLC) and hepatocellular carcinoma (HCC), only a minority of patients respond clinically.[1,2] This limited response is likely due, in part, to immunosuppressive factors within the tumor microenvironment (TME). Myeloid cells, specifically monocyte-derived macrophages (mo-Macs) and immature granulocytes (iPMNs), make up the majority of leukocytes in the TME and suppress anti-tumor immunity; pre-clinical work has revealed that tumor-derived CCR2 ligands and interleukin-8 (IL-8) play a key role in recruiting mo-Macs and iPMNs, respectively, to the TME.[3-7] Disrupting these signaling pathways appears to potentiate the role of PD-1 blockade in mouse models, although only modest clinical benefit has been demonstrated to date in metastatic cancer models. In this "window-of-opportunity" trial, patients will receive neoadjuvant nivolumab monotherapy or neoadjuvant nivolumab in conjunction with a CCR2/5 inhibitor or an anti-IL8 antibody prior to surgical resection, providing a unique opportunity to elaborate the specific effects of these agents on the TME and to identify factors that may allow clinicians to better predict response in the future.

Methods This phase IIa multi-cohort, two-stage trial was designed to assess the clinical efficacy of BMS-813160 (CCR2/5 inhibitor) and BMS-986253 (anti-IL8 antibody) in patients with resectable NSCLC and HCC. The trial contains 2 cohorts (NSCLC and HCC) consisting of 5 arms (figure 1); arms A and B will enroll patients with NSCLC and arms C, D, and E will enroll patients with HCC. Patients will be treated with neoadjuvant nivolumab either alone (arm C) or in combination with BMS-813160 (arms A and D) or BMS-986253 (arms B and E). The patients will then undergo surgical resection, followed by standard-of-care adjuvant therapy in the NSCLC cohort or adjuvant nivolumab therapy in the HCC cohort. The primary endpoint for the NSCLC cohort is major pathologic response, defined as ≤10% viable tumor at time of surgery. The primary endpoint for the HCC cohort is significant tumor necrosis, defined as >70% tumor necrosis at time of surgery. The secondary endpoints are time to surgery, safety and tolerability, radiographic response, progression-free survival, and overall survival. Tissue, blood, and stool will be collected prior to treatment and at the time of surgery. Deep immune monitoring will be performed using multiplex and single-cell analysis platforms to define the immunodynamic effects of the therapies.

631 **PHASE I DOSE ESCALATION STUDY IN PATIENTS WITH ADVANCED SOLID TUMORS WITH ANV419, A NOVEL FUSION PROTEIN SELECTIVE FOR IL-2Rβ/γ**

[1]Christoph Bucher, [2]Guzman Alonso, [3]Juanita Lopez, [4]Emiliano Calvo, [5]Markus Joerger, [3]Vicky Sanchez Perez, [4]Elena Corral, [1]Daniela Di Blasi*, [1]Kirsten Richter, [1]Christoph Huber, [1]Julie Mouton, [1]Silvio Costanzo, [1]Sangeeta Jethwa, [2]Elena Gerralda, [6]Heinz Läubli. *[1]Anaveon AG, Basel, Switzerland; [2]Vall d'Hebron, Barcelona, Spain; [3]Royal Marsden, London, UK; [4]START Madrid-CIOCC, Madrid, Spain; [5]Kantonsspital St. Gallen, St. Gallen, Switzerland; [6]University Hospital, Basel, Switzerland*

Background ANV419 is a fusion protein of an anti-IL-2 antibody and human-IL-2 with selective signaling through IL-2Rβ/γ thus limiting the side effects of activating the IL-2Rα/β/γ ANV419 is investigated in a phase I dose finding study in patients with advanced solid tumors (ANV419-001).

Methods The primary objective of ANV419-001 is safety and tolerability of ANV419. Secondary objectives include response rate (RECISTv1.1), pharmacokinetic and pharmacodynamic evaluation. ANV419 is administered as a 15 minutes intravenous infusion Q2W. As of 29th June 2022, 26 patients with Eastern Cooperative Oncology Group (ECOG) Performance Status 0 or 1 and a range of primary tumor types with multiple previous lines of therapy have been enrolled and dosed in 9 cohorts up to 243µg/kg.

Results ANV419 was generally well tolerated across multiple cycles, with no dose-limiting toxicities (DLTs) up to and including 243µg/kg. The most frequent ANV419 related adverse events (AEs), reported in at least 10% of patients, were chills, fever, fatigue, nausea, vomiting, cytokine release syndrome (CRS) and increased liver function tests, mainly Grade 1 and Grade 2. All drug related events were responsive to supportive care therapy and reversible.

A dose proportional increase in ANV419 plasma concentration results in an increased estimated half-life up to 28 hours at higher doses.

In this study, IL-6, IL-8, TNF-α, and IFN-γ levels (10-Plex Panel) were transiently increased at high doses (108 and 243µg/kg), 4 hours after infusion.

Pharmacodynamic evaluation of ANV419 on day 4 post-dosing (cycle 1 and 2) showed a selective and dose dependent proliferation of $CD8^+$ T and NK cells, with a lower increase of proliferating Tregs. As typical for IL-2 related lymphocyte sequestration, a transient dose dependent lymphopenia was observed in all patients lasting up to at least 72 hours after ANV419 infusion, followed by a dose dependent increasing lymphocyte counts up to 5.4-fold of baseline. Lymphocyte numbers keep increasing over multiple cycles up to 3.8-fold after 2 cycles (243µg/kg). In 21 patients with at least one post-baseline tumor response assessment, 52% of patients (n=11) achieved a response of SD or PR, with 10 SD, 1 PR and 10 PD.

Conclusions ANV419 maintains a favorable safety profile, while inducing a systemic inflammatory response in cancer patients with preferential proliferation of effector cells compared to high dose of IL-2. Dose escalation is ongoing. The preliminary efficacy data shows a potential for ANV419 as therapeutic option for patients with progressing/relapsing cancer. Updated data will be shared at the meeting.

Trial Registration NCT04855929

Ethics Approval The study ANV419-001 has been approved by the following Ethics committee:

632 CLINICAL UPDATE FROM A PHASE 1, FIRST-IN-HUMAN, OPEN-LABEL SINGLE AGENT STUDY OF SUPLEXA THERAPEUTIC CELLS IN PATIENTS WITH METASTATIC SOLID TUMOURS AND HAEMATOLOGIC MALIGNANCIES

[1]Rohit Joshi*, [2]Jeffrey Goh, [2]Warren Joubert, [3]Vineet Kwarta, [3]Meena Okera, [3]Sarwan Bishnoi, [4]Jim Lederer, [4]Frank Borriello, [4]Sharron Gargosky. *[1]Cancer Research South Australia, Adelaide, Australia; [2]Gallipoli Research Foundation, Brisbane, Australia; [3]Cancer Research South Australia (CRSA), Adelaide, Australia; [4]Alloplex Biotherapeutics Inc, Woburn, MA, USA*

Background SUPLEXA is a first-in-class, autologous, adoptive immunotherapy; prepared from patients' PBMCs it contains NK cells, NKT-like, gd T cells, and ab T cells of both the $CD8^+$ and $CD4^+$ variety primed for broad tumor cytolytic activity.

Methods This is a FIH Phase 1, non-comparative, open-label, basket-design study NCT05237206. The study is enrolling up to 40 participants in Australia in 2 cohorts: 1. Solid tumours cohort that includes subjects with histologically or cytologically or radiographically confirmed and 2. a haematologic malignancies cohort including subjects with histologically or cytologically confirmed multiple myeloma, lymphoma, and chronic lymphocytic leukemia. Primary objective is to assess safety and tolerability of SUPLEXA and the secondary objective is to assess the efficacy. All eligible subjects will receive a minimum 7.5×10^9 cumulative dose of SUPLEXA therapeutic cells. Each treatment is administered at least 1 week apart at Day 1 (baseline), Week 1, Week 2 and possibly more depending on manufacturing yield. The first 3 subjects in each cohort will be enrolled in a staggered manner, at least 1 week apart; these subjects will be evaluated for safety and if no safety concerned are identified, all remaining subjects will be enrolled. All subjects will be evaluated for DLTs, 1 week after the 1st dose and 2nd dose (prior to administration of 2nd dose and 3rd dose, respectively).

Results As of submission, 10 patients (8 female and 2 male; age 34-75years) have been enrolled. Cancer types have included squamous cell, ovarian, bladder, urothelial and pancreatic cancers. SUPLEXA therapy was successfully manufactured for all patients to receive the minimum course of 7.5×10^9 SUPLEXA cells. Treatment has been well tolerated with no study related SAEs or discontinuations. No clinical observations have been noted with clinical chemistry, hematology, urinalysis, or other serology, nor with ECG or other assessments. Of note there has been a mild transient observation of odour for 24hrs post infusion as commonly expected from the DMSO cellular cryopreservative used. Data for the first 3 participants has been reviewed by the DSMB and the study is now fully opened to enrolment.

Conclusions Trial is proceeding well with an excellent tolerability profile and ease of administration for the patients. Additional safety and efficacy data will be forthcoming.

633 A PHASE 1, FIRST IN HUMAN (FIH) STUDY OF AUTOLOGOUS MACROPHAGES CONTAINING AN ANTI-HER2 CHIMERIC ANTIGEN RECEPTOR (CAR) IN PARTICIPANTS WITH HER2 OVEREXPRESSING SOLID TUMORS

[1]Kim Reiss*, [2]Naoto Ueno, [3]Yuan Yuan, [4]Melissa Johnson, [5]E Claire Dees, [3]Joseph Chao, [6]Mathew Angelos, [7]Ramona Swaby, [7]Daniel Cushing, [7]Amy Ronczka, [7]Thomas Condamine, [7]Debora Barton, [7]Michael Klichinsky, [5]Yara Abdou. *[1]University of Pennsylvania Abramson Cancer, Philadelphia, PA, USA; [2]The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]City of Hope Cancer Center, Duarte, CA, USA; [4]Sarach Cannon Research Institute, Nashville, TN, USA; [5]University of North Carolina Lineberger, Chapel Hill, NC, USA; [6]Abramson Cancer Center, Philadelphia, PA, USA; [7]Carisma Therapeutics, Philadelphia, PA, USA*

Background Macrophages are phenotypically plastic cells that are abundant in the solid tumor microenvironment (sTME) and can promote tumor growth (M2) or enhance anti-tumor immunity (M1). Macrophage function can be redirected by CAR expression to selectively target and phagocytose antigen overexpressing cancer cells. CAR macrophages can reprogram the sTME and present neoantigens to T cells, leading to epitope spreading and anti-tumor immune memory.[1] HER2 overexpression promotes tumorigenesis in many solid tumors (table 1). CT-0508 is comprised of autologous monocyte-derived proinflammatory macrophages expressing an anti-HER2 CAR. Pre-clinical studies showed that CT-0508 induced targeted cancer cell phagocytosis while sparing normal cells, decreased tumor burden, prolonged survival, and was safe and effective in humanized xenograft mouse models of human HER2 overexpressing ovarian cancer. In immunocompetent mouse models of HER2 overexpressing solid tumors, syngeneic anti-HER2 CAR-M mediated tumor control and improved overall survival as compared to untreated or control untransduced macrophage (UTD) treated mice. Notably, anti-HER2 CAR-M treatment led to significant activation of the sTME, with notable infiltration of CD8+ and CD4+ T cells, NK cells, dendritic cells, and an increase in activated CD8+ tumor infiltrating lymphocytes. Anti-HER2 CAR-M were evaluated in a PD1 blockade resistant syngeneic model – mice that received both therapies had improved tumor control, overall survival, and TME activation as compared to either treatment alone, indicating synergy and the capacity for CAR-M to sensitive solid tumors to checkpoint blockade.

Methods This Phase 1, FIH study is evaluating safety, tolerability, cell manufacturing feasibility, trafficking, TME activation, and preliminary evidence of efficacy of investigational product CT-0508 in 18 participants with locally advanced (unresectable)/metastatic solid tumors overexpressing HER2. Pts previously treated with anti-HER2 therapies are eligible. Filgrastim mobilizes autologous hematopoietic progenitor cells for monocyte collection by apheresis. CT-0508 is manufactured, prepared, and cryopreserved from mobilized peripheral blood monocytes. Group 1 participants (n = 9; enrollment complete) received CT-0508 infusion split over Days 1, 3, and 5. Group 2 participants (n = 9) will receive CT-0508 single infusion on D1. Additional study cohorts include: CT-0508 co-administered with pembrolizumab and CT-0508 monotherapy administered intraperitoneally in participants with peritoneal predominant disease. Correlative assessments include pre- and post-treatment biopsies and blood samples for safety (immunogenicity), trafficking (PCR, RNA scope), CT-0508 persistence in blood and tumor, target antigen engagement, TME modulation (single cell RNA sequencing), immune response (TCR sequencing) and others.

634 A PHASE 1, FIRST-IN-HUMAN (FIH) CLINICAL TRIAL OF THE ANTI-HER2 CAR MACROPHAGE CT-0508 IN PARTICIPANTS WITH HER2 OVEREXPRESSING SOLID TUMORS

[1]Kim Reiss*, [2]Yuan Yuan, [3]Naoto Ueno, [4]Melissa Johnson, [5]E Claire Dees, [6]Mathew Angelos, [2]Joseph Chao, [6]Saar Gill, [6]Olga Shestova, [5]Jonathan Serody, [2]Saul Priceman, [7]Amy Ronczka, [7]Rehman Qureshi, [7]Poonam Sonawane, [7]Daniel Cushing, [7]Debora Barton, [7]Michael Klichinsky, [7]Thomas Condamine, [7]Ramona Swaby, [5]Yara Abdou.
[1]Abramson Cancer Center Univ of Penn, Philadelphia, PA, USA; [2]City of Hope Cancer Center, Duarte, CA, USA; [3]The Univ of Texas MD Anderson Cancer Center, Houston, TX, USA; [4]Sarah Cannon Research Institute Cancer Center, Nashville, TN, USA; [5]University of North Carolina Lineberger Comprehensive Cancer, Chapel Hill, NC, USA; [6]Univ of Pennsylvania Abramson Cancer Center, Philadelphia, PA, USA; [7]Carisma Therapeutics, Philadelphia, PA, USA

Background In pre-clinical studies, CAR macrophages (CAR-M) phagocytose tumor cells, activate the tumor micro-environment (TME), recruit T cells, and induce anti-tumor T cell immunity. CT-0508 is a first-in-class CAR-M product comprised of autologous monocyte-derived macrophages expressing an anti-HER2 CAR. Here we present preliminary clinical results from the CT-0508 Phase 1 FIH study.

Methods This multi-center, open-label study is evaluating CT-0508's safety, tolerability, and manufacturing feasibility in 18 participants with advanced solid tumors overexpressing HER2 with progression on prior therapies. Monocytes are isolated from mobilized apheresis products, differentiated into macrophages, and engineered with an anti-HER2 CAR. Group 1 participants (n = 9) receive a fractionated dose on days 1, 3, 5 and Group 2 participants (n = 9) receive the full dose on day 1. CT-0508 is administered without preparative chemotherapy. Serial blood samples and biopsies (baseline and 2 post-treatment) are collected to investigate safety, pharmacokinetics, and mechanism of action.

Results Nine participants (6F/3M) have been treated, comprising breast (4), esophageal (2), cholangiocarcinoma, ovarian, and parotid gland cancers, with a median age of 58. Participants had received a median of 3 (range, 2-11) prior lines of therapy; 8 had received prior anti-HER2 therapy. CT-0508 was successfully manufactured and well tolerated with no dose-limiting toxicities. Three related SAEs occurred in 2 participants: grade 1 CRS with hospitalization for monitoring and grade 2 infusion reaction that resolved within 1 hour were reported in one participant. Grade 2 CRS with fever and hypoxia occurred in another participant and resolved within ~ 72 hours. Five additional participants experienced Grade 1-2 CRS and/or infusion reactions with rapid resolution. There were no major organ toxicities and no on-target off-tumor toxicities. Post-infusion cytokines were transiently elevated in most participants enrolled in group 1 and were self-limiting. Four of 7 participants evaluated had stable disease. CT-0508 was transiently detectable in the blood and was detected in the TME 8 days and 4 weeks after infusion. CT-0508 modulated the TME, leading to myeloid cell activation, T cell infiltration, activation, and proliferation. TCR sequencing demonstrated newly expanding T cell clones in the blood post-treatment that accumulated within the TME, suggesting expansion of tumor-reactive T cells upon CT-0508 infusion. Data from participants enrolled in group 1 will be presented.

Conclusions CT-0508 was safe and feasible to manufacture. Early correlative data demonstrate trafficking, TME modulation,and induction of anti-tumor T cell immunity. The study is actively enrolling.

Background The group sequential, adaptively randomized, open-label, phase 2 KEYNOTE-495/KeyImPaCT trial (NCT03516981) demonstrated the feasibility of using prospective T-cell–inflamed gene expression profile ($Tcell_{inf}GEP$) and tumor mutation burden (TMB) dual biomarker status to assess the clinical activity of first-line pembrolizumab-based combination therapies in advanced non−small-cell lung cancer (NSCLC). Here, we present updated efficacy data relative to prespecified biomarker-defined subgroups for each treatment arm.

Methods Patients with previously untreated stage IV NSCLC were categorized by $Tcell_{inf}GEP$ and TMB dual biomarker status ($Tcell_{inf}GEP^{low}TMB^{non\text{-}high}$, $Tcell_{inf}GEP^{low}TMB^{high}$, $Tcell_{inf}GEP^{non\text{-}low}TMB^{non\text{-}high}$, $Tcell_{inf}GEP^{non\text{-}low}TMB^{high}$) then randomly assigned 1:1:1 to receive pembrolizumab (200 mg IV Q3W) plus the multikinase inhibitor (targeting VEGFRs 1-3, FGFRs 1-4, PDGFRα, RET, and KIT) lenvatinib (20 mg oral QD), CTLA-4 inhibitor quavonlimab (75 mg IV Q6W), or LAG-3 inhibitor favezelimab (initially 200 mg and then 800 mg IV Q3W). Adaptive randomization based on objective response rate (ORR) was employed, and frequent interim analyses were performed to quantify efficacy and assess for futility. The primary end point of investigator-assessed ORR per RECIST v1.1 was assessed using prespecified efficacy thresholds for each biomarker-defined subgroup: an ORR of >5% within the $Tcell_{inf}GEP^{low}TMB^{non\text{-}high}$ subgroup, >20% within the $Tcell_{inf}GEP^{low}TMB^{high}$ subgroup and $Tcell_{inf}GEP^{non\text{-}low}TMB^{non\text{-}high}$ subgroup, and >45% within the $Tcell_{inf}GEP^{non\text{-}low}TMB^{high}$ subgroup evaluated using a Bayesian posterior probability. Secondary end points included progression-free survival (PFS) per RECIST v1.1, overall survival (OS), and safety.

Results At data cutoff (March 21, 2022), 243 patients had been treated (pembrolizumab+lenvatinib, n=80; pembrolizumab+quavonlimab, n=82; pembrolizumab+favezelimab 200 mg, n=30; pembrolizumab+favezelimab 800 mg, n=51). Efficacy data are presented in **table 1**. ORR with pembrolizumab +lenvatinib in the $Tcell_{inf}GEP^{non\text{-}low}TMB^{non\text{-}high}$ subgroup met the prespecified efficacy threshold. The safety profile of each treatment arm was consistent with the known safety profile of each combination.

Conclusions Pembrolizumab-based combination therapy continued to show promising antitumor activity and durable response in the $Tcell_{inf}GEP^{non\text{-}low}TMB^{high}$ subgroup across all combinations. Response in the $Tcell_{inf}GEP^{non\text{-}low}TMB^{non\text{-}high}$ subgroup treated with pembrolizumab+lenvatinib met the prespecified efficacy threshold. Although response in the pembrolizumab+favezelimab arm did not reach the efficacy bar, there was a trend toward improved ORR in the $Tcell_{inf}GEP^{non\text{-}low}TMB^{high}$ subgroup versus the other 3 biomarker-defined subgroups; median PFS and OS were also numerically longer in the $Tcell_{inf}GEP^{non\text{-}low}TMB^{high}$ subgroup compared with the other 3 biomarker-defined subgroups. Prospective assessment of dual biomarkers, as performed in this study, may help identify patients with NSCLC most likely to respond to pembrolizumab-based combination therapies.

636 A PHASE 1, OPEN-LABEL, DOSE ESCALATION AND EXPANSION STUDY OF CUE-102 MONOTHERAPY IN HLA-A*0201 POSITIVE PATIENTS WITH WT1-POSITIVE RECURRENT/METASTATIC CANCERS

[1]Steven Margossian*, [2]John Powderly, [3]Nashat Gabrail, [4]Yvonne Saenger, [5]J Eva Selfridge, [6]Nataliya Uboha, [7]Jun Gong, [8]Brian Van Tine, [9]Olatunji Alese, [10]Dae Won Kim, [11]Wen Ma, [11]Tanios Bekaii-Saab, [11]Jeremy Jones, [12]Angela Alistar, [1]Laura Agensky, [1]Apollina Goel, [1]Reena Lynam, [1]Raymond Moniz, [1]Steve Quayle, [1]Cynthia Rajan, [15]Kenneth Pienta, [1]Matteo Levisetti. *[1]Cue Biopharma Inc., Boston, MA, USA; [2]Carolina BioOncology, Huntersville, NC, USA; [3]Gabrail Cancer Center, Canton, OH, USA; [4]Albert Einstein Cancer Center, Bronx, NY, USA; [5]UH Cleveland, Cleveland, OH, USA; [6]Carbone Cancer Center, Madison, WI, USA; [7]Cedar Sinai, Los Angeles, CA, USA; [8]Washington University, St Louis, MO, USA; [9]Emory University, Atlanta, GA, USA; [10]H. Lee Moffitt Cancer Center, Tampa, FL, USA; [11]Mayo Clinic, Rochester, MN, USA; [12]Carol G. Simon Cancer Center, Winston Salem, NJ, USA; [15]Johns Hopkins University School of Med, Cambridge, MD, USA*

Background Immuno-STATs™ are modular fusion proteins designed for the selective activation of tumor-antigen specific CD8+ T cells. CUE-102, the second Immuno-STAT in clinical trials, is composed of a human leukocyte antigen (HLA) complex, HLA-A*0201, a peptide epitope derived from the Wilms Tumor 1 (WT1) protein, and 4 molecules of reduced affinity human interleukin-2 (IL-2), and is designed to bind, expand, and activate WT1-specific CD8+ T cells for the treatment of WT1-positive cancers. In pre-clinical studies, CUE-102 elicits selective expansion of WT1-specific cytotoxic CD8+ T-cells in vitro and in vivo.[1]

Methods CUE-102-01 is a phase 1, open-label, 2-part, multicenter study evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity, and preliminary antitumor activity of CUE-102 monotherapy administered every three weeks in HLA-A*0201 positive patients with WT1 positive recurrent/metastatic Colorectal, Gastric/Gastroesophageal Junction (GEJ), Pancreatic and Ovarian cancer who have failed conventional therapies. Part A is a dose escalation phase following 3+3 design rules with a Bayesian Logistic Regression Model (BLRM) overlay. Dose levels that exhibit an immune response may be expanded to further characterize activity and toxicity. Part B is a dose expansion/confirmation phase in patients with colorectal cancer.

The primary objectives of Part A are to evaluate dose-limiting toxicities and maximum tolerated dose during the first cycle of treatment, to evaluate the pharmacokinetics (PK) of CUE-102, and to establish a recommended Phase 2 dose. Secondary objectives of Parts A and B include evaluating the safety and tolerability of CUE-102 using NCI CTCAE v5.0; preliminary antitumor activity by RECIST 1.1 including objective response rate (ORR), duration of response (DOR), durable stable disease (DSD) (SD $\geq$ 6 weeks), clinical benefit rate (CBR), progression-free survival (PFS); overall survival (OS); the potential for CUE-102 mediated immune response; and the potential immunogenicity of CUE-102. Exploratory objectives include evaluation of biomarkers of activity and immune effects, and preliminary antitumor activity by iRECIST.

Eligible patients must have locally advanced/nonresectable or metastatic disease, an ECOG status of 0 or 1, life expectancy > 12 weeks and measurable disease by RECIST 1.1 criteria. Patients with colorectal and cisplatin-sensitive ovarian cancer must have documented disease progression to 2 prior systemic treatment regimens (CUE-102 will be $\geq$ 3rd line therapy); patients with Gastric/GEJ, pancreatic and cisplatin-resistant ovarian cancer must have documented disease progression to 1 prior systemic treatment regimens (CUE-102 will be $\geq$ 2nd line therapy).

Results Trial is currently open and enrolling as of June 14, 2022.

Acknowledgements The authors would like to thank all the patients who are participating in this study. The study is sponsored by Cue Biopharma.

637 **PHASE IIA COMBINING NEO-201 WITH PEMBROLIZUMAB IN ADULTS WITH CHEMO-RESISTANT SOLID TUMORS**

[1]Princess Mark-Adjeli*, [1]Christina Annunziata, [1]Christopher Cole, [2]Maria Pia Morelli, [1]Ann McCoy, [3]Massimo Fantini, [3]Sharon Mavroukakis, [3]Anjum Zaki, [3]Kwong Tsang, [3]Philip Arlen. *[1]National Cancer Institutes, Bethesda, MD, United States; [2]MD Anderson, Houston, TX, United States; [3]Precision Biologics, Inc., Bethesda, MD, United States*

Background NEO-201 is a humanized IgG1 monoclonal antibody which binds to Core 1 and/or extended Core 1 O-glycans expressed by human solid and blood tumors as well as by human neutrophils. NEO-201 reacts against colon, pancreatic, non-small cell lung, head and neck, cervical, uterine and breast cancer, but it does not bind to most normal tissues. NEO-201 kills tumor cells via antibody dependent cell mediated cytotoxicity and complement dependent cytotoxicity. NEO-201 also binds to circulating regulatory T cells (Tregs). The low response rates and resistance to PD-1/PD-L1 blockade in solid cancers may be due to the activity of Tregs in the tumor microenvironment. Based on these data we hypothesize that combining NEO-201 with pembrolizumab for the treatment of solid tumors may overcome resistance to checkpoint inhibitors by depleting Tregs.

Methods The Clinical Trial NCT03476681 is open and recruiting patients at National Institutes of Health (USA).

Eligibility Criteria A. Subjects must be over 18 years old and have histologically or cytologically confirmed recurrent, locally advanced unresectable or metastatic Non-Small Cell Lung Cancer, Cervical Cancer, Head and Neck Squamous Cell Carcinoma, Uterine Carcinoma who have progressed during or after front-line standard of care treatment, including chemotherapy and/or targeted therapy.

B. At least 10% of tumor cells expressing NEO-201 target antigen on immunohistochemistry.

C. Patient is not a candidate for potentially curative surgery or radiation

Given that NEO-201 has not been previously administered with pembrolizumab, a safety lead-in will be conducted in three to six subjects who will receive NEO-201 at 1.5 mg/kg IV every 2 weeks, and pembrolizumab 400 mg IV every 6 weeks. The safety lead-in course will be 42 days in length and consist of 1 dose of pembrolizumab and 3 doses of NEO-201. Once safety is established, 21–31 subjects would be enrolled in the four disease groups. Primary and secondary objectives include determining Objective Response Rate and Progression Free Survival, characterizing the pharmacokinetics of NEO-201 in combination with pembrolizumab, exploring the effects of the combination on functions and phenotypes of immune subsets, modulation of serum levels of cytokines and soluble factors.

Trial Registration NCT03476681

638 **COMMANDER-001: A PHASE 1/2, FIRST-IN-HUMAN, MULTICENTER, OPEN LABEL STUDY OF SQZ-EAPC-HPV AS MONOTHERAPY AND WITH PEMBROLIZUMAB IN PATIENTS WITH HPV16+ RECURRENT, LOCALLY ADVANCED, OR METASTATIC SOLID TUMORS (TRIAL IN PROGRESS)**

[1]Meredith Pelster*, [2]Michael Gordon, [2]Justin Moser, [3]Trisha Wise-Draper, [4]Jong Chul Park, [5]Wade Iams, [6]Ricardo Zwirtes, [6]Julia Jennings, [6]Nathan Miselis, [6]Rui Ru Ji, [6]Scott Loughhead, [6]Howard Bernstein, [6]Armon Sharei, [7]Antonio Jimeno. *[1]Sarah Cannon Research Institute, Nashville, TN, USA; [2]HonorHealth Research and Innovation Inst, Scottsdale, AZ, USA; [3]University of Cincinnati Medical Center, Cincinnati, OH, USA; [4]Massachusetts General Hospital, Boston, MA, USA; [5]Vanderbilt University Medical Center, Nashville, TN, USA; [6]SQZ Biotechnologies, Watertown, MA, USA; [7]Colorado University Cancer Center, Aurora, CO, USA*

Background Antigen-specific CD8+ T cells are critical for mounting a potent immune response against tumors. Creation of T cell responses requires 3 key signals from antigen presenting cells (APCs): (signal 1) the peptide-MHC complex binding to the T cell receptor, (signal 2) costimulatory molecules that bind to T cell stimulatory domains, and (signal 3) inflammatory cytokines binding to receptors on T cells. To create enhanced APCs (eAPCs) from peripheral blood mononuclear cells (PBMCs), we used the Cell Squeeze® technology to deliver mRNAs encoding HPV16 E6 and E7 antigens (signal 1), CD86 (signal 2), and membrane-bound IL-2 and IL-12 cytokines (signal 3). Co-localizing these signals on the eAPC surface may enable more potent T cell stimulation and limit off-target effects from systemic exposure to signal 2 and 3. SQZ-eAPC-HPV is an improved 2nd generation product, with no HLA restrictions, that builds on the clinical and manufacturing experience with the 1st generation SQZ-PBMC-HPV product. This approach may enable rapid implementation across many tumor types as it facilitates exchange of mRNA to encode for other antigens or T cell activation signals.

Methods Trial Design: COMMANDER-001 is open for enrollment to patients (pts) with HPV16 driven recurrent, locally advanced, or metastatic solid tumors and includes dose escalation for eAPC monotherapy and in combination with pembrolizumab (pembro) (Part 1), and a lead-in where eAPC is given prior to treatment with pembro (Part 2). Part 1A will assess 3 eAPC monotherapy cohorts using a Bayesian optimal interval design enrolling 3 – 12 pts per cohort. After establishing a safe and tolerable dose (RP2D), Part 1B will assess the RP2D with pembro 200mg q3 weeks (w). Part 2 will explore giving 2 doses of eAPC before the pt receives pembro. Pts will receive eAPC q3w for up to 1 year or until available eAPC is exhausted. Pembro will be given for up to 2 years. Eligible pts will undergo 1 leukapheresis. Manufacturing takes <24 hours and the vein-to-vein time for the 1st dose is expected to be ~1 week. Preconditioning is not required, and the study will be primarily conducted out-patient.

Trial Registration NCT05357898

Ethics Approval The study is registered on clinicaltrials.gov and was approved by the Ethics Board of all institutions listed as recruiting.

639 **BASECAMP-1: LEVERAGING HLA LOSS OF HETEROZYGOSITY IN SOLID TUMORS BY NGS TO IDENTIFY PATIENTS WITH RELAPSED SOLID TUMORS FOR FUTURE CEA AND MSLN LOGIC-GATED TMOD™ CAR T-CELL THERAPY**

[1]Diane Simeone*, [2]Maria Pia Morelli, [3]J Randolph Hecht, [4]Sandip Patel, [5]Marwan Fakih, [6]Kedar Kirtane, [1]Theodore Welling, [1]Sally Lau, [7]Yi Lin, [8]Mitesh Borad, [3]Edward Garon, [3]Sarah Larson, [4]Shumei Kato, [4]Peter Vu, [6]Frederick Locke, [6]Dae Won Kim, [10]John Sunwoo, [9]David Miklos, [10]Matthew Frigault, [10]Marcela Maus, [11]Sarah Nikiforow, [11]Caron Jacobson, [13]Kirstin Liechty, [12]Armen Mardiros, [13]Ariane Lozac'hmeur, [13]Karl Beutner, [12]John Welch, [14]Eric Ng, [12]William Go, [15]David Maloney, [2]Scott Kopetz, [7]Julian Molina. *[1]New York University Langone Health, New York, NY, USA; [2]University of Texas MD Anderson Cancer, Houston, TX, USA; [3]University of California at Los Angeles, Los Angeles, CA, USA; [4]University of California San Diego, La Jolla, CA, USA; [5]City of Hope, Duarte, CA, USA; [6]H. Lee Moffitt Cancer Center, Tampa, FL, USA; [7]Mayo Clinic, Rochester, MN, USA; [8]Mayo Clinic Cancer Center, Scottsdale, AZ, USA; [9]Stanford University School of Medicine, Palo Alto, CA, USA; [10]Massachusetts General Cancer Center, Boston, MA, USA; [11]Dana-Farber Cancer Institute, Boston, MA, USA; [12]A2 Biotherapeutics, Inc., Agoura Hills, CA, USA; [13]Tempus, Chicago, IL, USA; [14]A2 Biotherapeutics, Agoura Hills, CA, USA; [15]Fred Hutchinson Cancer Research Center, Seattle, WA, USA*

Background Solid tumors comprise >90% of cancers. Non-small cell lung cancer (NSCLC), metastatic colorectal cancer (CRC), and pancreatic cancer are the leading causes of cancer-related mortality (5-year overall survival: 26%, 15%, and 11%, respectively).[1]

Chimeric antigen receptor (CAR) T-cell therapy has demonstrated clinical efficacy in hematologic malignancies.[2,3] However, translating engineered T-cell therapies to solid tumors has proven to be challenging due to a lack of tumor-specific targets that can discriminate cancer cells from normal cells. Previous studies using carcinoembryonic antigen (CEA) T-cell receptors and mesothelin (MSLN) CARs resulted in dose-limiting on-target, off-tumor toxicities.[4,5]

To create a therapeutic safety window, Tmod CAR T-cell therapy utilizes dual-signaling receptors to create a robust logic gate capable of killing tumor cells, while leaving healthy cells intact.[6,7]

The 2 receptors in Tmod CAR T-cell therapy comprise an activator that recognizes an antigen on the surface of tumor cells that may also be present on normal cells, such as CEA and MSLN, and a blocker that recognizes a second surface antigen from an allele lost only in tumor cells (figure 1).[8,9]

Human leukocyte antigen (HLA) loss of heterozygosity (LOH) offers a definitive tumor versus normal discriminator target for CAR T-cell therapy.[10] The frequency of HLA LOH among advanced NSCLC, CRC, and pancreatic cancers in the Tempus real-world dataset is 16.3% with a range of 15.6%-23.1%.[11] LOH can be reliably detected using the Tempus xT-Onco next-generation sequencing (NGS) assay.[12,13] Different activator/blocker combinations can be engineered with the Tmod platform technology and may be applied to T cells and natural killer cells in autologous and allogeneic settings.

BASECAMP-1 is a currently enrolling observational study with key objectives: 1) To identify patients with somatic HLA LOH eligible for Tmod CAR T-cell therapy, and 2) Subsequent apheresis and manufacturing feasibility for the future EVEREST CEA or MSLN Tmod CAR T-cell studies.

Methods BASECAMP-1 (NCT04981119) patient eligibility has 2 parts (figure 2): 1) Patients will be initially screened to identify germline HLA-A*02 heterozygosity by central NGS. If HLA-A*02 heterozygosity is confirmed, primary archival tumor tissue will be analyzed for somatic mutations by xT-Onco NGS testing; 2) If the tumor demonstrates HLA-A*02:01 LOH and the patient is eligible after screening, the patient will undergo apheresis. Banked T cells will be available for the autologous EVEREST Tmod CAR T-cell therapy interventional study to reduce waiting time at relapse.

Trial Registration ClinicalTrials. gov, NCT04981119

640 **COMBINATORIAL CHEMOIMMUNOTHERAPY BASED ON THE ANTIBODY-CYTOKINE FUSION PROTEIN L19TNF UNLEASHES POTENT ANTI-TUMOR IMMUNITY AGAINST TREATMENT-REFRACTORY GLIOBLASTOMA**

[1]Thomas Look, [2]Emanuele Puca, [2]Riccardo Stucchi, [2]Roberto De Luca, [2]Dario Neri, [1]Michael Weller, [2]Teresa Hemmerle*, [1]Tobias Weiss. *[1]Universitätsspital Zürich, Zürich, Switzerland; [2]Philogen S.p.A., Otelfingen, Switzerland*

Background Glioblastoma is a poorly immunogenic brain tumor and treatment options at recurrence after standard of care chemoradiation are very limited. Several immunotherapeutic strategies, including immune checkpoint inhibition and peptide vaccination, have failed to improve the survival of patients. Except from potentially regorafenib, no other agent has demonstrated superior activity to the alkylating chemotherapeutic lomustine. Here, we investigate a new combination treatment based on lomustine and on the tumor-targeting antibody-cytokine fusion protein L19TNF in preclinical glioma models and in patients with recurrent glioblastoma.

Methods Orthotopic immunocompetent mouse glioma models were used to study the anti-tumor activity of L19TNF in combination with (i) anti-PD1 antibody, (ii) bevacizumab, (iii) L19IL2, or (iv) lomustine. Tumor growth was monitored by MRI as well as survival. Single-cell RNA-sequencing, Flow cytometry and microscopy were used to characterize tumor-infiltrating-immune cells. MHC immunoaffinity purification and mass spectrometry were used to investigate the MHC immunopeptidome. Genetic mouse models enabled to study immune-dependent effects. Subsequently, the most efficient treatment combination, L19TNF plus lomustine, was translated to patients with recurrent glioblastoma within a phase I/II clinical trial (NCT04573192). The study has been approved by the Swiss national authority (Swissmedic reference number 2020DR1125) and the ethic committee (BASEC number 2020-02413).

Results The combination treatment based on lomustine and L19TNF cured the majority of immunocompetent orthotopic glioma-bearing mice, whereas other mono- or combination therapies had only limited anti-glioma activity. The investigation of the mechanisms of action revealed that lomustine plus L19TNF led to intratumoral necrosis, DNA damage and triggered a strong local anti-tumor immune response with increased MHC-I expression, presentation of neoepitopes and increased abundance of tumor-infiltrating lymphoid cells. In the first patients treated within a phase I/II clinical trial, the treatment was well tolerated, and durable objective tumor responses as well as disease stabilizations could be observed, even in patients with unmethylated MGMT promoter.

Conclusions The combination of L19TNF and lomustine is demonstrating promising anti-glioma activity. Additional patients are currently being recruited within a phase I/II clinical trial for patients with glioblastoma at first progression.

Trial Registration NCT04573192

STRONG IMMUNE RESPONSE TO THERAPEUTIC VACCINATION WITH EO2401 MICROBIOME DERIVED THERAPEUTIC VACCINE + NIVOLUMAB: INTERIM REPORT OF THE EOGBM1–18/ROSALIE STUDY

[1]Ana Maia*, [2]Hélène Toussaint, [2]Joao Gamelas Magalhaes, [3]David Reardon, [4]Ahmed IDBAIH, [5]Maria Vieito, [6]Ghazaleh Tabatabai, [7]Agostina Stradella, [8]François Ghiringhelli, [9]Michael C Burger, [10]Iris Mildenberger, [11]Ulrich Herrlinger, [5]Macarena Gonzalez, [8]Alice Hervieu, [7]Marta GilMartin, [6]Mirjam Renovanz, [4]Mehdi Touat, [3]Patrick Y Wen, [12]Antje Wick, [2]Laurent Chene, [1]Cécile Gouttefangeas, [2]Christophe Bonny, [2]Jan Fagerberg, [12]Wolfgang Wick. *[1]Eberhard-Karls-University Tuebingen, Germany; [2]Enterome, Paris, France; [3]Dana-Farber Cancer Institute, Boston, MA, USA; [4]Hôpital Universitaire La Pitié-Salpêtrie, Paris, France; [5]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [6]Universitätsklinikum Tübingen, Tübingen, Germany; [7]Institut Catala D'Oncologia Hospital, Barcelona, Spain; [8]Centre Georges-François Leclerc, Dijon, France; [9]Universitätsklinikum Frankfurt Goethe, Frankfurt, Germany; [10]Medizinische Fakultät Mannheim, Mannheim, Germany; [11]Universitätsklinikum Bonn, Bonn, Germany; [12]Universitätsklinikum Heidelberg Cancer, Heidelberg, Germany*

Background EO2401 is a therapeutic vaccine designed to activate memory commensal specific T-cells that are cross-reacting against validated tumor associated antigens (TAAs). EO2401 includes synthetically produced HLA-A2 peptides with molecular mimicry to TAAs (IL13Rα2, BIRC5 and FOXM1) upregulated in glioblastoma, and the CD4 helper peptide UCP2.

Methods Patients with glioblastoma at first progression after radiotherapy/temozolomide received EO2401 with nivolumab (EN), or EN with bevacizumab within trial EOGBM1-18 (NCT04116658). Blood collection was performed at baseline and then every two or four weeks. Immune responses were investigated either directly on cryopreserved PBMCs without stimulation (ex vivo), or after 12 days in vitro stimulation (IVS) using tetramer staining, IFNg ELISpot and intracellular cytokine staining. The study was approved by all participating institution's Ethics Boards.

Results Immune monitoring in EO2401 vaccinated patients demonstrates the ability of bacterial peptides to induce a strong CD8+ T cell response with cross-reactivity against human selected TAAs. Immune response against the 3 microbiome-derived peptides is demonstrated for 28 of 29 investigated patients using ELISpot after IVS. Post vaccination frequency of CD8+ T cells against bacterial peptide after IVS is extremely high, with a median of 5.5% of specific CD8+ T cells for EO2316 (max 18%), 16% for EO2317 (max 46%) and 14% (max 40%) for EO2318. Cross-reactivity against the pool of human peptides is demonstrated in 27/28 patients using ELISpot after IVS and validated using tetramer staining against BIRC5 and FOXM1. Polyfunctionality of CD8+ T cells effectors is supported by frequent expression of CD107a as well as IFN-g and TNF-a production after stimulation. Ex vivo, CD8+ T cells against at least one of the EO2401 peptides are detected in 26/28 evaluable patients with some patients exhibiting up to 5% of circulating specific CD8+ T cells. Memory specific CD8+ T cells response are found as early as two weeks after the first vaccination and maintenance of a strong and stable immune response could be detected for more than 10 months. CD4+ T cell response against the UCP2 helper peptide is demonstrated using IFN-g ELISpot after IVS.

Conclusions EO2401 vaccine demonstrates ability to generate fast and durable immune responses in patients treated with E02401/nivolumab +/- bevacizumab. Activation of specific T cells cross-reacting against commensal antigens and TAAs is thereby validated as an efficient approach to activate strong immune responses in a difficult to treat tumor with low neoantigen expression and poor T cell priming.

Trial Registration NCT04116658

Ethics Approval This study has obtained an ethics approval (Dana Farber Cancer Institute IRB: iRIS number 438532) and all participants gave informed consent before taking part.

642 **EO2401 MICROBIOME DERIVED THERAPEUTIC VACCINE + NIVOLUMAB, WITH/WITHOUT STANDARD CONTINUOUS, OR LOW-DOSE SYMPTOM DIRECTED, BEVACIZUMAB, IN RECURRENT GLIOBLASTOMA: PHASE 1–2 EOGBM1–18/ROSALIE STUDY**

[1]David Reardon*, [2]Ahmed Idbaih, [3]Maria Vieito, [4]Ghazaleh Tabatabai, [5]Agostina Stradella, [6]Francois Ghiringhelli, [7]Michael Burger, [8]Iris Mildenberger, [4]Ulrich Herrlinger, [3]Macarena González, [5]Marta GilMartin, [4]Mirjam Renovanz, [9]Mehdi Touat, [1]Patrick Wen, [4]Antje Wick, [10]Cecile Gouttefangeas, [10]Ana Maia, [11]Chistophe Bonny, [11]Jan Fagerberg, [12]Wolfgang Wick. *[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]Sorbonne Université, AP-HP, ICM,Hôpital Universitaire La Pitié-Salpêtrière, Paris, MA, France; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [4]Universitätsklinikum, Tübingen, Germany; [5]Institut Catala D'Oncologia, Hospital Duran i Reynals, Barcelona, Spain; [6]Centre Georges-François Leclerc, Dijon, France; [7]Universitätsklinikum Frankfurt Goethe-Universität, Frankfurt, Germany; [8]Medizinische Fakultät, Mannheim, Germany; [9]Hôpital Universitaire La Pitié-Salpêtrière, Paris, France; [10]Department of Immunology, Eberhard-Karls-University, Tuebingen, Germany; [11]Enterome, Paris, France; [12]Universitätsklinikum Heidelberg and German Cancer Research Center, Heidelberg, Germany*

Background EO2401 was designed to activate memory T cells cross-reacting with tumor associated antigens. EO2401 includes synthetically produced HLA-A2 peptides with molecular mimicry to antigens (IL13Rα2, BIRC5 and FOXM1) upregulated in glioblastoma, and the CD4 helper peptide UCP2.

Methods Patients with glioblastoma at first progression after radiotherapy/temozolomide received EO2401 (300 μg/peptide, q2w x4 then q4w) with nivolumab (3 mg/kg q2w; EN-regimen), or EN with bevacizumab (10 mg/kg q2w; ENB-regimen). In study part 2, low-dose bevacizumab (LDB) (5 mg/kg q2w up to 6 doses) could be used as symptom directed treatment of edema. The study, NCT04116658, was approved by all participating institution's Ethics Boards.

Results Part 1 included 40 patients (EN = 29, ENB = 11). Part 2 enrolled 36 patients treated with EN, and the possibility of symptom directed LDB. In study part 3, 15 further patients are to be treated with ENB (enrollment ongoing).

EN and ENB were well tolerated with EO2401 associated tox limited to local administration site reactions (45% of patients; events 70% Grade 1, 26% Grade 2, and 4% Grade 3). The frequency and severity of nivolumab-/bevacizumab-tox was consistent with historical single-agent data.

Immune monitoring demonstrated positive responses against the 3 microbiome-derived peptides for 28 of 29 patients investigated ex vivo or after in vitro stimulation (IVS). For some patients, positive response was already detected two weeks after the first vaccination and was maintained for more than 10 months. Cross-reactivity against the pool of 3 human target peptides was demonstrated in 27 of 28 patients using IFN-γ ELISpot assay.

For part 1, median progression-free survival (mPFS), and median survival for EN (n=29, median follow-up 14.0 months) were 1.8 and 10.6 months. Patients on ENB (n=11, median follow-up 9.6 months) had mPFS of 5.5 months and 9 patients were alive (7-12.4 months). Objective Response Rate (ORR)/Disease Control Rate (DCR) (ORR + stable disease) for EN and ENB were 10%/34% and 55%/82%.

Median treatment duration for EN in part 1 was 8.9 weeks (2 of 29 on treatment), while it was 12.0 weeks (21 of 36 on treatment) in part 2. Overall, in part 2, 13 patients (36%) received LDB.

Conclusions EO2401 was well tolerated and generated fast and durable immune responses in most patients. Addition of standard bevacizumab to EN improved PFS and ORR/DCR. Symptom directed LDB supported longer treatment durations. Updated safety, immunogenicity, and efficacy data from all parts of the trial will be presented.

Trial Registration NCT04116658

Ethics Approval This study has obtained an ethics approval (Dana Farber Cancer Institute IRB: iRIS number 438532) and all participants gave informed consent before taking part.

643 SPATIAL-TRANSCRIPTOMIC ANALYSIS OF NEOADJUVANT CHECKPOINT IMMUNOTHERAPY IN RECURRENT GLIOBLASTOMA

[1]Michael Schachter*, [2]Lu Sun, [1]Wesley Kwong, [1]Samantha Liang, [1]Sandra Santulli-Marotto, [1]Lacey Kitch, [2]Willy Hugo, [2]Robert Prins, [1]Dinesh Kumar. *[1]Parker Institute for Cancer Immunotherapy, Castro Valley, CA, USA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, USA*

Background Glioblastomas (GBMs) are a prevalent form of brain tumor with median overall survival of 1-1.5 years, and inevitable recurrence after initial surgical resection and chemotherapy. Less than half of patients are eligible for surgery at recurrence.[1] In many other cancers, checkpoint immunotherapies are efficacious, but GBMs resist treatment. Multiple resistance mechanisms may be at play and overcoming them is essential to improve immunotherapy response. The high heterogeneity of GBM, both in cellular phenotype and immune landscape, likely contributes to resistance. Although the GBM tumor-immune transcriptome is well-studied, spatial organization is an open frontier.

Methods Spatial transcriptomic samples were analyzed from a two-arm randomized trial for recurrent GBM patients (NCT04201873). One arm received neoadjuvant and adjuvant PD-1 mAb ("neoadjuvant" group), while the other received placebo ("placebo" group). Both groups received adjuvant autologous tumor lysate-pulsed DC vaccination. Tissue samples (N=10) were taken from on-study surgical resection, with 4 patients in the neoadjuvant group, 6 in placebo. The Visium spatial assay was applied to produce 3,140 +/- 969 transcriptomic "spots" per sample, 31,395 in total. Gene signature analysis quantified each spot's tumor-immune composition. Signatures were obtained from MSigDB Hallmarks, ImSig,[2] and Neftel et. al.[3] AUCell[4] was used to score signatures at each spot.

Results Analysis of glioma subtype signatures showed mesenchymal scores (MES1 and MES2) highly correlated [Pearson coefs. > 0.77], while astrocyte (AC), oligodendrocyte precursor (OPC), and neural precursor (NPC1 and NPC2) scores formed a second correlated group [Pearson coefs. > 0.5]. There was no discernable difference in correlation structure between neoadjuvant and placebo patients.

MES1-high spots had a characteristic signature of high macrophage, hypoxia, angiogenesis, glycolysis, interferon-gamma response, TGF-beta, and TNF-alpha scores [Pearson coefs. > 0.5]. AC, OPC and NPC-high spots correlated weakly to immune and vascular signatures [Pearson coefs. < 0.35]. Microglia did not correlate highly to other scores [Pearson coefs < 0.35].

Differential expression showed negative log fold-change (logFC) in glioma subtype scores for neoadjuvant patients, for all types except NPC2 [Wilcox tests, p < 0.001]. Negative logFC was observed for macrophages, TNF-alpha, hypoxia, and proliferation, but positive logFC for T-cells and microglia.

Conclusions Spatial-transcriptomic analysis suggests that patients treated with neoadjuvant immunotherapy have lower mesenchymal subtype scores, with lower proliferation, but higher T-cell scores. Subsequent analysis will relate neoadjuvant immunotherapy with spatial heterogeneity of T-cells, myeloid subtypes, glioma subtypes, and vascularization, to understand resistance mechanisms.

644 **MAJOR PATHOLOGIC RESPONSE AFTER A SINGLE RADIOTHERAPY FRACTION + A SINGLE PEMBROLIZUMAB DOSE GIVEN PREOPERATIVELY IN PATIENTS WITH CT1N0 TRIPLE NEGATIVE BREAST CANCER (TNBC) – PRELIMINARY RESULTS OF A PHASE 1B/2 STUDY (NCT04454528)**

Julia Tchou*, Amy Clark, Neil Taunk, Gary Freedman, Nucleus Xu, Andy Minn, Angela Bradbury, Angela Demichele Gross, Susan Domchek, Hayley Knollman, Rachel Jankowitz, Payal Shah, Oluwadamilola Fayanju, Anupma Nayak, Joseph Fraietta, Alexander Huang. *University of Pennsylvania, Wayne, PA, USA*

Background Pembrolizumab (Pembro) was recently approved for use in combination with neoadjuvant chemotherapy for the treatment of cT2-4N0-2 or T1cN1-2 triple negative breast cancer (TNBC).[1] For patients with early stage (e.g. cT1N0) disease, this regimen may be excessive.[2] We hypothesize that a single 7 Gy radiotherapy (RT) fraction directed at the tumor combined with a single Pembro dose given preoperatively (preop) in patients with early stage breast cancer is feasible and may result in pathologic response.

Methods Patients with cT1N0 TNBC or other subtypes and without a history of ipsilateral breast/chest wall RT or conditions that preclude Pembro treatment are eligible to enroll in this 21-day window of opportunity 3-armed study. Patients either receive RT, Pembro, then surgery; or Pembro, RT, then surgery; or Pembro only in arm 1, 2, or 3, respectively. The primary endpoints were feasibility and tolerability. The secondary endpoints were% change in tumor infiltrating lymphocytes (TILs) and pathologic response. A major pathologic response is defined as <10% residual invasive tumor in post-treatment resected tissues. All patients underwent standard of care adjuvant therapy following surgery.

Results Patients' clinical characteristics are summarized in Table 1. An initial 6 patients (phase 1b; 4 in arm 1 and 2 in arm 2) completed preop treatment with none experiencing >grade 2 skin toxicity or surgery delay (defined as >14 days), thus establishing feasibility. Study is expanded to phase 2 in which patients are assigned 1:1:1 into arms 1, 2, and 3 according to subtype. Comparison of pre- and post-treatment tissues demonstrated that ΔTILs increased significantly in TNBC (21 ±15%, n=9) than in other subtypes (1±2%, n=3†), p=0.049. Major pathologic response (PR) was observed in 3 of 9 TNBC (33%) (2 in arm 1; 1 in arm 2) including 1 with complete PR (arm 1).

Conclusions For the first time to our knowledge, a major PR was observed in TNBC after a single RT + 1 Pembro infusion given preop. Comprehensive digital spatial profiling of the pre- and post-treatment tumor microenvironment to identify potential biomarkers associated with PR is underway. Results of this proof-of-concept study may provide the rationale to evaluate the effectiveness of de-escalating preoperative combination immunotherapy in select patients in future studies.

645 PHASE I STUDY OF ADOPTIVE T CELL THERAPY FOLLOWING HER2-PULSED DENDRITIC CELL VACCINE AND PEPINEMAB/TRASTUZUMAB IN PATIENTS WITH METASTATIC HER2-POSITIVE BREAST CANCER (MBC)

[1]Hyo Han*, [2]Elizabeth Evans, [2]Terrence Fisher, [1]Hatem Soliman, [1]Hung Khong, [1]Aixa Soyano, [1]Ricardo Costa, [1]Loretta Loftus, [1]Kimberley Lee, [1]Avan Armaghani, [1]Hien Liu, [1]Frederick Locke, [1]Alexandria Shrewsbury, [1]Jessica Malka, [1]Lavakumar Karyampudi, [2]Maurice Zauderer, [1]Brian Czerniecki. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Vaccinex, Inc., Rochester, NY, USA*

Background Despite major improvement of overall survival of HER2+ MBC with effective HER2 targeted therapies, many patients experience significant toxicities and develop progressive disease during treatment. Therefore, new and more effective therapeutic options are needed. This novel approach will evaluate whether the combination of three immunotherapies in addition to trastuzumab: dendritic cell (DC) vaccination, anti-SEMA4D blocking antibody(pepinemab) and CD4+ T cell adoptive transfer can lead to improved outcomes for patients with MBC refractory to HER2-targeted agents.

BC have been considered as immunologically cold which is attributed to immune evasion and suppression of host effector immune cells homing into tumor bed. Progressive loss of Th1 immunity against HER2 oncodriver correlates with poor prognosis. HER2 peptide pulsed type I dendritic cells (HER2-DC1) restored anti-HER2 CD4+ Th1 immune response and improved pathologic complete response (pCR) in HER2+ BC.[1]

Antibodies to SEMA4D have been shown to modulate the TME by increasing effector cell infiltration and reducing immunosuppression.[1] In preclinical studies, treatment with anti-SEMA4D and HER2-DC1 in mice bearing established HER2+ tumors improved DC homing, expansion of CD4+ T cells, and complete tumor regression, compared to treatment with anti-SEMA4D or HER2-DC1 alone. Further, subsequent expansion and adoptive transfer of CD4+ T cells induced synergistic anti-tumor activity by activating CD8+ T mediated cytotoxicity. Pepinemab was well-tolerated[2,3] and showed signs of anti-tumor activity in in immunotherapy-resistant, PD-L1 negative/low non-small cell lung cancer patients when combined with checkpoint inhibitor (avelumab).[3]

Methods This open label Phase 1 study is enrolling up to 28 patients with HER2+ MBC. Patients will be treated with 6 weekly injections of dendritic cell (DC1) vaccines in combination with trastuzumab and pepinemab. We hypothesize these therapies may elicit CD4+ HER2-specific T cell responses. HER2-specific T cells will be expanded ex vivo and subsequently infused to patients following lymphodepletion with cyclophosphamide. Trastuzumab and pepinemab will be given as maintenance in addition to booster DC1 vaccines.

Patients (ECOG 0,1) must have had disease progression while on trastuzumab for the treatment of HER2+ MBC and received no more than 3 lines of therapy in the setting of metastatic disease. Dose escalation will consist of 3-6 patients each with increasing amounts of transferred CD4+ T cells, followed by dose expansion of 10 patients at the MTD. The primary objective is safety and tolerability; secondary objectives will include evaluation of T cell immunity and immune subsets, efficacy, PK/PD/ADA of pepinemab, and biomarker assessments.

Trial Registration NCT05378464

646 NEOADJUVANT IMMUNOTHERAPY COMBINING MAVEROPEPIMUT-S (MVP-S) WITH LETROZOLE DECREASES KI67 AND INCREASES TH1 IMMUNE RESPONSE IN HORMONE RECEPTOR POSITIVE (HR+) EARLY-STAGE BREAST CANCER (ESBC)

[1]Sasha Stanton*, [2]Lisa MacDonald, [2]Stephan Fiset, [2]Heather Hirsch, [2]Kabir Mody, [2]Jeremy Graff, [2]Aurelio Lobo, [2]Danielle Lanroue, [2]Heather Torrey, [3]Nicole Moxon, [3]Staci Mellinger, [3]Tracy Kelly, [1]David Page, [1]Kristina Young. *[1]Earle A. Chiles Research Institute, Portland, OR, USA*; *[2]IMV Inc., Dartmouth, Canada*; *[3]Providence Portland Cancer Institute, Portland, OR, USA*

Background HR+ ESBC is associated with a suboptimal pathologic complete response rate (pCR, ~10%) following neoadjuvant cytotoxic chemotherapy. A genomic analysis among Ki67-high HR+ tumors identified 8-fold upregulation of BIRC5 (survivin), a gene commonly overexpressed in several cancers that regulates apoptosis and cell cycle progression and that is associated with poor clinical outcome. Maveropepimut-S (MVP-S) is an immune-educating therapy including 5 HLA-restricted peptides from survivin leveraging the lipid-based DPX delivery platform. Treatment with MVP-S and intermittent, low-dose cyclophosphamide (CPA) has shown tumor infiltration of survivin-specific T cells in ovarian cancer. The goal of this study is to determine if MVP-S can be safely administered and whether MVP-S can instigate a survivin-specific immune response in this patient population.

Methods NCT04895761 is a phase I trial evaluating the safety and immunologic effects of neoadjuvant MVP-S plus letrozole. Three postmenopausal patients with T1c+ HR+HER2- breast cancer with Ki67>10% have been enrolled to arm A and received two doses of MVP-S and 7 weeks of neoadjuvant letrozole prior to surgery. The systemic type I survivin-specific immune response was measured by IFN-γ ELISPOT using the pooled peptides in MVP-S. Changes in tumor infiltrating lymphocytes (TILs) and Ki67 were determined. TILs were evaluated by hemoxylin and eosin staining (H&E) per Salgado *et al*.[1]

Results Three patients have tolerated letrozole and MVP-S well without dose reductions or delays in surgery. All toxicities related to MVP-S were grade 1 injection site reactions including pruritis, induration, and erythema, occurring in all three patients. All toxicities related to letrozole are expected including hot flashes and joint pains. All three patients had at least a 50% decrease in Ki67 between biopsy and surgery, from median 24% (range 12% to 43%) before treatment to median 6% (range 5% to 10%) after treatment. All patients had pre-treatment TIL of 5-10%. One patient had patchy infiltrate of TIL up to 40% in the tumor after treatment but the other two had no increase in TIL by H&E. One patient had 8-fold increase of survivin-specific circulating IFN-γ T cells at surgery. One patient did not have a significant increase over baseline and the third patient was not evaluable.

Conclusions Combining MVP-S and letrozole is safe and well tolerated to date as neoadjuvant therapy in HR+ early-stage breast cancer. This neoadjuvant regimen decreased Ki67 in all patients. One patient had significantly increased survivin-specific IFN-γ T cells and one had increased TILs in the tumor.

647 PHASE I STUDIES OF AGENT-797, A NOVEL ALLOGENEIC INVARIANT NATURAL KILLER T (INKT) CELL THERAPY, FOR THE TREATMENT OF PATIENTS WITH SOLID TUMORS OR MULTIPLE MYELOMA

[1]Don Stevens, [2]Clifton Mo, [3]Benjamin Garmezy, [1]John Hamm, [4]Benedito Carneiro, [5]Breelyn Wilky, [6]Rachel Sanborn, [7]Anthony El- Khoueiry, [8]Alexa Buffa, [9]Sonia De Munari, [9]Burcu Yigit, [9]Marco Purbhoo, [9]Mark Exley, [10]David Einstein*. *[1]Norton Cancer Institute, Louisville, KY, USA; [2]Dana-Farber Cancer institute, Boston, MA, USA; [3]Sarah Cannon Cancer Institute Nashville, Nashville, TN, USA; [4]Lifespan Cancer Institute, Providence, RI, USA; [5]University of Colorado Cancer Center, Aurora, CO, USA; [6]Earle A. Chiles Research Institute, Portland, OR, USA; [7]USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA; [8]Agenus Inc, Lexington, MA, USA; [9]MiNK Therapeutics, Lexington, MA, USA; [10]Beth Israel Deaconess Medical Center, Boston, MA, USA*

Background AgenT-797, is an allogeneic CD1d-restricted T cell population (iNKT) that responds to lipid antigenic stimulation with potent cytokine secretion. iNKTs promote innate and adaptive immunity, home to critical organs (e.g., liver/lung/bone marrow), suppress myeloid-derived suppressor cells, and recondition the tumor microenvironment. AgenT-797 is a scalable, off-the-shelf therapy that retains potent cytotoxicity after cryopreservation and can be administered without lymphodepletion. This analysis represents data from 2 ongoing phase 1 studies of agenT-797 in patients with relapsed/refractory (r/r) multiple myeloma (MM) (NCT04754100) and agenT-797 alone or combined with pembrolizumab or nivolumab in r/r solid tumors (NCT05108623).

Methods Patients with r/r solid tumors and measurable disease per RECIST 1.1 received either agenT-797 monotherapy at 4.3 x 10^6 cells/kg or 1.4 x 10^7 cells/kg or in combination with pembrolizumab or nivolumab. Patients with r/r multiple myeloma received agenT-797 at 1.4 or 4.3 x 10^6 cells/kg or 1.4 x 10^7 cells/kg after having failed at least three prior treatments (proteasome inhibitor, immunomodulatory agent and anti-CD38 antibody). Dose-escalation followed a 3+3 scheme and endpoints included safety, persistence of agenT-797, antitumor activity measured as duration of response, progression-free survival, and time to response. Adverse events (AEs) were reported per CTCAE v5.0 and dose limiting toxicities (DLTs) were evaluated.

Results Enrollment commenced May 2022; as of July, thirteen patients with r/r solid tumors (median age 62y, range 46-92) were treated with a single dose of agenT-797 as a monotherapy (cervical, gastric, breast, pancreas, thymoma, GU, others) or in combination with approved anti-PD-1 (NSCLC, RCC, SCC). In r/r multiple myeloma, four patients (median age 55y, range 50-72) with ECOG 0 and median 5 prior lines of therapy were treated with a single dose of agenT-797, without lymphodepletion in two escalating cohorts. No DLTs were observed. Tolerability was favorable with no cytokine release syndrome (CRS), neurotoxicity, or severe immune-related AEs. No patients experienced treatment-related serious adverse events nor AEs ≥grade 3. Enrollment is ongoing with early observations including reduction of liver mets and SD>3 (Rectal) and >50% reduction of tumor cells in bone marrow with SD>10 (multiple myeloma).

Conclusions AgenT-797 is a novel iNKT cell potential therapy for patients with solid tumor cancers and hematologic malignancies. Updated data on safety, efficacy, and translational analyses, including persistence, serum biomarkers, and alloimmunity, will be presented.

648 AUTOLOGOUS MACROPHAGE-BASED IMMUNOTHERAPY INDUCES A PRO-INFLAMMATORY STATE IN GBM TUMOR MICROENVIRONMENT – (TEM-GBM)

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0648

[1]Gaetano Finocchiaro*, [1]Bernhard Gentner, [2]Marica Eoli, [1]Francesca Farina, [1]Alessia Capotondo, [2]Elena Anghileri, [1]Matteo Barcella, [3]Valentina Brambilla, [2]Maria Grazia Bruzzone, [1]Matteo Carrabba, [2]Valeria Cuccarini, [4]Giorgio D'Alessandris, [2]Francesco Di Meco, [1]Valeria Ferla, [5]Alberto Franzin, [2]Paolo Ferroli, [1]Filippo Gagliardi, [2]Federico Legnani, [3]Stefania Mazzoleni, [1]Pietro Mortini, [1]Matteo Maria Naldini, [4]Alessandro Olivi, [4]Roberto Pallini, [2]Monica Patanè, [2]Rosina Paterra, [2]Bianca Pollo, [1]Marco Saini, [1]Silvia Snider, [3]Andrew Zambanini, [1]Naldini Luigi, [3]Carlo Russo, [1]Fabio Ciceri. *[1]San Raffaele Hospital, Milan, Italy; [2]Istituto Neurologico Carlo Besta, Milan, Italy; [3]Genenta Science, Milan, Italy; [4]Policlinico Gemelli, Rome, Italy; [5]Fondazione Poliambulanza, Brescia, Italy*

Background The dynamic regulation of the tumor microenvironment (TME) is a key mechanism driving clinical outcome with immunotherapies. The presence of different macrophage phenotypes in the TME may either promote tumor growth (M2) or phagocytose cancer cells and remodel the TME (M1). Influencing macrophage polarization may be an important target for immunotherapy.

Methods Temferon is an autologous HSC-based platform that delivers targeted IFNa into the TME via Tie-2 expressing monocytes, with transcriptional & post-transcriptional control mediated by miRNA target sequences. Temferon is being administered in a Phase 1/2a clinical trial in 21 newly diagnosed glioblastoma (GBM) patients with unmethylated MGMT promoter.

Results As of July 2022, 4 escalating doses of Temferon (0.5-3.0x10^6/kg) were tested across 17 patients assigned to 6 cohorts. Current total follow-up from Temferon infusion is 7–749 days (3–28 months after 1st Surgery). Seven recurrent tumors were resected and where enough fresh material was available gene-marked cells were identified in the CD45+ tumor infiltrate in 2/2 specimens (3%-5%). scRNA analysis of the myeloid TME compartment (n=4 Temferon patients) detected a broad induction of an IFN, TNF/NFkB and hypoxia response relative to n=6 standard-of-care treated patients and unveiled an overrepresentation of pro-inflammatory macrophage clusters. Strikingly, this closely resembled the microenvironmental changes observed in a murine GBM model treated with IFN gene therapy (Birocchi, Sci Transl Med, 2022), where a shift in the M2 to M1 macrophage balance was associated with tumor responses. Notably, the highest proportion of pro-inflammatory macrophages was detected in a stable lesion biopsied from a patient that had a contemporaneous progressing lesion, which instead contained the lowest pro-inflammatory macrophage quantity. Analysis of the T cell compartment (scRNAseq+TCRseq) of the stable lesion highlights the presence of specific CD8+ T cells clones characterized by an effector phenotype with an inflammatory profile (IFNa/g response, TNFa signaling).

Conclusions These data support the hypothesis that Temferon, by acting on the M1-M2 balance, favors a pro-inflammatory state that, as predicted by preclinical studies, induces an immune system reset that may favor containment of GBM growth.

Ethics Approval The TEM-GBM Clinical Trial (NCT03866109) has been reviewed and approved by the Italian Competent Regulatory Authority, AIFA, on 26/09/2018. The Coordinating Etichal Committee, San Raffaele Hospital (Milan), approved the study on 12/07/2018 and then on 11/10/2018.

649 **PHASE 1/2 STUDY OF AGENT-797, AN ALLOGENEIC INVARIANT NATURAL KILLER T (INKT) CELL THERAPY, IN SUBJECTS WITH MODERATE TO SEVERE ACUTE RESPIRATORY DISTRESS SYNDROME (ARDS) SECONDARY TO SARS-COV-2 (COVID-19)**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0649

[1]Marco Purbhoo, [1]Burcu Yigit, [1]Xavier Michelet, [1]Rachel Smith, [1]Darrian Moskowitz, [2]Maurice Kirby, [2]Alexa Buffa, [1]Sonia De Munari, [2]Waldo Ortuzar Feliu, [3]Koen Van Besien, [4]Don Stevens, [1]Mark Exley, [5]Terese Hammond*. *[1]MiNK Therapeutics, Lexington, MA, USA*; *[2]Agenus Inc, Lexington, MA, USA*; *[3]Weil Cornell Medicine, New York, NY, USA*; *[4]Norton Cancer Center, Louisville, KY, USA*; *[5]Providence Saint John's Health Center, Santa Monica, CA, USA*

Background AgenT-797 is a novel allogeneic iNKT cell therapy demonstrating activity in malignances and serious viral infections (i.e., SARS-CoV-2). In response to inflammatory injury, iNKTs home to critical organs, including lungs, dampen proinflammatory cytokines and protect epithelial tissues. INKTs drive response through activation of innate and adaptive immunity, recruitment/trans-activation of NK, B, and T cells, and myeloid cells via contact and soluble mediators. iNKTs represent a novel and attractive potential immunotherapy for viral ARDS. This analysis presents results from an ongoing phase 1/2 study of agenT-797 in mechanically ventilated patients with moderate to severe ARDS secondary to COVID-19; NCT04582201.

Methods As of February 2022, patients on mechanical ventilation with confirmed moderate to severe (Berlin Definition) ARDS, secondary to COVID-19 were treated with a single infusion of agenT-797 at 100, 300, or 1000 x 10^6 iNKT cells. Primary endpoint was safety and secondarily, time to extubation, prevention of secondary infections, persistence and alloimmunity were evaluated. Clinical benefit was defined as improvement/resolution of viral ARDS evaluated as time to extubation and survival at 30 days post-infusion.

Results Twenty evaluable patients were treated with agenT-797 with a median age of 66 years (range 26-77; 85% ≥65y). Patients enrolled early in pandemic (pre-vaccines) and were heavily pre-treated with remdesivir, steroids and/or tocilizumab. No dose-limiting toxicities were observed. Tolerability was favorable with no cytokine release syndrome (CRS), neurotoxicity, or severe immune-related AEs. One SAE was deemed possibly related to agenT-797 (Dyspnea, Grade 4). The most frequent AEs deemed possibly related was pyrexia (grade 1; n=6). Survival was 70% (14/20) in this predominantly elderly, mechanically ventilated population. Early signals of reduction in ARDS symptoms, rapid extubation, and reduction in secondary infections were observed.

AgenT-797 was detected in peripheral blood up to day 6 post-infusion, consistent with a rapid translocation from blood to tissue. Spikes in the blood during D1 and D2 showed a dose-proportional relationship, however, increased dose did not lead to prolonged peripheral persistence. Additional translational and biomarker evaluation is underway.

Conclusions In patients with severe viral ARDS secondary to SARS-COV-2, agenT-797 demonstrated encouraging survival and disease mitigating benefit with a favorable tolerability profile. The deep and broad activity observed is likely attributed to iNKT cells' ability to promote viral clearance, home to the lungs, and reduce inflammation. These findings support the potential for a variant-agnostic therapy for patients with viral ARDS, a condition for which there are currently no effective therapies.

Trial Registration NCT04582201

650

PELAREOREP COMBINED WITH ATEZOLIZUMAB AND CHEMOTHERAPY DEMONSTRATES ENCOURAGING RESULTS AS FIRST-LINE TREATMENT IN ADVANCED OR METASTATIC PANCREATIC DUCTAL ADENOCARCINOMA (PDAC) PATIENTS – INTERIM RESULTS FROM THE GOBLET STUDY

[1]Dirk Arnold, [1]Maike Collienne, [2]Alexander Stein, [3]Guy Ungerechts, [2]Eray Goekkurt, [4]Jack Chater, [5]Houra Loghmani, [5]Matt Coffey, [5]Richard Trauger, [6]Uwe Martens, [5]Thomas Heineman*. *[1]Asklepios Tumorzentrum Hamburg, Hamburg, Germany; [2]Hematology-Oncology Practice Eppendorf, Hamburg, Germany; [3]University Hospital Heidelberg, Heidelberg, Germany; [4]Klinikum Chemnitz gGmbH, Chemnitz, Germany; [5]Oncolytics Biotech, Calgary, Canada; [6]SLK-Kliniken Heilbronn GmbH, Heilbronn, Germany*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0650

Background Pelareorep (pela) is an intravenously administered, non-genetically modified oncolytic reovirus that selectively kills tumor cells and activates both innate and adaptive immune responses. In prior clinical trials, pela was shown to prime tumors for checkpoint inhibition by enhancing infiltration of lymphocytes into tumors and increasing PD-L1 expression. The GOBLET basket study was designed to assess the safety and efficacy of pela in combination with atezolizumab (atezo) +/- chemotherapy in multiple gastrointestinal cancer indications (PDAC, 1L MSI-H colorectal cancer, 3L MSS colorectal cancer, 2L anal carcinoma). Here we report the interim results for patients with advanced/metastatic PDAC.

Methods GOBLET is a phase 1/2 Simon two-stage study. PDAC patients enrolled in GOBLET are treated with pela, atezo and gemcitabine/nab-paclitaxel. They must have locally advanced/metastatic unresectable disease evaluable by RECIST v1.1, be ≥18 years old and have an ECOG score ≤1. The first stage enrolled 12 evaluable PDAC patients (evaluable patients must have at least one post-baseline tumor assessment). The primary objectives are safety and efficacy by investigator-assessed objective response rate (ORR). The protocol-specified Stage 1 success criterion for PDAC is ≥3 confirmed responses. In addition, blood samples collected at baseline (cycle 1 day 1 [c1d1]) and c2d1 of the 28-day treatment cycle will undergo T-cell receptor sequencing (TCR-seq) to assess treatment effect on the T-cell repertoire.

Results No safety signals have been observed in patients treated with pela, atezo and gemcitabine/nab-paclitaxel. Seven of 10 evaluable patients to date (28July2022) had a partial response at week 8 or later (3 confirmed, 4 currently unconfirmed), and 2 had stable disease for an objective response rate (ORR) of 70% and a clinical benefit rate (CBR) of 90%. TCR-seq revealed an expansion of T-cell clones, a decrease in clonal diversity, and an increase in T-cell fraction from c1d1 to c2d1 in all three patients for whom data are available. Updated tumor response and TCR-seq results will be presented.

Conclusions Consistent with previous studies in PDAC and other indications, pela in combination with chemotherapy and a checkpoint inhibitor is well-tolerated. The primary efficacy success criterion was met, and the high ORR and CBR observed in this study are very encouraging in comparison to tumor response rates observed in prior first-line PDAC treatment studies. The changes in T-cell repertoire observed in the first three patients are consistent with previous pelareorep/checkpoint inhibitor studies and will be further evaluated as possible biomarkers for response to therapy.

Trial Registration (Eudra-CT: 2020-003996-16)

Ethics Approval The study was approved by the ethic committee of Hamburg on February 22, 2021.

651 **PHASE 2 TRIAL OF AGEN1423, AN ANTI-CD73-TGFβ-TRAP BIFUNCTIONAL ANTIBODY, IN COMBINATION WITH BALSTILIMAB, WITH OR WITHOUT CHEMOTHERAPY IN SUBJECTS WITH ADVANCED PANCREATIC CANCER**

[2]Joseph Grossman, [2]Jaymin Patel, [2]Bonnie Bullock, [2]Benjamin Morin, [2]Lilian Gaynor, [3]Manuel Hidalgo, [1]Bruno Bockorny*. *[1]Beth Israel Deaconess Medical Center, Boston, MA, USA; [2]Agenus Inc., Lexington, MA, USA; [3]Cornell University, New York, NY, USA*

Background Immunotherapy has made relatively few inroads in pancreatic ductal adenocarcinoma (PDAC) due to its non-redundant mechanisms of resistance, underscoring the need to target alternative immune pathways using a multi-faceted approach. Transforming growth factor-beta (TGFβ) plays an important role in mediating primary resistance to programmed cell death protein/ligand 1(PD-1)/PD-(L)1 blockade. Active adenosine signaling and high basal CD73 expression (an enzyme involved in adenosine metabolism), represent another established resistance mechanism in PDAC and other solid tumors. AGEN1423 is a bifunctional humanized immunoglobulin (IgG1) antibody designed to target both CD73 and TGFβ with a unique mechanism of action featuring (1) preferential localization within the tumor microenvironment (TME) via its CD73 targeting moiety; (2) ability to reduce the concentration of adenosine in the TME by blocking CD73 enzymatic activity; and (3) inhibition the immunosuppressive effect of TGFβ via intracellular trapping. A Phase 1 dose escalation study of AGEN1423 monotherapy was already conducted in patients with advanced solid tumors. Collectively, AGEN1423 is a promising therapeutic investigational candidate designed to address two unique immunosuppressive resistance mechanisms in PDAC simultaneously.

Methods This open-label, two-cohort Phase 2 clinical trial was designed to assess the safety and efficacy of AGEN1423 plus balstilimab with or without chemotherapy in advanced PDAC. Eligible patients include individuals ≥18 years with histologically or cytologically confirmed metastatic or locally advanced PDAC, Eastern Cooperative Oncology Group performance status of 0 or 1 and adequate organ and bone marrow function. In cohort 1, twelve patients with advanced PDAC with progression after ≥1 prior lines of therapy will be enrolled to receive AGEN1423 30mg/kg plus balstilimab 3mg/kg on day 1 of a 14-day cycle. In cohort 2, twelve patients with metastatic PDAC following disease progression on fluorouracil-based therapy will be enrolled to receive AGEN1423 30mg/kg plus balstilimab 3mg/kg on days 1 and 15 of a 28-day cycle in combination with gemcitabine 1000 mg/m2 plus nab-paclitaxel 125 mg/m2 on days 1, 8 and 15 of a 28-day cycle. The primary endpoint is to assess the objective response rate (ORR) according to RECISTv1.1. Secondary endpoints include disease control rate (stable disease or a complete or partial response), overall survival and progression-free survival, and to evaluate safety and tolerability. Biopsies will be obtained at baseline and on-treatment for multiplex immunohistochemistry and additional genomic analyses to better understand changes in the tumor microenvironment following AGEN1423 and balstilimab treatment. Recruitment is anticipated to commence in Q3 2022.

A PHASE 1 DOSE ESCALATION STUDY OF GCC19CART A NOVEL COUPLEDCAR® THERAPY FOR SUBJECTS WITH METASTATIC COLORECTAL CANCER

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0652

[1]Naifei Chen, [2]Chengfei Pu, [1]Lingling Zhao, [3]Ning Li, [1]Chang Wang, [4]Yusheng Huang, [3]Suxia Luo, [5]Xun Li, [4]Zhenzhou Yang, [6]Jun Bie, [2]Ruihong Zhu, [2]Xi Huang, [2]Haiyang Tang, [1]Tingting Liang, [1]Yizhuo Wang, [2]Beibei Jia, [2]Dongqi Chen, [2]Eugene Kennedy, [2]Zhao Wu, [3]Yongping Song, [2]Lei Xiao, [1]Jiuwei Cui, [2]Lei Xiao*, [2]Victor Lu*. [1]*The First Bethune Hospital of JLU, Changchun, China*; [2]*Innovative Cellular Therapeutics, Shanghai, China*; [3]*Henan Cancer Hospital, Zhengzhou, China*; [4]*The Second Affiliated Hospital of CQMU, Chongqing, China*; [5]*The First Hospital of Lanzhou University, Lanzhou, China*; [6]*Nanchong Central Hospital, Nanchong, China*

Background Chimeric antigen receptor (CAR) T-cell therapy has shown remarkable clinical efficacy in hematologic malignancies but limited success in solid tumors. GCC19CART, the first clinical candidate from the CoupledCAR® solid tumor platform, is designed to overcome the limitations of conventional CAR T-cells in solid tumor malignancies by pairing solid tumor CAR T-cells with CD19 targeting CAR T-cells to amplify proliferation and activation of the solid tumor CAR T component. GCC19CART targets guanylate cyclase-C (GCC) which is expressed in the metastatic lesions of 70%-80% of subjects with colorectal cancers. A Phase 1 investigator-initiated clinical trial is underway in China for patients with relapsed or refractory metastatic colorectal cancer who have received at least 2 prior lines of therapy. Based on a data cut-off on December 13, 2021, 21 subjects have been enrolled in 2 dose escalation groups at 5 hospitals in China.

Methods Subjects are screened for GCC expression by immunohistochemistry. Eligible subjects undergo leukapheresis, a single dose of lymphodepleting chemotherapy (fludarabine 30mg/m2 and cyclophosphamide 300mg/m2) 3 days prior to infusion, and then administration of a single infusion of GCC19CART at one of two preassigned doses: $1x10^6$ or $2x10^6$ CAR T-cells/kg. Endpoints are safety and preliminary evidence of efficacy as determined by CT or PET/CT per RECIST 1.1 or PERCIST 1.0. All responses were confirmed by an independent third-party imaging contract research organization (CRO).

Results 13 subjects have been enrolled to dose level 1 ($1x10^6$ cells/kg) and 8 subjects have been enrolled to dose level 2 ($2x10^6$ cells/kg). The most common adverse events were cytokine release syndrome (CRS) in 21/21 subjects (Grade 1 19/21 (90.48%) or Grade 2 2/21 (9.52%)) and diarrhea in 21/21 subjects (Grade 1 6/21 (28.57%) Grade 2 5/21 (23.81%) Grade 3 9/21 (42.86%) or Grade 4 1/21 (4.76%)). Neurotoxicity was observed in 2/21 (9.52%) subjects at Grade 3 or 4 and resolved with corticosteroids. The combined overall response rate (ORR) for both dose levels was 28.6% (6/21). For dose level 1, the overall response rate (ORR) per RECIST 1.1 was 15.4% (2/13). Two subjects demonstrated a partial response (PR) while 3 additional subjects had partial metabolic response (PMR) on PET/CT with stable disease (SD) or progressive disease (PD) per RECIST 1.1. For dose level 2, The ORR per RECIST 1.1 was 50% (4/8). 4 subjects demonstrated a PR (3 at month 1, 1 at month 3 after being SD at month 1) and 2 additional subjects had PMR on PET/CT with SD per RECIST 1.1.

Conclusions GCC19CART demonstrated meaningful dose dependent clinical activity and an acceptable safety profile in relapsed or refractory metastatic colorectal cancer. This trial is ongoing and updated data will be presented. A United States based Phase 1 trial of GCC19CART is anticipated for mid-2022.

653 **APN401, A NOVEL EPIC-BASED ANTI-CANCER CELL THERAPY, CASE REPORT: CBL-B SILENCED, AUTOLOGOUS PBMCS INDUCED STABLE DISEASE IN AN APPENDIX CARCINOMA PATIENT**

[1]Romana Gugenberger*, [1]Alexander Dohnal, [2]Andreas Tanzmann, [2]Beate Pribitzer, [2]Felix Batrina, [2]Stefan Bunka, [2]Sophia Spagl, [2]Manuela Branka, [1]Sarah Bischof, [1]Kathrin Thell, [1]Mario Kuttke, [1]Maria Urban, [1]Hannes Muehleisen, [1]Bernhard Peball, [2]Markus Raderer, [2]Gerald Prager, [2]Nina Worel. [1]*invIOs GmbH, Vienna, Austria*; [2]*Medical University of Vienna, Vienna, Austria*

Background While the immune system of cancer patients is generally capable of generating tumor-specific effector cells, their function is impaired due to immune checkpoint control. We and others have shown that the E3 ubiquitin ligase Cbl-b (Casitas B-lineage lymphoma-b) functions as a master checkpoint and plays a central role in surpressing both adapative and innate anti-tumor responses. Thus, by blocking Cbl-b function, immune effector functions against tumor cells may be restored. We have developed a novel way to transiently silence Cbl-b in a patient's peripheral blood mononuclear cells (PBMCs), named APN401, an autologous cell therapy. The use of an innovative closed cell processing Enhancement Platform for immune Cells (EPiC) enables manufacturing of high numbers of modified PBMCs for APN401 in a short processing time and allows for same-day out patient therapy.

Methods In our ongoing phase 1b trial, a 59-year-old white male patient with appendix carcinoma was treated with APN401, a drug product composed of a suspension of his own viable PBMCs. Those PBMCs were transfected *ex vivo* with a small interfering ribonucleic acid (siRNA) in order to reduce Cbl-b expression by using the innovative EPiC manufacturing process, comprising (I) purification of PBMCs from leukapheresis products, (II) electroporation of PBMCs to incorporate Cbl-b siRNA and (III) final PBMC formulation for re-infusion. The entire manufacturing process requires less than 6 hours and is approved by the national competent authorities for a same-day out patient therapy in a phase 1b trial. The trial is evaluating clinical outcome, safety, activity, and potency of the drug product; in addition, specific biomarkers are being analyzed.

Results This case report is part of an open-label, multi-center, dose escalation and expansion clinical trial evaluating three dose levels of APN401 using a 3+3 design in advanced solid tumor patients. The first cohort of the phase 1b study demonstrated feasibility, safety and tolerability for the lowest dose level (infused cell number: 5.0×10^6 PBMCs/kg). The patient with appendix carcinoma presented stable disease after APN401 treatment. Subsequent biomarker analyses revealed increased IL-2 levels indicating potency and an elevated CD8/CD4 ratio suggesting potential cytotoxic efficacy. In stimulation assays with HLA-1 restricted viral or tumor antigens, increased IFNγ levels were detected as surrogate markers for improved immunity and tumor reactivity.

Conclusions Our findings highlight that APN401,an autologous cell therapy based on selective Cbl-b silencing, may be a safe, potent, and effective immunotherapy for solid tumors.

Ethics Approval The study is approved by Medical University of Vienna institution's independent Ethics Board, approval number 1778/2020.

654 PERSONALISED TUMOUR-TRAINED LYMPHOCYTES DERIVED FROM REGIONAL LYMPH NODES FOR TREATMENT OF COLORECTAL CANCER

Anne-Laure Joly*, Sofia Berglund, Erwan Le Maitre, Ana Lukic, Luigi Notari, Ola Nilsson, Guro Gafvelin, Hans Grönlund. *Karolinska Institutet, Stockholm, Sweden*

Background Adoptive T cell therapy as a treatment for solid tumours is gaining increasing interest. Cancer neoantigens as targets for such therapy is also gaining recognition. Personalised tumour trained lymphocytes (pTTL) is a novel autologous T cell therapy targeting patient-specific neoantigens. A phase I/II First in Human (FIH) clinical trial of pTTL in Stage IV colorectal cancer (CRC) patients will be initiated in the near future.

Methods pTTL is produced through *in vitro* expansion of T cells derived from regional lymph nodes (RLNs). The T cells derived from RLNs, nodes in anatomical proximity of the tumour, contain a pool of naive and antigen-experienced T cells enriched for tumour-antigen specificity. This enriched population is stimulated during pTTL production with an array of neoantigen epitopes individually designed using PIOR®, an in house-developed software for neoantigen detection and selection. Selected neoantigens are linked to paramagnetic particles using EpiTCer® technology. The resulting EpiTCer® particles are used to stimulate the RLN T cells via phagocytosis and presentation of the neoantigen epitopes by antigen-presenting cells. This process is HLA-independent. Each pTTL product is unique due to the personalised nature of cellular and molecular players (cancer characteristics, immune cell properties and neoantigens are specific to one single individual).

In the planned FIH trial patients with Stage IV CRC which have either no remaining relevant standard care therapies or which are in a scheduled break in such therapy can be included. pTTL will be administered as a single dose monotherapy after chemotherapy-based preconditioning with cyclophosphamide and fludarabine. The primary endpoint of the trial is safety of pTTL. Biomarker analysis of pTTL persistence and characteristics will also be central in trial assessments, and clinical outcome and response will be evaluated.

Results Clinical results are not yet available. We here present central pTTL product characteristics. We have found that pTTL can be manufactured with a high rate of success despite the patient-specific nature of each product. The majority of the cells in pTTL are T cells, with small proportions of remaining NK and B cells originating from the RLN. The CD4 and CD8 T cell ratio are variable. Main pTTL characteristics include a significant proportion of memory T cells and phenotypic markers indicating maintained functionality such as limited levels of Temra (late stage memory cells re-expressing CD45RA) and CD57+ T cells, and maintained expression of CD28. TCRseq data have shown increased clonality in pTTL compared to RLNs, indicating antigen-specific expansion.

Trial Registration EUDRA CT #2022-000394-96

Ethics Approval The trial have been approved by the Swedish Ethical Review Authority, Approval # 2022-01842-01

Consent Written informed consent will be requested from study participants in future, but no study subjects have yet been included.

655 PIVOTAL SCREENING AND PROPOSED TREATMENT ALGORITHM FOR IMMUNE CHECKPOINT INHIBITOR–INDUCED CARDIO/MYOTOXICITIES IN NEOADJUVANT-TREATED RECTAL CANCER PATIENTS: EXPERIENCE FROM THE CHINOREC TRIAL

[1]Johannes Laengle*, [1]Jutta Bergler-Klein, [1]Simon Hametner, [1]Ellen Gelpi, [1]Irene Kuehrer, [1]Branka Petricevic, [1]Askin Kulu, [2]Clemens Bittermann, [1]Anton Stift, [2]Friedrich Laengle, [1]Klaus Machold, [1]Stephan Blueml, [1]Michael Bergmann. *[1]Medical University of Vienna, Vienna, Austria*; *[2]State Hospital Wiener Neustadt, Vienna, Austria*

Background Myotoxicities (myositis, myocarditis or rhabdomyolysis) are rare (incidence 0.21%) but potentially life-threatening immune-mediated adverse reactions (IMARs) of immune checkpoint inhibitors (ICI), such as ipilimumab (IPI) or nivolumab (NIVO), with a case fatality rate (CFR) of up to 40%. The true incidence is likely to be underestimated and may not be representative for neoadjuvant treatment approaches in gastrointestinal (GI) cancers, especially in combination with chemoradiotherapy (CRT). Currently the summary of product characteristics (SmPC) does not suggest any pre-emptive screening and surveillance for myotoxicities.

Methods The CHINOREC study (NCT04124601) is an ongoing prospective, randomized, open-label, multicenter, phase II investigator-initiated trial (IIT). Patients with locally advanced rectal cancer (LARC) receive either neoadjuvant CRT (50 Gy + capecitabine 1650 mg/m^2/d PO) alone or in combination with a single dose of IPI 1 mg/kg IV and 3 cycles of NIVO 3 mg/kg IV Q2W, with subsequent surgical resection in a curative intend. Patients are continuously screened at baseline and throughout the whole study period for cardio/myotoxicity biomarkers, such as creatine kinase (CK), creatine kinase muscle-brain (CK-MB), myoglobin (MB), troponin T (TnT) and N-terminal prohormone brain natriuretic peptide (NT-proBNP).

Results From 06/2020-03/2022, 24 patients were randomized to the CRT+IPI/NIVO arm. Out of these, 4 patients (16%) developed a biopsy-proven myositis, of whom 2 (8%) were symptomatic (1 patient with a grade 4 SAE). All patients were promptly initiated with medical interventions in a step-up approach, starting at the first time of elevated cardio/myotoxicity biomarkers (regardless of symptoms). Patients received prednisolone 1-2 mg/kg with concomitant intravenous immunoglobulin (IVIG) 2 g/kg. If myotoxicity biomarkers did not improve, patients received plasma exchange (PLEX) and if further ineffective, infliximab 5 mg/kg IV. To this date all patients have resolved back to normal CK and MB levels. Although all myositis patients had strikingly elevated TnT (median peak 330 ng/L, 95% CI 39-3097) and NT-proBNP levels (median peak 655 pg/mL, 95% CI 507-1161) myocardial involvement/overlap could not be proven by cardiac magnetic resonance imaging (MRI), transthoracic echocardiogram (TTE), electrocardiography (ECG) and/or coronary computed tomography angiography (CTA). However, myocardial biopsies were not performed due to safety concerns.

Conclusions Patients receiving neoadjuvant ICI with CRT should be closely monitored by myotoxicity biomarkers for potentially severe ICI-induced myositis to initiate early counter treatment in a step-up approach. Highly elevated TnT values were observed despite the lack of myocarditis in cardiac diagnostic work-up. As treatment for ICI-induced myositis will concomitantly treat potential cardiotoxicity, myocardial biopsy may be debatable.

Acknowledgements This is an investigator-initiated trial (IIT), which received a research grant and the study medications from Bristol-Myers Squibb (BMS).

Trial Registration NCT04124601

Ethics Approval The study protocol was verified by the "Ethics Committee of the Medical University of Vienna" (EC No. 2040/2019).

Consent Written informed consent was obtained from the patient for publication of this abstract. A copy of the written consent is available for review by the Editor of this journal.

656 EXPLORATORY PLATFORM TRIAL TO EVALUATE IMMUNOTHERAPY COMBINATIONS WITH CHEMOTHERAPY FOR THE TREATMENT OF PATIENTS WITH PREVIOUSLY UNTREATED METASTATIC PANCREATIC ADENOCARCINOMA (REVOLUTION)

[1]Jaclyn Lyman*, [2]Eileen O'Reilly, [3]Zev Wainberg, [4]George Fisher, [5]Robert Wolff, [6]Andrew Ko, [7]Mark O'Hara, [8]Harshabad Singh, [7]Ravi Amaravadi, [9]Alec Kimmelman, [6]Eric Collison, [2]Danny Khalil, [1]Rosemarie Schmidberger, [1]Christopher Cabanski, [1]Stephen Maddock, [1]Marko Spasic, [1]Deena Maurer, [1]Diane Da Silva, [1]Christopher Perry, [1]Jia Xin Yu, [1]Lacey Padrón, [1]Samantha Bucktrout, [10]Lisa Butterfield, [1]Ramy Ibrahim, [1]Justin Fairchild, [1]Theresa LaVallee, [11]Thomas Lillie, [12]William Hoos, [13]Silvia Boffo, [1]Ute Dugan, [14]Jill O'Donnell-Tormey, [7]Robert Vonderheide. *[1]Parker Institute for Cancer Immunotherapy, San Francisco, CA, USA; [2]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]University of California, Los Angeles, Los Angeles, CA, USA; [4]Stanford University, San Francisco, CA, USA; [5]MD Anderson Cancer Center, Houston, TX, USA; [6]University of California, San Francisco, San Francisco, CA, USA; [7]University of Pennsylvania, Abramson Cancer Center, Philadelphia, PA, USA; [8]Dana-Farber Cancer Institute, Boston, MA, USA; [9]New York University School of Medicine, Perlmutter Cancer Center, New York, NY, USA; [10]Parker Institute for Cancer Immunotherapy, San Francisco, CA, USA; [11]PsiOxus Therapeutics, Ltd, Abingdon, UK; [12]1440 Foundation, Scotts Valley, CA, USA; [13]Bristol Myers Squibb, Princeton, NJ, USA; [14]Cancer Research Institute, New York, NY, USA*

Background Metastatic pancreatic adenocarcinoma (mPDAC) remains notoriously treatment-refractory, particularly to immunotherapy; however, recent promise has been demonstrated with chemoimmunotherapy combinations.[1,2] REVOLUTION is an adaptive platform trial, designed to further these advancements by assessing the safety and antitumor activity of parallel, novel chemoimmunotherapy combinations in patients with untreated mPDAC. Coupled with deep immune biomarker profiling, this approach will enable rapid insights from each combination, generating data to be leveraged for future cohorts. REVOLUTION also builds upon the collaborative framework between academic, nonprofit and industry partners, laid by the PRINCE trial.[1]

Methods REVOLUTION is an open-label, non-randomized, exploratory platform trial. Each cohort utilizes a Simon two-stage design: Stage 1 enrolling n=15 patients, expansion to Stage 2 (an additional n=15 patients) based on the totality of safety, efficacy and biomarker analyses.

Key inclusion criteria histologically or cytologically confirmed, treatment-naïve, recurrent or de novo mPDAC, measurable by RECIST 1.1. Primary endpoints: safety, as assessed by the incidence and severity of adverse events. Secondary endpoints: ORR (per RECIST 1.1), DCR, DOR, PFS, and OS. Exploratory endpoints: pharmacodynamics and association of tumor, blood, and stool biomarkers with clinical activity.

Three cohorts are underway, all using a backbone of standard-of-care gemcitabine/nab-paclitaxel (gem/nP).

Cohort A: nivolumab + ipilimumab + gem/nP. We hypothesize chemotherapy will induce antigen release, ipilimumab will enhance T cell activation, proliferation and tumor infiltration, and nivolumab will overcome immunosuppression while re-invigorating therapeutically relevant T cells.

Cohort B: high-dose hydroxychloroquine (HCQ), an autophagy inhibitor, + ipilimumab + gem/nP. The same mechanisms of action for chemotherapy and ipilimumab as Cohort A are hypothesized, with HCQ augmenting T cell priming and cytotoxicity by upregulating MHC-1.[3]

Cohort C: NG-350A, an intravenously administered adenovirus that selectively replicates in tumor cells and expresses a fully human agonistic CD40 monoclonal antibody, + ipilimumab + gem/nP. The same mechanisms of action for chemotherapy and ipilimumab as Cohorts A and B are hypothesized, with NG-350A re-programming the tumor microenvironment, activating antigen-presenting cells, and facilitating immune priming.[4]

In accordance with recent findings, all current cohorts are also testing a novel dosing schedule of ipilimumab (2 doses at 1 mg/kg, Q6W).[5]

Results Cohorts A and B are fully enrolled for Stage 1 and accumulating data to support an expansion decision. Cohort C is in development.

Acknowledgements We extend our gratitude to the patients and their families, as well as the clinical investigators and their site teams for making this trial possible. We also thank Jay Campbell and Samik Upadhaya at Cancer Research Institute for their collaboration. The study is funded by Cancer Research Institute, 1440 Foundation, Bristol Myers Squibb and PsiOxus Therapeutics, Ltd. Study drug is supplied by Bristol Myers Squibb and PsiOxus Therapeutics, Ltd.

657 **NT-I7, A LONG-ACTING IL-7, PLUS PEMBROLIZUMAB FAVORS CD8 T-CELL INFILTRATION IN LIVER METASTASES OF HEAVILY PRE-TREATED, IMMUNOLOGICALLY COLD, MSS-COLORECTAL AND PANCREATIC CANCER**

[1]Aung Naing*, [2]Sara Ferrando-Martinez, [2]Michael Ware, [1]Cara Haymaker, [2]Allison Bierly, [2]Jack Goon, [3]Marya Chaney, [2]Swati Dhar, [4]Chan-Young Ock, [5]Siyoung Lee, [4]Kyunghyun Paeng, [5]Taeseob Lee, [2]Tolani Adebanjo, [2]Se Hwan Yang, [2]Byung Ha Lee, [6]Richard Kim. *[1]MD Anderson Cancer Center, Houston, TX, USA; [2]NeoImmuneTech, Inc., Rockville, MD, USA; [3]Merck and Co., Inc., Kenilworth, NJ, USA; [4]Lunit, Inc., Seoul, Republic of Korea; [5]Geninus, Inc., Seoul, Republic of Korea; [6]Moffitt Cancer Center, Tampa, FL, USA*

Background Checkpoint inhibitors (CPI) have null objective response (ORR) and dismal disease control rates (DCR) in microsatellite-stable colorectal (MSS-CRC) and pancreatic cancer (PaC), due to low mutation burden and sparse T-cell infiltration. Liver metastases are common in these indications and are harder to infiltrate, further reducing the efficacy of immunotherapy. NT-I7 (efineptakin alfa) in combination with pembrolizumab has been shown to increase T-cell infiltration. This study explores the ability of NT-I7 and pembrolizumab to support T-cell infiltration in subjects with liver metastasis as a correlate of clinical efficacy.

Methods Open-label, phase 2a study in subjects with relapsed/refractory (r/r) CPI-naïve MSS-CRC and PaC. Subjects received NT-I7 at 1200 μg/kg every 6 weeks (Q6W) plus pembrolizumab at 200 mg Q3W. Antitumor activity was assessed by RECIST v1.1 and iRECIST. Pre-treatment and on-treatment biopsies were analyzed by Lunit SCOPE IO, an artificial intelligence-powered H&E analyzer, and immunohistochemistry. For exome sequencing analysis, single nucleotide variants and indels were detected and filtered by GATK Mutect2.

Results As of April 29, 2022, 53 subjects were evaluable. 67.9% of subjects had ≥2 prior therapies; 73.6% had liver metastasis and median tumor mutation burden (TMB; n=18) was 3.22 mutations/megabase. ORR was 3.8% per RECIST and 9.4% per iRECIST. Total density of tumor-infiltrating lymphocytes (TIL) significantly increased on-treatment, despite low TMB. Subjects with metastasis to sites other than the liver had 28.6% iORR and 71.4% iDCR, a remarkable result considering the lack of response with anti-PD(L)1 monotherapy, and significantly higher overall survival (OS; p=0.0241). However, NT-I7 and pembrolizumab still demonstrated benefit for patients with liver metastasis; with an iDCR of 25.6%. CD8 T-cell infiltration increased with treatment regardless of tissue location, including liver biopsies (p=0.0032). Lymphoid aggregates containing CD8+TCF1+ lymphocytes, suggestive of tertiary lymphoid structures, were observed on-treatment (n=14) in both liver and non-liver biopsies, including all 3 patients with objective response. Moreover, CD8+ T-cell infiltration was directly associated with OS (p=0.0002), suggesting that NT-I7 plus pembrolizumab increases intratumoral TIL density and CD8 T-cell infiltration in primary and metastatic locations to mediate clinical benefit.

Conclusions NT-I7 plus pembrolizumab shows remarkable efficacy in immunologically cold CPI-naïve r/r MSS-CRC and PaC in the absence of liver metastasis. Furthermore, this combination also increases T-cell infiltration in immune-excluded liver biopsies, favoring a hot tumor microenvironment that contributes to the overall high iDCR observed in these hard-to-treat CPI-resistant indications.

Acknowledgements The authors thank ICON for their partnership in conducting this trial.

658 A PHASE 2 STUDY TO ASSESS THE SAFETY, EFFICACY OF FLX475 COMBINED WITH PEMBROLIZUMAB IN PATIENTS WITH ADVANCED OR METASTATIC GASTRIC CANCER

[1]Paul Rhee*, [2]Do-Youn Oh*, [3]Min Hee Ryu, [4]Jun-Eul Hwang, [5]Jaeyong Cho, [6]Dae Young Zang, [7]Sang Cheul Oh, [8]Jeeyun Lee, [9]Keun-Wook Lee, [10]Sun Young Rha, [11]Byoung Yong Shim, [12]William Ho, [1]Taewan Kim, [1]Eunhye Baek, [1]SeungJae Baek, [13]Michael Chisamore. *[1]Hanmi Pharmaceutical Co., Ltd., Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Asan Medical Center, Seoul, Republic of Korea; [4]Chonnam National University Hwasun Hospital, Gwangju, Republic of Korea; [5]Gangnam Severance Hospital, Seoul, Republic of Korea; [6]Hallym University Medical Center, Anyang-si, Republic of Korea; [7]Korea University Guro Hospital, Seoul, Republic of Korea; [8]Samsung Medical Center, Seoul, Republic of Korea; [9]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [10]Yonsei University College of Medicine, Seoul, Republic of Korea; [11]St. Vincent's Hospital, Suwon, Republic of Korea; [12]RAPT Therapeutics, South San Francisco, CA, USA; [13]Merck and Co., Inc., Kenilworth, NJ, USA*

Background Regulatory T-cells (T_{reg}) maintain homeostasis and self-tolerance, but can also suppress anti-tumor immunity in the tumor microenvironment (TME), correlating with poor clinical outcomes. C-C chemokine receptor type 4 (CCR4), the cognate receptor of the secreted proteins C-C motif chemokine ligand 17 (CCL17), and 22 (CCL22), is the predominant chemokine receptor on human T_{reg} and is responsible for migration and accumulation of T_{reg} in the TME.[1, 2, 3] FLX475 is an orally available and selective small-molecule antagonist of CCR4 which demonstrated potent inhibition of CCL17- and CCL22-induced CCR4-mediated chemotaxis, an increase in the intratumoral T_{eff}/T_{reg} ratio, and anti-tumor efficacy as a single agent and in combination with checkpoint inhibitors.[4] Given the proposed mechanism of action, a Phase 2 study investigating the safety, efficacy of FLX475 in combination with pembrolizumab in patients with advanced or metastatic gastric cancer is being conducted.

Methods This is a Phase 2, open-label study to assess the safety and efficacy of FLX475 in combination with pembrolizumab in patients with advanced or metastatic gastric cancer. Patients were treated across 2 cohorts administered with 100mg PO QD of FLX475 and 200mg IV Q3W of pembrolizumab. In cohort 1, checkpoint inhibitor (CPI) naïve Epstein-Barr Virus (EBV)-negative gastric cancer patients who have progressed on at least 2 prior systemic treatments for advanced or metastatic gastric cancer were enrolled, and in cohort 2, CPI-naïve EBV-positive gastric cancer patients who had at least 1 prior systemic treatment for advanced or metastatic gastric cancer were enrolled.

Results Initial analysis of cohorts was performed when the first 10 patients of each cohort completed 4 cycles or after 2nd response assessment (Cut-off date: 11 Oct 2021 (cohort 1), 15 Apr 2022 (cohort 2)). Overall, FLX475 in combination with pembrolizumab was well-tolerated, with no new safety signal detected. The most common treatment-emergent adverse events (all grade) occurred in more than 20% of patients across cohorts were QTc prolongation, pruritus, anaemia, headache, abdominal pain, fatigue, and aspartate aminotransferase increased. There were no responses observed in the EBV-negative cohort of 10 patients. However, 6 partial responses (ORR: 60.0%, all confirmed) from EBV-positive cohort were reported. Pharmacokinetic data demonstrated that majority of patients achieved the target minimum FLX475 exposure level of 130 ng/mL after 1 week of dosing. Pharmacodynamic biomarker changes were observed in tumor demonstrating biological activity of FLX475.

Conclusions FLX475 in combination with pembrolizumab was well-tolerated and exhibited promising anti-tumor efficacy in patients with advanced or metastatic EBV-positive gastric cancer.

Acknowledgements Thanks to the patients, and to their families and caregivers for allowing us to be part of the journey.

RAPT Therapeutics, Inc., South San Francisco, CA, USA is providing FLX475 for the study.

Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA is providing pembrolizumab for the study.

Background COM701 a novel, 1st in-class, humanized IgG4 monoclonal antibody binds with high affinity to PVRIG, blocking its interaction with its natural ligand PVRL2 expressed in tumor cells and antigen-presenting-cells. We have reported antitumor and pharmacodynamic activity of COM701.[1] Anti-PD1/L1 therapies have limited to no activity in MSS-CRC. Therefore, novel ICI are urgently needed for the treatment of pts with MSS-CRC particularly pts with liver metastasis. We present preliminary clinical and translational results of the combination in pts with MSS-CRC.

Methods This is a phase I clinical trial of COM701 and nivolumab. Key objectives were safety/tolerability [primary], preliminary antitumor activity, immune-related changes [secondary/exploratory]. Key inclusion criteria: Age ≥18 yrs, histologically/cytologically confirmed advanced malignancy who have exhausted all available standard therapy or not a candidate for standard therapy, MSS-CRC determination per local testing. Pre- and on-treatment biopsies were obtained and analyzed by IHC for PDL1, CD8 expression and omics profiling.

Results Twenty two pts were enrolled: 2 pts combination dose-escalation [COM701 0.3,1mg/kg + nivolumab 360 mg] both IV Q3W and 20 pts dose-expansion cohort [COM701 20mg/kg + nivolumab 480mg IV Q4W]. Age ≤65 17/22, [77%], male 16/22 [73%], median [Min, Max] of 3 (2, 10) prior lines of therapy, 17/22 [77%] had liver metastases. Overall, ORR 9% (2/22 pts, PRs]; ORR 12% [2/17] in pts with liver metastases [1 PR, PFS 44 weeks; 1 PR, PFS 16 weeks due to brain metastasis, however, response of target and non-target lesions still maintained]; DCR (CR+PR+SD) 27% (6/22). No new safety findings are reported. In 13 paired biopsy samples, 9 demonstrated induction in PD-L1 expression (mean 16.3+/-7% PD-L1 CPS-score increase, $p<0.05$), suggesting TME immune-modulation following treatment. In pts with PR or SD >6months greater induction in PD-L1 expression was seen (49.7+/-14.9%). CD8 T-cell quantification was available in 12 paired biopsies with increase >1% in 8 pts (mean% CD8 increase of 9.1+/-4.4% , $p=0.08$), with substantial increases in responders (36.5% and 44.7%%CD8 increase). In responding pts IFNγ signature up-regulation, increased T-cell clonality and specific clonal expansion, were demonstrated between baseline and on-treatment biopsies.

Conclusions COM701 + nivolumab demonstrates preliminary antitumor activity in pts with heavily pretreated metastatic MSS-CRC with 12% ORR in pts with liver metastases [typically unresponsive to ICI]. TME immune modulation observed in the majority of pts, substantial in responders, suggests unique potential of COM701 in less inflamed tumors such as MSS-CRC. The combination warrants further development. Datacut June 17, 2022.

660 CLINICOPATHOLOGIC CHARACTERISTICS OF PATIENTS WITH METASTATIC COLORECTAL CANCER WITH MOLECULAR RESPONSES FOLLOWING TREATMENT WITH AN INDIVIDUALIZED NEOANTIGEN VACCINE REGIMEN

[1]Chih-Yi Liao*, [2]Benny Johnson, [3]Alexander Spira, [4]David Carbone, [5]Brian Henick, [2]Michael Overman, [1]Blase Polite, [4]Sameek Roychowdhury, [6]Amit Mahipal, [6]Daniel Ahn, [7]Melissa Johnson, [8]Desiree Schenk, [8]Kyounghwa Bae, [8]Matthew Davis, [8]Karin Jooss, [8]Andrew Ferguson, [9]Benjamin Solomon. *[1]University of Chicago, Chicago, IL, USA; [2]The University of Texas MD Anderson, Houston, TX, USA; [3]Virginia Cancer Specialists, Fairfax, VA, USA; [4]The Ohio State University Medical Center, Columbus, OH, USA; [5]Columbia University Medical Center, New York, NY, USA; [6]Mayo Clinic, Rochester, MN, USA; [7]Sarah Cannon Research Institute, Nashville, TN, USA; [8]Gritstone bio, Inc., Emeryville, CA, USA; [9]Peter MacCallum Cancer Centre, Melbourne, Australia*

Background Individualized neoantigen cancer vaccines aim to benefit patients by generating strong, durable neoantigen-specific CD8 T cells. Previous data showed extended overall survival (OS) in patients with metastatic colorectal cancer (CRC) who achieved a molecular response (MR) versus those who did not after individualized neoantigen vaccination in combination with nivolumab and ipilimumab.[1] We report updated OS and analysis of clinicopathologic features of patients achieving a MR.

Methods Patients with metastatic CRC, non-small cell lung cancer, or gastroesophageal adenocarcinoma who had received routine chemotherapy were treated in a Phase 1/2 first-in-human study (NCT03639714). The vaccine regimen consisted of sequential administrations of chimpanzee adenovirus and self-amplifying mRNA (samRNA) vectors encoding 20 patient-specific neoantigens in combination with nivolumab (IV 480 mg Q4W) and ipilimumab (SC 30 mg).

Results Thirteen of 29 patients treated had CRC. Six of these 13 had stable disease (SD) and 7 had progressive disease (PD) per RECIST v1.1. Six patients achieved a MR defined as $\geq$ -30% reduction in ctDNA. Patients with a MR had prolonged overall survival (OS) compared to patients without a MR (see Table 1). MR was not associated with primary tumor location, presence of liver metastases, or *RAS* mutations and patients with a MR were not enriched for higher tumor mutation burden (TMB), PD-L1, or T cell inflamed gene expression profiles (GEP), and had similar baseline ctDNA values based on variant allele frequency (VAF) (p-value=0.18) (table 1).

Conclusions Patients who achieved MR had extended OS compared with those patients without MR. Patients with a MR were not enriched based on primary or metastatic tumor site or known correlates of response to checkpoint inhibitors. The lower baseline VAF observed in patients with a MR may be reflective of VAF in early metastatic disease. A subsequent, ongoing randomized study is evaluating individualized neoantigen vaccine in the 1L maintenance setting (NCT05141721).

Acknowledgements We thank patients and their families for participating in this clinical study and Bristol-Myers Squibb for supply of nivolumab and ipilimumab.

661 **INITIAL RESULTS FROM A PHASE 1A/B STUDY OF IK-175, AN ORAL AHR INHIBITOR, AS A SINGLE AGENT AND IN COMBINATION WITH NIVOLUMAB IN PATIENTS WITH ADVANCED SOLID TUMORS AND UROTHELIAL CARCINOMA**

[1]David Aggen*, [2]Meredith McKean, [3]Nehal Lakhani, [4]Babar Bashir, [5]Jean Hoffman-Censits, [6]Omar Alhalabi, [7]Elizabeth Guancial, [8]Isaac Bowman, [9]Alan Tan, [10]Trupti Lingaraj, [10]Marissa Timothy, [10]Nerymar Ortiz-Otero, [10]Wilmin Bartolini, [10]Katherine Kacena, [10]Karim Malek, [10]Sergio Santillana, [11]Jason Luke. *[1]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Tennessee Oncology, Nashville, TN, USA; [3]START Midwest, Grand Rapids, MI, USA; [4]Thomas Jefferson University, Philadelphia, PA, USA; [5]Johns Hopkins, Baltimore, MA, USA; [6]MD Anderson Cancer Center, Houston, TX, USA; [7]Florida Cancer Specialists, Sarasota, FL, USA; [8]Banner Health, Gilbert, AZ, USA; [9]Rush University, Chicago, IL, USA; [10]Ikena Oncology, Boston, MA, USA; [11]University of Pittsburgh, Pittsburgh, PA, USA*

Background Aryl Hydrocarbon receptor (AHR) is a transcription factor activated by binding to ligands, including kynurenine, causing expression of immune modulating genes leading to immunosuppression. IK-175 is an oral, selective, small molecule being developed as a potential first-in-class AHR inhibitor to overcome the immunosuppressive effects driving resistance to PD-1/L1 inhibitors. Computational and tissue-based analyses revealed urothelial cancer as having high levels of AHR signaling and nuclear protein localization.

Methods Dose escalation patients with advanced solid tumors received escalating daily doses of IK-175 as monotherapy or in combination with nivolumab 480 mg IV every 4 weeks (mTPI-2 design). Expansion cohorts of both treatment arms enrolled heavily pretreated urothelial carcinoma patients, who have progressed within 12 weeks of last dose of PD-1/L1 inhibitors (Simon 2-stage design). Expansion cohorts were enriched to include AHR+ patients determined by immunohistochemistry using a cutoff of 65% cells with 2+/3+ staining. Study objectives included evaluation of safety, pharmacokinetics, pharmacodynamics, MTD, RP2D and antitumor activity (RECIST 1.1) of IK-175 in both arms.

Results As of June 24, 2022, 43 patients were evaluated: 26 monotherapy (from 200 to 1600mg PO daily) and 17 combination (800 and 1200mg PO daily). Median age was 70 years (range 28-82), 28/43 (65%) patients received ≥3 lines of prior therapy including CPIs. 4/11 monotherapy and 3/11 combination urothelial cancer patients had AHR+ tumors. In both treatment arms, MTD was not reached and 1200mg PO QD was the selected IK-175 expansion dose based on the totality of the data. Most common treatment-related adverse events (TRAEs) in monotherapy were nausea and rash with 3 patients (12%) reporting ≥Grade3 TRAEs (nausea, proteinuria, and adrenal insufficiency). Most frequent TRAEs in combination arm were fatigue and dysgeusia with 1 patient (6%) reporting ≥Grade3 TRAEs (immune-related arthritis). Other suspected immune-related AEs included adrenal insufficiency, proteinuria, rash, and myopathy. In dose escalation, 3/13 response-evaluable patients in monotherapy and 2/5 in combination had prolonged stable disease (range 16-74 weeks). Preliminary assessment of antitumor activity in 20 response-evaluable urothelial carcinoma patients in both treatment arms showed 3 confirmed partial responses, having DoR up to 11.7 months and ongoing. Updated results, immune monitoring, and biomarker analysis will be presented.

Conclusions In this initial analysis, IK-175 was well tolerated and showed encouraging antitumor activity in eligible urothelial cancer patients in both monotherapy and combination arms. Based on the objective responses observed in stage 1 of both cohorts, investigation of AHR inhibition with IK-175 in urothelial carcinoma is ongoing.

663 **PHASE 2 MULTI-COHORT CLINICAL STUDY EVALUATING DISITAMAB VEDOTIN ALONE AND IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH HER2-EXPRESSING UNRESECTABLE OR METASTATIC UROTHELIAL CARCINOMA (RC48G001, TRIAL IN PROGRESS)**

[1]Matthew Galsky*, [2]Peter O'Donnell, [3]Earle Burgess, [4]Michiel Van der Heijden, [5]Laurence Krieger, [6]Andrea Necchi, [7]Evan Yu, [8]Nobuaki Matsubara, [9]Matthew Campbell, [10]Saikrishna Gadde, [11]Jeanny Aragon-Ching, [12]Vadim Koshkin, [13]Wei Zhang, [13]Kevin Sokolowski, [14]Thomas Powles. *[1]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [2]University of Chicago, Chicago, IL, USA; [3]Atrium Health Levine Cancer Institute, Charlotte, NC, USA; [4]The Netherlands Cancer Institute, Amsterdam, Netherlands; [5]Genesis Care, North Shore, Sydney, Australia; [6]Vita-Salute San Raffaele University, Milan, Italy; [7]University of Washington, Seattle, WA, USA; [8]National Cancer Center Hospital East, Chiba, Japan; [9]MD Anderson Cancer Center, Houston, TX, USA; [10]University of Tennessee Medical Center, Knoxville, TN, USA; [11]Inova Schar Cancer Institute, Fairfax, VA, USA; [12]University of California San Francisco, San Francisco, CA, USA; [13]Seagen Inc., Bothell, WA, USA; [14]Barts Health NHS Trust, London, UK*

Background Urothelial carcinoma (UC) is the 10th most diagnosed cancer worldwide, with a mortality rate of 1.9 per 100,000.[1] Nearly 50% of patients cannot tolerate the standard cisplatin-based first-line (1L) chemotherapy, which presents a strong need to improve outcomes in both 1L and later lines of therapy.

Human epidermal growth factor receptor 2 (HER2) overexpression has been reported in multiple malignant tumors, including UC, and may be associated with poor outcomes.[2] No HER2-directed therapies are currently approved for the treatment of urothelial carcinoma.

Disitamab vedotin (DV; RC48-ADC) is an investigational antibody–drug conjugate comprised of a novel HER2-directed monoclonal antibody, disitamab, conjugated to monomethyl auristatin E (MMAE) via a protease-cleavable linker. DV elicits antitumor activity through multimodal mechanisms of action including MMAE-directed cytotoxicity, bystander effect, and immunogenic cell death.[3] DV is conditionally approved in locally advanced unresectable or metastatic urothelial carcinoma (LA/mUC) and gastric cancer in China and was granted Breakthrough Therapy designation by the FDA.[4]

Methods RC48G001 (NCT04879329) is a phase 2, multicohort, open-label, multicenter trial to evaluate DV in patients with HER2-expressing LA/mUC.

Patients are enrolled in 3 cohorts based on prior treatment and tumor HER2 expression by immunohistochemistry (IHC) and gene amplification (via in situ hybridization [ISH]), assessed centrally. Cohorts A and B are enrolling patients who have received prior systemic therapy (1 or 2 lines, including platinum-containing chemotherapy) and whose tumors are HER2-positive (IHC 3+, or 2+ and ISH-positive) or HER2-low (IHC 2+ and ISH-negative, or IHC 1+), respectively. Cohort C is enrolling first-line treatment-naïve patients in the LA/mUC setting, whose tumors have HER2-positive or HER2-low expression.

Cohorts A and B will evaluate DV as monotherapy (intravenous [IV] administration, once every 2 weeks [Q2W]). Cohort C will evaluate DV (IV, Q2W) +/– pembrolizumab (IV, Day 1 of each 6-week cycle).

Patients in all cohorts must have measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 and an Eastern Cooperative Oncology Group Performance Status of 0-1 in Cohorts A and B, and 0-2 in Cohort C.

The primary endpoint is confirmed objective response rate (cORR) assessed by blinded independent central review (BICR). Secondary endpoints include cORR by investigator assessment, overall survival, duration of response, progression-free survival, disease control rate per RECIST v1.1 by BICR and investigator assessment, safety, and pharmacokinetic parameters.

Enrollment for all cohorts is ongoing in North America and Europe, and planned in Latin America, Asia-Pacific, and Israel.

664 A PHASE I TRIAL OF TREMELIMUMAB, DURVALUMAB (MEDI4736) AND BELINOSTAT IN *ARID1A* MUTATED CANCERS WITH FOCUS ON UROTHELIAL CARCINOMA (RESOLVE)

Sumati Gupta*, Benjamin Maughan, Manish Kohli, Bradley Cairns, Umang Swami, Neeraj Agarwal. *Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, USA*

Background *ARID1A* loss by mutation or deletion is the most common chromatin remodeling genomic alteration in cancer and occurs in about a fourth of all urothelial carcinoma (UC). Histone deacetylase inhibition (HDACi) has clinical benefit in *ARID1A* mutated UC.[1] *ARID1A* loss in cancer confers vulnerability to immune checkpoint inhibition (ICI) due to its association with microsatellite instability, high tumor mutational burden, increased expression of programmed death-ligand 1, and immune-active tumor microenvironment.[2] *ARID1A* mutation and inflammatory tumor microenvironment are associated with prolonged survival in metastatic UC treated with ICI.[3] The combination of HDACi plus ICI may enhance anti-tumor activity,[4] especially when used in a phased manner.[5] RESOLVE is a phase 1 study to study the dosing, safety, and efficacy of a phased regimen of tremelimumab and durvalumab (dual ICI) in combination with belinostat (HDACi) in advanced cancers with *ARID1A* loss, with a focus on UC.

Methods We are currently enrolling patients in this phase 1 open-label, dose-escalation, and safety-evaluating study of a phased triplet combination in a single cohort of patients with locally advanced or metastatic UC with *ARID1A* mutation. The primary objectives are to assess the recommended phase II dose of belinostat in combination with tremelimumab and durvalumab in advanced solid tumors harboring *ARID1A* mutations and to assess the ongoing safety of the combination. The secondary objective is to determine the efficacy of the triplet combination in patients with locally advanced or metastatic UC with *ARID1A* mutation.

Patients are treated with a fixed-dose intravenous regimen of tremelimumab 300 mg once with durvalumab 1500 mg on the first day of the first cycle. Belinostat is administered intravenously starting at cycle 2 in combination with durvalumab 1500 mg every three weeks for 6 cycles. This is followed by a maintenance phase of durvalumab 1500 mg every four weeks for a total treatment period of up to two years. Phase 1A begins with a single patient dose acceleration of belinostat from a dose of 750 mg/m^2 to 1000 mg/m^2 daily for five days, then administered every three weeks, with the expansion of cohort enrollment at the maximum-tolerated dose in phase 1B portion of the study. Patients with unresectable locally advanced or metastatic UC (variant histology is allowed) that harbor *ARID1A* loss of function genomic alterations are eligible for the study. Tissue and peripheral blood are collected at baseline, treatment, and progression for correlative studies. (NCT05154994)

665 **JAVELIN BLADDER MEDLEY: A PHASE 2 TRIAL OF AVELUMAB IN COMBINATION WITH OTHER ANTITUMOR DRUGS AS FIRST-LINE MAINTENANCE THERAPY FOR ADVANCED UROTHELIAL CARCINOMA**

[1]Jean Hoffman-Censits, [2]Petros Grivas, [3]Thomas Powles, [4]Danko Martincic, [5]Jessica Hawley, [6]Karin Tyroller, [7]Sonja Seeberger, [7]Silke Guenther, [7]Natalia Jacob, [7]Keyvan Tadjalli Mehr*, [8]Noah Hahn. *[1]The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Johns Hopkins Medical Institutions, Baltimore, MA, USA; [2]University of Washington, Fred Hutchinson Cancer Center, Seattle, WA, USA; [3]Barts Cancer Institute, Experimental Cancer Medicine Centre, Queen Mary University of London, St Bartholomew's Hospital, London, UK; [4]Beacon Cancer Care, Coeur d'Alene, ID, USA; [5]Division of Medical Oncology, University of Washington, Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA, USA; [6]EMD Serono, Billerica, MA, USA; [7]The Healthcare Business of Merck KGaA, Darmstadt, Germany; [8]Johns Hopkins University, Johns Hopkins Greenberg Bladder Cancer Institute, Baltimore, MD, USA*

Background In the JAVELIN Bladder 100 trial (NCT02603432), avelumab (anti–PD-L1) first-line (1L) maintenance + best supportive care (BSC) significantly prolonged overall survival (OS) and progression-free survival (PFS) vs BSC alone in patients with advanced urothelial carcinoma (UC) that had not progressed with 1L platinum-based chemotherapy. Results led to the approval of avelumab 1L maintenance therapy in various countries worldwide and inclusion in international treatment guidelines. We hypothesized that avelumab-based combinations may further improve outcomes in this setting. The JAVELIN Bladder Medley trial will investigate such combinations as 1L maintenance therapy for advanced UC.

Methods JAVELIN Bladder Medley (NCT05327530) is a phase 2, randomized, multicenter, open-label, parallel-arm, umbrella trial. Eligible patients aged ≥18 years should have unresectable locally advanced or metastatic UC that has not progressed (complete or partial response, or stable disease) after 4-6 cycles of 1L chemotherapy (gemcitabine + cisplatin or carboplatin) and ECOG PS 0-1. After 4-10 weeks from end of chemotherapy, 252 patients will be randomized 1:2:2:2 to avelumab 800 mg every 2 weeks as monotherapy (control) or combined with sacituzumab govitecan (anti-Trop2/topoisomerase inhibitor conjugate) 10 mg/kg on days 1 and 8 of 21-day cycles, M6223 (anti-TIGIT) 1600 mg every 2 weeks, or NKTR-255 (IL-15 agonist) 3 μg/kg every 4 weeks. Randomization is stratified by presence of visceral metastases at start of 1L chemotherapy. Treatment will continue until progression, unacceptable toxicity, withdrawal of consent, or initiation of a new anticancer treatment. Data from the control group may be extended by combining with external data from the avelumab arm of the JAVELIN Bladder 100 trial. Primary endpoints are PFS based on investigator assessment (RECIST 1.1) and safety/tolerability of the combination regimens. Secondary endpoints include OS, objective response and duration of response based on investigator assessment (RECIST 1.1), and pharmacokinetics. The trial opened in June 2022 with sites planned to recruit in the US, Europe, Asia, and Australia.

666 PHASE 2, SINGLE ARM STUDY OF CG0070 COMBINED WITH PEMBROLIZUMAB IN PATIENTS WITH NON-MUSCLE INVASIVE BLADDER CANCER (NMIBC) UNRESPONSIVE TO BACILLUS CALMETTE-GUERIN (BCG)

[1]Roger Li*, [2]Gary Steinberg, [3]Edward Uchio, [4]Donald Lamm, [5]Shah Paras, [6]Ashish Kamat, [7]Trinity Bivalacqua, [8]Vignesh Packiam, [9]Michael Chisamore, [10]John McAdory, [10]Paola Grandi, [10]Nataliya Hnat, [10]James Burke. *[1]H. Lee Moffitt Cancer Center and Research, Tampa, FL, USA; [2]NYU Langone Health, New York, NY, USA; [3]University of California, Irvine, CA, USA; [4]BCG Oncology, Phoenix, AZ, USA; [5]Mayo Clinic, Rochester, MN, USA; [6]The University of Texas MD Anderson, Houston, TX, USA; [7]University of Pennsylvania, Philadelphia, PA, USA; [8]University of Iowa, Iowa City, IA, USA; [9]Merck and Co., Inc., Kenilworth, NJ, USA; [10]CG Oncology, Irvine, CA, USA*

Background CG0070, is an Ad5-based oncolytic vaccine engineered to express GM-CSF and replicate selectively in tumor cells with mutated or deficient RB. The CG0070 mechanism of action includes cell lysis and immunogenic cell death which is enhanced in the presence of GM-CSF. In an open label ph. 2 study, an overall CR rate of 62% and a CR at 12 months (m) of 29% have been observed in patients with high risk NMIBC previously treated with BCG.

IV pembrolizumab, was recently approved by the FDA for patients with BCG-unresponsive CIS (with or without papillary tumors) with an overall complete RR of 41% and a 12 m CR rate of ~20%.

This ph. 2 study will assess the potential synergy of the two agents in the treatment of BCG-unresponsive NMIBC.

Methods 35 pts with BCG-unresponsive CIS with or without concurrent Ta or T1 disease will be treated with intravescical CG0070 ($1x10^{12}$ vp) in combination with pembrolizumab at a dose of 400 mg IV q6 weeks. CG0070 will be administered weekly x 6 as induction followed by weekly x 3 maintenance instillations at months 3, 6, 9, 12, and 18. Patients with persistent CIS or HG Ta at 3 m may receive re-induction with weekly x 6 of CG0070. Pembrolizumab will be administered up to 24 m. Assessment of response will include q 3 m cystoscopy with biopsy of areas suspicious for disease, urine cytology, CTU/MRU, and mandatory bladder mapping biopsies at 12 m. Recurrence of HG disease will be enumerated as disease recurrence.

The primary endpoint of the study is CR at 12 m. Secondary endpoints will include CR at any time, progression free survival, duration of response, cystectomy free survival and the safety.

Results Enrollment has been completed. Based on follow up thus far, CR rate of 92% (22/24) at 3 m has been observed. All patients in CR at 3 m remain in CR at downstream timepoints including: 14/16 at 6 m, 9/11 at 9 m, and 6/8 at 12 m. Treatment related AE are consistent with those observed in studies of each agent alone.

Conclusions This initial data on the efficacy and safety of CG0070 plus pembrolizumab for the treatment of BCG unresponsive NMIBC is encouraging. Data on efficacy and safety for all enrolled patients, N=35, as well as biomarker (CAR, E2F, and PDL1) assessment will be presented at the time of the conference.

667 A PHASE 1, MULTIPLE-DOSE STUDY TO EVALUATE THE SAFETY AND TOLERABILITY OF XMAB®819 (ENPP3 X CD3) IN SUBJECTS WITH RELAPSED OR REFRACTORY CLEAR CELL RENAL CELL CARCINOMA (RCC)

[1]Sumanta Pal*, [2]Sreeni Yalamanchili, [2]Huajiang Li, [2]Jitendra Kanodia, [2]Raphael Clynes, [2]Zequn Tang, [3]Benjamin Garmezy. *[1]City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [2]Xencor, Inc., San Francisco, CA, USA; [3]Tennesse Oncology, Nashville, TN, USA*

Background Despite multiple advances in the treatment of metastatic RCC based on VEGF-directed therapies and immune checkpoint inhibitors (ICIs), few patients are ultimately cured. Therapies exploiting novel targets are greatly needed. A detailed antigen screen identified ENPP3 (Ectonucleotide pyrophosphatase/phosphodiesterase family member 3) as having consistent high expression in RCC (among other histologies), and low expression in adjacent normal tissue. ENPP3 is a transmembrane ectoenzyme, thought to be involved in hydrolysis of extracellular nucleotides. XmAb819 is an affinity-tuned 2+1 (high-avidity bivalent ENPP3 binding with low-affinity monovalent CD3 binding) bispecific antibody that was engineered for preferential engagement of high ENPP3-expressing cancer cells relative to low ENPP3-expressing normal cells, with the goal of preferentially inducing T–cell-mediated killing of the cancer cells. In addition, the expression of ENPP3 in healthy human tissues is generally low and typically localized apically which is likely to make it inaccessible to XmAb819 and/or T cells.

Methods This is a US based, multicenter, open-label, multiple-dose study designed in 2 parts with up to 95 participants: Part A dose escalation, to establish a priming dose, step-up priming dose(s), a cohort limit dose, and the dosing schedule; and Part B dose expansion, to further evaluate safety and tolerability, as well as provide an initial evaluation of efficacy for the relevant dose regimens established in Part A. The primary objectives are safety and tolerability, and to identify the doses and schedule for expansion. XmAb819 will be administered weekly by IV dosing on Day 1 of each priming dose(s) and Days 1, 8, and 15 for the cohort limit dose of each 21-day cycle. All eligible subjects will have relapsed or refractory RCC and have undergone disease progression on standard-of-care therapies including combination of immune checkpoint inhibitors followed by targeted therapies or immune checkpoint inhibitors plus anti-vascular endothelial growth factor agents in combination or sequentially.

Enrollment has been initiated.

668 A PHASE 2 STUDY OF VUDALIMAB, A PD-1 X CTLA-4 BISPECIFIC ANTIBODY, PLUS CHEMOTHERAPY OR TARGETED THERAPY IN PATIENTS WITH MOLECULARLY DEFINED SUBTYPES OF METASTATIC CASTRATION-RESISTANT PROSTATE CANCER

[1]Mark Stein*, [2]Oscar Goodman, [3]Tanya Dorff, [4]Vivek Narayan, [5]Jose Avitia, [6]Rana McKay, [7]Luke Nordquist, [8]Matthew Rettig, [9]Michael Schweizer, [10]Roby Thomas, [11]Michael Silverman, [12]Li Yao, [12]Raphael Clynes, [12]Jolene Shorr. *[1]Columbia University Irving Medical Cntr, New York City, NY, USA; [2]Comprehensive Cancer Centers of Nevada, Las Vegas, NV, USA; [3]City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [4]Hospital of University of Pennsylvania, Philadelphia, PA, USA; [5]New Mexico Oncology Hematology Consult, Albuquerque, NM, USA; [6]University of California, San Diego, La Jolla, CA, USA; [7]Urology Cancer Center, Omaha, NE, USA; [8]VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA; [9]University of Washington/Fred Hutchinson, Seattle, WA, USA; [10]University of Pittsburgh Medical Center, Pittsburgh, PA, USA; [11]BioStrategics, Ltd, Marblehead, MA, USA; [12]Xencor, Inc, Monrovia, CA, USA*

Background Immune checkpoint inhibitor (ICI) monotherapy generally has shown limited clinical benefit in unselected patients with metastatic castration-resistant prostate cancer (mCRPC); thus, strategies to improve response and/or identify patients more likely to respond to treatment are being investigated. Combination anti-PD-1/CTLA-4 therapy has shown better outcomes than either therapy alone. Altering the tumor microenvironment to promote antitumor immunity by combining ICIs with chemotherapy or targeted agents also has potential to increase clinical benefit. Finally, tumors with selected molecular characteristics, including those associated with aggressive variant disease, CDK12 inactivation, and microsatellite instability high (MSI-H) status, have shown increased sensitivity to ICIs. Vudalimab (XmAb20717) is a humanized bispecific monoclonal antibody that simultaneously targets PD-1 and CTLA-4 and binds preferentially to PD-1/CTLA-4 dual-positive cells. In a Phase 1 study, vudalimab monotherapy was generally well-tolerated and associated with complete and partial responses in patients with multiple tumor types, including mCRPC.[1] This Phase 2 study is designed to evaluate the safety and antitumor activity of vudalimab in combination with other anticancer agents or alone in mCRPC patients with and without specific tumor molecular subtypes.

Methods This multicenter, open-label study is being conducted at approximately 20 sites in the United States. Patients with mCRPC that progressed following treatment with $\geq$ 2 lines of therapy are enrolled into parallel cohorts based on the presence or absence of molecular abnormalities from prior sequencing reflecting the metastatic state: aggressive variant (Cohort 1), homologous recombination deficient or CDK12 mutation positive PARP inhibitor progressor (Cohort 2) or PARP inhibitor naïve (Cohort 3), MSI-H or mismatch repair deficient (Cohort 4), and no targetable mutation (Cohort 5). Patients receive vudalimab 10 mg/kg intravenously every 2 weeks plus either carboplatin AUC 4/cabazitaxel 20 mg/m^2 (or docetaxel 60 mg/m^2, if chemotherapy naïve) every 3 weeks (Cohorts 1, 2, 5; n=20 each) or olaparib 300 mg 2x/day (Cohort 3; n=20), or as monotherapy (Cohort 4; n=5). The study includes review of data from a subset of combination chemotherapy patients by a safety review committee. The primary objective of the study is to evaluate the safety/tolerability of treatment based on adverse events. Secondary objectives include evaluating objective response (RECIST 1.1, as modified by PCWG3), radiographic progression-free survival, and PSA response. Exploratory objectives include assessing pharmacodynamic activity in peripheral blood and tumor, and correlations of response with cohort-specific molecular tumor characteristics.

Results Enrollment is underway, and initial safety data review has been completed. Preliminary safety and activity data will be presented.

Trial Registration NCT05005728

669 **USE OF HPV16 CIRCULATING TUMOR DNA DETECTED IN LIQUID BIOPSIES TO PREDICT RESPONSE IN PATIENTS WITH ADVANCED HPV16-POSITIVE CERVICAL CANCER**

Paula Bousquet, Milena Blaga, Berit Nicolaisen, Karsten Bruins Slot, Agnete Fredriksen, Karoline Schjetne*. *Nykode Therapeutics, Oslo, Norway*

Background Circulating tumor DNA (ctDNA) can potentially provide a valuable tumor-specific and non-invasive biomarker for longitudinal monitoring of a patient's response to therapy. We aimed to quantify HPV16 ctDNA in patients with advanced cervical cancer and explore the potential use of ctDNA to predict on treatment clinical responses to VB10.16 in combination with atezolizumab.

Methods This open-label, single-arm, Phase 2a trial was conducted in patients with HPV16-positive recurrent or metastatic cervical cancer. Patients received multiple doses of the therapeutic DNA vaccine VB10.16 in combination with the PD-L1 inhibitor atezolizumab.

Blood specimens were collected at baseline and every 9 weeks during treatment to quantitatively determine the HPV16 E7 viral DNA in plasma by duplex digital PCR (dPCR).

The primary endpoint of the trial was the objective response rate assessed by an independent central review using RECIST version 1.1 criteria. HPV16 ctDNA was correlated with the defined clinical response as an exploratory endpoint. The study was approved by the national regulatory authorities and Independent Ethic Committees (NCT04405349).

Results Of the 39 patients included in the efficacy population of this interim analysis, 21 had detectable HPV16 ctDNA samples at baseline. The presence of ctDNA at baseline was not associated with clinical benefit. However, early reduction of HPV16 ctDNA after treatment start correlated with clinical response and prolonged progression-free survival ($p < 0.0021$). Patients who had a clearance of HPV ctDNA to levels below the detection limit, all achieved some level of clinical benefit (DCR 100%). In contrast, on-treatment increases in HPV16 ctDNA was associated with poor clinical outcomes and a shortened time to progression, indicating that on-treatment changes in HPV16 ctDNA levels may predict responses to treatment with VB10.16 and atezolizumab in cervical cancer.

Conclusions Analysis of liquid biopsies in patients with HPV16-positive recurrent or metastatic cervical cancer, treated with VB10.16 in combination with atezolizumab indicate that monitoring HPV16 ctDNA may predict clinical outcome and duration of response in a HPV16-specific therapy setting.

Trial Registration NCT04405349

Ethics Approval The study was approved by the national regulatory authorities and Independent Ethic Committees (NCT04405349).

670 CORRELATION OF DURABILITY OF RESPONSE WITH BEST RESPONSE OR EARLY DISCONTINUATION: A POST HOC ANALYSIS OF THE GARNET ENDOMETRIAL CANCER COHORTS

[1]Lucy Gilbert*, [2]Kathleen Moore, [3]Vanessa Samouëlian, [4]Cara Mathews, [5]Maria-Pilar Barretina-Ginesta, [6]Janet Rader, [7]Anna Tinker, [8]Adriano Gravina, [9]Joanna Pikiel, [10]Grace Antony, [10]Eleftherios Zografos, [10]Jennifer Veneris, [11]Ana Oaknin. *[1]McGill University Health Centre, Montreal, Quebec, Canada; [2]University of Oklahoma HSC, Oklahoma City, OK, USA; [3]Centre Hospitalier de l'Uni de Montréal, Montréal, Canada; [4]Women and Infants Hospital of RI, Providence, RI, USA; [5]Medical School University of Girona, Girona, Spain; [6]Medical College of Wisconsin, Milwaukee, WI, USA; [7]University of British Columbia, Vancouver, Canada; [8]Ist Na Tumori Fondazione G. Pascale, Naples, Italy; [9]Regional Center of Oncology, Gdansk, Gdansk, Poland; [10]GSK, Hertfordshire, UK; [11]Hospital Universitari Vall d'Hebron, Barcelona, Spain*

Background The potential benefits of immunotherapy following discontinuation for reasons other than progressive disease (PD) are not well described. Furthermore, some patients may benefit from remaining on immunotherapy beyond 2 years. We evaluated ORR and DOR in subgroups of patients with endometrial cancer (EC) per reason for treatment discontinuation and duration of treatment ≥2 years.

Methods GARNET is a multicenter, open-label, single-arm phase 1 study. Patients were assigned to cohort A1 (mismatch repair deficient [dMMR]/microsatellite instability–high [MSI-H] EC) or A2 (MMR proficient [MMRp]/microsatellite stable [MSS] EC) based on immunohistochemistry assessment. Patients received 500 mg of dostarlimab IV Q3W for 4 cycles, then 1000 mg Q6W until PD, discontinuation, or withdrawal; treatment could be considered beyond 2 years following discussion between sponsor and investigator. Primary endpoints were ORR, DOR, and safety. Subgroups in this post hoc analysis were thus: patients who discontinued treatment due to PD, those who discontinued for reasons other than PD, patients who remained on treatment for ≥2 years, and patients who discontinued before 2 years.

Results 299 patients with dMMR and MMRp EC were included in the efficacy-evaluable population. 88 patients discontinued for reasons other than PD, 164 discontinued for PD, and 47 remain on treatment (table 1). The median duration of follow-up was 27.7 months, and median DOR (mDOR) was not reached (NR) for patients who discontinued for reasons other than PD; 75% (18/24) of responders remain in response. mDOR was 9.8 months for patients discontinuing due to PD and was NR for those who remain on treatment; 90.9% (40/44) of responders who remain on treatment remain in response.

Nearly 52% of patients with complete response, partial response (PR), or stable disease (SD) remained on treatment for ≥2 years (46 of 89 responders). Of those patients who were on treatment for ≥2 years, 59.6% had PR and 8.5% had SD as their best response. 25% of patients (12/47) who remained on treatment for ≥2 years had MMRp/MSS tumors.

Safety has been previously reported.1

Conclusions Patients demonstrated durable responses to treatment when they discontinued for reasons other than PD. Meaningful durability (≥2 years) was observed even in patients with SD and PR. Biomarkers of durable responses to immunotherapy are needed.

Trial Registration NCT02715284

671 **A PHASE 1 ADOPTIVE CELL THERAPY USING DRUG-ENHANCED, TUMOR-INFILTRATING LYMPHOCYTES, DETIL-0255, IN ADULTS WITH ADVANCED MALIGNANCIES**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0671

[1]Eugenia Girda*, [2]Emese Zsiros, [3]John Nakayama, [4]Sarah Whelan, [4]Srinand Nandakumar, [4]Seema Rogers, [4]Beverly Benson, [4]Michael Lotze, [4]Robert Brown, [5]Robert Wenham. *[1]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, USA; [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [3]Allegheny Health Network, Pittsburgh, PA, USA; [4]Nurix Therapeutics, Inc., San Francisco, CA, USA; [5]Moffitt Cancer Center, Tampa, FL, USA*

Background Tumor-infiltrating lymphocytes (TIL) are a heterogeneous population of T cells that recognize multiple endogenous tumor antigens but may have developed an exhausted phenotype due to the tumor microenvironment. While existing TIL therapies produce durable responses in patients with melanoma, cervical, and head and neck cancers, poor *in vitro* cell expansion, limited short-lived *in vivo* persistence, and diminishing potency restrict this approach's broader application. DeTIL-0255 (drug-enhanced TIL [DeTIL]) is an autologous adoptive cell therapy (ACT) derived from a patient's tumor and expanded *ex vivo* with NX-0255, a small-molecule inhibitor of the E3 ligase, Casitas B-lineage lymphoma proto-oncogene B (CBL-B). CBL-B is expressed in T cells, where it functions as a regulator of immune cell activation, in part by requiring CD28 co-stimulation in addition to T cell receptor activation. Desirable properties enhanced by DeTIL-0255 compared with TIL include increased number of stem-like $CD39^-$/$CD69^-$, and $CD8^+$ T cells associated with persistence, as well as enhanced cytolytic function. ACT with T cells expanded *ex vivo* using NX-0255 demonstrated increased anti-tumor activity, longer survival, increased stem-like phenotype, and persistence of tumor antigen-specific T cells in mouse tumor models. Adoptive cell transfer of DeTIL-0255 may, therefore, exhibit broader functional activity than conventional TIL, potentially conferring improved anti-tumor activity and response.

Methods NX-DeTIL-0255-201 is a Phase 1 multicenter, open-label study of DeTIL-0255 administered with systemic high-dose IL-2 following nonmyeloablative lymphodepleting chemotherapy in patients with advanced gynecological malignancies for whom standard therapy with proven clinical benefit does not exist, is no longer effective, or is inappropriate. Primary objectives are to evaluate safety, tolerability, and preliminary antitumor activity of DeTIL-0255. A safety run-in will consist of 3 to 6 patients treated with DeTIL-0255 and evaluated for dose-limiting toxicity (DLT). The DLT period starts with DeTIL-0255 infusion and ends after 28 days. The safety run-in will investigate DeTIL-0255 at a dose range of 1 to 150 x 10^9 CD3+ T cells (exact dose varying based on expansion potential of DeTIL-0255 from tumor biopsies). Following the safety run-in, cohort expansion will further evaluate the safety and antitumor activity of DeTIL-0255 in patients with recurrent/persistent platinum-resistant epithelial ovarian cancer, cervical carcinoma, and endometrial cancer. Key eligibility criteria include measurable disease, a resectable lesion for TIL harvest, $\geq$2 prior lines of therapy, and an Eastern Cooperative Oncology Group performance status 0 or 1. The study is expected to enroll ~54 patients in ~10 sites across the United States. NCT05107739

PHASE I CLINICAL TRIAL OF AUTOLOGOUS T-CELLS GENETICALLY ENGINEERED WITH A CHIMERIC RECEPTOR TO TARGET THE FOLLICLE-STIMULATING HORMONE RECEPTOR (FSHR) IN PATIENTS WITH RECURRENT OVARIAN CANCER (OVCA)

[1]Robert Wenham*, [2]Marco Davila, [1]Daniel Abate-Daga, [1]Melissa McGettigan, [1]Xuefeng Wang, [1]Theresa Boyle, [3]Pamela Garzone, [3]Amit Kumar, [1]Jose Conejo-Garcia. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Roswell Park Cancer Center, Buffalo, NY, USA; [3]Anixa Biosciences Inc., San Jose, CA, USA*

Background Epithelial OVCA remains a highly fatal disease. FSHR is a tissue specific antigen expressed in >55% of high-grade epithelial OVCAs of different histological types. No significant FSHR expression is found in non-ovarian healthy tissues in women (figure 1). The treatment of OVCA patient derived xenografts with FSHCER T (FSH-Chimeric Endocrine Receptor + T-Cell (CER T)) cells (figure 2) in controlled, paired, mice was shown to effectively redirect the cytotoxic activity of T cells against patient-derived FSHR+ ovarian carcinomas (figure 3).[1] We hypothesize targeting FSHR in women with FSHR+ OVCA will result in improved response rates due to engraftment, expansion, and survival of these adoptively transferred FSHCER T cells and will have acceptable toxicity.

Methods This is an open phase 1 dose-escalation study (NCT05316129) in high-grade epithelial OVCA to assess the safety of autologous T cells genetically modified to express CER targeting FSHR. Primary objective is to assess the safety of the intraperitoneal (IP) and intravenous (IV) infusions of FSHCER T cells with or without prior cyclophosphamide plus fludarabine. Secondary objectives include antitumor efficacy, persistence of transferred FSHR T cells, expansion of endogenous tumor-targeted cells, and to compare IP and IV routes of administration.,

A screening part of the study will examine archived tissue from patients with recurrent platinum resistant or refractory OVCA following 2-8 prior lines of chemotherapy. Those who demonstrate positive or indeterminate FSHR Expression by an RNA Salah Targeted Expression Panel (STEP) will be eligible to screen for the treatment dose-escalation portion. Additional criteria include measurable or evaluable disease; performance status 0-2; adequate bone marrow, renal, and hepatic function; and eligibility for IP catheter placement.

If a patient is unable to be treated in the IP arm, the patient may be treated in the IV arm in the lowest unfilled cohort for that arm. Cohorts of 3 to 6 patients will be infused with escalating doses of FSHCER T cells to establish the maximum tolerated dose (MTD) with 6 planned dose levels: 1×10^5, 3×10^5, 1×10^6, 3×10^6, and 1×10^7 FSHCER T cells/kg. If the MTD is not established after 3×10^6, then next cohorts will receive conditioning cytoxan/fludarabine 5 days before starting T-cell infusion at dose levels 1×10^6, 3×10^6 and 1×10^7 FSHCER T cells/kg. Following determination of MTD, an expansion phase will be initiated.

Background Cervical cancer is the fourth most common cancer affecting women globally, but treatment options and outcomes for patients with recurrent or metastatic disease remain limited. Zimberelimab is a novel, fully human anti-PD-1 monoclonal antibody with high affinity and selectivity for PD-1. The objective of this study (ClinicalTrials.gov identifier: NCT03972722) was to evaluate zimberelimab, a novel, anti-programmed cell death protein 1 monoclonal antibody, in patients with programmed death ligand-1-positive recurrent or metastatic cervical cancer that had progressed after first- or subsequent-line platinum-containing standard chemotherapy.

Methods In this single-arm, phase II study, eligible patients in 27 Chinese sites were assigned to receive intravenous zimberelimab 240 mg as monotherapy every 2 weeks until confirmed disease progression, death, intolerable adverse effects, or withdrawal from the study. The primary endpoint was the objective response rate (ORR) assessed per Response Evaluation Criteria in Solid Tumors (version 1.1) by an independent review committee. Secondary endpoints included duration of response (DoR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety.

Results Ninety participants were included in the full analysis set, with a median follow-up of 11.5 months. Complete and partial responses were achieved by 4 and 21 patients, respectively, corresponding to an ORR of 27.8% (95% confidence interval [CI], 18.85 to 38.22; $P < .0001$ vs historical controls). Median OS and DoR were not reached during the study: 12-month OS rates were 54% (95% CI, 41 to 66) and 6-month DoR rates were 84% (95% CI, 58 to 95). Median PFS was 3.7 months and the 12-month PFS rate was 15% (95% CI, 2 to 42). Treatment-related adverse events (TRAEs) occurred in 78.1% of participants, with hypothyroidism (25.7%) and anemia (19.0%) being the most frequently reported. Grade $\geq$ 3 TRAEs occurred in 22.9% of participants.

Conclusions Zimberelimab monotherapy demonstrated durable antitumor activity and an acceptable safety profile in patients with recurrent or metastatic cervical cancer that had progressed after first- or subsequent-line platinum-containing standard chemotherapy. Further investigation of zimberelimab in patients with cervical cancer is warranted.

Trial Registration NCT03972722

Ethics Approval This phase II, single-arm, open-label study (NCT03972722) enrolled patients at 27 sites in China. The study was approved by the ethics committee at each participating center and was conducted in accordance with the Declaration of Helsinki and Good Clinical Practice for Drug Trials. All participants provided signed informed consent before any study procedure.

IMMUNOCERV, AN ONGOING PHASE II TRIAL COMBINING PDS0101, AN HPV-SPECIFIC T CELL IMMUNOTHERAPY, WITH CHEMOTHERAPY AND RADIATION FOR TREATMENT OF LOCALLY ADVANCED CERVICAL CANCERS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0674

MD Anderson Cancer Center, Houston, TX, USA

Background Human Papillomavirus (HPV) cancers are uniquely antigenic with a ubiquitous and essential expression of the viral proteins E6 and E7. Radiation therapy is essential in treating locally advanced HPV-associated cancers, including cervical cancers. Radiation therapy (RT) may synergize with immunotherapy to stimulate T-cell mediated anti-tumor affects by increasing T-cell flux in tumors and promoting pathways that result in increased antigen presentation. To evaluate this, we are conducting a single-arm phase II trial combining PDS0101, an E6/7 HPV16 T-cell activating immunotherapy delivered subcutaneously, combined with the standard of care chemoradiation for patients with locally advanced squamous cell cervical cancer with either lymph node metastasis or tumors of >5 cm.

Methods 17 patients of a planned 35 have enrolled in the study. Patients receive 5 doses of PDS0101 starting 10 days before RT, then on Days 7, 28, and 49 (± 5 days) during the 7-week course of treatment and again after chemoradiation is complete at Day 170 (± 14 days). To date, eight patients have completed treatment and were evaluated with a post-treatment Positron Emission Tomography (PET) scan to assess the response. Tumor specimens were collected at baseline and end of treatment and were evaluated for changes in T-cell activation.

Results Seven of 8 patients (87.5%) enrolled on IMMUNOCERV demonstrated a complete response (CR) on PET at 3 months. For comparison, 40 of 54 (74.1%) patients treated on a prospective tissue collection protocol with standard of care chemoradiation had a CR on PET after 3 months. The observed 1-year disease-free survival rate for IMMUNOCERV patients is 85.7%, and the 1-year overall survival is 100%. The percentage of polyfunctional CD8+ T-cells expressing granzyme B and Ki67 increased from baseline to end of treatment (38.5% vs. 65.4%, p = 0.0253). There were also enhanced signals in the single function CD8+ T-cells (granzyme B, Ki67, and CD69). However, there were no significant changes in these markers for patients treated with a prospective tissue collection protocol. Toxicity attributable to PDS0101 included self-limited Grade 1 and 2 local injection site reactions in 7 patients (3 Grade 1 and 4 Grade 2).

Conclusions In an ongoing trial, PDS0101 HPV-specific immunotherapy is safe and well tolerated in combination with chemoradiation. The combination treatment appears to result in an expansion of intratumoral activated T-cells expressing granzyme B. Further analysis will determine if the combination results in sufficiently high disease-free survival rates in patients with locally advanced cervical cancer.

Acknowledgements We thank PDS biotechnology (Dr. F. Bedu-Addo, Dr. L. Wood) for providing PDS0101.

Trial Registration NCT04580771

Ethics Approval All patients were enrolled under a protocol approved by the UT M.D. Anderson Cancer Center Institutional Review Board (MDACC 2019–1260) and written informed consent were obtained from all patients.

Background Eftilagimod alpha (efti) is a soluble LAG-3 protein targeting a subset of MHC class II molecules that mediate antigen-presenting cell (APC) and then CD8 T-cell activation. Data from a non-randomized, phase II trial of efti plus pembrolizumab (TACTI-002) showed encouraging antitumor activity and manageable safety when given as second-line treatment of patients with recurrent or metastatic head and neck squamous cell carcinoma (RM-HNSCC). TACTI-003 (NCT04811027) is a multicenter, open-label, randomized phase IIb trial to investigate efti plus pembrolizumab in the first line setting for RM-HNSCC.

Methods A total of 154 patients (pts) are currently being recruited into two cohorts (A+B). In cohort A, pts with tumors that are CPS$\geq$1 will be randomly assigned 1:1 to receive either efti (30 mg subcutaneously Q2W for initial 6 months, thereafter Q3W) plus pembrolizumab (400 mg intravenously Q6W) for up to two years or pembrolizumab alone. Randomization will be stratified by CPS (1-19 vs. $\geq$ 20) and ECOG PS (0 vs. 1). Pts with tumors that are CPS<1 will receive efti plus pembrolizumab (cohort B). Imaging will be performed every 9 weeks. The primary endpoint (EP) is the objective response rate (ORR) by RECIST1.1. Secondary EPs include overall survival, ORR according to iRECIST, time to and duration of response, disease control rate, progression-free survival, the occurrence of anti-efti -specific antibodies, safety, and quality of life. Exploratory endpoints comprise biomarkers.

676 A PHASE 2 STUDY OF EVORPACEPT (ALX148) IN COMBINATION WITH PEMBROLIZUMAB AND CHEMOTHERAPY IN PATIENTS WITH ADVANCED HEAD AND NECK SQUAMOUS CELL CARCINOMA (HNSCC); ASPEN-04

[1]Ezra Cohen*, [2]Kevin Harrington, [3]Jean-Pascal Machiels, [4]Sjoukje Oosting, [5]Bhumsuk Keam, [6]Beatriz Cirauqui, [7]Annette Lim, [8]Keun-Wook Lee, [9]Tim Welliver, [9]Christine Ju, [9]Feng Jin, [9]Alison Forgie, [9]Jaume Pons, [9]Sophia Randolph, [9]Athanasios Tsiatis. *[1]University of California San Diego, La Jolla, CA, USA; [2]The Royal Marsden Hospital, Sutton, UK; [3]Cliniques Universitaires Saint-Luc, Brussels, Belgium; [4]University Medical Center Groningen, Groningen, Netherlands; [5]Seoul National University Hospital, Seoul, Republic of Korea; [6]Institut Catala d'Oncologia Badalona, Barcelona, Spain; [7]Peter MacCallum Cancer Centre, Parkville, Australia; [8]Seoul National University College, Seoul, Republic of Korea; [9]ALX Oncology Inc, South San Francisco, CA, USA*

Background Anticancer immunity relies on the release of tumor antigens and subsequent activation of both the innate and adaptive immune systems. After cytotoxic chemotherapy induces neoantigen release, myeloid checkpoint inhibitors have been shown to help potentiate innate immune cell activity including antigen presentation. CD47, a marker of self, interacts with SIRPa on myeloid immune cells and can be upregulated by cancer cells to evade immune responses. Evorpacept is a high affinity CD47-blocking fusion protein with an inactive Fc region designed to safely enhance standard anticancer therapeutics. Pembrolizumab, a T cell checkpoint inhibitor, represents a standard treatment option for patients with previously untreated recurrent/metastatic (R/M) HNSCC, both as a monotherapy and in combination with 5FU + platinum. Through increased activation of the immune system, the combination of evorpacept + pembrolizumab + 5FU/platinum might have greater anti-tumor activity in R/M HNSCC than standard therapeutic approaches. This combination approach could be especially beneficial to R/M HNSCC patients with low PD-L1 expression, where anti-PD-(L)1 therapy historically has diminished efficacy. The combination of evorpacept + pembrolizumab + 5FU/platinum has undergone preliminary testing in the Phase 1 ASPEN-01 study,[1] demonstrating tolerability and clinical response. In previously untreated patients with R/M HNSCC treated with evorpacept + pembrolizumab + 5FU/platinum regardless of PD-L1 expression, objective responses including complete response were demonstrated.

Methods ASPEN-04 (figure 1) is an ongoing non-comparative, open-label, randomized Phase 2 global study for patients with metastatic or unresectable recurrent HNSCC who have not yet received first-line treatment. After an initial safety lead-in cohort, ~162 patients will be randomized using a 2:1 allocation to receive evorpacept + pembrolizumab + chemotherapy (5FU + either cisplatin or carboplatin) or pembrolizumab + chemotherapy, regardless of PD-L1 expression. Minimization factors used to randomize patients include geography, PD-L1 combined positive score, and human papilloma virus (HPV) (p16) status. Patients in the evorpacept treatment arm will receive evorpacept 45 mg/kg IV Q3W. All patients will receive pembrolizumab 200 mg IV Q3W (maximum of 35 cycles) and standard administration of 5FU and platinum agents. The co-primary endpoints in this trial are 12-month overall survival rate and objective response rate using RECIST v1.1. Key secondary endpoints include duration of response, progression-free survival, overall survival, and safety. Exploratory endpoints will characterize pharmacodynamic properties.

Acknowledgements We would like to thank all the participating patients, their families, and site research teams.

677 **A PHASE 2, OPEN-LABEL, MULTICENTER STUDY OF INCAGN01876 (ANTI-GITR AGONIST) IN COMBINATION WITH RETIFANLIMAB (ANTI–PD-1) IN RECURRENT OR METASTATIC HEAD AND NECK SQUAMOUS CELL CARCINOMA**

[1]Rom Leidner*, [2]Robert Haddad, [3]Nawel Bourayou, [3]Sonia Ioannidis, [3]Feng Zhou, [3]Zhiwan Dong, [4]Ezra Cohen. *[1]Earle A. Chiles Research Institute, Portland, OR, USA; [2]Dana Farber Cancer Institute, Boston, MA, USA; [3]Incyte Biosciences International Sàrl, Wilmington, DE, USA; [4]University of California San Diego, La Jolla, CA, USA*

Background Although anti–programmed cell death (PD)-ligand (L)1 therapies have improved clinical outcomes in patients with PD-L1+ recurrent or metastatic head and neck squamous cell carcinoma (r/m HNSCC), many patients do not respond or develop resistance. Reactivation of antitumor immune responses through a combination of co-inhibitory and co-stimulatory pathways may offer improved patient outcomes. Engagement of the glucocorticoid-induced tumor necrosis factor receptor family-related protein (GITR) promotes effector T-cell proliferation and activation while inhibiting regulatory T cells. In preclinical cancer models, the combination of PD-1 blockade and anti-GITR agonist monoclonal antibodies has led to long-term survival. Preliminary clinical data suggest that combined blockade using anti–PD-(L)1 and anti-GITR antibodies has an acceptable safety profile and antitumor activity in solid tumors including HNSCC. Therefore, this study aims to assess the safety, efficacy, pharmacokinetics, and pharmacodynamics of INCAGN01876 (anti-GITR agonist) in combination with retifanlimab (anti–PD-1) in patients with r/m HNSCC with GITR+ tumors whose disease has progressed on or after prior systemic treatment.

Methods This open-label, multicenter, single-arm, phase 2 clinical study (NCT05359692) will enroll approximately 50 patients into part 1 (safety lead-in; n≤12) and part 2 (expansion; n≤38). In part 1, patients will receive intravenous (IV) INCAGN01876 at 2 dose levels (300 or 600 mg) every 2 weeks (q2w) plus IV retifanlimab 500 mg every 4 weeks (q4w). Dose escalation will follow the BOIN design algorithm until identification of a pharmacologically active dose or the maximum tolerated dose, or the maximum dose of 600 mg q2w is reached. Part 2 will enroll up to 32 anti–PD-(L)1 treatment-experienced and 6 anti–PD-(L)1-naive patients. Patients will receive IV INCAGN01876 at the recommended phase 2 dose in combination with IV retifanlimab 500 mg q4w for up to 2 years. The primary endpoints are the safety and tolerability of INCAGN01876 in combination with retifanlimab (part 1) and the objective response rate determined by investigator assessment per Response Evaluation Criteria in Solid Tumors (RECIST v1.1) in all patients previously treated with anti–PD-(L)1 therapy (parts 1 and 2). Secondary endpoints include duration of response, disease control rate, progression-free survival according to RECIST v1.1, and safety and tolerability of INCAGN01876 in combination with retifanlimab in anti–PD-(L)1-naive and previously treated patients. Exploratory endpoints include pharmacokinetics, pharmacodynamics, and overall survival assessments of INCAGN01876 in combination with retifanlimab.

Trial Registration Clinicaltrials. gov identifier NCT05359692

Ethics Approval The study protocol was approved by institutional review boards or independent ethics committees at participating centers.

678 **A PHASE 2 STUDY OF EVORPACEPT (ALX148) IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH ADVANCED HEAD AND NECK SQUAMOUS CELL CARCINOMA (HNSCC); ASPEN-03**

[1]Kevin Harrington*, [2]Ezra Cohen, [3]Bhumsuk Keam, [4]Jean-Pascal Machiels, [5]Sjoukje Oosting, [6]Brett Hughes, [7]Jong Chul Park, [8]Tim Welliver, [8]Christine Ju, [8]Feng Jin, [8]Alison Forgie, [8]Jaume Pons, [8]Sophia Randolph, [8]Athanasios Tsiatis. *[1]The Royal Marsden Hospital, Sutton, UK; [2]University of California San Diego, La Jolla, CA, USA; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Cliniques Universitaires Saint-Luc, Brussels, Belgium; [5]University Medical Center Groningen, Groningen, Netherlands; [6]Royal Brisbane and Women's Hospital, Brisbane, Australia; [7]Massachusetts General Hospital Cancer Ce, Boston, MA, USA; [8]ALX Oncology Inc, South San Francisco, CA, USA*

Background Both innate and adaptive immune responses are important components of anticancer immunity. CD47 is a marker of self that interacts with SIRPa on myeloid immune cells, inhibiting their function. CD47 is upregulated by tumors to evade immune responses and its expression is associated with poor prognosis. Evorpacept is a high affinity CD47-blocking fusion protein with an inactive Fc region designed to be safely combined with and to enhance the efficacy of standard anticancer therapeutics. Pembrolizumab inhibits PD-1/PD-L1 signaling, which is a T cell immune checkpoint, and pembrolizumab has demonstrated anti-tumor efficacy through activation of tumor-infiltrating lymphocytes. Evorpacept used in combination with pembrolizumab has the potential to augment both innate and adaptive anti-tumor immune responses. Pembrolizumab as a single agent is a standard treatment option for patients with previously untreated recurrent or metastatic (R/M) HNSCC with PD-L1-positive (combined positive score [CPS] $\geq$1) tumors. The combination of evorpacept + pembrolizumab has shown acceptable tolerability and preliminary efficacy in patients with advanced HNSCC in $\geq$2nd line in the ongoing Phase 1 ASPEN-01 study.[1]Patients who had not received prior checkpoint inhibitor treatment and who were treated with evorpacept + pembrolizumab regardless of PD-L1 expression level (n=10) experienced a 40% objective response rate (ORR) and 22.1 months median overall survival (OS), comparing favorably with historical controls.

Methods ASPEN-03 (figure 1) is an ongoing non-comparative, open-label, randomized Phase 2 global study of evorpacept + pembrolizumab or pembrolizumab alone in patients with metastatic or unresectable recurrent, PD-L1-positive (CPS $\geq$1) HNSCC who have not yet received first-line treatment. After an initial safety lead-in cohort, ~177 patients will be randomized 2:1 to receive evorpacept + pembrolizumab or pembrolizumab alone. Minimization factors used to randomize patients include geography, CPS, and human papilloma virus (HPV) (p16) status. Patients in the evorpacept + pembrolizumab treatment arm will receive evorpacept 45 mg/kg IV Q3W. All patients will receive pembrolizumab 200 mg IV Q3W (maximum of 35 cycles). The co-primary endpoints in this trial are 12-month overall survival (OS) rate and ORR using RECIST v1.1. Key secondary endpoints include duration of response, progression-free survival, OS, and safety. Exploratory endpoints will characterize pharmacodynamic properties.

679 NT-I7 FOR THE TREATMENT OF LOCALLY RECURRENT SQUAMOUS CELL CARCINOMA OF HEAD AND NECK UNDERGOING SALVAGE SURGERY: A CLINICAL TRIAL IN PROGRESS

[1]Hyunseok Kang*, [1]Matthew Spitzer, [1]Mi-Ok Kim, [1]Patrick Ha, [1]Daniel Johnson, [2]Byung Ha Lee, [2]Se Hwan Yang. *[1]University of California, San Francisco, San Francisco, CA, USA; [2]NeoImmune Tech, Inc, Rockville, MD, USA*

Background The current standard of care for recurrent/metastatic squamous cell carcinoma of head and neck (SCCHN) includes immune checkpoint inhibitors, which have demonstrated survival benefit. However, overall response rate remains around 10-15% and almost 40% of patients do not benefit from the therapy. We have identified low baseline absolute lymphocyte count (ALC) as a predictive biomarker associated with a lower likelihood of response to immune checkpoint inhibitors.[1]Patients with higher ALC tend to respond better to immune checkpoint inhibitors, but a majority of patients tend to have low baseline ALC from previous radiation.[2] The cytokine interleukin-7 (IL-7) promotes the proliferation and survival of naïve and memory T-cells, without inducing proliferation of immunosuppressive regulatory T-cells. Administration of IL-7 induces T-cell expansion without evidence of hyperinflammation or acute cytokine storm in murine preclinical models; however, this approach was limited by the short half-life of IL-7. NT-I7 (efineptakin alfa) is a fusion product of IL-7 with a human Fc domain and a longer half-life. NT-I7 has demonstrated an excellent safety profile and the ability to significantly and persistently expand peripheral ALC [SFM1] in phase 1/2 studies. This is a window of opportunity study of a single dose of NT-I7 in patients with locally recurrent squamous cell carcinoma of head and neck undergoing salvage surgery (NCT04588038).

Methods Patients with recurrent SCCHN (SCC of oral cavity, oropharynx, hypopharynx and larynx) undergoing curative intent salvage surgery are eligible. Patients will receive a single intramuscular injection of NT-I7 up to 2 weeks prior to planned surgery, after pre-treatment core biopsies are collected. Surgical specimens will be collected at the time of surgery for analysis of tumor infiltrating lymphocytes[HL1] and immune cell subsets. Peripheral blood will be collected pre-treatment, at the time of surgery and post-operatively (36 days after surgery). The primary objective is to establish the safety and feasibility of administering a pre-operative dose of NT-I7 in this population. Secondary[ALB2] objectives are (1) to determine changes in ALC in peripheral blood, (2) to examine changes in tumor infiltrating lymphocytes (TILs) [SFM3] , (3) to evaluate changes in immune subsets in peripheral blood after a single injection of NT-I7 and (4) to assess exploratory biomarkers for pharmacodynamic (PD) activity in peripheral blood and/or tumor tissue[SFM4] . Baseline biopsy and surgical specimens will be compared to describe and compare TILs. The study plans to enroll 10 patients and is currently on-going.

680 **A PHASE 1B OPEN-LABEL, SINGLE-ARM DOSE EXPANSION STUDY OF IK-175, AN ORAL AHR INHIBITOR, IN COMBINATION WITH NIVOLUMAB IN PATIENTS WITH PRIMARY PD-1 INHIBITOR RESISTANT ADVANCED HEAD AND NECK CANCER**

Trupti Lingaraj*, Marissa Timothy, Nerymar Ortiz-Otero, Wilmin Bartolini, Katherine Kacena, Karim Malek, Sergio Santillana. *Ikena Oncology, Boston, MA, USA*

Background Despite recent advances with immunotherapy in head and neck squamous cell carcinoma (HNSCC), many patients progress and develop resistance to checkpoint inhibitors. Aryl hydrocarbon receptor (AHR) is a ligand-activated nuclear transcription factor that regulates the activity of multiple innate and adaptive immune cells. Kynurenine, a ligand generated from tryptophan by IDO1 and TDO2, binds AHR and leads to a net immunosuppressive tumor microenvironment. HNSCC has been found to have high prevalence of nuclear AHR protein expression, indicative of active AHR signaling, making AHR an attractive therapeutic target. IK-175 is an oral selective, small molecule that is being developed as potential first-in-class AHR inhibitor for the treatment of cancer. Given the role of AHR in mediating immunosuppression, IK-175 may overcome the immunosuppressive effects driving resistance to PD-1 inhibitors in HNSCC and improve the clinical activity of nivolumab.

Methods This is a phase 1b, open-label, multicenter, dose-expansion study of IK-175 in combination with nivolumab in adult patients with primary programmed cell death-1 (PD-1) inhibitor resistant metastatic or locally incurable, recurrent head and neck squamous cell carcinoma (HNSCC). IK-175 is administered orally at a dose of 600mg QD (Cohort 1) or 450mg q12h (Cohort 2) in 28 day-cycles in combination with nivolumab (480 mg q4w on Day 1 of every cycle). AHR nuclear localization is being studied as a potential predictive biomarker in patients with HNSCC. The study will enroll unselected HNSCC patients as well as an enriched population that includes patients with AHR + tumors as determined by immunohistochemistry. Key eligibility criteria include patients with histologically confirmed advanced HNSCC that have progressed within 12 weeks of initiation of a PD-1 inhibitor, whether administered alone or in combination with chemotherapy. The primary objectives are to determine the safety, tolerability, and preliminary antitumor activity (ORR, DCR, and DOR) of IK-175 in combination with nivolumab. Secondary objectives are to evaluate the pharmacokinetics of IK-175 and its active metabolites and to assess additional parameters of preliminary antitumor activity (PFS). Key exploratory objectives are to evaluate pharmacodynamic effects on paired tumor biopsies and peripheral immune cells, to assess candidate baseline biomarkers, and correlative analyses of tumor AHR nuclear localization with disease response. Estimated enrollment is approximately 54 patients; the study started in July 2022.

Lee Moffitt Cancer Center, Tampa, FL, USA; [2]Stanford University School of Medicine, Stanford, CA, USA; [3]Washington University School of Medicine, St Louis, MO, USA; [4]Massachusetts General Hospital, Boston, MA, USA; [5]University of Washington, Seattle, WA, USA; [6]Vanderbilt University Medical Center, Nashville, TN, USA; [7]Karmanos Cancer Center, Detroit, MI, USA; [8]Yale School of Medicine, New Haven, CT, USA; [9]The University of Texas MD Anderson, Houston, TX, USA; [10]University of Arizona Cancer Center, Tucson, AZ, USA; [11]Emory University, Atlanta, GA, USA; [12]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [13]Johns Hopkins University, Baltimore, MD, USA; [14]University of Michigan, Ann Arbor, MI, USA; [15]Affiliated Oncologists, LLC, Chicago Ridge, IL, USA; [16]Gabrail Cancer and Research Center, Canton, OH, USA; [17]George Washington University Cancer Center, Tucson, DC, USA; [18]Cue Biopharma Inc, Boston, MA, USA*

Background Immuno-STATs™ are modular fusion proteins designed for the selective delivery of IL-2 to tumor-antigen specific CD8+ T cells. CUE-101, the first Immuno-STAT in clinical trials, is composed of a human leukocyte antigen (HLA) complex, HLA-A*0201, a peptide epitope derived from the HPV16 E7 protein, and 4 molecules of reduced affinity human interleukin-2 (IL-2) designed to bind, expand, and activate HPV16-specific CD8+ T cells for the treatment of HPV16+ cancers.

Methods CUE-101-01 is a first-in-human study in patients with HLA-A*0201 genotype and HPV16+ recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). R/M HNSCC patients refractory to $\geq$ 1 platinum- or checkpoint-inhibitor-based systemic therapies received CUE-101 monotherapy. Patients with previously untreated PD-L1+ (CPS $\geq$ 1) R/M HNSCC received CUE-101 and pembrolizumab 200 mg. Therapy was administered every 3 weeks until disease progression or unacceptable toxicity. Escalating doses of CUE-101 monotherapy or in combination with pembrolizumab were evaluated, followed by expanded enrollment at the recommended phase 2 dose (RP2D). Objectives included evaluation of safety, pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity.

Results As of July 25, 2022, 62 patients have received CUE-101 ranging from 0.06 to 8 mg/kg/dose. The most common adverse events included fatigue (46%), anemia (24%), chills (24%), and hyponatremia (22%). In the monotherapy dose escalation portion, a MTD was not identified, and 4 mg/kg was chosen as the RP2D based on PK, PD, and preliminary clinical activity. CUE-101 dose escalation from 1 to 4 mg/kg in combination with pembrolizumab 200 mg has been completed with no DLTs observed and expansion of CUE-101 at 4 mg/kg with pembrolizumab is ongoing. PK data demonstrate dose-dependent increases in drug exposure that are sustained upon repeat dosing. PD data demonstrate selected expansion of HPV-16 $E7_{11-20}$-specific CD8+ T cells in the peripheral blood. Of the 19 evaluable patients treated with CUE-101 monotherapy at the RP2D of 4 mg/kg, 1 patient experienced partial response (PR) and 7 stable disease (SD) for $\geq$ 12 weeks. Of the 10 evaluable patients treated with CUE-101 plus pembrolizumab, 3 patients experienced PR (2 confirmed) and 2 patients SD for $\geq$ 12 weeks.

Conclusions CUE-101 has a manageable safety profile and demonstrates activity alone and in combination with pembrolizumab.

682 **CHANGING THE RADIATION AND IMMUNE-ONCOLOGY PARADIGM WITH THE RADIOENHANCER NBTXR3: OVERCOMING RESISTANCE TO ANTI-PD-1 BLOCKADE FROM THE BENCH TO THE CLINIC**

[1]Ari Rosenberg*, [2]Jessica Frakes, [3]Jiaxin Niu, [4]Jared Weiss, [2]Jimmy Caudell, [5]Patricia Said, [5]Pavel Tyan, [5]Sebastien Paris, [6]Tanguy Seiwert, [4]Colette Shen, [5]Sergio Szyldergemajn, [5]Omar Vivar, [5]Leonard Farber. [1]*University of Chicago, Chicago, IL, USA*; [2]*Moffitt Cancer Center, Tampa, FL, USA*; [3]*Banner MD Anderson Cancer Center, Gilbert, AZ, USA*; [4]*University of North Carolina, Chapel Hill, NC, USA*; [5]*Nanobiotix, Paris, France*; [6]*Johns Hopkins Medicine, Baltimore, MD, USA*

Background Numerous recent studies have assessed the future direction of radiation oncology. Now more than ever there is a need to examine the changing landscape of novel agents and approaches that improve radiation efficacy as well as amplify the immune response with certain therapies. Immune checkpoint inhibitors (ICIs) have led to improved treatment outcomes in a variety of cancers, however many patients exhibit resistance. Overcoming this resistance is a major challenge in immuno-oncology. Radiation therapy (RT) has emerged as a promising combination with ICIs since it may act in some settings to produce an immunomodulatory effect. NBTXR3, a radioenhancer, is injected one time intratumorally and activated by RT. NBTXR3 increases RT energy deposition inside tumor cells, subsequent tumor cell death, and tumor antigen release and thus in combination with ICI may overcome resistance.

Methods Pre-Clinical: Abscopal assays were conducted in immunocompetent mice. Anti-PD-1 sensitive or resistant lung tumor cell lines were injected in both flanks. Intratumoral injection of NBTXR3 (or vehicle) followed by RT was performed in right flank (primary) tumors only. Some mice also received anti-PD-1 injections. Tumor growth was monitored, and tumor immune cell infiltrates analyzed by immunohistochemistry (IHC).

Clinical A multicenter phase I trial [NCT03589339] is evaluating NBTXR3/RT/anti-PD-1 in 3 cohorts of patients with advanced solid tumors eligible for anti-PD-1: 1) Locoregional recurrent or recurrent and metastatic HNSCC, 2) Lung metastases, or 3) Liver metastases. NBTXR3 was administered by intratumoral injection. Stereotactic body RT (SBRT) was delivered at tumor-site selective doses per standard practice.

Results Pre-clinical studies demonstrated that NBTXR3/RT induces an immune response not observed with RT alone and enhances systemic control. IHC showed significant increase of CD8+ T-cell infiltrates in both NBTXR3/RT treated, and untreated tumors. Furthermore, NBTXR3/RT/anti-PD-1 improved local and systemic control in mice bearing anti-PD-1 resistant lung tumors, produced long-term memory, and reduced spontaneous lung metastases.

NBTXR3 intratumoral injection was feasible and safe. Preliminary signs of efficacy were observed in patients treated with NBTXR3/RT/anti-PD-1 including in patients refractory to anti-PD-1. Responses in distal, non-irradiated lesions were also observed in patients with resistance to anti-PD-1.

Conclusions With demonstrated radioenhancement as well as immune system priming, NBTXR3 positions itself to be a paradigm shift catalyst in the treatment of cancers in a variety of clinical settings- definitive, palliative, and metastatic. These data support further development of NBTXR3 in combination with anti-PD-1 as well as other ICIs.

683 CD8 T CELL REPERTOIRE ANALYSIS OF PATIENTS WITH RESECTABLE HEAD AND NECK CANCER ENROLLED IN A PHASE II NEOADJUVANT STUDY OF α-PD1 ADMINISTERED ALONE OR IN COMBINATION WITH α-CTLA4 OR α-LAG3

[1]Patricia Santos, [1]Aditi Kulkarni, [2]Housaiyin Li*, [1]Jie Chen, [1]Lazar Vujanovic, [1]Seungwon Kim, [1]Umamaheswar Duvvuri, [1]Dan Zandberg, [1]Robert Ferris. *[1]UPMC Hillman Cancer Center, Pittsburgh, PA, USA; [2]University of Pittsburgh, Pittsburgh, PA, USA*

Background Head and neck squamous cell carcinomas (HNSCC) are caused by alcohol and/or tobacco-derived exposure to carcinogens or by malignant transformation following oncogenic HPV infection. Standard of care regimen for HNSCC involve surgical resection followed by radiation or chemoradiation. Recently, monoclonal antibodies against immune checkpoint inhibitors (ICI) have been approved for patients with unresectable or metastatic disease.[1] However, response rate for ICI remains low in HNSCC and other solid tumors (20-40%).[2] Thus, there is a need to better understand the mechanisms involved in heterogenous responses to ICI and to identify new targets that may sensitize HNSCC to combinatorial treatments. As part of a Phase II study examining the safety and tolerability of α-PD1 administered alone or in combination with α-CTLA4 or α-LAG3, the alterations in T cell receptor (TCR) clonotypes and changes in transcription profiles in CD8 T cells from blood and tumor following mono- and combinatorial immune checkpoint blockade (ICB) in treatment naïve HNSCC patients were analyzed.

Methods Subjects with resectable, stage III/IVa HNSCC were stratified based on HPV, PD-L1, and LAG3 status and randomized into 3 treatment arms: α-PD1 alone, α-PD1+α-CTLA4, or α-PD1+α-LAG3 prior to surgical resection. Blood and tumor samples were collected at baseline and on the day of surgery (21-35 days after ICB) and processed to generate single cell suspensions as previously described.[3] FACS-sorted CD45+CD3+ cells were used to generate single cell RNA (scRNA) 5' gene expression libraries and TCR libraries using 10x Genomics workflow. Libraries were sequenced and data was processed using Cellranger 5.0.0 (10x Genomics). Data analysis was performed using R (v4.2.0) packages Seurat (v4.1.1), scRepertoire (v1.6.0) and Immunarch (v0.6.9).

Results To date, 34/60 patients have been enrolled in the trial. Based on scRNA data available from accrued patients (n=25), the proportion of CD8 T cells in the tumor increased after treatment in patients randomized to α-PD1+α-CTLA4 arm. Patients treated with α-PD1+α-LAG3 show an increase in CD8 TCR repertoire diversity as measured by Gini-Simpson index and had more TCR clones occupying 50% of the repertoire in post-treatment tumors compared to baseline. Overlap analysis on the number of TCR clones shared between post-treatment versus baseline did not show any significant differences across treatment arms. Trial accrual is still in progress and further analysis is currently ongoing to 1) correlate these data with clinical outcomes and 2) further investigate changes in transcriptional profiles of expanded clones in tumors across different treatment arms and by response.

684 **NBTXR3 ACTIVATED BY RADIOTHERAPY IN COMBINATION WITH NIVOLUMAB OR PEMBROLIZUMAB IN PATIENTS WITH ADVANCED CANCERS: RESULTS FROM AN ONGOING DOSE ESCALATION PHASE I TRIAL (STUDY 1100)**

[1]Colette Shen*, [2]Jessica Frakes, [3]Jiaxin Niu, [1]Jared Weiss, [2]Jimmy Caudell, [4]Tanguy Seiwert, [5]Patricia Said, [5]Mickael Guedj, [5]Pavel Tyan, [5]Omar Vivar, [5]Sergio Szyldergemajn, [5]Leonard Farber, [6]Ari Rosenberg. *[1]University of North Carolina, Chapel Hill, NC, USA; [2]Moffitt Cancer Center, Tampa, FL, USA; [3]Banner MD Anderson Cancer Center, Gilbert, AZ, USA; [4]Johns Hopkins Medicine, Baltimore, MD, USA; [5]Nanobiotix, Paris, France; [6]University of Chicago, Chicago, IL, USA*

Background Immune checkpoint inhibitors (ICIs) have changed how cancer patients are treated, still, most patients ultimately develop resistance. Overcoming or preventing this resistance is a major clinical challenge. NBTXR3, when injected intratumorally, has been shown preclinically to enhance RT energy deposition, subsequent tumor cell death, and tumor antigen release to effectively expand T-cell repertoire. NBTXR3/RT thus has the potential to trigger both a local and a systemic immune response to help improve ICI treatment.

Methods Study 1100 is a phase I dose escalation/expansion trial [NCT03589339] evaluating NBTXR3 activated by stereotactic body radiotherapy (SBRT) and followed by anti-PD-1 therapy (either nivolumab or pembrolizumab) in 3 cohorts of patients (pts) with advanced solid tumors. Pts are either resistant to prior ICI or naïve. Escalation cohorts were defined by site of injection: head & neck (H&N) lesions, lung, or liver metastases. SBRT was delivered as per standard practice. The primary objective of the escalation phase was to determine the NBTXR3/RT/anti-PD-1 recommended phase 2 dose for each cohort. Secondary objectives were feasibility, safety, and anti-tumor efficacy (objective responses).

Results 28 patients have been treated in the dose escalation phase in two escalating dose-levels for each cohort: 11 H&N, 10 lung, and 7 liver. Median age was 66.5 years. Two DLTs occurred in 1 pt at the first dose level in the H&N cohort. Grade $\geq$ 3 NBTXR3-related AEs occurred in 4 (14.3%) pts. SBRT+ ICI safety profile was in line to previously reported. Among 20 pts evaluable for efficacy, overall tumor responses were observed in 8/20 (40%) with disease control observed in 15/20 (75%) respectively, including durable complete responses. Objective tumor responses were observed in patients resistant to prior ICI. Updated safety and efficacy results will be presented.

Conclusions NBTXR3/RT/anti-PD-1 is feasible, predictable and safe in pts with recurrent HNSCC, lung, or liver metastases. The RP2D was defined. This new treatment shows promising early signs of efficacy. Subgroup analyses are ongoing and might help improve further results in specific populations. Overall, these results support evaluation of NBTXR3/RT/anti-PD-1 in the ongoing enlarged expansion phase.

685 PRELIMINARY RESULTS OF MT-401 IN POST-TRANSPLANT MRD+ AML PATIENTS

[1]Mythili Koneru*, [1]Juan Vera, [2]Shukaib Arslan, [3]Hongtao Liu, [4]Margarida Magalhaes-Silverma, [5]Nelli Bejanyan, [6]Antonio DiStasi, [7]Betul Oran, [8]Jingmei Hsu, [1]Robin McCallum, [1]Silvia Quintero, [1]Gerald Garrett, [1]Karrie Wang, [1]Eric Smith, [1]Tsvetelina Hoang, [1]Tara Shahim, [1]Jeannette Crisostomo, [1]Anna Wilga-Savitski, [1]Jennifer Pickering, [1]Laura Angelo, [1]Anastasiya Smith. *[1]Marker Therapeutics, Houston, TX, USA; [2]City of Hope, Los Angeles, CA, USA; [3]University of Chicago, Chicago, IL, USA; [4]University of Iowa, Iowa City, IA, USA; [5]Moffitt, Tampa, FL, USA; [6]University of Alabama, Birmingham, AL, USA; [7]MDACC, Houston, TX, USA; [8]Cornell, New York City, NY, USA*

Background Measurable residual disease (MRD) testing has become more prevalent in AML. MRD positivity is associated with increased relapse risk and shorter survival in AML, and currently, there no approved therapies for these patients. Zedenoleucel (also known as MT-401) is a non-genetically modified allogeneic multi-tumor associated antigen (mTAA)-specific T cell therapy with selectivity to multiple tumor antigens, specifically preferentially expressed antigen in melanoma (PRAME), Wilms' tumor 1 (WT1), New York esophageal 1 (NY-ESO-1) and Survivin.

Methods A multicenter Phase 2 study (ARTEMIS) evaluating the safety, tolerability and efficacy of zedenoleucel in patients with AML, including MRD^+patients, post-HSCT is ongoing. The study explores this therapy in patients with no active disease [in complete remission (CR) and MRD^-] or in patients with active disease (frank relapse or MRD^+). Patients may receive up to 3 consecutive infusions of zedenoleucel as a monotherapy (50-200 $\times$ 10^6 cells every 2 weeks) at weeks 0, 2 and 4 during the Intervention Period, and enter Follow-up at Week 8. Primary endpoints include various safety measurements. Efficacy evaluations occur at weeks 8, 12, 18, 24, 48 and yearly for 4 years using ELN recommendations for standard AML response criteria. MRD testing was done by flow cytometry or molecular testing (e.g. RT-PCR).

Results No concerning safety signals arose, including any dose-limiting toxicities in safety lead-in patients. The MRD^+patients had a variety of genetic mutations/abnormalities. One patient with NPM1 mutation converted from MRD^+ to MRD^- at week 8 evaluation. Another patient with RUNX1 genetic abnormality showed a decrease in MRD by PCR from a starting baseline of 0.8093% to resolution via peripheral blood at approximately 32 weeks post-treatment with MT-401. T cell composition of the product consisted of 71% $CD4^+$ and 24% $CD8^+$ T cells. T cell receptor (TCR) analysis identified 3,117 antigen-specific clones (881 Survivin, 783 NY-ESO-1, 750 PRAME, 709 WT1). Immune monitoring of this patient using biomarker analysis showed T cell specificity not only for the targeted antigens but also for non-targeted antigens over time, thereby demonstrating epitope spreading. Interestingly, the tumor antigen composition by RNASeq identified an antigen expression profile that changes over time and inversely correlates with the presence of antigen-specific T cells, demonstrating the interplay of tumor cell immunogenicity and antigen-specific T cells.

Conclusions The preliminary ARTEMIS results showed that administration of MT-401 converted MRD^+patients to MRD^- indicating that early intervention with MT-401 administration at MRD^+ stage in post-transplant AML can be beneficial.

Ethics Approval Ethics approval has been obtained by the Western IRB and participants gave informed consent before taking part. IRB tracking number is 20192173.

686 MECHANISM OF ACTION OF LAVA-051, A BISPECIFIC Vγ9Vδ2 T-CELL ENGAGER (BSTCE), CONFIRMED IN THE CLINICAL SETTING

[1]Roeland Lameris, [2]Jurjen Ruben, [2]Rob Roovers, [1]Arnon Kater, [2]Thilo Riedl, [2]Victoria Iglesias, [3]Annemiek Broijl, [2]Ilse Tuinhof, [2]Sanjana Umarale, [2]Anton Adang, [1]Tanja de Gruijl, [2]Paul Parren, [2]Benjamin Winograd*, [4]Hans Van der Vliet. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]LAVA Therapeutics N.V, Utrecht, Netherlands; [3]Erasmus MC, Rotterdam, Netherlands*

10.1136/jitc-2022-SITC2022.1

Amsterdam UMC, LAVA Therapeutics N.V., Amsterdam, Netherlands

Background LAVA-051, a CD1d-targeting first-in-class bispecific single domain antibody (27 kDa), was brought into the clinic based on its high potency antitumor activity through dual engagement of Vγ9Vδ2-T and iNKT cells, and a low risk of cytokine release syndrome (CRS).

Methods A phase 1 study using LAVA-051 is ongoing in patients with relapsed/refractory MM or CLL to determine the recommended phase 2 dose (RP2D). This study has been approved by relevant ethics committees (NCT04887259). A panel of specific pharmacodynamic assays is included to determine the pattern of change in the binding of LAVA-051 to patients' peripheral blood Vγ9Vδ2-T cells (i.e. Vγ9Vδ2-TCR occupancy) and in the frequency and activation status of Vγ9Vδ2-T and iNKT cells in circulation. Data presented are focused on the comparison of clinical to pre-clinical observations.

Results LAVA-051 triggers Vγ9Vδ2-T and iNKT cell mediated pro-inflammatory cytokine production, proliferation and anti-tumor activity in *in vitro* and *ex vivo* assays using patient $CD1d^+$ AML, CLL and MM cells. In addition, LAVA-051 induced a strong anti-tumor effect *in vivo* in a CDX model using NSG mice with intermittent dosing. In a non-human primate (NHP) model utilizing a cross-reactive CD1d-Vγ9 bsTCE there was clear observation of Vγ9Vδ2-T cell engagement as reflected by a (temporary) decrease in circulating Vγ9Vδ2-T cells after dosing and concomitant upregulation of the activation marker CD69. As of July 2022, doses up to 100x the starting dose have been evaluated as safe in the clinical setting with 8 patients treated in total; importantly no CRS was observed. A similar temporary decrease in Vγ9Vδ2-T cells with consistent upregulation of activation markers (CD25 and CD69) as was seen in the NHP study has been observed in the clinic. In the NHP model, dose-dependent binding of the bsTCE to peripheral blood Vγ9-T cells was observed up to several days after injection. Similarly in the clinic, Vγ9Vδ2-TCR occupancy was shown to increase with higher dose cohorts with a current maximum of 20.9% receptor occupancy after dosing (45μg). The frequency and activation status of iNKT cells has been assessable in the clinic and will continue to be evaluated with escalating doses.

Conclusions LAVA-051 has demonstrated on-mechanism pharmacodynamics in the clinic, reflective of pre-clinical findings. The differentiating importance of these pharmacodynamic parameters with any correlating preliminary antitumor activity will be further elucidated in determining the RP2D and schedule; updated comparative data will be presented at the congress.

Trial Registration NCT04887259

Ethics Approval This study has been approved by relevant ethics committees in the Netherlands, Spain and Italy (EUDRACT: 2020-004583-26). Informed consent was obtained from all patients prior to their participation.

687 **PROTEOMIC PROFILING IN BLOOD IDENTIFIES NOVEL PRETREATMENT AND MECHANISTIC MARKERS RELATED TO INFLAMMATORY ADVERSE EVENTS IN RELAPSED/REFRACTORY LARGE B-CELL LYMPHOMA AFTER AXICABTAGENE CILOLEUCEL**

[1]Kelly Speth, [1]Gayatri Tiwari, [1]Sabina Adhikary*, [1]Qinghua Song, [1]Justin Chou, [2]Frederick Locke, [3]Caron Jacobson, [4]David Miklos, [5]Olalekan Oluwole, [6]Marie José Kersten, [7]Max Topp, [1]Jenny Kim, [1]Adrian Bot. *[1]Kite, a Gilead Company, Santa Monica, CA, USA; [2]Moffitt Cancer Center, Tampa, FL, USA; [3]Dana-Farber Cancer Institute, Boston, MA, USA; [4]Stanford University School of Medicine, Stanford, CA, USA; [5]Vanderbilt University Cancer Center, Nashville, TN, USA; [6]Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands; [7]Universitätsklinikum Würzburg, Wurzburg, Germany*

Background Axicabtagene ciloleucel (axi-cel) is an autologous anti-CD19 CAR T-cell therapy approved for patients with relapsed/refractory (R/R) large B-cell lymphoma (LBCL) and follicular lymphoma. In the ZUMA-1 pivotal study, Grade ≥3 cytokine release syndrome (CRS) and neurological events (NE) were observed in 13% and 28% of patients, with median time to onset of any grade at 2 and 5 days, respectively.[1] Using conventional low-throughput platforms (eg, multiplex ELISA), pretreatment markers, including serum levels of LDH, IL-6, and IL-15, demonstrated a positive association with Grade ≥3 CRS and/or NE.[2] We sought to explore biological mechanisms and novel markers underlying the development of early-onset (within 5 days post-CAR T-cell infusion) Grade ≥3 CRS and NE using high-throughput Olink® proteomic profiling.

Methods Serum samples collected prior to conditioning chemotherapy (baseline) and immediately prior to CAR T-cell therapy (Day 0) for 142 patients with R/R LBCL treated in ZUMA-1 Phase 2 Cohorts 1, 2, and 4 were analyzed by Olink® panels comprising 1,458 markers. Association between marker expression and early Grade ≥3 toxicity was evaluated using Wilcoxon test and logistic regression. Weighted gene coexpression network analysis (WGCNA)[3] was performed to identify highly coexpressed protein clusters, which were used for gene ontology (GO) analysis for biological interpretation. Machine learning methods were used to select features and build classifiers.

Results Twenty-four patients (17%) experienced Grade ≥3 CRS and/or NE within 5 days post–CAR T-cell infusion. Univariate and WGCNA analyses demonstrated that clusters of pretreatment markers were associated with these toxicities; these clusters correlated positively with poor prognosis factors (eg, International Prognostic Index and baseline tumor burden). GO analysis applied to these clusters showed enrichment of proteins involved in metabolic processes and leukocyte activation. Machine learning demonstrated excellent performance (mean AUC >0.80 in both training and testing runs) of groups of Olink® markers in classifying patients with early high-grade toxicity. Further, we observed that IL-1/IL-6 pathway markers (eg, IL-1A and OSMR) were useful in identifying Grade ≥3 CRS, while inflammatory endothelial markers (eg, ACE2, CEACAM1, ICAM2, and ADAM15) could classify patients with both Grade ≥3 CRS and NE upon axi-cel treatment.

Conclusions Our proteomic analysis supports the relevance of previously described markers. In addition, we have identified potential markers that are mechanistically involved in the development of high-grade toxicity. Safety of CAR T-cell therapy may be improved by optimization of product or conditioning regimen to reduce adverse event-dependent proinflammatory activities while maintaining efficacy.

KS and GT contributed equally.

688 PREDICTION OF HCC RESPONSE TO NEOADJUVANT IMMUNOTHERAPY USING MULTIPARAMETRIC MAGNETIC RESONANCE IMAGING: A PRELIMINARY STUDY

[1]Octavia Bane*, [1]Enamul Bhuiyan, [1]Paul Kennedy, [1]Muhammed Shareef, [1]Pauline Hamon, [1]Mark Buckup, [1]Sacha Gnjatic, [2]Stefanie Hectors, [2]Hung Kam Cheung, [2]Elizabeth Miller, [1]Maria Isabel Fiel, [1]Stephen Ward, [1]Myron Schwartz, [1]Thomas Marron, [1]Miriam Merad, [1]Bachir Taouli. *[1]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [2]Regeneron, Tarrytown, NY, USA*

Background Despite advances in therapy, the prognosis of hepatocellular carcinoma (HCC) remains poor. The introduction of biologic drugs, including immune check-point inhibitors, has revolutionized HCC treatment. However, only a portion of patients with HCC respond to immunotherapy and predicting response is an unmet need. In this preliminary study, we assessed the value of quantitative multiparametric MRI (mpMRI) for predicting HCC response to neoadjuvant immunotherapy.

Methods In this prospective IRB-approved single-center study, we included 17 patients (M/F 14/3, mean age 65y) with resectable HCC who underwent mpMRI including T1 mapping, 3D MR elastography (MRE), diffusion-weighted imaging (DWI), and dynamic contrast-enhanced (DCE)-MRI with a hepatobiliary contrast agent (gadoxetic acid, Eovist/Primovist, Bayer), at pre-treatment and after completion of anti PD-1 immunotherapy (cemiplimab) as part of a trial. All patients underwent surgical resection. HCC lesions were identified by an experienced radiologist and regions of interest were placed to measure tumor native and post-contrast T1 measured during hepatobiliary phase (T1-HBP), tumor stiffness (TS), apparent diffusion coefficient (ADC), and perfusion parameters. The reference standard was the histopathologic percentage of necrosis. Patients with significant tumor necrosis (STN $\geq$50%) were considered responders. MRI parameters were compared between responders and non-responders by Mann-Whitney U test, and their diagnostic performance to predict response to treatment was assessed by ROC analysis.

Results 17 HCC lesions (6.4±4.9 cm, range 2.0-19.0 cm) were resected in 17 patients. At pre-treatment MRI, tumor native T1 and upslope from DCE-MRI were prolonged in responders compared to non-responders, and predicted response with good diagnostic performance (table 1; T1 AUC(CI)=0.82 (0.58-0.99), upslope AUC(CI)=0.80(0.58-0.99). The other parameters had no value in predicting response to immunotherapy (AUC range 0.52-0.68). Tumor native T1 and T1-HBP increased with degree of tumor necrosis at resection (%).

Conclusions Our results demonstrate the potential utility of native T1 and upslope measured with DCE-MRI for predicting HCC response to neoadjuvant immunotherapy. These findings require validation in an independent study.

Acknowledgements Regeneron Pharmaceuticals, Inc. funded the study. We would like to thank our clinical coordinators, Jordan Cuevas and Jenna Korotkin for helping with patient consent and for maintaining the study database. Enamul H. Bhuiyan gratefully acknowledges Professor Steven Sourbron, The University of Sheffield for his generosity to provide updated PMI software.

PRELIMINARY RESULTS OF A PILOT STUDY OF INTRATUMORAL INJECTION OF AUTOLOGOUS DENDRITIC CELLS AFTER HIGH-DOSE CONFORMAL EXTERNAL BEAM RADIOTHERAPY IN UNRESELTABLE PRIMARY LIVER CANCERS

[1]Lionel Kankeu Fonkoua*, [1]Panwen Wang, [1]Christopher Hallemeier, [1]Thomas Atwell, [1]Nguyen Tran, [2]Amit Mahipal, [1]Elham Babadi, [1]Svetlana Bornschlegl, [1]Anatilde Gonzalez Guerrico, [1]Kodi Martinez, [1]Gabrielle McCoy, [1]Kevin Regan, [1]Zuoyi Shao, [1]Henan Zhang, [1]Junwen Wang, [1]Ying Li, [1]Allan Dietz, [1]Haidong Dong, [1]Yi Lin, [1]Sean Park, [1]Lewis Roberts. *[1]Mayo Clinic, Rochester, MN, USA; [2]Case Western Reserve University, Cleveland, OH, USA*

Background Survival outcomes for patients with unresectable primary liver tumors (hepatocellular carcinoma [HCC] and intrahepatic cholangiocarcinoma [iCCA]) remain dismal, despite available locoregional and systemic treatment options. This pilot study aims to evaluate the safety and tolerability of intratumorally delivered autologous dendritic cell (DC) vaccine after external beam radiotherapy (EBRT) in unresectable HCC and iCCA. We hypothesize that *in situ* DC-mediated tumor vaccination via radiation-induced immunogenic cell death, will elicit tumor-specific immunity and improve clinical outcomes.

Methods Enrolled subjects undergo leukapheresis for DC manufacturing prior to EBRT administration as per standard of care for unresectable localized HCC/iCCA. After EBRT, 7 monthly ultrasound-guided intratumoral injections of mature DC (30-60 million cells) are administered (figure 1). An adjuvant booster (Prevnar vaccine) is given with the first 3 injections. The primary endpoint is the incidence of significant toxicity, and secondary endpoints include objective response rate (ORR) and survival. Pre/post-treatment peripheral blood samples are collected for immune correlative studies, including multiparametric flow cytometry and single-cell RNA sequencing.

Results As of July 28, 2022, eight subjects have enrolled (5 HCC; 3 iCCA) with five (3 HCC; 2 iCCA) having completed the protocol and three (2 HCC; 1 iCCA) currently in active phase. DC manufacturing success has been 100% and the maximal dose of 60 x 10^6 DC appears to be tolerated without autoimmunity or grade $\geq$ 3 adverse events (AEs), with the exception of one subject with grade 3 hyperbilirubinemia. The most common AEs include limited injection site pain and nausea. Early response data from the five subjects who have completed the protocol is encouraging with ORR of 60% (n=3, all partial response). One responder with iCCA has an ongoing response at 2 years (figure 2), and another HCC subject had stable disease for over one year. Preliminary cellular immunophenotyping and T cell receptor (TCR) clonotyping/profiling has revealed both the emergence of new TCR clones and expansion of existing TCR clones, including clones with tumor reactive and cytotoxic profile, suggesting this combination could enhance tumor reactive cytotoxic T cell response (figure 3). However, many of the TCR clones also have early exhaustion signal with upregulation of multiple checkpoint receptors. Thus, incorporating immune checkpoint inhibition (ICI) may help further enhance the cytotoxic functions of these TCR clones.

Conclusions Despite being preliminary, data from subjects treated to date suggest a favorable safety profile, encouraging signs of efficacy and induction of tumor-specific immunity which could be further enhanced by the addition of ICI.

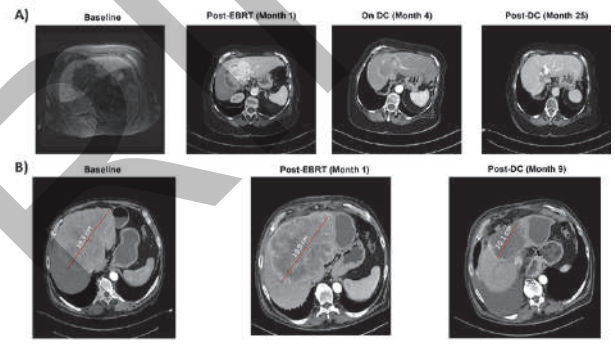
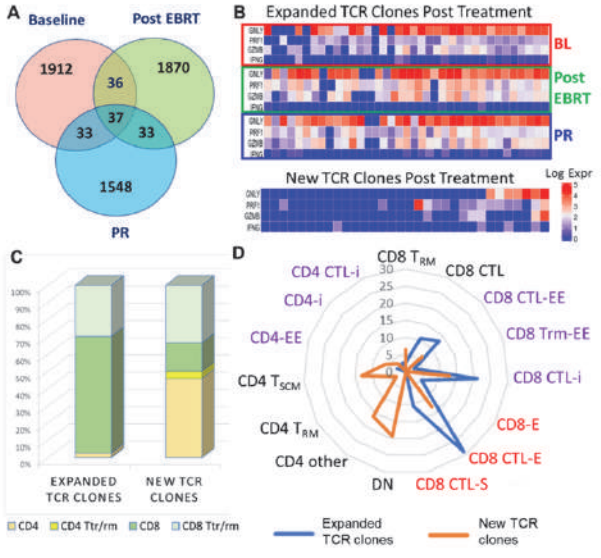
Abstract 689 Figure 1 NCT03942328 study schema.



Abstract 689 Figure 2 Representative images of treated patients. Patients with iCCA (A) and HCC (B) treated with EBRT and intratumoral DC injection on NCT03942328 study. Reduction in tumor size, corresponding to partial response is seen and is ongoing at 25 months and 9 months post-enrollment, respectively.



Abstract 689 Figure 3 TCR repertoire changes with EBRT and DC. (A) The number of unique and shared TCR clones from baseline (BL) to post-EBRT and after DC, at the time of partial response (PR) are shown.

(B) Heatmap of for TCR clones' RNA expression are show here for cytotoxic functions: GNLY, PRF1, GZMB; and for cytokine IFNG. Most of the TCR clones that are expanded with treatment have increased expression for cytotoxicity and IFNG (top 3 panels). In contrast, few new TCR clones post treatment have cytotoxic or IFNG expression (bottom panel). (C) While majority of the expanded clones are CD8, new TCR clones post-treatment are both CD4 and CD8, with a much smaller percentage having tissue/tumor origin. (D) Majority of the expanded TCR clones post- treatment have inhibited (-I, one or more checkpoints expressed), early exhausted (-EE), exhausted (-E) or senescent (-S) transcriptome. In contrast, new TCR clones post treatment have more stem memory and tissue derived resident memory profile.

690 **CORRELATES OF POOR RESPONSE TO NEOADJUVANT ANTI-PD-1 THERAPY IN HEPATOCELLULAR CARCINOMA (HCC) INCLUDE WNT PATHWAY ACTIVATION AND LOSS OF HLA EXPRESSION**

[1]Kunal Kundu, [1]Nathalie Fiaschi, [1]Wei Wang, [1]Baijun Kou, [2]Assaf Magen, [2]Pauline Hamon, [2]Sacha Gnjatic, [2]Myron Schwartz, [2]Alice Kamphorst, [2]Thomas Marron, [2]Miriam Merad, [1]Chunguang Guo, [1]Gavin Thurston, [1]Namita Gupta, [1]Kamil Cygan*. *[1]Regeneron Pharmaceuticals, Tarrytown, NY, USA; [2]Icahn School of Medicine at Mount Sinai, New York, NY, USA*

Background Although anti-PD-1/PD-L1 therapy has improved patient outcomes in the past decade, only a subset of patients shows clinical benefit.[1] Furthermore, many responders develop acquired resistance after initial responses.[2] Therefore, understanding baseline correlates of response and mechanisms of resistance is necessary for improving anti-PD-1/PD-L1 efficacy. In a neoadjuvant Phase 2 study (NCT03916627), patients with resectable hepatocellular carcinoma (HCC) were treated with cemiplimab, a PD-1 antibody. Pathologic Tumor Necrosis (PTN) of at least 50% at resection was used as the exploratory endpoint. Here we review possible biomarkers to identify responders and explore potential underlying mechanisms of resistance.

Methods Tumor samples collected at baseline and time of resection were analyzed by multiplex immunohistochemistry. Nucleic acid isolates from tumor, adjacent normal tissue, and matched blood were analyzed by RNA and whole exome DNA sequencing. OptiType was used to infer HLA haplotype. Loss of heterozygosity (LOH) was calculated by a custom workflow.

Results At baseline, higher levels of tumor-infiltrating T cells were present in Responders with PTN (N=5) compared with Non-responders to cemiplimab (N=15). The trend was consistent and amplified when measured at resection. However, clinical responses were also observed in patients with low levels of baseline T cell infiltration. Clinical efficacy was associated with presence of HLA-A*24:02 allele (N=5; 4 Responders and 1 Non-responder). Response to cemiplimab was independent of baseline tumor mutation burden, underlying viral etiology, or PD-L1 expression in the tumor. WNT pathway activating mutations, a previously reported mechanism of immunotherapy resistance,[3] were enriched in Non-responders (6 Non-responders vs. 1 Responder; mutations in 4 baseline and 5 resection samples) and correlated with low CD8 T cell infiltration at baseline and low CD8 and CD4 T cell infiltration at resection. Loss of WNT pathway mutations were observed on treatment in one Responder and one Non-responder. The Responder displayed LOH at the HLA locus during treatment and subsequently relapsed. On-treatment acquired WNT pathway mutations were identified in 3 out of 7 patients that relapsed.

Conclusions Preliminary analyses suggest that high levels of baseline tumor-infiltrating T cells is associated with clinical response to cemiplimab in HCC. The presence of WNT pathway activating mutations is indicative of low T cell infiltration and may be a potential negative predictor of clinical benefit with cemiplimab. One patient showed LOH at the HLA locus associated with clinical progression, suggesting potential alternative disease escape. Additional mechanisms of resistance are under investigation.

691 **IMMUNE PRESSURE IN AN ADVANCED HEPATOCELLULAR CANCER PATIENT FOLLOWING TREATMENT WITH PERSONALIZED NEOANTIGEN DNA VACCINE (GNOS-PV02) IN COMBINATION WITH PLASMID IL-12 (PIL12) AND ANTI-PD1 (PEMBROLIZUMAB)**

[1]Mark Yarchoan*, [2]Edward Gane, [3]Renzo Perales, [3]Alfredo Perales-Puchalt, [4]Gabor Bartha, [3]Sarah Rochestie, [3]Neil Cooch, [3]Joann Peters, [3]Ildiko Csiki, [3]Jian Yan, [3]Niranjan Sardesai. *[1]The Johns Hopkins Hospital, Baltimore, MD, USA; [2]The University of Auckland, Auckland, New Zealand; [3]Geneos Therapeutics, Plymouth Meeting, PA, USA; [4]Personalis, Inc, Menlo Park, CA, USA*

Background Tumor immune editing and escape are key mechanisms of cancer progression and metastatic dissemination. However, immune editing in response to therapeutic cancer vaccines has been challenging to demonstrate in patients. Neoantigens derived from tumor-specific mutations are promising targets for immunotherapy. They can be incorporated in personalized cancer vaccines (PCV) to prime T cell activation. Here, we report evidence of immune editing in a patient treated with a therapeutic neoantigen DNA PCV from the ongoing GT-30 advanced hepatocellular carcinoma single-arm open-label multi-center phase Ib/IIa trial.

Methods A 74 yo white male, having progressed on multiple prior lines of therapy including ablation, TACE and lenvatinib, was enrolled in the GT-30 study. Following WES and transcriptome analysis of the primary liver tumor biopsy, a DNA PCV encoding 29 neoantigens (GNOS-PV02) was manufactured. GNOS-PV02 (1mg) and pIL12 (0.3mg) were administered intradermally Q3w x 4 doses; Q9w thereafter. Pembrolizumab 200mg IV was administered Q3w. Treatment response was evaluated Q9w by RECIST 1.1. Pre-treatment and on-treatment biopsy samples and periodic blood samples were evaluated retrospectively for neoantigen repertoire, immune responses and ctDNA.

Results GNOS-PV02+pIL12+pembrolizumab treatment resulted in a partial response, with target lesion reduction of -36% at w9 deepening to -59% at w54 by RECIST1.1. TCR/TIL analysis of w9 biopsy versus screening biopsy samples revealed the expansion and infiltration of multiple new T-cell clones post-vaccination. PBMC analysis by IFNg ELISpot detected strong T-cell response to 4/29 vaccine epitopes. Flow cytometry analysis showed antigen-specific, activated (CD69+, Ki67+) CD8 and CD4 T-cells at high frequency. A new, distal adrenal lesion was detected at w18 that increased in size by w54. Sequencing of the adrenal lesion at w54 identified 25 neoantigens, including 16 shared with the primary liver lesion. However all 4 of the vaccine epitopes with strongest ELISpot responses were absent in the adrenal lesion, consistent with neoantigen loss resulting from immune editing and subsequent clonal escape. ctDNA analysis was consistent with complete response of the liver-specific tumor clone by w21 persisting through w57 but showed an increasing frequency of the adrenal specific tumor ctDNA over time.

Conclusions We documented evidence of PCV immune pressure induced clonal escape via the emergence and growth of a new distal lesion despite the primary lesion showing continued and deepened response. Such ongoing analysis of immune response and ctDNA for monitoring tumors offers a means to dynamic cancer therapy, whereby therapeutic vaccines with evolved neoantigen panels may be designed against new, or newly unresponsive, lesions.

692 **CIRCULATING TUMOR DNA ANALYSIS OF ADVANCED HEPATOCELLULAR CANCER (HCC) PATIENTS TREATED WITH NEOANTIGEN TARGETED PERSONALIZED CANCER DNA VACCINE (GNOS-PV02) IN COMBINATION WITH PLASMID IL-12 (PIL12) AND ANTI-PD1 (PEMBROLIZUMAB)**

[1]Renzo Perales, [1]Alfredo Perales-Puchalt, [2]Gabor Bartha, [2]Josette Northcott, [2]Richard Chen, [2]John Lyle, [2]Dan Norton, [1]Neil Cooch, [3]Edward Gane, [4]Mark Yarchoan, [5]Thomas Marron, [1]Sarah Rochestie, [1]Joann Peters, [1]Ildiko Csiki, [1]Jian Yan*, [1]Niranjan Sardesai. *[1]Geneos Therapeutics, Plymouth Meeting, PA, USA; [2]Personalis, Inc, Menlo Park, CA, USA; [3]The University of Auckland, Auckland, New Zealand; [4]The Johns Hopkins Hospital, Baltimore, MD, USA; [5]The Tisch Cancer Institute, New York, NY, USA*

Background Recent advances in circulating tumor DNA (ctDNA) analysis have enabled the non-invasive detection of mutations that lead to resistance mechanisms and therapeutic and disease monitoring in cancer patients. Improvements in whole exome sequencing with high sensitivity and specificity has made it feasible to interrogate a large number of genes simultaneously. We sought to evaluate the clinical utility of ctDNA analysis for longitudinal tracking of cancer neoantigen targets and for monitoring of disease status in advanced cancer patients being treated with aDNA personalized cancer vaccine (PCV). Our results also inform the kinetics of somatic variants included in the PCV (neoantigen vaccine targets) as well as the larger set of all variants identified in the tumor (MRD targets).

Methods Patients with unresectable or metastatic HCC with progression on, or intolerance to, first-line therapy with tyrosine kinase inhibitors were enrolled into the Phase Ib/IIa GT-30 study [NCT04251117]. Tumors were biopsied for exome and transcriptome sequencing and a patient-specific neoantigen DNA vaccine (GNOS-PV02) was designed. Patients were treated with GNOS-PV02 (1mg) and DNA plasmid encoded IL-12 (0.34mg) in combination with pembrolizumab (200mg). Treatment response was evaluated by RECIST 1.1. Prospectively collected pre- and post-treatment samples from 17 patients were batched and analyzed by personalized ctDNA assays. Somatic mutation calls were made using Personalis ACE® exome data from tumor tissue biopsies. Capture probe panels were designed for the two sets of targets. ctDNA was extracted from the plasma samples; up to 50ng was used as input for deep sequencing. Advanced noise suppression, mutation calling, aggregate tumor tracking and MRD calling was performed using NeXT ctDNA technology.

Results Pre-treatment ctDNA magnitude varied widely across patients for both neoantigen targets and MRD targets. Although analyzed retrospectively, changes in ctDNA magnitude over time correlated well with disease status in most patients. ctDNA broadly tracked with MRI scans for monitoring objective responses (CR and PR). In patients with tumor recurrence and/or emergence of de novo metastatic lesions, an increase in target copy number or mean tumor molecules/ml was detected prior to confirmation by MRI. Patient level data from the ongoing GT-30 clinical trial will be discussed at the meeting.

Conclusions Our analysis indicated that ctDNA can be a useful tool for monitoring disease in a patient specific manner. The ease of sample handling and analysis, and rapid availability of data, could enable the use of ctDNA monitoring to allow real time clinical treatment decision making for personalized cancer immunotherapy.

693 PERSONALIZED DNA NEOANTIGEN VACCINE (GNOS-PV02) IN COMBINATION WITH PLASMID IL-12 AND PEMBROLIZUMAB AS SECOND-LINE (2L) TREATMENT FOR ADVANCED HEPATOCELLULAR CARCINOMA (HCC)

[1]Edward Gane*, [2]Mark Yarchoan, [3]Thomas Marron, [4]Sarah Rochestie, [4]Renzo Perales, [4]Neil Cooch, [4]Jian Yan, [4]Joann Peters, [5]David Weiner, [4]Ildiko Csiki, [4]Alfredo Perales-Puchalt, [4]Niranjan Sardesai. *[1]The University of Auckland, Auckland, New Zealand; [2]The Johns Hopkins Hospital, Baltimore, MD, USA; [3]The Tisch Cancer Institute, New York, NY, USA; [4]Geneos Therapeutics, Plymouth Meeting, PA, USA; [5]The Wistar Institute, Philadelphia, PA, USA*

Background Hepatocellular carcinoma (HCC) is a low TMB tumor with largely immune-excluded phenotype. Anti-PD1 monotherapy for 2L HCC has response rates of 12-18%. Therapeutic cancer vaccines targeting neoantigens can generate tumor-specific T-cell immunity, potentially enhancing responses to anti-PD1 therapy. GNOS-PV02 is a personalized cancer DNA vaccine encoding up to 40 patient-specific neoantigens. GT-30 trial is an ongoing single-arm open-label multi-center phase Ib/IIa study to evaluate safety, immunogenicity, and efficacy of GNOS-PV02 administered in combination with plasmid-encoded IL-12 (pIL12) and pembrolizumab.

Methods Patients with unresectable or metastatic HCC and progression or intolerance on first-line therapy with tyrosine kinase inhibitors (sorafenib or lenvatinib) are enrolled. Tumors are biopsied for exome and transcriptome sequencing, peripheral blood is collected for germline sequencing, and a patient-specific vaccine is designed, optimized and manufactured, all in 6-8 weeks. GNOS-PV02 (1mg) and pIL12 (0.34mg) are administered via intradermal injection and electroporation Q3w x 4 doses, Q9w thereafter. Pembrolizumab 200mg is administered IV Q3w. Treatment response is evaluated Q9w by RECIST 1.1. Blood samples are collected pre-treatment, Q3w until w12, then Q12w for immunological analyses. Tumor biopsy is obtained at w9 for TME assessment.

Results As of cutoff date of June 30, 2022, 24 patients were enrolled with median age 66.5 years (range 40-78 years). There were no DLTs, GNOS-PV02+pIL12 related SAEs, or Grade 3 or 4 AEs reported. Two cases of hypothyroidism and immune nephritis, likely immune-mediated were noted, however no increase in irAEs or SAEs was seen with the combination therapy relative to previously known pembrolizumab monotherapy data. ORR (mITT) per RECIST 1.1 was 29.2% (7/24). Disease control rate was 54.2% (13/24) consisting of 2 CR, 5 PR, 6 SD, 10 PD. One patient early-terminated due to a non-treatment-related SAE six days after their sole PCV dose and was deemed unevaluable but included in the mITT analysis. One patient with a radiological PR after five PCV doses achieved secondary resectability, and discontinued therapy to pursue resection without disease recurrence. Novel and expanded T cell clones, predominantly CD8+ with activated phenotype, were identified in all evaluated patients via pre-/post-vaccination analysis of TCR repertoire in peripheral blood and tumor tissue. These clones trafficked to the TME by w9, potentially mediating the observed tumor regressions.

Conclusions GNOS-PV02 + INO-9012 combined with pembrolizumab in the 2L setting was well tolerated and induced tumor-neoantigen-directed CD8+ T cells and TILs. Data to date suggest clinical benefit relative to PD1 monotherapy in patients with advanced HCC.

Trial Registration NCT04251117

Ethics Approval For GT-30 trial, the protocols were approved by Johns Hopkins Medicine Review Boards (CR00039002/IRB00227771), Icahn School of Medicine-Program for the Protection of Human Subjects (20-00076 GCO#1), and Northern A Health and Disability Ethics committee (Ethics ref: 20/NTA), respectively. Written informed consent was obtained from each patient prior to the patient participating in the trial.

694 **AN OPEN-LABEL PHASE I DOSE-ESCALATION CLINICAL TRIAL TO EVALUATE THE SAFETY, TOLERABILITY, PHARMACOKINETIC PROFILE AND PRELIMINARY EFFICACY OF VG161 IN PATIENTS WITH ADVANCED PRIMARY LIVER CANCER**

[1]Yinan Shen*, [2]Guoming Shi, [1]Xingmei Liang, [1]Xinyan Jin, [1]Youlei Wang, [1]Guyue Wei, [2]Yi Chen, [2]Xiaoyong Huang, [2]Jiacheng Lu, [3]Huiqun Xia, [3]Miao Xiao, [3]Shah Rahimian, [3]Ronghua Zhao, [1]Yuwei Li, [1]Danni Lin, [1]Tian Fang, [1]Wei Chen, [1]Tao Ma, [1]Xueli Bai, [1]Tingbo Liang. *[1]The First Affiliated Hospital, ZJU, Hangzhou, China; [2]Zhongshan Hospital, Fudan University, Shanghai, China; [3]Virogin Biotech, Vancouver, Canada*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0694

Background VG161 is a novel HSV-1 oncolytic virus expressing IL-12, IL-15, IL-15 receptor alpha subunit isoform 1 (IL-15Rα), and a PD-1/PD-L1 blocking peptide (TF-Fc). This is to report the preliminary clinical and translational data from 11 efficacy evaluable patients.

Methods In this multicenter phase I trial, we enrolled 11 patients with advanced primary liver cancer refractory to standard therapy including immune checkpoint inhibitor (ICI). VG161 was administrated by imaging guided intra-tumoral injection. Based on preclinical NOAEL, the initial dose level was 1×10^8 PFU/subject, followed with 4 cohorts (1×10^8, QD for D1 and D2; 1×10^8, QD for D1-3; 1.3×10^8, QD for D1-3; and 1.7×10^8, QD for D1-3). Fast titration design was used for the first 2 cohorts and followed by standard 3 + 3 design. For PK and viral shedding, virus DNA was measured in blood, urine, oral and injection site swabs by a validated PCR test. Changes of cytokines and lymphocyte subsets in blood was also measured. Antitumor activity was assessed by RECIST1.1 and iRECIST. Overall survival (OS) was recorded.

Results Eleven patients (aged from 43-74, 9 males and 2 females; 8 HCC and 3 ICC) were enrolled between April 2021 and January 2022. By 10 May 2022, all patients had at least one tumor assessment. No dose limiting toxicity (DLT) was observed. The most common treatment related adverse event (TRAE) was fever (100%). No dose limiting toxicity (DLT) was observed. One serious adverse events (SAEs), Grade 2 sub-facial paralysis (33.3%) was seen in 1 patient, which is related to study drug, no immune-related adverse events (irSAEs) occurred. One ICC patient in 3rd cohort (9%) had immune partial response (iPR) with PFS of 5.3 month based on both iRECIST and RECIST 1.1. Another 2 patients with HCC in the 1st and 2nd cohort had prolonged PFS of 3.7 and 11.5 months respectively. The levels of each T cell immune-related parameter including PD-L1, PD-1, CD69 and CD8+Ki67^{high} of subjects in each cohort showed an increasing trend after VG161 administration. To date, the median follow-up time is 7.8(2.3-15.6), significantly prolonged OS was seen in 5 patients received ICI after the trial ($p=0.025$).

Conclusions Image guided IT injection of VG161 up to 3 times of 1.7×10^8 PFU/subject was safe and well tolerated, with no unexpected viral spread or shedding. The efficacy of prolonged PFS in 3 patients and PR in 1 patient is encouraging and needs to be further investigated. Clinical trial information: NCT04806464.

Trial Registration NCT04806464

Ethics Approval The study was approved by the Ethics Committee of the First Affiliated Hospital, School of Medicine, Zhejiang University, approval number 20191101.

IMMUNE CORRELATES ASSOCIATED WITH CLINICAL BENEFIT IN PATIENTS WITH IMMUNE CHECKPOINT REFRACTORY HPV-ASSOCIATED MALIGNANCIES TREATED WITH TRIPLE COMBINATION IMMUNOTHERAPY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0695

Meghali Goswami*, Julius Strauss, Yo-Ting Tsai, Caroline Jochems, Jennifer Marte, James Gulley, Jeffrey Schlom, Renee Donahue. *National Cancer Institute, Bethesda, MD, USA*

Background Globally more than 600,000 cases of HPV-associated cancers occur annually. Approximately 15-20% of cases respond to PD-(L)1 inhibitors, and approximately 30%, including 10% of immune checkpoint inhibitor (ICI) refractory patients, respond to bintrafusp alfa, a bifunctional fusion protein targeting TGF-β and PD-L1. Thus, for most patients who are ICI refractory, there is no effective therapy. Preclinical studies have shown that the triple combination of bintrafusp alfa, M9241, a tumor-targeting IL-12 immunocytokine, and PDS0101, a therapeutic vaccine targeting HPV-16, resulted in maximal tumor reduction. A phase II trial (NCT04287868) evaluating this triple therapy has shown a manageable safety profile and preliminary evidence of clinical activity in ICI refractory HPV-associated cancers, with 45% of patients having disease reduction, including 27% with objective responses.

Methods Peripheral blood from patients with ICI refractory HPV-associated malignancies (n=27) treated with the triple therapy was analyzed prior to and 2 weeks post first treatment (a timepoint prior to restaging) for multiple serum cytokines and soluble factors, complete blood counts, and 158 immune cell subsets. HPV-16 specific T-cells were assessed before and during treatment in a subset of patients (n=14). Immune parameters were evaluated for changes with therapy and compared between patients deriving clinical benefit (with a best overall response of stable disease, partial response, or complete response) versus those with progressive disease (PD).

Results The triple therapy promoted a pro-inflammatory serum cytokine and factor milieu, and significantly increased NK cells (p=0.002) and decreased conventional dendritic cells (cDCs, p=0.001), plasmacytoid DCs (p=0.011), CD4+ T-cells (p=0.008), CD8+ T-cells (p=0.004), T-regulatory-cells (p=0.002), and B-cells (p=0.042). HPV-16 specific T-cells were increased >2 fold after therapy in 11/14 patients evaluated. Before therapy, patients developing clinical benefit from the triple therapy had significantly higher levels of CD8+ naïve T-cells (p=0.037), trends of higher CD8:MDSC ratios (p=0.098), and significantly lower levels of cDCs (p=0.019) and classical monocytes (p=0.049), than patients developing PD. A greater early increase (2 weeks after one treatment cycle) in soluble granzyme B (p=0.004), TNFa (p=0.013), and monocytes (p=0.025), and less of a decrease in cDCs (p=0.006) associated positively with clinical benefit, while trends of an increase in the neutrophil to lymphocyte ratio (p=0.073) associated inversely.

Conclusions These studies interrogating the peripheral immunome add insight into the combined mechanism of action of bintrafusp alfa, M9241, and PDS0101 in patients with HPV-associated cancers, and provide valuable information to identify ICI refractory patients potentially more likely to benefit from immunotherapy.

Ethics Approval All patients gave written informed consent for participation. This study was approved by the National Cancer Institute's Institutional Review Board. The trial registration number is NCT04287868.

696 **ABATACEPT FOR IMMUNE CHECKPOINT INHIBITOR ASSOCIATED MYOCARDITIS (ATRIUM): A PHASE 3, INVESTIGATOR-INITIATED, RANDOMIZED, DOUBLE BLIND, PLACEBO-CONTROLLED TRIAL**

[1]Kerry Reynolds*, [1]Meghan Mooradian, [1]Daniel Zlotoff, [2]Paul Ridker, [1]Tomas Neilan, On Behalf Of The ATRIUM Investigators. *[1]Massachusetts General Hospital, Boston, MA, USA; [2]Brigham and Women's Hospital, Boston, MA, USA*

Background Patients with myocarditis secondary to treatment with an immune checkpoint inhibitor (ICI) represent a poor prognosis population with a high unmet clinical need. Data from multiple independent international cohorts have shown that the rate of major adverse cardiac events (MACE) with ICI myocarditis despite administration of corticosteroids ranges from 25-50%. Abatacept is a selective co-stimulation modulator that inhibits T cell activation by binding to CD80 and CD86, thereby blocking its interaction with CD28. In case reports, abatacept has been used to treated ICI myocarditis. The use of abatacept in ICI myocarditis is supported by animal models of ICI myocarditis, with the administration of abatacept leading to a reduction in cardiac immune activation and increased survival.

Methods The abatacept for immune checkpoint inhibitor associated myocarditis (ATRIUM) trial is designed as a phase 3, investigator-initiated, randomized, double-blind, placebo-controlled study to evaluate the efficacy and safety of abatacept compared to placebo in 390 hospitalized participants with ICI associated myocarditis. Hospitalized participants diagnosed with ICI-related myocarditis, aged $\geq$18 years, with serum evidence of ongoing myocardial injury (troponin $\geq$5 times the upper limit normal), and treated, or with intent to treat, with 1000 mg of solumedrol/day are eligible. Participants will receive either abatacept (10 mg/kg) or placebo given IV followed by study drug infusion/placebo again at 24 hours and on day 14 with an optional 4th dose on day 28. The primary aim is to test whether abatacept, as compared to placebo, is associated with a reduction in MACE among participants hospitalized with myocarditis secondary to an ICI. The primary outcome, MACE, is a composite of cardiovascular death, nonfatal sudden cardiac arrest, cardiogenic shock, significant ventricular arrhythmias, significant bradyarrhythmias, or incident heart failure. Each component of the primary composite end point will be evaluated individually as a secondary endpoint, as are troponin levels, rates of deep venous thrombosis and pulmonary embolism, and incidence rates of treatment-related adverse events. Exploratory outcomes focus on cancer outcomes, healthcare utilization, quality of life, and correlative studies.

This study is recruiting at time of submission. Clinical trial information: NCT05335928.

Trial Registration
NCT05335928

Ethics Approval The clinical trial protocol has been approved by the Mass General Brigham Institutional Review Board (Protocol #:2021P003690) and all participants will provide informed consent before taking part.

697 A PHASE 1 STUDY OF AMG 119, A DLL3-TARGETING, CHIMERIC ANTIGEN RECEPTOR (CAR) T CELL THERAPY, IN RELAPSED/REFRACTORY SMALL CELL LUNG CANCER (SCLC)

[1]Lauren Byers*, [1]John Heymach, [1]Don Gibbons, [1]Jianjun Zhang, [2]Alberto Chiappori, [3]Erik Rasmussen, [3]Benjamin Decato, [3]Marie-Anne Smit, [3]Nooshin Hashemi Sadraei. *[1]MD Anderson Cancer Center, Houston, TX, USA; [2]Moffitt Cancer Center, Tampa, FL, USA; [3]Amgen Inc., Thousand Oaks, CA, USA*

Background AMG 119 is a CAR-T cell therapy that targets delta-like ligand 3 (DLL3), an inhibitory Notch ligand that is expressed on the surface of most SCLC cells. In preclinical studies, AMG 119 specifically lysed DLL3-expressing SCLC cell lines and inhibited tumor growth in SCLC xenograft models.[1]

Methods Primary objectives of this open-label, phase 1 study are to determine the safety, tolerability, and optimum cell dose of AMG 119 in adults with relapsed/refractory SCLC who progressed after ≥1 platinum-based chemotherapy regimen. Safety, efficacy, pharmacokinetics, and biomarkers were assessed.

Results At data cutoff, 5 adult subjects (median age: 59 years [range, 33-64], ECOG status: 0-1, ≥ 1 prior line of anticancer therapy) had received at least 1 intravenous infusion of AMG 119 as part of cohort 1 (n = 3; 3×10^5 cells/kg) or cohort 2 (n = 2; 1×10^6 cells/kg) in the dose exploration phase. One subject in cohort 1 and both subjects in cohort 2 were re-treated with a second dose.

Post-infusion, a grade 1 treatment-related adverse event (TRAE) was noted in 1 subject (seizure), grade 2 TRAEs in 2 subjects (anemia and supraventricular tachycardia), and a grade 3 TRAE in 1 subject (pneumonitis; cohort 1). No dose-limiting toxicities or grade 4/5 TRAEs were observed.

Among evaluable subjects (n=4), a confirmed partial response (PR) was seen in 1 subject (cohort 2) 1.1 months after the first dose. Two subjects had stable disease, including 1 subject who experienced a 16% decrease in sum of the target lesions from baseline. One subject had progressive disease. Median progression-free survival was 3.7 months (range, 1.1-6.7) and median overall survival was 7.4 months (range, 4.6-18.9).

AMG 119 exhibited peak expansion 1-3 weeks after infusion; CAR-T cells were detectable up to 86 days in both cohorts. A preliminary dose-response relationship was observed with higher CAR-T cell expansion (~14-fold increased C_{max} and $AUC_{0\text{-}28d}$) in the subject with confirmed PR compared with the nonresponder (cohort 2). DLL3 expression was detected by immunohistochemistry on >85% of tumor cells in all evaluable subjects at all assessed timepoints. Changes in serum/whole blood markers were consistent with a pharmacodynamic response. The subject who achieved PR exhibited a rapid decline in total circulating tumor cell levels within 7 days of treatment initiation.

Conclusions AMG 119, the first CAR-T cell therapy for SCLC, was associated with a manageable safety profile and promising anti-tumor activity. Enrollment is currently paused but may resume.

Acknowledgements The authors would like to acknowledge Vijay Upreti, Di Zhou, Beate Sable, and Amrita Pati (all Amgen) for their contributions to this study and abstract.

Trial Registration NCT03392064

698 A PHASE 2 STUDY OF DURVALUMAB COMBINED WITH CHEMOTHERAPY AND STEREOTACTIC BODY RADIOTHERAPY (SBRT) IN PATIENTS WITH OLIGOMETASTATIC NON-SMALL CELL LUNG CANCER (NSCLC) (SABRCURE TRIAL)

[1]Ming Chen*, [2]Honglian Ma, [2]Xianghui Du, [2]Yujin Xu, [2]Yongling Ji, [2]Zhengbo Song. *[1]Sun Yat-sen University Cancer Center, Guangzhou, China; [2]Zhejiang Cancer Hospital, Hangzhou, China*

Background Immunotherapy +/- chemotherapy is currently the standard of care for metastatic NSCLC, but strategies to expand the benefit are still needed. Oligometastatic NSCLC is a state of limited disease in which widespread metastasis has not yet evolved. Locally radiotherapy achieves prolonged progression- free survival and overall survival in a small proportion of well selected oligometastatic NSCLC patients[1]. Preliminary evidence suggests high dose fractionated radiotherapy, such as SBRT, in combination with systemic immunotherapy has a synergistic effect and may enhance survival[2]. Durvalumab (PD-L1 antibody) is approved as consolidation therapy for unresectable, locally advanced NSCLC who have not progressed following chemoradiotherapy. These findings support further investigation of durvalumab + SBRT combinations in oligometastatic NSCLC who received standard systematic therapy.

Methods SABRCURE is an open-label, phase 2 study evaluating the efficacy and safety of durvalumab combined with SBRT and chemotherapy in oligometastatic stage IV NSCLC. Key eligibility criteria include no more than 5 metastatic lesions in up to 3 organs, EGFR/ALK/ROS1 wild type, no previous systemic therapy or brain metastases. Forty patients will be enrolled and receive durvalumab 1500mg + platinum-doublet chemotherapy every 3 weeks for 4 cycles, and then durvalumab 1500mg every 4 weeks monotherapy until disease progression or up to 24 months. Patient without progression after 4 cycles durvalumab + chemotherapy will receive stereotactic body radiotherapy. SBRT will be started within 2 weeks after chemotherapy completion and administered to primary lesion and all known metastatic lesions, with a total dose of 50-60Gy in≤10 fractions. The primary endpoint is progression free survival (PFS) per RECIST v1.1. Secondary end points are objective response rate (ORR), overall survival (OS) , safety and treatment failure pattern. This study was funded by AstraZeneca China.

699 **INTERIM RESULTS FROM A PHASE IB, FIRST-IN-HUMAN STUDY OF A NOVEL COMPLEMENT FACTOR H INHIBITOR (GT103) IN PATIENTS WITH REFRACTORY NON-SMALL CELL LUNG CANCER (NSCLC)**

[1]Jeffrey Clarke*, [1]Thomas Stinchcombe, [1]Jeffrey Crawford, [2]Hirva Mamdani, [1]Lin Gu, [1]Neal Ready, [1]Andrew Nixon, [1]Stephen Baleviic, [1]Michael Campa, [1]Liz Gottlin, [1]Ryan Bushey, [1]James Herndon, [1]Scott Antonia, [3]Edward Patz, [4]George Simon. *[1]Duke University Medical Center, Durham, NC, USA; [2]Maranos Cancer Institute, Detroit, MI, USA; [3]Grid Therapeutics; Duke University, Durham, NC, USA; [4]H Lee Moffitt Cancer Center, Tampa, FL, USA*

Background Complement factor H (CFH) modulates immune self-recognition and complement mediated cytotoxicity by regulating the alternative pathway of the complement cascade. Overexpression of CFH can facilitate immune evasion and is associated with poor prognosis in NSCLC. Discovery of CFH autoantibodies in patients with early-stage lung cancer led to the development of GT103, a first-in-class IgG3 monoclonal antibody inhibitor of CFH which has demonstrated preclinical anti-tumor activity.

Methods We conducted a multi-institutional, first-in-human, phase Ib study of GT103 in patients with advanced, refractory NSCLC. A standard '3+3' dose escalation schema was utilized with four dose levels of GT103 (0.3, 1, 3, 10 mg/kg) administered IV every 3 weeks until disease progression or unacceptable toxicity. The dose limiting toxicity (DLT) observation period included cycle 1 and radiographic disease assessment using RECIST 1.1 was performed before every third cycle. Three additional patients were enrolled at the highest dose level to confirm the maximum tolerated dose. We present the interim results of the dose escalation portion of the trial.

Results Twenty-one patients were enrolled and received protocol treatment. Median age was 63 years (range 50-78). All 21 patients had stage 4 disease, 81% had received prior immunotherapy, 8 patients (38%) had known brain metastases, and a majority of patients had adenocarcinoma histology (67%). Median number of prior lines of therapy was 3 (range 2-8). DLT was observed in 2 patients; one patient at the 0.3 mg/kg dose level experiencing grade 3 acute kidney injury and one patient at 1 mg/kg dose level experiencing grade 2 colitis. No DLT was observed at the 3 and 10 mg/kg dose levels. Six patients (28%) experienced grade 2 or higher treatment-related adverse events. In addition to DLTs, treatment related grade 2-3 adverse events included grade 2 anorexia (n=1), grade 2 colitis (n=1), grade 2 and grade 3 lymphopenia (n=2), grade 2 creatinine increase (n=1), and grade 2 psoriasis flare (n=1). Stable disease was demonstrated in 5/21 (24%) patients and no objective responses were seen. The median progression-free survival observed was 42 days (95% CI: 40-NE) and the median number of cycles of treatment received was 2 (range 1-8). Updated pharmacokinetic data and correlative analyses of circulating biomarkers will be presented at time of the meeting.

Conclusions GT103 was well tolerated during dose escalation including at the 10 mg/kg level and demonstrated an acceptable safety profile in refractory NSCLC population. A separate phase 2 study of combination GT103 with anti-PD1 therapy is planned in NSCLC.

700 LUCA-MERIT-1: FIRST-IN-HUMAN OPEN LABEL DOSE CONFIRMATION TRIAL EVALUATING SAFETY, TOLERABILITY, AND EFFICACY OF BNT116 ALONE AND IN COMBINATIONS IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

[1]Patrick Forde, [2]Akin Atmaca, [3]Neru Munshi*, [4]Malgorzata Kaczorowska, [4]Patrick Brueck, [4]Thomas Schell, [4]Oezlem Tuereci, [4]Ugur Sahin. *[1]Johns Hopkins University, Baltimore, MD, USA; [2]Krankenhaus Nordwest, Frankfurt a.M., Germany; [3]BioNTech US, Cambridge, MA, USA; [4]BionTech SE, Mainz, Germany*

Background Lung cancer is the leading cause of cancer deaths worldwide.[1] The diagnosis of non-small cell lung cancer (NSCLC) is often made when the disease is already advanced or metastatic (Stage IIIB/IV).[2] The approved Programmed Cell Death protein 1/Programmed Cell Death Ligand 1 (PD-1/PD-L1) inhibitors have demonstrated substantial anti-tumor activity; however, a majority of patients do not respond to therapy or only respond for a limited time.[3-7] BNT116 is an intravenously (IV) administered cancer immunotherapy consisting of a mixture of six liposomally formulated ribonucleic acids (RNA) each of which encodes for a different tumor-associated antigen. BNT116 alone or in combination with either docetaxel or the PD-1 inhibitor cemiplimab (Libtayo®) may have synergistic anti-tumor effects, thus potentially addressing the unmet medical need of these cancer patients.

Methods The trial comprises four cohorts, each with a single-step dose confirmation using a 3+3 design in both monotherapy and in combinations followed by an expansion phase including up to 20 patients in each cohort. Depending on the cohort, patients with histologically confirmed unresectable or metastatic NSCLC, measurable disease by Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 and the ability to tolerate additional PD-1 inhibitor therapy are included. In all cohorts, the first dose of BNT116 is given at 60 µg total RNA (Cycle 1 Day 1 [C1 D1]). Depending on Safety Review Committee decisions, all subsequent doses of 90 µg total RNA are given once weekly for the initial 7 weeks followed by every 3-week (Q3W) dosing on Day 1 of each cycle. Cemiplimab (350 mg) may be added at the discretion of the investigator in Cohort 1 after the second cycle. Patients in cohort 2 and 4 receive cemiplimab starting with C1 D1. Docetaxel will be administered at the approved dose of 75 mg/m^2 IV Q3W on Day 2 of each cycle (Cohort 3). Primary endpoints are occurrence of dose limiting toxicities and adverse events coded using MedDRA® assessed according to National Cancer Institute – Common Terminology Criteria for Adverse Events v5.0. Secondary endpoints are related to clinical activity, e.g., tumor assessments, as per RECIST 1.1.

The first patient was dosed in JUL 2022, with enrolment expected for approximately 12 months.

The study was approved by IRB/IEC, approval numbers: 2022-03/1691 (Turkey), OGYÉI/6962-9/2022 (Hungary), and US and Spain (approval numbers for the later were not provided).

Acknowledgements This trial is sponsored by BioNTech SE. The authors would like to acknowledge Suma Guttal for medical writing support.

Background Immune Checkpoint Inhibitors (ICIs) are associated with long-term survival in ~20% of advanced NSCLC patients while biological mechanisms triggering resistance are not fully elucidated. Myeloid-Derived Suppressor Cells (MDSC) might however play a key role. The PIONeeR project (NCT03493581, ANR-17-RHUS-0007) aims to predict the response/resistance to PD1/L1 ICIs in advanced NSCLC patients through comprehensive agnostic multiparametric biomarker assessment. Here, the combination of both lymphoid and myeloid lineages infiltration in the tumor is evaluated on tissue collected at diagnosis to predict outcome.

Methods Tumor samples from 60 advanced NSCLC patients, all ECOG PS0/1, treated with standard PD1/L1 monotherapy as ≥2nd line of treatment were studied. PD1/L1 ICIs Overall Response Rate was assessed by RECIST 1.1. Multiplex IHC assay Brightplex® TCE (former Immunoscore® CR T cells exhaustion) quantifies T-lymphocytes allowing tumor stratification into 4 groups: Hot, Parenchyma Hot, Cold and tumors with Stromal TILs.[1] Brightplex® MDSC assay quantifies myeloid cells (monocytes, neutrophils and other granulocytes), Monocytic- (M-) and PolyMorphoNuclear- (PMN-) MDSC. Correlation analyses: spearman non-parametric test. Association between biomarkers: Fisher's exact test. Samples' classification: unsupervised neural-network-based machine learning algorithm Self-Organizing Maps (SOM). Statistical significance of overall (OS) and progression-free survival (PFS) differences between groups: log-rank test.

Results Patients were mainly male (60%), smokers (98.33%), <70yrs (71.66%), median PFS was 3.9 months. Across the 60 tumors, M-MDSC were not correlated to any other cell type while PMN-MDSC were negatively correlated to Monocytes (R=-0.28) and highly correlated to granulocytes (R=0.85), even more when removing neutrophils (R=0.93). SOM clustering on myeloid cells alone did not allow any patients stratification regarding PFS nor OS. Considering previously described patient groups through Brightplex® TCE [1], the 20 "Hot tumors", with high T-cells infiltration initially presenting the best PFS (median PFS=8.1months) were split into 2 groups. Patients' subgroup with high PMN-MDSC and granulocytes tumor infiltration included no responder and had poor survival: 20% PFS at 20months vs 70% (p=0.035) in patients with low-infiltrated tumors, which included the 3 responders. Interestingly, in the 17 "Cold tumors", high infiltration of PMN-MDSC and granulocytes also identified 5 patients with worse prognostic: at 2.5 months, only 20% PFS vs 58% in the low-density group (NS) (table 1).

Conclusions Brightplex® TCE and MDSC assays in combination allowed the stratification of advanced NSCLC patients in 5 subgroups, among which two subgroups with poor outcome and no responder, representing 45% of the total population that would likely not benefit from anti-PD1/L1 monotherapy.

702 TERTIARY LYMPHOID STRUCTURES (TLS) OBSERVED IN NON-SMALL CELL LUNG CANCER (NSCLC) TUMORS TREATED WITH PULSED ELECTRIC FIELDS

[1]Jeff Iding, [2]Paul VanderLaan, [3]Marcelo Jimenez, [3]José Fernández García-Hierro, [4]Javier Flandes Aldeyturriaga, [5]Erik HFM van der Heijden, [6]Calvin SH Ng, [6]Rainbow WH Lau, [3]Maria Ludeña, [4]Rafael Carías, [4]Oderay Cedeño, [7]Alicia Moreno-Gonzalez, [7]Beryl Hatton, [7]William Krimsky*. *[1]MedStar Health and affiliated hospitals, Baltimore, MD, USA; [2]Board-Certified Anatomic Pathologist, Boston, MA, USA; [3]Hospital Universitario de Salamanca, Salamanca, Spain; [4]Hospital Universitario Fundación Jiménez, Madrid, Spain; [5]Radboudumc, Nijmegen, Netherlands; [6]The Chinese University of Hong Kong, Hong Kong, China; [7]Galvanize Therapeutics, San Carlos, CA, USA*

Background Tertiary lymphoid structures (TLS) may develop in non-lymphoid tissues in response to a variety of different stimuli and can serve as foci for generating anti-tumor immunity.[1] TLS formation is emerging as a strong prognostic and predictive biomarker[2] associated with patient survival benefits in NSCLC.[3,4]Pulsed Electric Fields (PEF) have been reported to induce an immunogenic form of cell death and thus may enhance adaptive immunity in the setting of cancer. The treat-and-resect INCITE ES study enrolled adults with suspected or confirmed NSCLC stage IA2-IB (>1 to ≤4 cm) and without a history of treatment for cancer within the previous two years.

Methods The INCITE ES study design includes both control and treatment groups with 8 enrolled control group subjects and 30 enrolled treatment group subjects. Treatment group subjects received PEF (Aliya™ System, GTI-00018 investigational device; Galvanize Therapeutics, San Carlos, CA) either percutaneously or endoscopically at time of biopsy prior to surgical resection. Blood, bronchoalveolar lavage (BAL) when applicable, and tissue samples were collected over the course of the study for appropriate pre- and post-PEF comparison.

Serial histologic sections were obtained from an initial cohort of 12 patients (n=1 control, n=11 treatment group) on the day of surgery 17-21 days post-PEF delivery, stained for standard H&E as well as duplex stained for pan-cytokeratin (panCK) and CD20, and reviewed by an independent pathologist.

Results TLS were identified and characterized according to their maturity and localization within or adjacent to the tumor (see criteria in Table 1). Intratumor TLS were observed admixed among tumor cells or within the invasive margin (figures 1 to 5), including within the cellular depletion zone induced by PEF (figures 6 and 7). Independent of tumor morphology, a significant quantity of 49.8 ± 55.8 TLS per tumor was observed post-PEF (n=11, average ± S.D.). TLS across treated tumors showed varying proportions of mature vs. immature TLS, using the criteria in Table 1. No TLS were identified in the available pre-PEF biopsy specimens (figures 2 and 8). TLS density was greater in PEF specimens compared to the non-treated control, where only three immature TLS were observed (figure 9).

Conclusions This initial cohort suggests that PEF may induce the formation of TLS within the tumor, including proximal to the PEF delivery zone. The observed density and detection of mature TLS may suggest ongoing immune activity. As such, PEF has the potential to induce or enhance an immune response irrespective of tumor morphology.

Trial Registration The study is registered on clinicaltrials.gov (NCT04732520).

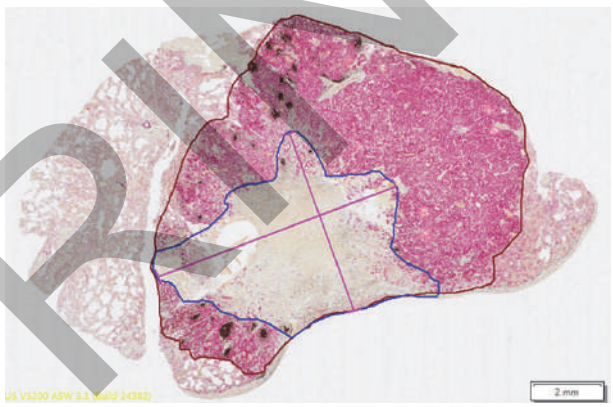
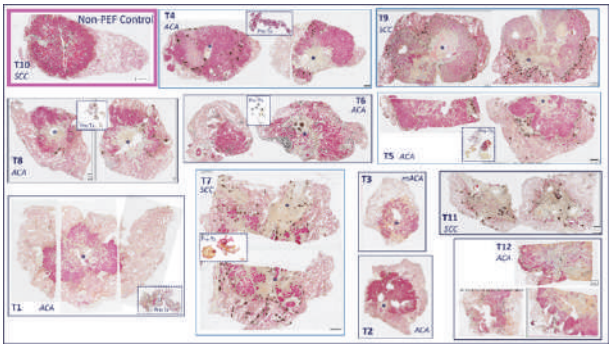
Ethics Approval This abstract discusses the INCITE ES clinical study. Participants gave informed consent before taking part in the study. The study obtained ethics approval from the Ethics Committee for Research with Drugs (CEIm) of the Salamanca Health Area (Salamanca, Spain, reference 20/1615 (E.C.P.S.), Committee on Research Involving Human Subjects (CMO) of Radboud University Medical Center (Nijmegen, the Netherlands, NL76406.091.21), and the Joint Chinese University of Hong Kong – New Territories East Cluster Research Ethics Committee (Hong Kong SAR, reference 2021.294-T).

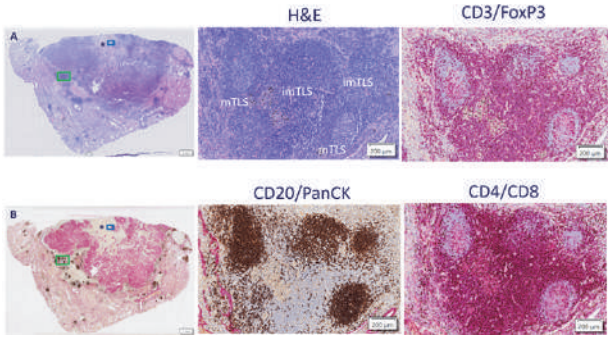


Abstract 702 Figure 1 Example of outlined resected tumor region and CDZ post-PEF. Tumors were resected post PEF delivery and underwent immunostaining. The duplex staining with PanCK (pink) identifies epithelial cells and CD20+ B cells (brown). Areas of dense pink coloration are tumor and the remaining tissue is non-cancerous lung parenchyma. The residual tumor area is outlined in maroon to the leading tumor edge adjacent to non-cancerous lung parenchyma. The PEF-induced cellular depletion zone (CDZ) is outlined in blue. On average, the CDZ measures 0.9 ± 0.3 cm (longest dimension) by 0.6 ± 0.2 cm (longest perpendicular dimension) after a single PEF delivery (n=9).

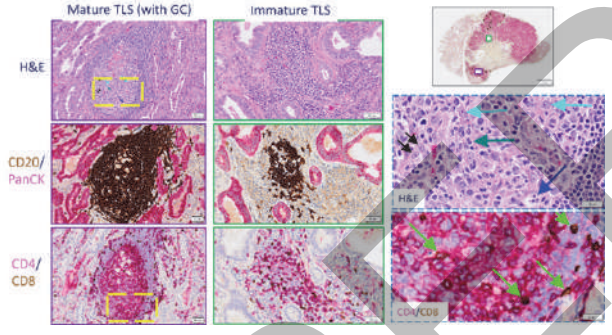


Abstract 702 Figure 2 Compilation of resected NSCLC tumors from INCITE ES study. Tumors underwent duplex PanCK and CD20+ staining. One non-treatment control specimen resected 35 days post biopsy is included (T10). Tumors after a single delivery of PEF energy were resected 17 to 21 days after PEF. Inset images are of pre-PEF biopsy specimens with duplex stain, when available. Colored asterisk (*) in each image denotes the estimated location of the cellular depletion

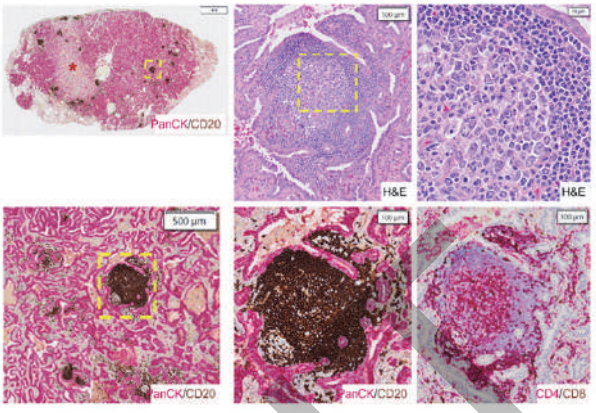
zone. Acronyms ACA, mACA, and SCC indicate tumor histopathology adenocarcinoma, mucinous adenocarcinoma, and squamous cell carcinoma, respectively.



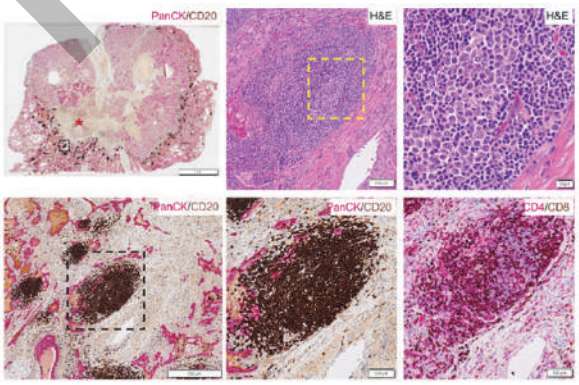
Abstract 702 Figure 3 TLS in tumor periphery 19 days after a single PEF delivery. Representative H&E and IHC images of a right upper lobe tumor. Characterization of the TLS indicates presence of CD20+ B cells (brown), CD3+ T-cells (red), FoxP3+ regulatory T-cells (Tregs, brown), CD4+ helper T-cells (red) and cytotoxic CD8+ T-cells (brown). Higher magnification images of the area denoted by the green box in A and B show two mTLS and two immature imTLS. Asterisks (*) in images shown in A and B denote the estimated location of the cellular depletion zone.



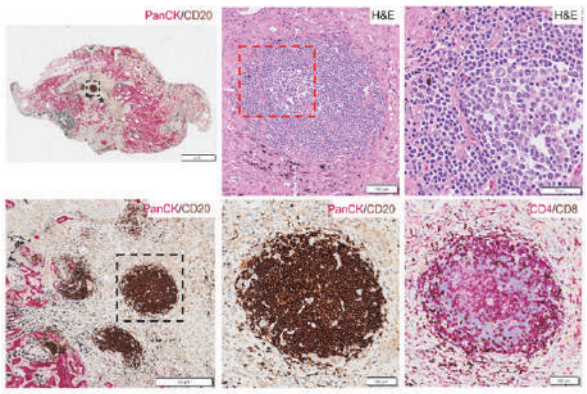
Abstract 702 Figure 4 Mature and immature TLS in a tumor post-PEF energy delivery. Representative H&E and IHC images of a left lower lobe tumor. Purple-outlined (left column) and green-outlined (middle column) boxes representing mature TLS (mTLS) and immature TLS (imTLS), respectively, are higher power magnification of the specimen sampled at approximately 7 o'clock and 12 o'clock, respectively, in the wide field view (upper right). Both mTLS and imTLS are identified by a collection of dense, small CD20+ B cells (brown, middle row), generally juxtaposed with T cell aggregate (CD4+ helper T-cells (red) and cytotoxic CD8+ T-cells (brown), bottom row). The mTLS contains a germinal center (GC) discernable via H&E. The center of the GC is shown in the right column (yellow-dashed outline represents area of higher magnification) to identify dendritic cells (black arrows) and CD8+ T-cells (bright green arrows). Mature CD20+ B cells within the GC exhibit the characteristic morphology of proliferating centroblasts (cyan arrows) and centrocytes (dark green arrow). A GC may also contain tingible body macrophages (dark blue arrow) licensed for phagocytosis by follicular dendritic cells within the germinal center.



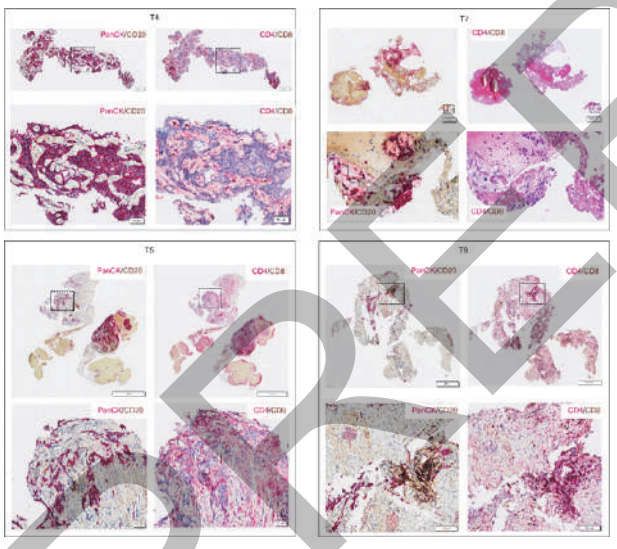
Abstract 702 Figure 5 Representative mature TLS located intratumorally post-PEF. Images were captured from duplex PanCK and CD20, duplex CD4 and CD8, and H&E-stained tissue sections of tumor T4. The whole tissue from the resection sample is shown with red asterisk (*) denoting the estimated location of the cellular depletion zone and the yellow dashed box indicating the mTLS within the tumor bed that is shown at higher magnification as indicated in subsequent image panels. The mTLS contains a germinal center (GC) discernable via H&E. The high magnification image of the region denoted by the dashed yellow box in the H&E image demonstrates mature CD20+ B cells within the GC exhibiting the characteristic morphology of proliferating centroblasts and centrocytes. Accumulation of CD4+ and CD8+ T cells can be seen within and surrounding the mTLS.



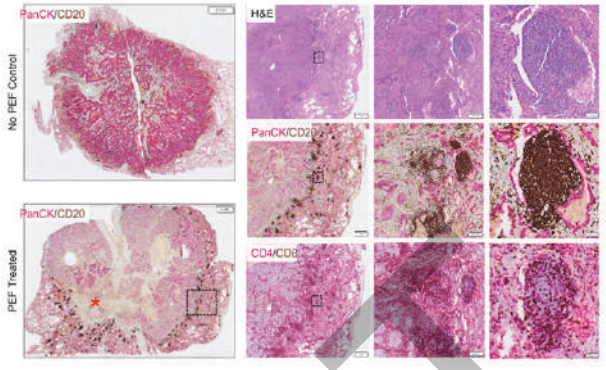
Abstract 702 Figure 6 A mature TLS located at the CDZ-lung parenchyma interface. Images were captured from duplex PanCK and CD20, duplex CD4 and CD8, and H&E-stained tissue sections of tumor T9. The whole tissue from the resection sample is shown with the red asterisk (*) denoting the estimated location of the CDZ and the black dashed box indicating the mTLS that is shown at higher magnification as indicated in subsequent image panels. The mTLS contains a germinal center (GC) discernable via H&E. The high magnification image of the region denoted by the dashed yellow box in the H&E image demonstrates mature CD20+ B cells within the GC exhibiting the characteristic morphology of proliferating centroblasts and centrocytes. Accumulation of CD4+ and CD8+ T cells can be seen within and surrounding the mTLS.



Abstract 702 Figure 7 A mature TLS located within the cellular depletion zone (CDZ). Images were captured from duplex PanCK and CD20, duplex CD4 and CD8, and H&E-stained tissue sections of tumor T6. The whole tissue from the resection sample is shown with the black asterisk (*) denoting the estimated location of the CDZ and the black dashed box indicating the mTLS within the CDZ that is shown at higher magnification as indicated in subsequent image panels. The mTLS contains a germinal center (GC) discernable via H&E. The high magnification image of the region denoted by the dashed red box in the H&E image demonstrates mature CD20+ B cells within the GC exhibiting the characteristic morphology of proliferating centroblasts and centrocytes. Accumulation of CD4+ and CD8+ T cells can be seen within and surrounding the mTLS.



Abstract 702 Figure 8 Representative pre-PEF tumor biopsy specimens. Images were captured from duplex PanCK and CD20 and duplex CD4 and CD8 stained tissue sections of tumors T4, T5, T7, and T8. The black dashed box indicates the region of the tissue at shown at higher magnification in the lower panels for each sample. While some CD20+ staining is evident in the pre-treatment biopsy from sample T8, this did not meet the criteria for being considered a TLS.



Abstract 702 Figure 9 TLS accumulation in PEF-treated tumor and control tumor. Non-PEF control (T10) and a PEF-treated (T9) demonstrating the accumulation of TLS at the tumor periphery in the PEF-treated sample. Images were captured from duplex PanCK and CD20, duplex CD4 and CD8, and H&E-stained tissue sections. The whole tissue from the resection sample is shown with the red asterisk (*) denoting the estimated location of the CDZ in the PEF-treated sample, and the black dashed box indicating an imTLS that is shown at the invasive tumor margin at higher magnification as indicated in subsequent image panels (right). Accumulation of CD4+ and CD8+ T cells can be seen within and surrounding the imTLS.

703 FIRST-LINE TUMOR TREATING FIELDS (TTFIELDS; 150 KHZ) THERAPY PLUS PEMBROLIZUMAB FOR ADVANCED OR METASTATIC INTRATHORACIC NON-SMALL CELL LUNG CANCER: THE PHASE 2 EF-36/KEYNOTE B36 PILOT STUDY

[1]Rupesh Kotecha*, [2]Corey Langer, [3]Vinicius Ernani, [4]Anne Tsao. [1]*Miami Cancer Institute, Miami, FL, USA*; [2]*Hospital of University of Pensylvania, Philadelphia, PA, USA*; [3]*Mayo Clinic Arizona, Phoenix, AZ, USA*; [4]*MD Anderson Cancer Center, Houston, TX, USA*

Background Tumor Treating Fields (TTFields) therapy is a loco-regional treatment modality approved for glioblastoma and malignant pleural mesothelioma. Effectiveness of TTFields (150 kHz) therapy plus pemetrexed in recurrent non-small cell lung cancer (NSCLC) was previously demonstrated in a phase 1/2 study. TTFields therapy plus standard of care (SOC; docetaxel or immune checkpoint inhibitors) vs SOC alone is currently being evaluated in the large phase 3 LUNAR study (NCT02973789). Given that preclinical data show that TTFields induce immunogenic cell death and enhance efficacy of PD-1 inhibitors, investigation of this combination in a clinical population is warranted.

Methods EF-36/KEYNOTE B36 (NCT04892472) is a multicenter, phase 2, open-label study evaluating efficacy and safety of TTFields (150 kHz) therapy plus pembrolizumab for first-line treatment of advanced NSCLC. The study was approved by the institutional review board/ethics committee as required for each participating site. Patients ($\geq$ 22 years) with Eastern Cooperative Oncology Group performance status 0–1 and treatment-naïve advanced or metastatic intrathoracic, PD-L1 positive (tumor proportion score [TPS] $\geq$ 1%) NSCLC are eligible. Patients with epidermal growth factor receptor-sensitizing mutations or anaplastic lymphoma kinase translocation NSCLC are ineligible. Patients stratified by PD-L1 expression (TPS $\geq$ 50% vs TPS 1–49%) will receive TTFields therapy $\geq$ 18 h/day, via the NovoTTF-200T System, with pembrolizumab 200 mg intravenously every 3 weeks (Q3W), until disease progression per Response Evaluation Criteria in Solid Tumors v1.1. Follow-up is Q3W, with computerized tomography (CT) scans Q9W. Primary endpoint is objective response rate (ORR). Secondary endpoints include overall survival (OS), progression-free survival (PFS), duration of response, disease control rate, and safety. ORR, OS, and PFS in patients with TPS $\geq$ 50% and TPS 1–49% are also secondary endpoints. The device manufacturer will provide patients and caregivers with technical and lifestyle integration training, and guidance on preventing and managing skin effects, via Device Support Specialists and field personnel. Usage information from the device is provided to physicians to aid discussions with patients and maximize usage. This novel support framework helps ensure patients can confidently operate the NovoTTF-200T System and integrate TTFields therapy into daily life, improving usage duration and optimizing patient outcomes. A sample size of 66 is required to achieve 80% power to detect ORR of 40% at 1-sided alpha level 0.1, using 1-sample exact test for proportion, considering < 10% loss to follow-up. Recruitment is ongoing; planned interim analysis will occur after enrollment of 15 patients with $\geq$ 1 follow-up CT scan.

Trial Registration NCT04892472

Ethics Approval The study was approved by the institutional review board/ethics committee as required for each participating site

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0703

704 PHASE I STUDY OF TISLELIZUMAB IN COMBINATION WITH BEVACIZUMAB AND PEMETREXED IN FIRST-LINE TREATMENT FOR ADVANCED ELDERLY NON-SQUAMOUS NON-SMALL CELL LUNG CANCER: TRIAL IN PROGRESS

Xiubao Ren, Liang Liu*. *Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background Lung cancer has higher incidence and mortality in the elderly population, although substantial evidence confirms the efficacy of PD-1/L1 inhibitors in combination with chemotherapy for advanced non-small cell lung cancer (NSCLC) regardless of PD-L1 expression. However, efficacy and safety of immunotherapy in elderly NSCLC remains unclear, with most evidence is sourced from subgroup analysis of prospective clinical trials.[1] Elderly lung cancer patients often have more underlying diseases and function of major organs decreases with ageing,[2] safety is certainly a key factor that must be carefully considered when these patients receive treatment because of poor tolerability. Therefore, we designed the study of tislelizumab in combination with pemetrexed and bevacizumab for the treatment of elderly non-squamous NSCLC. To improve safety and tolerability, we remove the more toxic platinum from the chemotherapy regimen, and the anti-angiogenic agent bevacizumab, with relatively mild adverse effect, was added to avoid decreased efficacy. This study aims to explore the efficacy and safety of this treatment regimen in elderly NSCLC patients.

Methods This open-label, single arm, phase I clinical study is enrolling patients aged≥65 years with histologically or cytologically confirmed, untreated IIIB/IIIC/IV(according to AJCC 8th) non-squamous NSCLC. Patients must have measurable disease per RECIST v1.1; ECOG PS of 0 or 1; without harboring EGFR-sensitizing mutation or ALK and ROS1 gene translocation; no active autoimmune disease, bleeding risk, or coagulation disorders. Patients will receive 4 cycles of pemetrexed (500mg/m^2, d1) Q3W and tislelizumab (200mg, d4) Q3W in combination with bevacizumab (7.5mg/kg, d1) Q3W followed by tislelizumab (200mg, d1) Q3W and bevacizumab (7.5mg/kg, d1) Q3W, until disease progression, unacceptable AEs, investigator/patient decision or 2 years. The primary endpoint is objective response rate (ORR) by RECIST v1.1. Secondary endpoints include overall survival (OS), progress-free survival (PFS), duration of response (DOR), health-related quality of life (HRQoL) and safety. HRQoL is assessed using EORTC QLQ-C30 questionnaires; AEs are graded according to NCI CTCAE v5.0. This study will enroll 30 patients and enrollment is ongoing.

Trial Registration ClinicalTrials. gov NCT05273814

705 PHASE 2 STUDY OF SEA-CD40 COMBINATION THERAPIES IN ADVANCED MALIGNANCIES (SGNS40–002, TRIAL IN PROGRESS)

[1]April Salama*, [2]Meredith McKean, [3]Thaddeus Beck, [4]Omid Hamid, [5]Sandeep Mashru, [6]Sapna Patel, [7]Timothy Kuzel, [8]Michael Castine, [9]Vincent Ma, [10]Keenan Fenton, [10]Jonathan Hayman, [11]Adil Daud. *[1]Duke Cancer Institute, Durham, NC, USA; [2]Sarah Cannon Research Institute, Nashville, TN, USA; [3]Highlands Oncology, Springdale, AR, USA; [4]The Angeles Clinic and Research Institute, a Cedars-Sinai Affiliate, Los Angeles, CA, USA; [5]Kaiser Permanente, Portland, OR, USA; [6]MD Anderson Cancer Center, Houston, TX, USA; [7]Rush Medical College, Chicago, IL, USA; [8]Hematology Oncology Clinic, Baton Rouge, LA, USA; [9]University of Wisconsin Carbone Cancer Center, Madison, WI, USA; [10]Seagen Inc., Bothell, WA, USA; [11]University of California, San Francisco Medical Center, San Francisco, CA, USA*

Background While immunotherapy has improved outcomes for patients with metastatic non-small cell lung cancer (NSCLC) and melanoma, most progress despite standard treatment. Therefore, treatments with the potential to enhance the efficacy of existing immunotherapy-based regimens are being actively examined to further improve outcomes in these diseases.

CD40 is a tumor necrosis factor receptor expressed on multiple immune cell populations as well as on tumor cells. CD40 activation drives B- and T-cell activation to evoke tumor-specific cytotoxic T-cell responses. SEA-CD40 is an investigational, receptor-agonistic, nonfucosylated, humanized IgG1 monoclonal antibody (mAb) directed to CD40. SEA-CD40 binds with high affinity to FcγRIIIa and CD40, resulting in enhanced effector function and CD40 agonism, allowing amplification of immune stimulation and antitumor activity.

Preclinical studies have shown that SEA-CD40 combined with chemotherapy and pembrolizumab resulted in significant antitumor activity. This combination regimen has also demonstrated a tolerable safety profile, encouraging antitumor activity, and evidence of persistent immune activation in an ongoing phase 1 study (SGNS40-001, NCT02376699). Given the preclinical and clinical data supporting SEA-CD40 combined with pembrolizumab and/or chemotherapy, further investigation into additional diseases is warranted.

Methods SGNS40-002 (NCT04993677) is a phase 2, open-label, multicenter trial designed to assess the antitumor activity, safety, and tolerability of SEA-CD40 in combination with pembrolizumab and/or chemotherapy in adults (≥18 years) with NSCLC or melanoma. Five indication-specific cohorts will explore 2 different regimens: cohorts 1–3 will receive SEA-CD40 with pembrolizumab while cohorts 4 and 5 will receive SEA-CD40, pembrolizumab, carboplatin, and pemetrexed.

Cohort 1 will enroll patients with relapsed or refractory metastatic melanoma (≤3 prior lines of therapy, including an anti–programmed death/ligand 1 (PD-1/PD-L1) mAb within 90 days), cohort 2 will enroll patients with metastatic uveal melanoma, and cohort 3 will enroll patients with metastatic PD-1/PD-L1–naïve melanoma. Patients in cohorts 2 and 3 must have no prior therapy for advanced disease except adjuvant/neoadjuvant therapy. Cohorts 4 and 5 will include patients with NSCLC with a PD-L1 tumor proportion score of 1–49% or <1%, respectively.

The primary endpoint is investigator-assessed confirmed objective response rate per Response Evaluation Criteria in Solid Tumors Version 1.1 (RECIST v1.1). Secondary endpoints include incidence of adverse events; laboratory abnormalities; treatment interruptions, reductions or discontinuations; disease control rate; duration of response; progression-free survival; and overall survival. Exploratory endpoints include pharmacokinetic parameters, antidrug antibodies, biomarkers of response, and patient-reported quality of life. Enrollment is ongoing in North America and Europe.

Trial Registration NCT04993677

Ethics Approval Institutional review boards or independent ethics committees of participating sites approved the trial, which will be conducted in compliance with the Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice. All patients will provide written informed consent.

Consent All patients will provide written informed consent.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0705

706 **NOUS-PEV, A NOVEL PERSONALIZED VIRAL-BASED PRIME/BOOST CANCER IMMUNOTHERAPY TARGETING PATIENT-SPECIFIC NEOANTIGENS: INTERIM RESULTS FROM THE FIRST SUBJECTS IN THE PHASE 1B STUDY**

[1]Oliver Bechter*, [2]Juan Martin-Liberal, [3]Anna D'Alise, [3]Guido Leoni, [3]Gabriella Cotugno, [3]Loredana Siani, [3]Rosa Vitale, [3]Valentino Ruzza, [3]Elisa Micarelli, [3]Irene Garzia, [4]Thea Faivre, [4]Sven Gogov, [4]Patricia Delaite, [5]Stefano Colloca, [5]Maria Ambrosio, [5]Rossella Merone, [3]Elisa Scarselli, [6]Stefan Symeonides. *[1]Leuven Cancer Institute, Leuven, Belgium; [2]Catalan Institute of Oncology, Barcelona, Spain; [3]Nouscom Srl, Rome, Italy; [4]Nouscom AG, Basel, Switzerland; [5]Reithera Srl, Roma, Italy; [6]Edinburgh Cancer Centre, Edinburgh, UK*

Background NOUS-PEV is a vector based personalized cancer vaccine, expressing about 60 patient specific neoantigens identified by next generation sequencing (NGS). Vaccination consists of Great Ape Adenoviral (GAd) prime followed by Modified Vaccinia Ankara (MVA) boosts. The study is a dose-confirmation and cohort expansion, phase 1b, first in human (FIH) trial (NCT04990479) evaluating safety, tolerability, immunogenicity and preliminary anti-tumour activity of NOUS-PEV in combination with the PD-1 blocking antibody pembrolizumab.

Methods The study is enrolling treatment-naïve subjects with unresectable stage III/IV cutaneous melanoma and/or PD ligand 1 (PD-L1) $\geq$ 50% stage IV non-small cell lung cancer. Following pembrolizumab induction treatment (3 cycles), the vaccines are administered intramuscularly: the GAd priming dose concomitantly with pembrolizumab at week 10 (4th pembrolizumab infusion) followed by 3 boosts of MVA, each 3 weeks apart. Baseline and on treatment tumor biopsies are collected at screening and post 1st MVA, respectively. PBMC are collected at baseline, post pembrolizumab, and post each vaccination for evaluation of immune response. Clinical response is evaluated according to RECIST v1.1 by CT scan according to standard of care.

Results All vaccines were made and administered on time to the three melanoma subjects in the dose-confirmation cohort. As of June 2022, the median follow-up is 6.9 months (range 3.0-11.5). No dose limiting toxicities (DLTs) were observed, and the treatment was safe and no NOUS-PEV related AEs >Grade 1 were observed, allowing the enrollment of subjects in the expansion cohort.

In the first subject, the first CT scan before vaccination showed initial SD with dynamic of growth in target lesion size, that then reverted after NOUS-PEV administration, resulting in a confirmed PR deepening over time. The second subject had a PR already at the first CT scan, further deepened after the vaccination. The third subject had PD at the first scan before vaccination and discontinued based on the confirmatory scan.

Vaccine-induced immunogenicity was demonstrated by *ex-vivo* interferon-gamma ELISpot in 2 evaluable subjects who showed clinical response, with detection of potent neoantigen specific immune response to multiple neoantigens in the peripheral blood and induction of both CD4 and CD8 T cell responses. NGS analysis of baseline and on-treatment biopsies showed an increased T cell infiltrate, with expansion and diversification of the TCR repertoire post treatment.

Conclusions NOUS-PEV in combination with anti-PD1 is safe and well tolerated. Data show that vaccination elicits a robust immune response which correlates with preliminary clinical activity.

Trial Registration NCT04990479

Ethics Approval The study was approved by UZ Leuven Ethics Committee (Study Reference S64578) and by Research Ethics Committee of Fundacion Jimenez Diaz, Madrid

707 A PHASE 1, OPEN-LABEL, DOSE FINDING STUDY OF NI-1801, A BISPECIFIC MESOTHELIN X CD47 ENGAGING ANTIBODY, IN PATIENTS WITH MESOTHELIN EXPRESSING SOLID CANCERS

[1]Emanuela Romano, [2]Jacques Medioni, [3]Thibault De La Motte Rouge, [4]Nicolas Fischer, [5]Clélia Bardonneau, [4]Walter Ferlin, [4]Dirk Hose, [4]Anja Seckinger*, [5]Matteo Simonelli, [6]Giuseppe Curigliano. *[1]Institut Curie, Paris, France; [2]Hôpital Européen Georges Pompidou, Paris, France; [3]Centre Eugène Marquis, Rennes, France; [4]Light Chain Bioscience – Novimmune SA, Geneva, Switzerland; [5]IRCCS Humanitas Research Hospital, Milan, Italy; [6]European Institute of Oncology, IRCCS, Milan, Italy*

Background Mesothelin (MSLN) is highly expressed in many solid tumors while expression in normal tissue is limited, thus representing an attractive target for immunotherapeutic approaches. NI-1801 is a fully human IgG1 bispecific antibody based on the kl-body format.[1,2] NI-1801 targets MSLN with a high-affinity arm coupled to a low affinity-optimized CD47-blocking arm. This unbalanced affinity enables the selective CD47-blockade on MSLN-expressing cells. Additionally, NI-1801 contains an unmodified IgG1 Fc and can therefore mediate effector functions. *In vitro*, NI-1801 induces antibody-dependent cellular phagocytosis (ADCP) and antibody-dependent cell-mediated cytotoxicity of MSLN-positive cancer cells. ADCP is negligible or unaffected by a CD47-sink effect mimicked by CD47-expressing red blood cells. NI-1801 does not induce *in vitro* hemagglutination or platelet aggregation. *In vivo*, NI-1801 inhibits tumor growth in xenograft models. NI-1801 was well tolerated and demonstrated favorable PK in multiple non-human primate studies.

Methods Study LCB-1801-001 (NCT05403554) is a first-in-human clinical trial of NI-1801 in patients with MSLN-expressing solid malignancies. Part A (dose escalation) evaluates the safety and tolerability of NI-1801, to determine the maximum tolerated dose (MTD) and the non-tolerated toxic dose. The decision to include additional patients as well as dose escalation decisions are made at the discretion of the Safety Review Committee (SRC). Intrapatient dose escalation is permitted by SRC approval. Part B (cohort expansion) will further evaluate the safety and efficacy in up to 20 additional subjects to determine the recommended Phase 2 dose. Expansion may occur at the MTD established in Part A, or at an alternative tolerable dosing schedule, based on review of safety and PK/PD data by the SRC. Treatments are administered intravenously in 28-day cycles for up to 6 months until disease progression, unacceptable toxicity, or investigator/patient decision to withdraw. Treatment can extend for patients without disease progression. The starting dose is 15 mg (fixed dose). Subsequent doses are given QW in Cycles 1/2 and Q2W in Cycles 3-6. LCB-1801-001 study enrolls patients since April 2022 and is ongoing in France and Italy. Adverse events are assessed according to CTCAE v5, tumor response is determined according to RECIST 1.1. Key inclusion criteria include (1) histologically or cytologically confirmed diagnosis of epithelial ovarian cancer (high-grade serous or endometroid), triple-negative breast cancer, or non-squamous non-small cell lung cancer, (2) advanced, metastatic, or recurrent disease, and (3) MSLN expression with staining intensity of $\geq$2+ as per immunohistochemistry in $\geq$60% of tumor cells.

708 MEDI1191 (IL-12 MRNA) INDUCES PERIPHERAL AND INTRATUMORAL IMMUNOSTIMULATORY EFFECT IN PATIENTS WITH CUTANEOUS OR SUBCUTANEOUS (C/SC) LESIONS

[1]Michael Abadier*, [1]Emily Jennings, [1]Jim Eyles, [1]Philip Martin, [1]Fernanda Pilataxi, [1]Yuling Wu, [1]Xiaoru Chen, [1]Analia Azaro, [1]Benjamin Ridgway, [1]Marc Phillips, [2]Benedito Carneiro, [3]Omid Hamid, [4]Thomas Marron, [5]Dmitriy Zamarin, [6]Eduardo Castañón, [7]Sandip Patel, [8]Elena Garralda, [9]Vivek Subbiah, [10]Anthony El-Khoueiry, [1]Paula Fraenkel, [1]Nicholas Durham. *[1]AstraZeneca, Waltham, MA, USA; [2]Legorreta Cancer Center at Brown University, Providence, RI, USA; [3]The Angeles Clinic and Research Institute, Los Angeles, CA, USA; [4]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [5]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [6]Clinica Universidad de Navarra, Navarra, Spain; [7]University of California San Diego, La Jolla, CA, USA; [8]Vall d'Hebron Institute of Oncology, Barcelona, Spain; [9]MD Anderson Cancer Center, Houston, TX, USA; [10]USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA*

Background MEDI1191 is an investigational therapy composed of mRNA encoding bioactive interleukin-12 (IL-12p70) in a lipid nanoparticle optimized for intratumoral injection. We hypothesized that intratumoral injection of MEDI1191 will reprogram the immunosuppressed tumor microenvironment (TME) and increase cytotoxic T-cell recruitment, proliferation and activation.

Methods In an ongoing phase 1 dose escalation study (NCT03946800), patients with C/SC lesions received 0.1-12μg MEDI1191 sequentially (Part 1A) or concurrently (Part 1B) with intravenous durvalumab (1500 mg).[1] Clinical samples were collected to monitor changes in peripheral cytokines, circulating tumor (ct) DNA, peripheral and tumoral gene signatures and T cell infiltration.

Results Peripheral blood cytokine analysis revealed increased serum IL-12 levels in 27/29 (93%) patients post first injection and was associated with ≥2-fold increase in serum IFN-γ in 24/29 (83%) patients. The IFN-inducible chemokines (CXCL9, CXCL10 and CXCL11) in periphery were detected at the protein and transcriptomic levels. In 11 patients whose blood samples underwent bulk RNA sequencing, markers of activated peripheral T cells were detectable over time with increased mean fold change of GZMB, IFNG and IL12RB1 gene expression in patients with partial response (PR, n=1) or stable disease (SD, n=5) patients. Pre-treatment expression of the genes encoding key mediators of cytotoxic T-cell function were potential predictors of response as observed by significantly higher expressions of peripheral IL12RB1 and IFNG genes at baseline in PR/SD patients.

Using immunohistochemistry (IHC), we observed ≥ 2-fold increase in CD8 T cells (8/17, 47%) and Ki-67+CD3+ T-cells (7/17, 41%) in tumor biopsies 15 days post first injection. Patients with increased intratumoral CD8 T cells by IHC and RNA sequencing showed higher tumoral GZMB and IFNG gene expression. In 9 patients with evaluable tumor biopsies at baseline and post-treatment, we observed an increase in antitumor gene signatures, including activated CD8 (7/9, 78%), activated NK (7/9, 78%), M1 macrophages (7/9, 78%) and IFN-γ signaling (8/9, 89%). Consistent with IL-12's role as a central mediator of Th1 cell development, we observed an increase in Th1 signature and STAT4 gene (6/9, 67%). Analysis of ctDNA in plasma of 17 patients demonstrated >50% reduction in mutant allele frequency in 2/3 patients who developed PR.

Conclusions Intratumoral injection of MEDI1191 induces pharmacodynamic changes within the TME such as increase in activated T cell infiltration and upregulation of anti-tumor gene signatures. There was an associated immunomodulatory effect in the periphery, including elevated IL-12, IFN-γ and activated T-cells.

Trial Registration NCT03946800

709 PHASE II STUDY TO ASSESS THE SAFETY AND EFFICACY OF THE CLEVER-1 ANTIBODY BEXMARILIMAB IN COMBINATION WITH PD-1 BLOCKADE IN PATIENTS WITH ADVANCED SOLID TUMORS – BEXCOMBO

[1]Petri Bono*, [2]Juho Jalkanen, [2]Inka Pawlitzky, [3]Marie-Louise Fjaellskog, [3]Cecilia Ahlin. [1]*University of Helsinki, Helsinki, Finland*; [2]*Faron Ldt, Turku, Finland*; [3]*Faron, Boston, MA, USA*

Background Clever-1 is an immunosuppressive scavenger receptor expressed on tumor associated macrophages[1-2]. High levels of Clever-1 are associated with poor survival, T-cell exclusion and dysfunction, and immunotherapy resistance[3-7]. Bexmarilimab (Bex) is a novel humanized anti-CLEVER-1 IgG4-antibody that induces IFN-γ upregulation, which is required for PD-L1 upregulation and response to PD-1blockade[8]. Bex is currently evaluated as monotherapy in a phase I/II study (MATINS; NCT03733990) in patients with advanced solid tumors and in combination with standard of care in patients with hematological malignancies (BEXMAB; NCT05428969). Preliminary data show well tolerated safety profile and promising clinical activity with disease control rates up to 40% translating into enhanced survival[9]. In addition, early analyses suggest that lower levels of proinflammatory cytokines at base line or higher CLEVER-1 expression in tumor can predict for a superior clinical outcome. The BEXCOMBO study will assess the safety and efficacy of Bex in combination with PD-1 blockade in 1st line setting in patients with advanced solid tumors expressing CLEVER-1 and with modest response to PD-1 blockade. It is anticipated that the induction of IFN-γ production by Bex will result in enhanced clinical efficacy from PD-1 blockade in patients lacking pre-existing immune activation.

Methods BEXCOMBO is a single arm multicentre clinical study with an adaptive design (figure 1). The study uses a Simon's 2-stage design (Stage 1 n=15: Stage 2 n=40 for each indication). Study treatment will be initiated in patients with advanced head and neck squamous cell (HNSCC) with the potential to open patient cohorts with advanced urothelial carcinoma and non-small cell lung cancer (NSCLC) or other indications based on emerging translational and clinical data. Patient selection based upon lower baseline levels of proinflammatory cytokines or higher levels of CLEVER-1 expression will be considered if supported by translational data. Patients will be treated at the Recommended Phase 2 Dose of Bex in combination with standard of care PD1 blockade until progression or unacceptable toxicity. The primary endpoints are objective response rate based on Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST v1.1) and duration of response. Key secondary endpoints include time to response by RECIST 1.1, disease control rate, progression-free survival, overall survival, safety and CLEVER-1 and PD-L1 expression levels in tumor biopsy; as well as IFNγ and TNFα levels in serum.

710 **SAFETY AND SURVIVAL RESULTS FROM A PHASE 1/2 TRIAL OF INTRATUMORAL AGENT INT230–6 (CISPLATIN VINBLASTINE) INDUCES IMMUNOLOGICAL CANCER CELL DEATH ALONE OR WITH PEMBROLIZUMAB IN PATIENTS WITH REFRACTORY, METASTATIC CANCERS**

[1]Jacob Thomas*, [1]Anthony El-Khoueiry, [1]Diana Hanna, [2]Anthony Olszanski, [3]Nilofer Azad, [4]Giles Whalen, [5]Matthew Ingham, [6]Luis Camacho, [7]Franco Abbate, [8]Lewis Bender, [7]Ian Walters, [9]Lillian Siu. *[1]University of Southern California, Los Angeles, CA, USA; [2]Fox Chase Cancer Center, Philadelphia, PA, USA; [3]Johns Hopkins University, Chevy Chase, MD, USA; [4]UMASS Memorial, Worchester, MA, USA; [5]Columbia University Irving Cancer Ctr, New York, NY, USA; [6]Houston Methodist, Houston, TX, USA; [7]Intensity Therapeutics, Westport, CT, USA; [8]Intensity Therapeutics, Inc., Westport, CT, USA; [9]Princess Margaret Cancer Center, Toronto, Canada*

Background Study IT-01, KN-A10: INT230-6 is a new product with a unique dual anti-cancer mechanism. The drug is comprised of cisplatin and vinblastine co-formulated with a molecule that enables drug dispersion throughout an injected tumor and diffusion into cancer cells. The drug directly kills cancer and activates an immune response. Results from a neo-adjuvant breast cancer study confirms that a single injection induces necrosis in up to 95% of a tumor and recruits TILs.[1]

Methods INT230-6 intratumoral (IT) treatments are Q2W up to 5 followed by maintenance dosing Q9W. Dose is set by the tumor's longest diameter or volume. Pembrolizumab is 200mg IV Q3W in the INT230-6 comboniation arm. Biopsies from the injected tumor at pretreatment and day 28 are sent for immunohistochemistry analysis. Endpoints are safety and exploratory efficacy by overall survival.

Results Sixty-four subjects received INT230-6 alone (median 4 prior treatments). Thirty received INT230-6 + pembrolizumab (median 3 prior). There were 652 image-guided INT230-6 IT injections (378 to visceral tumors eg lung, liver, pancreas) median 5 injections, range (1,50). Doses ranged from 0.14 up to 175mL (87.5 mg of cisplatin, 17.5mg vinblastine – much higher than typical IV doses). The INT230-6 arm enrolled 19 cancer types; the PEM combination recruited primarily colon, pancreatic, TNBC or bile duct cancers. IHC results show marked reduction in DAPI of proliferating cancer cells with influx of CD4 and CD8 T-cells. Non-injected visceral tumors shrank in several INT230-6 monotherapy subjects. Due to drug absorption or immune influx RECIST is not ideal for use with INT230-6 (ASCO2022). Overall survival is preferred. The estimated median OS (mOS) was 361 days for INT230-6; the mOS for the combination has not been reached (173 days of median follow-up). Pharmacokinetics shows >95% of the active agents remain in the injected tumor at 1 hour[2] compared to IV. The most common (>20%) treatment-related adverse events (TRAEs) for INT230-6 alone/combination were localized pain (59%/50%), nausea (39%/13%), fatigue (28%/20%) and vomiting (23%/20%). The incidence of grade 3 TRAEs for the INT230-6 and combination arms were 10% and 20%. One combination patient had a grade 4 neutrophil decrease that quickly resolved. No patient discontinued therapy due to treatment toxicities.

Conclusions Intratumoral injections of large drug volumes into visceral tumors was feasible and well-tolerated. Biopsies confirmed immunological cell death. OS was compelling for this heavily pretreated population lacking standard therapeutic options. INT230-6 may offer a well-tolerated treatment for refractory patients and is entering randomized controlled trials.

711 INTERIM RESULTS OF A PHASE 2 STUDY OF NIVOLUMAB AND RELATLIMAB IN ADVANCED MISMATCH REPAIR DEFICIENT (DMMR) CANCERS RESISTANT TO PRIOR PD-(L)1 INHIBITION

Katherine Bever*, Hao Wang, Jennifer Durham, Colleen Apostol, Nilofer Azad, Ilene Browner, Stephanie Gaillard, Daniel Laheru, Valerie Lee, William Sharfman, Mark Yarchoan, Qingfeng Zhu, Robert Anders, Andrew Pardoll, Suzanne Topalian, Nicolas Llosa, Elizabeth Jaffee, Dung Le. *Johns Hopkins University, Baltimore, MD, USA*

Background Cancers deficient in DNA mismatch repair (dMMR) are highly immunogenic but exhibit variable benefit from immune checkpoint inhibitors targeting programmed cell death-1 (PD-1)/PD-1 ligand (PD-L1). Other immune checkpoints are upregulated in these tumors and may be acting in parallel, in particular, lymphocyte activation gene 3 (LAG-3) which mediates exhaustion of activated T cells. The clinical relevance of the LAG-3 pathway has recently been demonstrated in 1L advanced melanoma (Tawbi NEJM 2022). We hypothesized that the addition of a LAG-3 blocking antibody (relatlimab) to a PD-1i (nivolumab) may overcome resistance to PD-(L)1 blockade in advanced dMMR tumors.

Methods Patients with advanced dMMR cancers that progressed during or within 6 months of PD-(L)1 inhibitor-containing therapy and after at least 12 weeks of therapy, and met other eligibility criteria were enrolled. Patients were treated with relatlimab 160 mg + nivolumab 480 mg (Cohort 1) every 4 weeks until intolerance or progression. Biopsies were obtained at baseline and on-treatment. The primary endpoint of the study is objective response rate according to RECIST 1.1. The outcomes of patients enrolled on Cohort 1 as of April 2022 are reported herein.

Results 15 patients were enrolled on Cohort 1 between November 2018 and April 2022. Of 13 patients evaluable for response (median follow up=12.4 months), partial response by RECIST 1.1 was observed in 1 patient with small bowel adenocarcinoma at 17 months (response duration of 11+ months), and 1 patient with colorectal cancer achieved a complete response at 18 months. An additional 5 patients achieved a best response of stable disease (SD), including one patient with 24% reduction in SLD ongoing at 41+ months. Treatment related adverse events (trAEs) occurred in 6 patients (40%) and were all G1-2 in severity. One patient discontinued treatment due to trAE (G2 oral pain/mucositis). Updated results will be presented at the time of the conference.

Conclusions Relatlimab + nivolumab is well tolerated and results in response or prolonged disease stability in some patients with advanced dMMR cancers that progressed on anti-PD-(L)1 therapy. Correlative analysis is ongoing to evaluate markers predictive of clinical benefit.

712 RETROSPECTIVE TUMOR MICROENVIRONMENT ANALYSIS FROM A PERSONALIZED NEOTCR-T CELL THERAPY CLINICAL TRIAL AND ITS POTENTIAL APPLICATIONS FOR OFF-THE-SHELF HPV TCRS

Eric Stawiski*, Chad Smith, Tyler Borrman, Zheng Pan, Stefanie Mandl, Vinnu Bhardwaj.
PACT Pharma, South San Francisco, CA, USA

Background We have developed a state-of-the-art approach to validate predicted neoepitopes (neoEs) and their cognate T cell receptors (neoTCRs) by capturing neoepitope-specific T cells from peripheral blood. This neoTCR discovery and validation process is being applied in a phase I clinical trial (NCT03970382) evaluating personalized neoTCR-T cell therapy to treat patients across eight solid tumor types. We have since expanded our mission to discover off-the-shelf TCRs against recurrent epitopes including HPV+ cancers. The tumor microenvironment (TME) has been shown to critically influence responses to immunotherapy making it paramount to explore in the context of adoptive cell therapy.

Methods Using bulk RNA-seq data from biopsies, we examined the TME of both our clinical cohort (n=137) as well as TCGA H&N samples (n=485). To do this we measured 29 gene expression signatures that capture specific aspects of largely pro or anti-tumor infiltrates that were previously described as being predictive to response to immunotherapy. These signatures were used for K-means clustering with 4 distinct subsets, Immune Enriched (IE), Depleted (D), Fibrotic (F), Immune Enriched/Fibrotic (IE/F) across 6 different cancer types.

Results TME subtypes were predictive of response to ICI in a previously published Melanoma data set ($p=0.04$).[1] Screening biopsies from patients enrolled in our clinical trial consisted of 22% D, 30% F, 23% IE and 25% IE/F (n=137) across 6 solid tumor types. Amongst samples screened for autologous TCRs (n=64), TME subtype did not affect our ability to isolate TCRs from patients with a median of 2 TCRs for D and IE, 3 for F and 0 for IE/F (ranges 0-10) (p-value = 0.62). We observed a significant positive correlation between ovarian TCR capture and MHCII presentation as well as Treg and Th2 Trafficking ($p<0.001$), which may be general markers for inflammation. Amongst samples that were ultimately dosed with autologous TCRs, 2/3 had unfavorable TME's (D=7, F=3). TCGA H&N samples that were HPV- (n=414) had 19% IE, 21% IE/F, 28% D, and F 31%. In contrast HPV+ cancers (n=71) showed a significant enrichment for IE samples (61%) and depletion of D and F subtypes (16% and 5% respectively).

Conclusions Retrospective analysis shows no correlation with TME subtype and our ability to isolate autologous TCRs from those patients. The current trial shows lower levels of immunotherapy favorable subtypes. In contrast HPV+ cancers show high levels of immunotherapy responsive subtypes suggesting it may be a favorable cancer indication for adoptive cell therapy.

713 THE PRAME OPPORTUNITY – HIGH PEPTIDE COPY NUMBERS, HOMOGENOUS EXPRESSION AND HIGH PREVALENCE TO ADDRESS A BROAD PATIENT POPULATION ACROSS DIFFERENT SOLID CANCERS WITH TCR-BASED THERAPEUTICS

[1]Cedrik Britten*, [2]Dejka Araujo, [3]Linus Backert, [4]Carsten Bokemeyer, [5]Richard Carvajal, [6]Manik Chatterjee, [7]Asim Dash, [3]Lena Freudenmann, [3]Jens Fritsche, [3]David Fuhrmann, [3]Valentina Goldfinger, [8]Tobias Holderried, [3]Franziska Hoffgaard, [3]Jens Hukelmann, [2]Amir Jazaeri, [2]Ahmed Kaseb, [3]Florian Köhler, [3]Daniel Kowalewski, [9]Jason Luke, [2]Van Morris, [7]Shivani Mukhi, [3]Martina Ott, [5]Ran Reshef, [3]Michael Römer, [3]Lida Rostock, [3]Swapna Satam, [7]Arun Satelli, [3]Christoph Schräder, [7]Merline Thambi, [2]Apostolia Tsimberidou, [3]Maike Wagner, [10]Martin Wermke, [3]Heiko Schuster, [3]Oliver Schoor, [1]Toni Weinschenk. *[1]Immatics N.V., Tuebingen, Germany; [2]MD Anderson Cancer Center, Houston, TX, USA; [3]Immatics Biotechnologies GmbH, Tuebingen, Germany; [4]University Medical Center Hamburg-Eppend, Hamburg, Germany; [5]Columbia University, New York, NY, USA; [6]University Hospital Würzburg, Würzburg, Germany; [7]Immatics US, Inc., Houston, TX, Germany; [8]University Hospital Bonn, Bonn, Germany; [9]University of Pittsburgh, Pittsburgh, PA, USA; [10]University Hospital Dresden, Dresden, Germany*

Background Several peptide-HLA targets for T cell receptor (TCR)-based immunotherapies are currently being evaluated in the field, however, many are limited by their overall low prevalence, low copy numbers or relevant expression in healthy tissues. A T cell target with nearly ideal properties has high, homogenous and prevalent expression across multiple cancers in the absence of significant safety/toxicity liabilities. Here, we describe the in-depth characterization of an HLA-A*02:01-presented peptide derived from the cancer germline antigen preferentially expressed antigen in melanoma (PRAME) that opens an avenue of new opportunities for patients with solid cancers which we aim to leverage by two distinct TCR-based therapeutic modalities, TCR-engineered T cells (ACTengine® IMA203) and TCR Bispecifics (TCER® IMA402).

Methods PRAME target peptide presentation and mRNA expression in tumor and normal tissues was assessed by quantitative mass spectrometry (MS) and transcriptomics. *In situ* hybridization was used to analyze target homogeneity. We compare target prevalences based on IMADetect® qPCR testing of screening biopsies from clinical trial patients with prevalences based on a PRAME target tailored, MS-based mRNA expression threshold applied to a large RNA sequencing dataset.

Results PRAME RNA expression is elevated across many tumor types and only minimal in some normal tissues except testis. As demonstrated by MS, RNA expression does not translate into relevant peptide presentation on normal tissues. Peptide copy numbers range from 100 to 1,000 peptide copies per cell (target density) in the majority of tumor tissues as measured by highly sensitive MS-based AbsQuant® technology. Histologic analysis of PRAME RNA in different solid tumors demonstrates homogenous expression of PRAME with a high frequency of positive tumors cells. PRAME shows a prevalence between 80-100% in uterine and ovarian carcinoma, sarcoma subtypes, cutaneous and uveal melanoma and high prevalence in many other solid cancer types, such as cholangiocarcinoma, lung, kidney, breast, head and neck, esophageal, bladder and hepatocellular carcinoma. Prevalence numbers obtained during patient screening in our clinical trials match predicted prevalences. Interim phase 1a data from the IMA203 TCR-T trial (cut-off Oct 05, 2021) showed clinical responses in head and neck carcinoma, synovial sarcoma, uveal melanoma, and cutaneous melanoma.

Conclusions Here, we demonstrate comprehensive target characterization and validation data supporting the nearly ideal target properties of PRAME that can be exploited for the benefit of patients: PRAME is highly cancer-associated, homogenously expressed, presented at high target density, highly prevalent across many solid cancers and clinically validated, underlining its potential to reach a large cancer patient population.

Trial Registration NCT03686124

Ethics Approval The study was approved by the institutional review board/ethics committee as required for each participating site.

714 ATOR-1017, A 4–1BB ANTIBODY, DEMONSTRATES PROMISING SAFETY AND PROOF OF MECHANISM IN A FIRST-IN-HUMAN STUDY IN PATIENTS WITH ADVANCED SOLID MALIGNANCIES

[1]Ana Carneiro*, [2]Sumeet Ambarkhane, [2]Karin Enel Smith, [3]Gustav Ullenhag, [2]Lena Schulz, [2]Tova Landstrom, [2]Peter Ellmark, [2]Malin Carlsson, [4]Jeffrey Yachnin. *[1]Skåne University Hospital, Lund, Sweden; [2]Alligator Bioscience AB, Lund, Sweden; [3]Uppsala University Hospital, Uppsala, Sweden; [4]Karolinska Universitetssjukhuset, Solna, Sweden*

Background ATOR-1017 is a human Fcγ-receptor cross-linking dependent IgG4 4-1BB (CD137) agonist. ATOR-1017 activates T cells and natural killer cells in the tumor environment, leading to immune-mediated tumor cell killing.

Methods In this first-in-human, dose escalation, multicenter, phase 1 study, adult patients with solid tumors refractory to standard therapy were enrolled in single patient cohorts for doses up to 40 mg, and thereafter in cohorts of 3-6 patients. Intra-patient dose escalation is allowed. ATOR-1017 is administered intravenously as monotherapy (as flat dose) every three weeks until disease progression or unacceptable toxicity. The primary objectives are assessment of safety (maximum tolerated dose (MTD), adverse events (AEs), dose-limiting toxicities (DLT)), and determination of recommended phase 2 dose. Secondary and exploratory objectives include pharmacokinetics (PK), immunogenicity, efficacy (by iRECIST), and Pharmacodynamic (PD) biomarkers.

Results At cut off date 14 June 2022, 25 patients (20 females/5 males), with median age 57 years (34-76), median of 3 (1-9) prior lines of chemotherapy and/or median 1 (1-3) lines of immunotherapy, 21 (84%) with disease stage IV at entry had been treated. Ten dose levels were evaluated; 0.38mg, 1.5mg, 5mg, 15mg, 40mg, 100mg, 200mg, 360mg, 600mg, and 900mg. Treatment-related AEs (TRAEs) were reported in 13 patients (52%); most common (≥10%) were fatigue (16%) and neutropenia (12%). Five patients experienced a grade 3-4 TRAE; neutropenia (n = 2), febrile neutropenia (n = 1), non-cardiac chest pain (n = 1), increased liver enzymes (n = 1) and leukopenia/thrombocytopenia (n = 1). No patients discontinued due to TRAEs, no DLTs were observed, and MTD has not been reached. Three patients remained on treatment and 22 had discontinued treatment [(confirmed disease progression (n = 12), clinical deterioration (n = 6), withdrawal of consent (n = 1), death due to disease progression (n = 2), investigator's decision (n=1)]. The median time on treatment was 12.1 weeks (range 5.3-67.3). A dose-proportional pharmacokinetics was observed. PD biomarkers demonstrated activation of peripheral CD8 T cells and a dose-dependent increase in soluble 4-1BB confirming biological activity and proof-of-mechanism. Stable disease was observed in 13 patients (52%), which lasted longer than 6 months for 6 (24%) patients (of which 2 had ovarian cancer).

Conclusions ATOR-1017 demonstrated excellent safety at doses up to 900 mg, together with a favorable PK profile, confirmation of biologic activity and signs of clinical benefit. These data warrant further development of ATOR-1017, a 4-1BB agonistic antibody, in combination with other therapeutic approaches in solid tumors.

715 EMERGING RESULTS FROM THE USE OF AN ONCOLYTIC ADENOVIRUS ARMED WITH TNFA AND IL-2 (TILT-123) IN DIFFERENT PHASE I SOLID TUMOR CLINICAL TRIALS

[1]Victor Cervera-Carrascon, [2]Inge Svane, [3]Katriina Peltola, [4]Tuomo Alanko, [4]Riitta Korpisaari, [5]Susanna Juteau, [4]Marjut Jaakkola, [4]Jorma Sormunen, [4]Juha Kononen, [2]Eva Ellebaek Steensgaard, [2]Tine Monberg, [2]Marco Donia, [6]Amir Khammari, [6]Brigitte Dreno, [1]Joao Santos, [1]Suvi Sorsa, [1]Riikka Havunen, [1]Akseli Hemminki. *[1]TILT Biotherapeutics Ltd, Helsinki, Finland; [2]CCIT, Herlev, Denmark; [3]Comprehensive Cancer Centre, Helsinki, Finland; [4]Docrates Cancer Centre, Helsinki, Finland; [5]Helsinki University Hospital, Helsinki, Finland; [6]CRCINA Inserm, CHU Nantes, Nantes, France*

Background After the first Immune Checkpoint Inhibitor (ICI) was approved (ipilimumab, 2011 for cancer therapy, the list of indications routinely treated with ICIs keeps increasing. In this new era of cancer immunotherapy, the major drawback of the approach is the difficulty in delivering long term benefits to a larger portion of patients. Different forms of immunotherapy used in solid tumor cancer patients seem to work better in immunologically hot tumors. To that extent, TILT-123 (an Oncolytic Adenovirus armed with TNFa and IL-2) was designed to stimulate the immune system within the tumor to enable subsequent forms of immunotherapy. After discovery and preclinical testing, the therapy was taken into clinical trials in 2020. Two years after, four Phase I clinical trials are ongoing where TILT-123 is being tested to determine its safety as monotherapy (NCT04695327), together with adoptive cell therapy using tumor-infiltrating lymphocytes (NCT04217473), and ICIs (NCT05271318, NCT05222932).

Methods These phase I open-label, dose-escalation clinical trials, have the primary endpoint of establishing safety of the treatments in patients with injectable advanced refractory and recurrent solid tumors, that cannot be treated with curative intent. Safety is evaluated based on the occurrence of adverse events, impact on vital signs and safety laboratory tests. Additionally, secondary endpoints relative to the trials include efficacy of the approaches and mechanistic analyses based on biological samples, including studies on the presence and persistence of virus in different fluids and tissues, as well as, the proteomic and transcriptomic changes seen in tumors after therapy. Antitumor efficacy, according to RECIST 1.1/iRECIST/PET criteria, has been recorded in different patients.

Results Interim safety data emerging from patients treated with TILT-123 (n=18 patients), provided confidence to continue dose escalation as the investigational medicinal product did not cause dose limiting toxicities. The most frequent treatment related adverse events, as judged by investigators, were fever, nausea, chills and fatigue, typically low grade according to the CTCAE v5.0. Systemic antitumor efficacy according to RECIST 1.1/iRECIST/PET criteria has been seen in several patients. Biological sample analyses demonstrate the remodeling of the tumor microenvironment towards an antitumor status, when studying the T cell presence and the immune signature within the tumor.

Conclusions Preliminary data emerging from Phase I clinical trials using TILT-123, point to an adequately safe approach able to induce antitumor activity, both as monotherapy and in combination. Dose escalation continues in pursuit of a recommended dose to use in Phase II clinical trials.

Acknowledgements The clinical trials reported above were made possible due to the magnificent teamwork from the trial sites and the willingness of patients to collaborate in this research. Authors are thankful to the entire Cancer Gene Therapy Group of University of Helsinki for their valuable support. Funded by TILT Biotherapeutics Ltd.

716 **AURELIO-04: A PHASE 2, OPEN-LABEL, SINGLE-ARM, MULTICENTER STUDY TO DETERMINE THE EFFICACY AND SAFETY OF SOT101 IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH SELECTED ADVANCED SOLID TUMORS**

[1]Stephane Champiat*, [1]Aurelien Marabelle, [2]Diwakar Davar, [3]Peter Grell, [1]Kaissa Ouali, [1]Anna Patrikidou, [4]Andreu Schoenenberger, [4]Lenka Palova Jelinkova, [4]Irena Adkins, [5]Sascha Tillmanns, [5]Joachim Kiemle-Kallee, [5]Richard Sachse, [6]Elena Garralda. *[1]Gustave Roussy, Villejuif, France; [2]University of Pittsburgh, Pittsburgh, PA, USA; [3]Masaryk Memorial Cancer Institute, Brno, Czech Republic; [4]SOTIO Biotech a.s., Prague, Czech Republic; [5]SOTIO Biotech AG, Basel, Switzerland; [6]Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Background SOT101 (INN: nanrilkefusp alfa), a fusion protein of IL-15 and the IL-15 receptor α sushi+ domain, was investigated in AURELIO-03 (NCT04234113), a phase 1 dose-escalation study, as monotherapy and in combination with pembrolizumab. In that trial, combination had a favorable safety profile and MTD was not reached up to the recommended phase 2 dose (RP2D) for monotherapy. Maximum activation of natural killer cells was observed already at low dose levels, maximum $CD8^+$ T cell activation was reached from 9 to 12 μg/kg, no relevant effect on T regulatory cells was observed. Therefore, 12 μg/kg SOT101 was selected as combination RP2D. Encouraging efficacy signals were observed, even in immune checkpoint inhibitor (CPI)-relapsed patients. For combination therapy, the majority of patients had clinical benefit.[1,2] Study AURELIO-04 (NCT05256381) aims to further evaluate the efficacy of SOT101 in combination with pembrolizumab in selected solid tumor indications.

Methods AURELIO-04 is a phase 2 single-arm study in:

- Non-small cell lung cancer after a CPI and/or platinum regimen, with no EGFR or ALK aberration
- Unresectable or metastatic MSI-H/dMMR colorectal cancer
- First-line cutaneous squamous cell carcinoma not curable by surgery or radiation and second-line after a CPI regimen
- Hepatocellular carcinoma after a CPI regimen
- Metastatic castrate-resistant prostate cancer (mCRPC) after docetaxel
- Ovarian cancer after a platinum regimen

Main inclusion criteria are measurable disease as per RECIST 1.1, accessible tumor tissue, ECOG PS 0-1, adequate organ function, no prior IL-2 or IL-15 therapy. For mCRPC, a defined number of patients with non-measurable disease is allowed.

Patients will receive 12 μg/kg SOT101 s.c. on days 1, 2, 8, and 9 in combination with 200 mg pembrolizumab i.v. on day 1 every 3 weeks until disease progression or unacceptable toxicity.

Primary endpoint is overall response rate (ORR) per RECIST 1.1. Key secondary endpoints include efficacy parameters such as progression-free survival, frequency and severity of treatment-emergent adverse events, pharmacokinetics (PK) including population PK, pharmacodynamics, and immunogenicity parameters.

Approximately 55 patients per indication will be enrolled. No formal testing of statistical hypotheses is planned, analyses will be descriptive. Considering benchmark ORRs, a futility analysis is planned for each indication separately. Exploratory analyses include immune and molecular biomarkers.

Recruitment started in June 2022.

717 INTERIM CLINICAL UPDATE OF THE PHASE 1B TRIAL OF ATRC-101 AS MONOTHERAPY OR IN COMBINATION WITH PEMBROLIZUMAB FOR SELECT ADVANCED SOLID TUMORS

[1]Bartosz Chmielowski*, [2]John Weroha, [3]Susanna Ulahannan, [4]John Powderly, [5]Frances Valdes-Albini, [6]Tanios Bekaii-Saab, [7]Deborah Doroshow, [8]Alejandro Recio-Boiles, [9]Jordan Berlin, [10]Yan Xing, [11]Sudha Khurana, [11]Jonathan Benjamin, [12]Steven Isakoff, [13]Benjamin Weinberg. *[1]University of California Los Angeles, Los Angeles, CA, USA; [2]Mayo Clinic College of Medicine and Sci, Rochester, MN, USA; [3]OU Health Stephenson Cancer Center, OKC, OK, USA; [4]Carolina BioOncology Institute, Huntersville, NC, USA; [5]University of Miami, Miami, FL, USA; [6]Mayo Clinic Comprehensive Cancer Center, Phoenix, AZ, USA; [7]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [8]The University of Arizona Cancer Center, Tucson, AZ, USA; [9]Vanderbilt University Medical Center, nashville, TN, USA; [10]City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [11]Atreca, Inc., San Carlos, CA, USA; [12]Massachusetts General Hospital, Boston, MA, USA; [13]Georgetown University Medical Center, Washington, DC, USA*

Background ATRC-101 is an engineered, fully human, monoclonal antibody identified via the Atreca discovery platform that targets a novel tumor-specific ribonucleoprotein complex.

Methods ATRC-101-A01 is a Phase 1b dose escalation and expansion trial of ATRC-101 administered to participants with select solid tumors as monotherapy every 3 (Q3W-Mono) or 2 (Q2W-Mono) weeks and in combination with pembrolizumab (Q3W-Pembro). Participants in Q3W-Pembro must have had suboptimal response to prior/ongoing anti-PD-1/PD-L1 and deemed to potentially benefit from addition of ATRC-101. Objectives include safety (primary), pharmacokinetics, immunogenicity, recommended dose for expansion, and anti-tumor activity (RECIST v1.1). Biomarker analyses include immunohistochemical staining for target expression and $CD8^+$ T cell infiltration in baseline and on-treatment tumor biopsies. For participants described herein, target expression was analyzed retrospectively.

Results As of data cut-off (February 15, 2022), 50 heavily pretreated participants (median prior lines of therapy 5, range 1–11) received ≥1 dose of ATRC-101 (Q3W-Mono, n=37; Q2W-Mono, n=9; Q3W-Pembro, n=4). ATRC-101 was administered at 0.3 mg/kg (n=3), 1 mg/kg (n=6), 3 mg/kg (n=12), 10 mg/kg (n=13), and 30 mg/kg (n=16). Tumor types included colorectal (n=24), breast (n=8), ovarian (n=7), non-small cell lung (NSCLC, n=5), melanoma (n=3), head and neck squamous cell (n=2), and urothelial (n=1).

Dose escalation has been completed for Q3W-Mono and is ongoing for other cohorts. To date, no dose-limiting toxicities have been reported and no maximum tolerated dose identified. The dose for ongoing cohorts is 30 mg/kg.

Treatment-emergent adverse events (TEAEs) are summarized in Table 1. None resulted in treatment discontinuation or dose reduction. Grade ≥3 TEAEs occurred in 13 (26%) participants. Grade ≥3 TEAEs considered by investigators as related to ATRC-101 occurred in 3 (6%) participants (tumor pain, headache, small intestinal obstruction).

There was one partial response (NSCLC) in Q3W-Mono (30 mg/kg) and one complete response (melanoma) in Q3W-Pembro (10 mg/kg). The latter participant had previously progressed during treatment with nivolumab. An additional 5 participants experienced stable disease (SD) as best response, with reductions in target lesions. Target expression, as detected retrospectively by immunohistochemical analysis of screening tumor biopsies, was associated with achievement of SD or better and with reduction in the sum of diameters of target lesions.

Conclusions ATRC-101, without and with pembrolizumab, has been well tolerated and has demonstrated anti-tumor activity among target expressers. Enrollment in specific expansion cohorts now requires pretreatment tumor biopsies demonstrating ATRC-101 target expression (H-score ≥50) by immunohistochemistry. Updated data will be presented at the meeting.

Trial Registration NCT04244552

Ethics Approval This trial was approved by the institutional review board or ethics committee as required for each participating site.

Abstract 717 Table 1 Cumulative safety data as of February 15, 2022

Table 1: Cumulative safety data as of February 15, 2022

	Q3W-Mono					Q2W-Mono			Q3W-Pembro	
ATRC-101 dose, mg/kg	0.3	1	3	10	30	1	3	10	10	30
n	3	3	9	7	15	3	3	3	3	1
Number of cycles	11	7	37	18	47	8	14	8	12	1
Participants with ≥1 TEAE, n (%)	3 (100)	3 (100)	9 (100)	7 (100)	13 (86.7)	3 (100)	3 (100)	3 (100)	3 (100)	1 (100)
Participants with ≥1 Grade ≥3 TEAE, n (%)	1 (33.3)	1 (33.3)	3 (33.3)	2 (28.6)	0	1 (33.3)	0	1 (33.3)	0	0
Participants with ≥1 Grade ≥3 treatment-related TEAE, n (%)	0	0	2 (22.2)[1]	1 (14.3)[2]	0	0	0	0	0	0

1. Preferred terms for Grade ≥3 treatment-related TEAE – tumor pain and headache.
2. Preferred term for Grade ≥3 treatment-related TEAE – small intestinal obstruction.

Q2W-Mono = ATRC-101 monotherapy every 2 weeks cohort; Q3W-Mono = ATRC-101 monotherapy every 3 weeks cohort; Q3W-Pembro = ATRC-101 every 3 weeks + pembrolizumab cohort; TEAE = treatment-emergent adverse event.

718 **PRELIMINARY RESULTS OF GII-101-P101 (KEYNOTE-B59): GI-101 (CD80-IGG4 FC-IL2V) AS A SINGLE AGENT AND IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH ADVANCED AND/OR METASTATIC SOLID TUMORS**

[1]Byoung Chul Cho*, [1]Sang Shin, [2]Jae Lyun Lee, [3]Byoung Shim, [4]Hyo Lee, [5]Nari Yun, [5]Mina Ham, [5]YunHee Jeong, [5]Wooyul Lee, [5]Hyunjin Kang, [5]Jisoo Kim, [5]Myoung Ho Jang. *[1]Severance Hospital, Seoul, Korea, Republic of; [2]Asan Medical Center, Seoul, Korea, Republic of; [3]St. Vincent's Hospital, Seoul, Korea, Republic of; [4]Chungnam National University Hospital, Daejeon, Korea, Republic of; [5]GI Innovation, Seoul, Korea, Republic of*

Background GI-101 is a novel bispecific fusion protein containing CD80 and interleukin-2 variant, designed to boost immune cell proliferation including cytotoxic T and NK cells without increasing Treg cell. A first-in-human study was performed to evaluate safety and efficacy of GI-101 as a monotherapy and in combination with pembrolizumab.

Methods Patients (pts) with advanced/metastatic solid tumors that have progressed on standard of care (SOC), or for whom no SOC exists, or SOC was deemed not appropriate, received escalating doses of GI-101 monotherapy or GI-101 in combination with 200 mg pembrolizumab intravenously every 3 weeks. The primary objective was to assess safety, tolerability and maximum tolerated dose and/or RP2D utilizing a conventional 3+3 design.

Results 25 pts received GI-101 monotherapy (n=16) or in combination with pembrolizumab (n=9) between Aug 2021 and July 2022. The median number of prior systemic therapies was 3 [1–6] and 64% of pts were previously treated with immunotherapy. No dose-limiting toxicities up to 0.15 mg/kg were reported with planned dose level of 0.002~0.6 mg/kg. Treatment-related adverse events (TRAEs) occurred in 11 (69%) and 5 (56%) pts in the single and combination cohorts, respectively. Three pts experienced Grade 3+ TRAEs (19%) with GI-101 monotherapy and no Grade 3+ TRAEs were reported with combination. Anti-tumor activities were seen both in single agent and in combination. One confirmed partial response (PR), among 16 pts, in metastatic urothelial carcinoma with a time to progression of 121 days was observed with GI-101 monotherapy. The patient previously experienced immunotherapy with best response of progressive disease. Additionally, two ongoing pts were observed PRs in combination cohorts among nine pts [one confirmed PR in non-small cell lung cancer (NSCLC) and 1 unconfirmed PR in metastasis of unknown origin]. The NSCLC patient had acquired resistance to previous immunotherapies with best response of PR and stable disease (SD), respectively. In single and combination cohorts of diverse tumor types, five and three pts had SDs. Median duration of treatment was 61 (15–171+) days. Systemic exposure to GI-101 increased with dose-escalation with half-life of 7.5~10.1 hours, resulting in a dose-dependent increase in NK and CD8+ T cells, without significant impact on Treg cells in peripheral blood.

Conclusions GI-101 was well tolerated as monotherapy and in combination with pembrolizumab in pts with previously treated, advanced solid tumors. Preliminary anti-tumor activity was seen both in monotherapy and in combination with pembrolizumab. The dose-escalation is currently ongoing to identify RP2D.

719 PHASE 1 STUDY OF THE PORCUPINE (PORCN) INHIBITOR RXC004 IN COMBINATION WITH THE PD-1 INHIBITOR NIVOLUMAB IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Natalie Cook, [2]Sarah Blagden, [3]Juanita Lopez, [4]Debashis Sarker, [5]Alastair Greystoke, [5]Saira Bashir, [2]Aglaia Skolariki, [2]Salma ElBadri, [4]Cienne Morton, [6]Ana OrtegoFranco, [3]Shybi MohamedKhan, [7]Catherine Eagle, [7]Eimear Flanagan, [7]Louise Goodwin, [7]Caroline Phillips, [7]Jane Robertson*, [7]Craig Tilston, [7]Helen Timmis, [8]Simon Woodcock, [5]Ruth Plummer. *[1]University of Manchester, The Christi, Manchester, UK; [2]Oxford University Hospitals, Oxford, UK; [3]Royal Marsden Hospital, London, UK; [4]Guy's Hospital NHS Trust, London, UK; [5]The Freeman Hospital, Newcastle-upon-Tyne, UK; [6]University of Manchester, The Christie, Manchester, UK; [7]RedX Pharma Plc, Alderley Edge, UK; [8]RedX Pharma, Alderley Edge, UK*

Background Tumour-derived Wnt-ligand signalling leads to a reprogramming of the immune microenvironment and is implicated in intrinsic and adaptive resistance to Immune Checkpoint Inhibitor (ICI) therapy. Specifically, Wnt-ligand signaling is correlated with reduced CD8+ve T-cell infiltration,[1] and ICI resistance[2] in multiple cancers.[3] Inhibition of Wnt-ligand signalling can enhance ICI efficacy by (i) reversing dendritic cell tolerization, (ii) decreasing generation of Treg cells, and (iii) reducing the recruitment of myeloid-derived suppressor cells in tumor models.[4]

RXC004 is a novel small molecule inhibitor of PORCN, a protein-serine-O-palmitoyltransferase [5]. PORCN is essential for post-translational modification of Wnt ligands which is required for downstream Wnt signaling. RXC004 thus has potential for monotherapy efficacy in Wnt-ligand driven tumors i.e. cancers with RNF43 mutations or R-Spondin fusions, or with high Wnt-ligand activity. Furthermore, RXC004 can reverse immune evasion in mouse models,[5] and may therefore restore ICI sensitivity in ICI resistant tumors when co-administered.

This abstract reports the second module of a multi-modular adaptive design protocol (NCT03447470). The first module was previously reported[6] and the recommended Phase 2 dose (RP2D) for RXC004 monotherapy was 2mg QD.

Methods This was an open label, 3+3 dose escalation study. Following a single dose with a 7-day washout, patients received RXC004 QD in 28-day cycles, and nivolumab 480mg i.v every 4 weeks.

The primary objectives were to assess safety and tolerability and define a RP2D of RXC004 to combine with ICIs. Secondary objectives were Pharmacokinetics (PK) and RECIST response. Exploratory objectives included changes in circulating immune subsets by flow cytometry, and cytokines by a bead-based multiplexed immunoassay.

Results Between 24/03/2021 and 30/06/2022, 14 patients with unselected advanced solid tumors received RXC004 at doses of 1mg and 1.5mg QD, in combination with nivolumab.

The AE profile for the combination was broadly similar to RXC004 monotherapy. The most common treatment-related AEs were nausea, dysgeusia, fatigue, anorexia and weight loss. No grade 4/5 AEs, bone events or immune-related AEs were reported.

RXC004 PK exposure in the combination did not exceed the 2mg QD monotherapy exposure. Disease control was observed in some patients in the 1.5mg QD combination cohort.

Conclusions In patients with unselected cancers, RXC004 was safe and tolerated at doses up to 1.5mg QD in combination with standard dose nivolumab. The RP2D was 1.5mg QD. RXC004+ICI combinations will now be investigated in selected patients with Wnt-ligand driven tumors.

ENHANCING THE ANTI-TUMOR IMMUNITY AND THERAPEUTIC POTENTIAL OF ICT01, A BUTYROPHILIN3A-TARGETED, γ9δ2 T CELL-ACTIVATING MONOCLONAL ANTIBODY, WITH LOW DOSE IL-2 IN PATIENTS WITH ADVANCED SOLID TUMORS: THE EVICTION-2 TRIAL

[1]Johann De Bono*, [2]Stephane Champiat, [2]Francois-Xavier Danlos, [3]Martin Wermke, [4]Volker Kunzmann, [5]Aude de Gassart, [5]Emmanuel Valentin, [6]Marina Iche, [5]Maelle Mairesse, [5]Patrick Brune, [7]Daniel Olive, [5]Paul Frohna. http://dx.doi.org/10.1136/jitc-2022-SITC2022.0720

Background ICT01 is an anti-BTN3A mAb that selectively activates γ9δ2 T cells to orchestrate a robust antitumor immune response of the innate and adaptive immune systems that leads to solid tumor infiltration of activated γ9δ2 T cells, CD8 T cells, and NK cells. (EVICTION trial (NCT04243499); SITC 2021, #503) However, the pharmacodynamic effects of ICT01 are dependent on an adequate population of γ9δ2 T cells, which is lacking in most advanced cancer patients. ICT01 plus low-dose SC (LDSC) IL-2 has been shown to safely and selectively increase the number of γ9δ2 T cells, without Treg expansion, in non-human primates.

Methods EVICTION-2 (NCT05307874) is a phase I/IIa basket trial including Bayesian dose escalation across 8 dose cohorts that is being conducted at 4 clinical sites in the UK, France and Germany. ICT01 is administered IV on day 1 of each Q3W cycle (1, 5, 20 or 75mg) and LDSC IL-2 (1 or 2 MIU/m2) on days 1-5 of the first 3 cycles to patients with colorectal (CRC), ovarian (OV), prostate, or pancreatic cancer. Efficacy evaluable patients are defined as receiving ≥3 cycles with a ≥Wk 8 RECIST assessment. Blood samples are collected for immunophenotyping by flow cytometry and cytokine analysis (IFNγ, TNFa, IL-1b/2/4/6/8/10/12/13) on days 1, 5, 8 and 15 of each cycle. Tumor biopsies (baseline, Day 28) for flow cytometry, IHC, and Nanostring profiling. Patients are monitored during the first 21-day cycle for DLTs and a safety review committee determines if dose escalation can continue.

Results Cohort 1 (n=2) received 1 MIU/m2 IL-2 + 1 mg ICT01 with rapid activation and complete migration of ?9δ2 T cells within 30 minutes post ICT01 without any DLTs. This was followed by an absolute increase of ?9δ2 T cells that peaked on day 15 of 52K (CRC pt; 7.5x increase; 12% of total T cells) and 236K (OV pt; 2.2x increase; 43% of total T cells). ?9δ2 T cells returned to baseline in the CRC pt, while the OV patient had ~300K at the time of C2, which was well tolerated. Additionally, rapid activation and migration of CD4 and CD8 T cells, NK cells, and granulocytes were observed on day 1. Cytokine, biopsy and RECIST results will be presented. Dose escalation to 5mg ICT01+ 1 MIU/m2 IL-2 and 1 mg ICT01 +2MIU/m2 IL-2 is ongoing.

Conclusions LDSC IL-2 plus ICT01 safely and significantly increase the number of activated ?9δ2 T cells with broad immune activation.

721 PIXATIMOD (P) IN COMBINATION WITH NIVOLUMAB (N) +/- LOW-DOSE CYCLOPHOSPHAMIDE (CY) IN ADVANCED CANCERS: A PHASE IIA BASKET TRIAL

[1]Diwakar Davar*, [2]Hong Wang, [1]Sarah Behr, [1]Aubrey Murano, [1]Sarah Johnson, [1]Amy Rose, [3]Darryn Bampton, [3]Keith Dredge, [1]Hassane Zarour, [1]John Rhee, [1]Liza Villaruz, [1]Yana Najjar, [1]Jason Luke. *[1]UPMC Hillman Cancer Center, Pittsburgh, PA, USA; [2]University of Pittsburgh, Pittsburgh, PA, USA; [3]Zucero, Brisbane, Australia*

Background Immune checkpoint inhibitors (ICI) directed against PD-(L)1 are associated with improved response rates in melanoma (MEL), and squamous/non-squamous non-small cell lung cancer (NSCLC).[1-4] Conversely, anti-PD(L)1 blockade is minimally efficacious in microsatellite stable (MSS) colorectal carcinoma (CRC). Pixatimod (P) is a heparan sulfate (HS) mimetic that is a cholestanol-sulfotetrasaccharide conjugated small molecule compound with unique NK- and T cell-dependent immunomodulatory properties. P does not possess CpG ODN motifs and hence does not activate TLR9 directly. Rather, P increases CpG ODN accumulation in lysosomal compartment of DCs, leading to enhanced production of IL-12 and NK cell activation.[5] Preclinically, in combination with anti-PD-1, P led to increased infiltration of both central and effector memory CD4 and CD8 T cells in a IL-12 and TLR9 dependent fashion in multiple tumor modes.[5-9] Low dose Cy has immunostimulatory and antiangiogenic properties and has synergy with CpG,[10, 11] and PD-1 ICI.[12] In MSS mCRC, P/N demonstrated objective response rate (ORR) 12% in a Phase Ib study.[13]

We hypothesized that P and nivolumab (N) combination may overcome resistance in PD-1 relapsed/refractory (R/R) tumors; and that the addition of Cy may facilitate P+N activity in MSS CRC.

Methods This is a nonrandomized, open-label, multichort, phase IIA study (NCT05061017) evaluating several pixatimod combinations in 3 cohorts (figure 1). The recommended phase 2 dose (RP2D) of P is 25mg IV Q1W and N is dosed at 480mg IV Q4W. Immunomodulatory dose of Cy is 50 mg twice daily, 1-week-on, 1-week-off.

P+N+low-dose Cy will be evaluated in PD-1 naïve MSS CRC (cohort 1). P+N will be evaluated in PD-1 R/R melanoma (cohort 2) and NSCLC (cohort 3). In 1st stage of each cohort, 9-13 patients will be enrolled. If $\geq$1 response(s) are seen, 8-14 additional patients will be enrolled in the 2nd stage.

The primary endpoint in this Simon two-stage trial is objective response rate (ORR) using RECIST v1.1. Key secondary endpoints include ORR by iRECIST, median and landmark survival (PFS, OS) and safety. Exploratory endpoints will characterize pharmacokinetics, immune contexture, immunophenotypic analyses and gut microbiome pre- and post- treatment blood, tumor and stool samples.

722 **CBL-B SILENCED, AUTOLOGOUS PBMCS AS A NOVEL ANTI-CANCER THERAPY USING THE CLOSED CELL PROCESSING PLATFORM EPIC – A PHASE 1B TRIAL WITH APN401**

[1]Romana Gugenberger*, [1]Alexander Dohnal, [1]Kathrin Thell, [1]Sarah Bischof, [1]Mario Kuttke, [1]Bernhard Peball, [1]Hannes Muehleisen, [1]Maria Urban, [2]Andreas Tanzmann, [2]Beate Pribitzer, [2]Felix Batrina, [2]Stefan Bunka, [2]Sophia Spagl, [2]Manuela Branka, [2]Markus Raderer, [2]Gerald Prager, [2]Thorsten Fuereder, [2]Nina Worel. [1]*invIOs GmbH, Vienna, Austria*; [2]*Medical University of Vienna, Vienna, Austria*

Background Tumor-specific immune cells possessing effector functions to infiltrate and eradicate tumors circulate in peripheral blood and can infiltrate tumors but are impaired in their effector functions due to immune checkpoint control by Cbl-b (Casitas B-lineage lymphoma-b). Further, tumor antigen (TA) expression and recognition is limited in time and magnitude due to frequent alterations in the TA repertoire and low abundance of TA-specific immune cells within a patient's peripheral blood mononuclear cells (PBMCs). Here, we present a clinical trial of an autologous cell therapy APN401 that blocks Cbl-b in patient PBMCs using a rapid manufacturing process with the goal of enhancing immune effector functions and cytotoxicity against tumor cells. For this, we have developed the closed cell processing Enhancement Platform for immune Cells (EPiC). This platform enables manufacturing of high numbers of PBMCs with transiently silenced Cbl-b in a short processing time for the drug product (DP) APN401. In a first clinical phase 1b multiple dose study, APN401 showed clinical safety and tolerability in patients with advanced solid tumors (NCT02166255).

Methods The APN401 DP is manufactured by the 3-step EPiC process comprising (I) purification of PBMCs from leukapheresis products, (II) electroporation of PBMCs to incorporate Cbl-b siRNA and (III) final PBMC formulation for re-infusion. The final DP is specified for release according to GMP standards specific for ATMPs. The entire process requires less than 6 hours and is approved by the national competent authorities for a same-day out patient therapy in a phase 1b trial. This clinical trial is designed as an open-label, multi-center, dose escalation and expansion study and is performed in two parts. In Part A the maximum tolerated dose (MTD) will be determined, evaluating three dose levels of APN401. Key eligibility criteria include patients with advanced solid tumors for whom standard therapies have failed. Part B is an expansion study at the MTD with 15 patients for each of three specific tumor types – lung cancer, colorectal cancer and squamous cell carcinoma of the head and neck.

Results The ongoing phase 1b Part A study demonstrates the feasibility of APN401 autologous cell therapy through releasing 14 manufacturing batches (mean manufacturing dose: 5.3 x 10^9 PBMCs) of Cbl-b silenced patient PBMCs. Safety and tolerability have been shown for the first dosing cohort (infused cell number: 5.0 x 10^6 PBMCs/kg). Dose escalation is ongoing, and patients are being enrolled in the second dosing cohort (1.5 x10^7 PBMCs/kg).

Ethics Approval The study is approved by Medical University of Vienna institution's independent Ethics Board, approval number 1778/2020.

723 A PHASE 1, FIRST-IN-HUMAN, OPEN-LABEL, MULTICENTER STUDY OF INCA32459, A BISPECIFIC ANTI–PD1 AND ANTI–LAG-3 ANTIBODY, IN PATIENTS WITH SELECT ADVANCED MALIGNANCIES

[1]Sarina Piha-Paul*, [2]Nawel Bourayou, [3]Richard Schaub, [3]Yan-ou Yang, [3]Wendy Wei, [3]Patrick Mayes, [4]Tara Gangadhar. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Incyte Biosciences International Sàrl, Wilmington, DE, USA; [3]Incyte Corporation, Wilmington, DE, USA; [4]Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA, USA*

Background Anti–programmed cell death (PD)-ligand (L)1 therapies have improved clinical outcomes in patients with various cancers.[1] However, many patients either do not respond or develop resistance, partly due to additional immune checkpoint receptors including lymphocyte activation gene-3 (LAG-3), which is frequently co-expressed with PD-1 on tumor-infiltrating lymphocytes.[2, 3] Combined anti–PD-1 and anti–LAG-3 therapy has demonstrated improvements in clinical outcomes compared with anti–PD-1 alone.[4] Co-targeting PD-1 and LAG-3 with a bispecific antibody has the potential to demonstrate enhanced clinical activity compared with individual monoclonal antibodies by achieving synergistic blockade. Therefore, this study aims to assess the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary clinical efficacy of INCA32459, a bispecific anti–PD-1 × anti–LAG-3 antibody, in patients with advanced malignancies.

Methods This first-in-human, multicenter, open-label, dose-escalation, dose-expansion phase 1 clinical study will enroll approximately 120 patients into separate dose-escalation (n≈40) and dose-expansion phases (n≈80; figure 1). Patients with select advanced malignancies will be eligible to participate in the dose-escalation phase and will receive intravenous INCA32459 starting at dose level 1 every 3 weeks. Dose escalation will proceed according to a protocol-defined statistical hybrid design[5] to assess the safety and tolerability of INCA32459 and determine the maximum tolerated dose and/or the recommended doses for expansion. The dose-expansion phase will consist of 2 tumor-specific cohorts. Cohort 1 will enroll patients with unresectable or metastatic melanoma who have experienced disease progression after standard therapy (n≈40). Cohort 2 will enroll patients with recurrent or metastatic PD-L1+ (combined positive score ≥1) squamous cell carcinoma of the head and neck who have experienced disease progression after standard therapy (n≈40). Treatment will be administered in 3-week cycles up to a maximum duration of 2 years. The primary endpoints are safety and tolerability as assessed by occurrence of dose-limiting toxicities and incidence of treatment-emergent adverse events (TEAEs), including overall TEAEs and TEAEs that lead to treatment interruption or withdrawal. Secondary endpoints include objective response rate, disease control rate, and duration of response as determined by investigator assessment according to Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 or Lugano criteria (for patients with B-cell lymphomas); pharmacokinetic parameters; and PD-1 receptor occupancy in peripheral blood samples.

Trial Registration ClinicalTrials. gov registration pending

724 A PHASE I STUDY OF HCW9218, A BIFUNCTIONAL TGF-β ANTAGONIST/IL-15 PROTEIN COMPLEX, IN ADVANCED SOLID TUMORS

[1]Melissa Geller*, [1]Manish Patel, [2]Hing Wong, [2]Peter Rhode, [2]Philip Arlen, [2]Pallavi Chaturvedi, [2]Jack Egan, [2]Giles Leclerc, [1]Martin Felices, [1]Shannon Lunn, [1]Bethany Hanke, [1]Deepa Kolseri, [1]Rose Wangen, [1]Jeffrey Miller. [1]*University of Minnesota, St. Paul, MN, USA*; [2]*HCW Biologics, Miramar, FL, USA*

Background HCW9218 is a bifunctional protein complex comprising dimeric extracellular domains of the human transforming growth factor beta (TGF-β) receptor II and human interleukin-15 (IL-15). HCW9218 acts to (1) stimulate immune effector cells and (2) sequester soluble immunosuppressive TGF-β.[1, 2] The primary objective of this Phase I first-in-human clinical trial is to determine the maximum tolerated dose of HCW9218 in advanced solid tumors.

Methods HCW9218 is administered subcutaneously in the outpatient setting once every 3 weeks for a minimum of two cycles. HCW9218 dose range was established through extensive nonclinical studies using the MABEL approach. Patients' assigned dose levels range from 0.25 mg/kg (DL1) to 1.2 mg/kg (DL4). Correlative analyses include HCW9218 immunogenicity and pharmacokinetic profiles, serum cytokine levels and lymphocyte number, phenotype and function.

Results Since 4/2022, three patients have been dosed. Patient #1 had a recurrent GI stromal tumor, received one dose but elected to discontinue due to metastatic bone pain. He experienced an injection site reaction lasting >72 hours requiring dose expansion to 3 subjects. Patient #2 had recurrent colon cancer, received 2 doses and discontinued due to unrelated grade 3 ascites requiring paracentesis and disease progression. Patient #3 had recurrent ovarian cancer and has received 2 doses to date. There has been one grade 3 adverse event (AE). The most common AEs have been grade 1-2 injection site reactions. Unexpectedly, patients at the DL1 level exhibit consistent and robust immune activity for at least 2 weeks after a single dose (figure 1). PBMNC and serum were collected prior to dose 1, and at 2 to 15 days after dosing. All subjects had a robust increase in NK cell proliferation (81% Ki-67$^+$ by day 8 after dosing vs.12.6% pre-dosing), which corresponded to an increased mean percent of NK cells to 34% of lymphocytes (12.6% pre-dosing). These responses were sustained through day 15, a biologic effect beyond that previously observed for other IL-15 agonists. By day 14, 44% of NK cells were CD56^{bright}. Additionally, there was a modest increase in Ki-67$^+$ CD8$^+$ T cells at day 8. No treatment-mediated effects were seen on serum IL-1α, IL-1β, IL-6, IFN-γ or TNFα, whereas levels of TGF-β1 and TGF-β2 were reduced (as expected) and MCP-1 was elevated. Preliminary pharmacokinetic analysis showed a Cmax at 20-73h post-dosing and half-life of ~78h.

Conclusions HCW9218 safely and robustly expands NK cells after a single dose and escalation continues as planned to DL2 (0.5 mg/kg).

725 PHASE I SAFETY AND PRELIMINARY EFFICACY OF PM8002 IN SUBJECTS WITH ADVANCED SOLID TUMORS, A BISPECIFIC ANTIBODY TARGETING PD-L1 AND VEGF-A

[1]Ye Guo, [2]Suxia Luo, [3]Yanru Qin, [4]Yongmei Yin, [5]Guiling Li, [6]Jingfen Wang, [7]Yongsheng Li, [8]Jun Guo, [9]Feng Zhang, [9]Yi Huang, [10]Hong Luo, [11]Dongqing Lv, [12]Cheng Ying, [13]Chunyan Wang, [14]Chuan-Chu Chou*, [14]Chundan Gong, [14]Ruixia Chang, [14]Jing Liu, [14]Guoqiang Hu. *[1]Shanghai East Hospital, Shanghai, China; [2]Henan Cancer Hospital, Zhengzhou, China; [3]The First Affiliated Hospital, Zhengzhou, China; [4]Jiangsu Province Hospital, Nanjing, China; [5]Union Hospital Tongji Medical College, Wuhan, China; [6]Linyi Cancer Hospital, Linyi, China; [7]Chongqing University Cancer Hospital, Chongqing, China; [8]Peking University Cancer Hospital and Inst, Beijing, China; [9]Hubei Cancer Hospital, Wuhan, China; [10]Chongqing Cancer Hospital, Chongqing, China; [11]Taizhou Hospital of Zhejiang Provinc, Taizhou, China; [12]Jilin Cancer Hospital, Jilin, China; [13]Liaoning Cancer Hospital, Shenyang, China; [14]Biotheus Inc., Westfield, NJ, USA*

Background PD-L1 and VEGF play important roles in immune escape and tumor angiogenesis and thus enhance cancer growth and metastasis. PM8002 is a bispecific antibody targeting PD-L1 and VEGF-A. Here we present the results from a Phase I first-in-human dose-escalation and ongoing expansion study of PM8002 in advanced solid tumors.

Methods This study includes a standard 3+3 dose escalation stage (Part A: single dosing of 1, 3, 10, 20, 30, and 45 mg/kg for 3-week DLT evaluation, then administration Q2W if the subject did not experience DLT) followed by dose expansion (Part B). Primary endpoints include safety and tolerability for Part A, and ORR per RECIST 1.1 for Part B. Secondary endpoint includes pharmacokinetics (PK).

Results As of June 15, 2022, a total of 59 subjects had received at least one dose of PM8002, including 18 subjects in Part A (3 subjects per 1, 3, 10, 20, 30 and 45 mg/kg dose-levels), and 41 subjects in Part B (1mg/kg Q2W [n=1], 10mg/kg Q2W [n =1], 20mg/kg Q2W [n=18], 20mg/kg Q3W [n=4] and 30mg/kg Q3W [n=17]). In part A, no DLTs were observed and MTD was not reached. Of the 59 subjects, the median duration of PM8002 exposure was 8.1 weeks (range, 3.0—29.0 weeks). Any-grade TRAEs occurred in 40 subjects (67.8%), with 9 subjects (15.3%) reported with $\geq$ Grade 3 TRAEs. 9 subjects (15.3%) discontinued PM8002 administration due to TRAEs. The most common TRAEs were proteinuria (18.6%), thrombocytopenia (11.9%), aspartate aminotransferase increase (10.2%). Any-grade irAEs occurred in 24 subjects (40.7%), with 4 subjects (6.8%) reported with $\geq$ Grade 3 irAEs. PK analysis showed a linear dose-exposure relationship with PM8002 dosing from 1 to 45 mg/kg. $T_{1/2}$ varied from 4.2—8.9 days. Peripheral PD-L1 receptor occupancy exceeded 95% in the 10 mg/kg and higher dose groups. In part B, 30 subjects completed at least one efficacy evaluation. The ORR per RECIST 1.1 by investigator was 20%, with 6 PRs in subjects with ovarian cancer (n=1, 20mg/kg Q2W), colorectal cancer (n=1, 10mg/kg Q2W), renal cell carcinoma (n=3, 30mg/kg Q3W) and NSCLC (n=1, 20mg/kg Q2W). Fifteen subjects achieved best responses of stable disease, with a total DCR of 70%. 20 mg/kg Q2W and 30 mg/kg Q3W were recommended as the RP2D for further clinical study.

Conclusions PM8002 showed an acceptable safety profile and encouraging antitumor activity in refractory solid tumors. Phase II clinical trials with PM8002 as a monotherapy or in combination with chemotherapy are ongoing for multiple indications.

726 PHASE I RESULTS OF FT516, AN OFF-THE-SHELF, IPSC-DERIVED NK CELL THERAPY EXPRESSING A HIGH-AFFINITY, NON-CLEAVABLE CD16 (HNCD16) COMBINED WITH AVELUMAB IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Martin Gutierrez*, [2]Manish Patel, [3]Feng Liu, [3]Peter Szabo, [3]Bob Valamehr, [3]Yu-Waye Chu, [3]Brandon Beagle, [3]Jeffrey Chou, [4]David Hong. *[1]Hackensack University Medical Center, John Theurer Cancer Center, Hackensack, NJ, USA; [2]University of Minnesota. Masonic Cancer Center, Rochester, MN, USA; [3]Fate Therapeutics, Inc., San Diego, CA, USA; [4]MD Anderson Cancer Center, Houston, TX, USA*

Background FT516 is an allogeneic, off-the-shelf natural killer (NK) cell cancer immunotherapy derived from a clonal master induced pluripotent stem cell (iPSC) line expressing hnCD16 to optimize antibody-dependent cellular cytotoxicity (ADCC) when combined with monoclonal antibodies (mAbs). A Phase I dose-escalation study of FT516 in combination with rituximab for patients with B-cell lymphomas has shown favorable safety and anti-tumor activity.[1] We report results from a Phase I dose-escalation study of FT516 in combination with avelumab for patients with advanced solid tumors.

Methods Patients initially received 2 treatment cycles, with the option for 2 additional cycles, each cycle consisting of 3 days of outpatient conditioning chemotherapy (cyclophosphamide 500 mg/m^2 and fludarabine 30 mg/m^2) followed by 3 once-weekly doses of FT516 with subcutaneous IL-2 (6 MIU). Avelumab 800 mg was administered every 2 weeks until progression. FT516 dose escalation was based on 3+3 design. Endpoints included safety, tolerability, and anti-tumor activity.

Results As of a data cutoff of 16 May 2022, 12 patients (non-cutaneous melanoma [6], cutaneous melanomas [4], non-small cell lung cancer and triple-negative breast cancer [1 each]) with a median of 3 prior therapies were treated, including 11 patients who received prior anti–PD-(L)1 therapy. Doses of 90 million (n=3), 300 million (n=3), or 900 million (n=6) FT516 cells/dose were administered. No dose-limiting toxicities, graft vs. host disease, neurotoxicity, FT516-related Grade $\geq$3 adverse events (AEs), or FT516-related serious AEs were reported. Grade 1 cytokine release syndrome was reported in 1 patient. Tumor burden reduction was observed in 6 patients, with a median peak reduction of 12.9% (range 3.5, 50); 1 patient with cutaneous melanoma refractory to 2 prior anti-PD-1 containing regimens achieved and maintained partial response per iRECIST through 6.2 months after initiation of treatment, and 6 patients had stable disease per iRECIST with median duration of disease control of 4.9 (range 3.8, 10.9) months.

Conclusions Up to 900 million FT516 cells administered with IL-2 in multiple doses and multiple cycles in combination with avelumab are safe and tolerable, with evidence of anti-tumor activity following failure of prior anti-PD-(L)1 therapy. These data support the development of next-generation iPSC-derived NK cells engineered with additional synthetic functional elements designed to enhance anti-tumor activity in solid tumors.

727 INTERIM PHASE I CLINICAL DATA OF FT538, AN OFF-THE-SHELF, MULTIPLEXED-ENGINEERED, IPSC-DERIVED NK CELL THERAPY, COMBINED WITH MONOCLONAL ANTIBODIES IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Martin Gutierrez*, [2]Melissa Johnson, [3]David Sommerhalder, [4]Wells Messersmith, [5]Haeseong Park, [6]Muhammad Furqan, [7]Jason Chesney, [8]Ryan Bjordahl, [8]Lingmin Zeng, [8]Peter Szabo, [8]Yu-Waye Chu, [8]Brandon Beagle, [8]Bob Valamehr, [8]Jeffrey Chou, [9]David Hong. *[1]Hackensack University Medical Center, John Theurer Cancer Center, Hackensack, NJ, USA; [2]Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN, USA; [3]NEXT Oncology, San Antonio, TX, USA; [4]University of Colorado Cancer Center, Aurora, CO, USA; [5]Alvin J Siteman Cancer Center, Washington University in Saint Louis, Saint Louis, MO, USA; [6]University of Iowa Hospitals and Clinics, Holden Comprehensive Cancer Center, Iowa City, IA, USA; [7]University of Louisville, James Graham Brown Cancer Center, Louisville, KY, USA; [8]Fate Therapeutics, Inc., San Diego, CA, USA; [9]MD Anderson Cancer Center, Houston, TX, USA*

Background Clonal induced pluripotent stem cell (iPSC) lines serve as a renewable source for mass production of immune cells, enabling engineered cell therapies to be administered off-the-shelf in multi-dose regimens to patients, including in combination with other anti-cancer agents. In preclinical solid tumor models, iPSC-derived natural killer (NK) cells have been observed to synergize with monoclonal antibodies (mAbs), including anti-PD-1/L1 checkpoint blockade and antibody-dependent cellular cytotoxicity (ADCC)-competent mAbs, resulting in greater anti-tumor activity. FT538, a first-of-kind, multiplexed-engineered NK cell therapy generated from a clonal master engineered iPSC line, incorporates 3 synthetic elements for enhanced innate immunity: (1) high-affinity 158V, non-cleavable CD16 Fc receptor that maximizes ADCC; (2) IL-15/IL-15 receptor fusion that promotes cytokine-autonomous persistence; (3) CD38 knockout that provides improved metabolic fitness and resistance to oxidative stress within the tumor microenvironment.[1] We intend to report initial clinical data from a Phase I study of FT538 combined with mAbs in patients with advanced solid tumors.

Methods FT538-102 is a Phase I dose-escalation study (ClinicalTrials.gov: NCT05069935) investigating FT538 combined with anti-PD-1/L1 or ADCC-competent mAbs in advanced solid tumors. Treatment consists of two, 29-day treatment cycles, each consisting of 3 days outpatient conditioning chemotherapy (cyclophosphamide 500 mg/m^2 and fludarabine 30 mg/m^2), followed by 3 outpatient once-weekly doses of FT538; mAbs are administered at standard dose and schedule. Key study endpoints include determining the recommended Phase II dose, safety and tolerability, anti-tumor activity, pharmacokinetics, and anti-product immunogenicity of FT538.

Dose escalation is based on a modified toxicity probability interval algorithm dose-escalation design with a starting dose level of 100 million FT538 cells/dose in combination with avelumab or pembrolizumab in PD-L1-expressing solid tumors; trastuzumab in HER2-expressing tumors; or cetuximab in colorectal cancer, squamous head and neck or lung cancers, or epidermal growth factor receptor-mutated lung cancer.

Results As of 14 July 2022, 7 patients were treated at the first dose level of 100 million FT538 cells/dose combined with avelumab (3), trastuzumab (1), or cetuximab (3). No dose-limiting toxicities, and no events of any grade of cytokine release syndrome, immune effector cell-associated neurotoxicity syndrome, or graft vs. host disease, were reported. No FT538 treatment-related Grade $\geq$3 adverse events (AEs), or serious AEs were observed. Dose escalation is ongoing.

Conclusions Interim clinical data, including safety and tolerability and initial anti-tumor activity, from the ongoing Phase I dose-escalation study of FT538 combined with anti-PD-1/L1 or ADCC-competent mAbs in advanced solid tumors will be presented at the conference.

728 PHASE 1 STUDY OF P-MUC1C-ALLO1 ALLOGENEIC CAR-T CELLS IN PATIENTS WITH EPITHELIAL-DERIVED CANCERS

[1]Jason Henry*, [2]David Oh, [3]Jeff Eskew, [4]Joaquina Baranda, [5]Ildefonso Ismael Rodriguez Rivera, [6]Ecaterina Dumbrava, [7]Ezra Cohen, [8]Rajesh Belani, [8]Joanne McCaigue, [8]Devon Shedlock, [8]Julia Coronella, [8]Christopher Martin, [8]Hamid Namini, [8]Ann Murphy, [8]Eric Ostertag. *[1]Sarah Cannon Research Institute, Denver, CO, USA; [2]University of California, San Francisco, CA, USA; [3]Poseida Therapeutics, Kansas City, MO, USA; [4]University of Kansas Cancer Center, Kansas City, KS, USA; [5]NEXT Oncology, San Antonio, TX, USA; [6]MD Anderson Cancer Center, Houston, TX, USA; [7]University of California, San Diego, La Jolla, CA, USA; [8]Poseida Therapeutics, Inc, San Diego, CA, USA*

Background There is an urgent unmet medical need for patients with advanced unresectable and/or metastatic carcinomas. Mucin 1 (MUC1) is a well-characterized heterodimeric glycoprotein that is overexpressed on many epithelial-derived tumors and consists of non-covalently linked N-terminal (MUC1-N) and C-terminal (MUC1-C) monomers. The MUC1-C epitope is selectively seen in epithelial-derived solid tumors such as breast, colorectal, ovarian, gastric, lung carcinoma and others. MUC1-C is also expressed broadly and accessibly throughout tumor tissue due to the loss of cell polarity, one of the hallmarks of tumorigenesis. P-MUC1C-ALLO1 is a fully allogeneic CAR-T targeting the MUC1-C epitope and is manufactured using non-viral transposon-based integration (piggyBac® DNA Delivery System) that results in a highly enriched T stem cell memory (T_{SCM}) product. It contains 3 transgenes: an anti-MUC1-C humanized scFv-based CAR, a DHFR drug selection gene to improve product homogeneity, and an iCasp9-based safety switch gene to allow for rapid ablation of the CAR-T if required. The cells are gene edited using the Cas-CLOVER™ Site-Specific Gene Editing System to eliminate expression of endogenous T cell receptors in all cells via knockout of the T cell receptor beta chain 1 gene to prevent graft-vs-host (GvH) response, and the β2-microglobulin gene to eliminate expression of MHC class I to attenuate host-vs-graft responses. Preclinical efficacy was observed with P-MUC1C-ALLO1 in murine models of triple negative breast cancer and ovarian cancer, providing rationale for this first-in-human (FIH) Phase 1 trial.

Methods This is a Phase 1, multi-center, open-label, FIH, 3+3 design to evaluate P-MUC1C-ALLO1 in patients with advanced or metastatic epithelial-derived cancers measurable by RECIST 1.1 and refractory/ineligible to standard of care therapy. Up to 100 patients will be enrolled into 4 arms of single and cyclic administrations using two different lymphodepletion (LD) regimens (cyclophosphamide/fludarabine ± rituximab). Planned dose escalation in each arm ranges from 0.75 to 15 x 10^6 cells/kg.

Primary objectives for this study include defining maximum tolerated dose (MTD), evaluation of overall safety and tolerability, preliminary efficacy, and disease response. Exploratory endpoints will include MUC1-C tumor expression and correlation to response, P-MUC1C-ALLO1 cell kinetics, and biomarker analysis including MUC1 related tumor markers CA15-3 and CA27-29 and CTCs.

Results To date, three patients have been treated with P-MUC1C-ALLO1 (esophageal adenocarcinoma, colorectal adenocarcinoma, and breast cancer). P-MUC1C-ALLO1 treatment to date has been well tolerated, with no dose limiting toxicities, CRS, or GvH disease observed. This study continues to recruit subjects and updated data will be presented.

729 **TARGETING EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR)-EXPRESSING SOLID TUMORS WITH AFM24, A NOVEL CD16A BISPECIFIC INNATE CELL ENGAGER: COMPREHENSIVE CORRELATIVE SCIENCE FINDINGS FROM A PHASE 1 STUDY**

[1]Gabriele Hintzen*, [1]Susanne Wingert, [1]Michael Emig, [2]Pilar Nava-Parada, [1]Kerstin Pietzko, [1]Laura Kohlhas, [1]Uwe Reusch, [3]Melissa Berrien-Elliott, [3]Todd Fehniger, [3]Mark Foster, [4]Paolo Nuciforo, [5]Ester Castillo Andreo, [1]Sina Staeble, [1]Paulien Ravenstijn, [1]Bettina Rehbein, [1]Erich Rajkovic, [1]Arndt Schottelius, [1]Joachim Koch. *[1]Affimed GmbH, Heidelberg, Germany; [2]Affimed Inc, New York, NY, USA; [3]Washington University, Missouri, USA; [4]Vall d'Hebron University Hospital, Barcelona, Spain; [5]Cancer Genomics Group, Vall d'Hebron Institute of Oncology, Vall d'Hebron University Hospital, Barcelona, Spain*

Background AFM24 is an innate cell engager that binds both EGFR on tumor cells and CD16A on natural killer (NK) cells and macrophages. The primary mechanism of action is the induction of antibody-mediated cellular cytotoxicity and antibody-mediated cellular phagocytosis towards EGFR-positive tumor cells, independent of EGFR mutational status. This innovative, targeted approach utilizes patient's own innate immunity and redirects NK cells and macrophages to tumors.

Methods An ongoing Phase 1/2a study (NCT04259450) is evaluating the safety and efficacy of AFM24 in patients with metastatic, treatment-refractory tumors known to express EGFR and has completed dose-escalation. The longitudinal effects on the immune system were examined to confirm the pharmacodynamic (PD) activity of AFM24.

Patients received AFM24 intravenously at 14–720 mg once weekly in 28-day cycles until disease progression, intolerable toxicity, investigator discretion, or patient withdrawal. Extensive correlative science analysis included profiling of pharmacokinetics, PD activity, anti-drug antibodies and CD16A receptor occupancy (CD16ARO). Comprehensive analyses of peripheral blood (PB) leukocytes and tumor biopsies were performed.

Results In total, 35 patients were treated with AFM24; tumor types included colorectal (19/35; 13 KRAS and/or NRAS and/or BRAF mutants), non-small cell lung cancer (8/35; 7 EGFR mutant) and others (8/35). A favorable safety profile in all cohorts was revealed, and an approximate half-life of 11 days was established. An exposure-response model correlating plasma concentration of AFM24 with CD16ARO demonstrated that AFM24 binds to NK cells in circulating blood, approaching a plateau at 480 mg. Mass cytometry revealed enhanced expression of activation marker CD69 on NK cells even at low doses (14–80 mg), which coincided with a transient loss of NK cells from the PB, possibly indicating migration of NK cells to the tumor. Cytotoxic CD8 T cells showed a continuous increase of Ki-67 expression in the periphery, indicating crosstalk with the adaptive immune system. T cells in the tumor bed also substantially increased. Tumor EGFR expression was maintained during treatment.

Conclusions This analysis supports the PD activity of AFM24; NK cell changes in PB suggest that AFM24 activates and redirects NK cells from PB to EGFR–positive tissue. T cells are activated within the periphery, and T cell numbers increase in tumors, which may indicate stimulation of anti-cancer activity of the adaptive immune system as an indirect effect of AFM24. Clinical and correlative science from the escalation phase of the study supports further investigation of AFM24 anti-tumor activity in EGFR-expressing tumor-specific cohorts.

731 A FIRST-IN-HUMAN TRIAL OF AN INTEGRIN BETA-6 TARGETED ANTIBODY-DRUG CONJUGATE (ADC), SGN-B6A, IN PATIENTS WITH ADVANCED SOLID TUMORS: INTERIM RESULTS OF A PHASE 1 STUDY (SGNB6A-001)

[1]Antoine Hollebecque*, [2]Juanita Lopez, [3]Sarina Piha-Paul, [4]Afshin Dowlati, [5]Amita Patnaik, [6]Vladimir Galvao, [7]Bruno Buckorny, [8]Kartik Sehgal, [9]Edwin Kingsley, [10]Rachel Sanborn, [11]Solange Peters, [12]Yan Sun, [12]Gabriela Patilea-Vrana, [12]Natalya Nazarenko, [13]Emiliano Calvo. *[1]Institut Gustave Roussy, Villejuif, France; [2]The Royal Marsden Hospital (Surrey), London, UK; [3]The University of Texas, Houston, TX, USA; [4]Case Western Reserve University, Cleveland, OH, USA; [5]START San Antonio, San Antonio, TX, USA; [6]Vall d'Hebron Institute of Oncology, Barcelona, Spain; [7]Beth Israel Deaconess Medical Center, Boston, MA, USA; [8]Dana-Farber Cancer Institute, Boston, MA, USA; [9]Comprehensive Cancer Centers of Nevada, Las Vegas, NV, USA; [10]Earle A. Chiles Research Institute, Portland, OR, USA; [11]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [12]Seagen Inc., Bothell, WA, USA; [13]START Madrid-CIOCC, Madrid, Spain*

Background Integrin beta-6 plays a role in tumor pathogenesis and invasiveness, and is correlated with poor outcomes in several cancers, making it a therapeutic target of interest.[1,2] SGN-B6A is an investigational vedotin ADC comprised of an integrin beta-6-directed monoclonal antibody conjugated to monomethyl auristatin E (MMAE) via a protease-cleavable linker. SGN-B6A elicits antitumor activity through MMAE-mediated cytotoxicity, bystander effect, and immunogenic cell death.[3] Herein, we present the first clinical data in Part A (dose escalation) of a Phase 1 clinical trial evaluating SGN-B6A.

Methods SGNB6A-001 (NCT04389632) is a Phase 1, open-label, multicenter dose-escalation/expansion study evaluating the safety, pharmacokinetics, and antitumor activity of SGN-B6A (confirmed objective response per Response Evaluation Criteria in Solid Tumors v1.1) in adults with advanced solid tumors.

Part A is enrolling patients with histologically or cytologically confirmed metastatic or unresectable solid tumors, relapsed or refractory disease or intolerance to standard-of-care therapies. Data for continuous weekly dosing (Days 1, 8, and 15 in a 21-day cycle [Q1W]) and intermittent dosing (Days 1 and 8 in a 21-day cycle [2Q3W]) are presented in this abstract.

Results As of 10 May 2022, 30 patients in Q1W (0.8, 1.0, and 1.2 mg/kg) and 18 patients in 2Q3W (1.2 or 1.25 mg/kg) received SGN-B6A. Baseline demographics are outlined in Table 1.

In Q1W, 1 dose limiting toxicity (DLT) of stomatitis (5.9%) was reported at the 1.2 mg/kg dose level (n=17; Table 2). The most common treatment-related adverse events (TRAEs) in Q1W across all doses (n=30) were fatigue (26.7%), peripheral sensory neuropathy (23.3%), alopecia (20%) and decreased appetite (20%). The most common Grade $\geq$ 3 TRAE reported across all dose groups was neutropenia (10%).

In 2Q3W (n=18), two patients experienced DLTs (diarrhea, neutropenia, and rash maculo-papular [5.6%]). The most common TRAEs were alopecia, diarrhea, and peripheral sensory neuropathy (16.7% each), and the most common Grade $\geq$ 3 TRAEs were diarrhea, hyperglycemia, and neutropenia (11.1%).

Objective responses were observed in Q1W and 2Q3W in several tumor types including non-small cell lung, head and neck squamous cell, esophageal, and cutaneous squamous cell cancer, starting at 1.2 mg/kg. Detailed efficacy results will be presented.

Conclusions SGN-B6A at both dosing schedules demonstrated an acceptable safety profile, with more favorable tolerability at 2Q3W (table 2). Preliminary antitumor activity has been observed starting at 1.2 mg/kg. Enrollment in Part B (dose expansion) is ongoing.

732 FIRST-IN-HUMAN TRIAL TO EVALUATE SAFETY, PK/PD AND INITIAL CLINICAL ACTIVITY OF NM21–1480, AN AFFINITY-BALANCED PD-L1X4–1BBXHSA TRISPECIFIC ANTIBODY: RESULTS OF PHASE 1 DOSE ESCALATION

[2]Jason Luke, [3]Melissa Johnson, [4]Shirish Gadgeel, [5]Alexander Spira, [6]James Yang, [7]Jennifer Johnson, [8]Taryn Losch-Beridon, [8]Daniel Snell, [8]Stefan Warmuth, [8]Maureen Cleaver, [8]Elmar vom Baur, [8]David Urech, [8]Peter Lichtlen, [1]David Hong*. *[1]Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Cancer Immunotherapeutics Center, UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA, USA; [3]Department of Medicine, Sarah Cannon Research Institute, Nashville, USA, Nashville, TN, USA; [4]Department of Internal Medicine, Henry Ford Cancer Institute, Henry Ford Health System, Detroit, MI, USA; [5]Virginia Cancer Specialists, Fairfax, VA, USA; [6]National Taiwan University and Department of Oncology, National Taiwan University Hospital, Taipei City, Taiwan, Republic of China; [7]Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA, USA; [8]Numab Therapeutics AG, Wädenswil Switzer, Wädenswil, Switzerland*

Background NM21-1480 is a tri-specific Fc-lacking antibody that agonizes 4-1BB and blocks PD-L1/PD-1 signaling, designed to restrict activation of the 4-1BB pathway to the tumor microenvironment.[1] NM21-1480 contains an ultra-potent PD-L1 blocking moiety and an affinity-balanced 4-1BB binding moiety to assure maximal activity on both pathways over a broad dose range. Here we report the results of the Phase 1 dose-escalation part of the ongoing First-in-Human Phase 1/2a clinical trial with NM21-1480.

Methods Patients with metastatic or unresectable solid tumors not eligible for standard therapy received flat-dose NM21-1480 (0.15–800mg) intravenously every 2 weeks until disease progression or unacceptable toxicity. Primary endpoints were dose-limiting toxicities (DLTs) and adverse events (AEs). Secondary endpoints included pharmacokinetic (PK) parameters and anti-drug antibody (ADA) assessments. Pharmacodynamic (PD) biomarkers and antitumor activity (RECIST1.1) were assessed as exploratory endpoints.

Results 26 patients with various primary solid tumors were enrolled (median age: 63 years). Patients had previously received a median (range) of 3.5 (1–10) treatments; 62% of whom had prior anti-PD-(L)1 immunotherapy. As per 14 July 2022 patients received a median (range) of 4 (1-19) biweekly NM21-1480 infusions. Full peripheral receptor occupancy at trough level was observed at the dose of 24mg or above. Maximum tolerated dose was not reached; 1 patient experienced a DLT. The most common (≥10% of patients) treatment-related AEs (all grades; Grades 3–4) were infusion-related reactions (27% (11% at 800mg dose); 0%), fatigue (12%; 0%) and transaminase elevations (12%; 4%) according to CTCAEv5.0. One patient each experienced treatment-related Grade-3 transaminase elevations and adrenal insufficiency, respectively; no treatment-related adverse event higher than Grade 3 occurred. In the 24mg-800mg dose range, disease control, i.e., at least stable disease at first assessment at 8 weeks, occurred in 12/21 patients (57%). One patient demonstrated an unconfirmed partial response at Week 16. PD activity on PD-L1 blockade as well as 4-1BB signaling was observed and remained stable at a broad dose range (24-800mg). Based on the totality of the data derived from safety/immunogenicity, PK/PD and clinical activity, the 800mg flat dose of NM21-1480 has been selected for further clinical evaluation.

Conclusions NM21-1480 demonstrated biological activity associated with a manageable safety profile. Encouraging early clinical activity across different dose levels was observed in a heavily pretreated population with advanced solid tumors, including those resistant to prior immunotherapy or typically less sensitive to ICIs. Enrollment into expansion cohorts will start in the second half of 2022.

733 A PHASE 2 STUDY OF VUDALIMAB (XMAB®20717), AN ANTI-PD-1/CTLA-4 BISPECIFIC ANTIBODY, IN PATIENTS WITH SELECTED GYNECOLOGICAL MALIGNANCIES AND HIGH-RISK METASTATIC CASTRATION-RESISTANT PROSTATE-CANCER

[1]June Hou*, [2]Oscar Goodman, [3]David Berz, [4]Li Yao, [4]Nital Soni. [1]*Columbia University Irving Medical Center, New York, NY, Untied States*; [2]*Comprehensive Cancer Centers of Nevada, Las Vegas, NV, USA*; [3]*Valkyrie Clinical Trials, Los Angeles, CA, USA*; [4]*Xencor, Inc., Monrovia, CA, USA*

Background Vudalimab (XmAb20717) is a humanized bispecific monoclonal antibody that simultaneously targets PD-1 and CTLA-4 and binds preferentially to PD-1/CTLA-4 dual-positive cells. In a Phase 1 study, vudalimab was generally well-tolerated and associated with complete and partial responses in various solid tumor types, including ovarian cancer and metastatic castration-resistant prostate cancer (mCRPC).[1] These tumor types typically are not responsive to single-agent immune checkpoint inhibitor (ICI) therapy but have shown better outcomes in studies in which anti-PD-1 and CTLA-4 therapies have been combined. This Phase 2 study is designed to evaluate the safety and antitumor activity of vudalimab in selected gynecological oncologic indications and high-risk mCRPC.

Methods This is a multicenter, two-stage, open-label study being conducted in the United States. Patients with histologically confirmed platinum-resistant high-grade serous ovarian cancer; chemotherapy relapsed or refractory clear cell ovarian, endometrial, or peritoneal cancer; ICI-refractory microsatellite stable (MSS) endometrial cancer (EC); previously treated recurrent or metastatic cervical cancer; or high-risk mCRPC will be enrolled into parallel cohorts. Patients must have measurable disease by response evaluation criteria in solid tumors (RECIST) 1.1. Prior treatment with anti-PD-1 and PDL-1/PDL-2 therapy is excluded, except for patients with MSS EC and cervical cancer; prior anti-CTLA-4 treatment is excluded for all patients. Vudalimab will be administered intravenously every 3 weeks at a fixed dose of 1000 mg (1200 mg for patients $\geq$ 80 kg). Antitumor effects will be evaluated using RECIST 1.1; additionally, disease assessment via bone scans and PSA will be performed in patients with mCRPC. Safety and tolerability will be assessed based on treatment-emergent adverse events. Pharmacodynamic effects in peripheral blood and tumor, and potential biomarkers associated with clinical response will be explored. In Stage 1 (n = 10/cohort), a primary endpoint of objective response rate (ORR) $\geq$ 20% at 12 weeks (based on investigator review) will determine which cohorts advance into Stage 2 (n = 20/cohort), where primary and secondary endpoints of ORR (based on independent central review) and duration of response, respectively, will be determined for the combined number of patients enrolled into Stages 1 and 2 (n = 30). Enrollment has been initiated.

Trial Registration NCT05032040

734 A PHASE 1 STUDY EXPLORING THE SAFETY AND TOLERABILITY OF THE SMALL-MOLECULE PD-L1 INHIBITOR, INCB099280, IN PATIENTS WITH SELECT ADVANCED SOLID TUMORS

[1]Hans Prenen*, [2]Thierry Lesimple, [3]Marie Robert, [4]Brant Delafontaine, [5]Jean-Pascal Machiels, [6]Tarek Meniawy, [7]Eric Van Cutsem, [8]Nuria Kotecki, [9]Sarina Piha-Paul, [10]Michael Schweizer, [11]Shirish Gadgeel, [12]Jeannie Daniel, [12]Louis Viviers, [12]Jason Howe, [13]Antoine Italiano. *[1]University Hospital Antwerp, Antwerp, Belgium; [2]CLIP2 and ARPEGO Networks, Rennes, France; [3]Unicancer Group ICO René Gauducheau Site, CLIP2 and ARPEGO Networks, Saint-Herblain, France; [4]Drug Research Unit Ghent, UZ Ghent, Ghent, Belgium; [5]Cliniques Universitaires Saint-Luc, UCLo, Brussels, Belgium; [6]Linear Clinical Research and University, Nedlands, Western Australia, WV, Australia; [7]University Hospitals Gasthuisberg, Leuve, Leuven, Belgium; [8]Institut Jules Bordet, Brussels, Belgium; [9]University of Texas MD Anderson Cancer, Houston, TX, USA; [10]Univeristy of Washington and Fred Hutchi, Seattle, WA, USA; [11]Henry Ford Cancer Institute/Henry Ford Health, Detroit, MI, USA; [12]Incyte Corporation, Wilmington, DE, USA; [13]Early Phase Trials Unit, Institut Bergon, Bordeaux, France*

Background INCB099280 is an orally administered, small-molecule inhibitor of programmed cell death ligand 1 (PD-L1). This is an ongoing, phase 1, open-label, multicenter study.

Methods Eligible patients are aged ≥18 years with advanced solid tumors and an Eastern Cooperative Oncology Group performance status of 0–1. Patients had disease progression after treatment with available therapies or were ineligible for or without access to standard treatment. The study is being conducted in two parts: in part 1, a Bayesian optimal interval design is being used to identify the maximum tolerated dose (MTD) of INCB099280; in part 2, two doses have been expanded for patients with various tumor types who were immunotherapy-naive. The primary endpoints are (1) safety and tolerability as measured by monitoring frequency/severity of adverse events (AEs) and (2) determining a pharmacologically active dose and/or MTD. Anti-tumor activity is assessed using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1.

Results As of April 22, 2022, 73 patients had received INCB099280 at total daily doses ranging from 100 to 800 mg. Among all patients, median (range) age was 62 (21–82) years, 60.3% were women, 57.5% were white, 43.8% had gastrointestinal malignancies, 56.2% had ≥2 prior lines of therapy, and 6.8% had prior exposure to an immune checkpoint inhibitor. 46 patients (63.0%) discontinued treatment, 38 of whom discontinued for disease progression. Treatment-emergent AEs (TEAEs) occurring in >20% of patients were decreased appetite, fatigue, nausea, anemia, diarrhea, asthenia, and vomiting. Serious TEAEs (SAEs) occurred in 21 patients (28.8%); SAEs occurring in >1 patient were pneumonia and sepsis (n=3 each) and anemia, dyspnea, and urinary tract infection (n=2 each). Grade ≥3 treatment-related TEAEs occurred in 5 patients (6.8%): asthenia, fatigue, elevated lipase, decreased appetite, hypophagia, and confusional state (n=1 each). One patient had a protocol-defined dose-limiting toxicity (DLT; 600-mg once-daily group; unable to receive ≥75% of the prescribed dose owing to vomiting). The 600-mg once-daily dose was expanded in 9 patients with no further DLTs. Several responses have been observed, and updated results will be presented.

Conclusions INCB099280 was generally well tolerated at total daily doses up to 800 mg. Unlike with the first-generation oral PD-L1 inhibitor INCB086550, no dose-limiting immune-mediated peripheral neuropathy has occurred to date with INCB099280. Preliminary efficacy indicates anti-tumor activity. Continued investigation and further development are warranted.

735

A PHASE 1/2 STUDY OF REGN7075 (EGFRXCD28 COSTIMULATORY BISPECIFIC ANTIBODY) IN COMBINATION WITH CEMIPLIMAB (ANTI–PD-1) IN PATIENTS WITH ADVANCED SOLID TUMORS: INITIAL DOSE-ESCALATION RESULTS

[1]Melissa Johnson*, [2]Nehal Lakhani, [3]Eugenia Girda, [4]Anthony Olszanski, [5]Lawrence Fong, [6]Hyunsil Han, [6]Kerry Casey, [6]Siyu Li, [6]Jennifer Visich, [6]Dmitris Skokos, [6]Frank Seebach, [6]Israel Lowy, [6]Matthew Fury, [6]Melissa Mathias, [7]Neil Segal. *[1]Sarah Cannon Research Institute, Nashville, TN, USA; [2]START Midwest, Grand Rapids, MI, USA; [3]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, USA; [4]Fox Chase Cancer Center, Philadelphia, PA, USA; [5]University of California, San Francisco, CA, USA; [6]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA; [7]Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background There is a need to develop novel immunotherapeutic approaches to enhance responses to immune checkpoint blockade. REGN7075 is a human costimulatory bispecific antibody designed to bridge epidermal growth factor receptor (EGFR)-expressing tumor cells with CD28-positive T cells to support further T-cell activation by endogenous tumor antigens [1, 2] (figure 1). We initiated a first-in-human, open-label, Phase 1/2 dose-escalation and expansion study evaluating the safety, tolerability, pharmacokinetics, and preliminary antitumor activity of REGN7075 (EGFRxCD28) in combination with cemiplimab (anti–PD-1) in patients with advanced solid tumors (figure 2; NCT04626635).

Methods We report preliminary results of the dose-escalation phase (Bayesian optimal interval design; Part 1), in which heavily pre-treated patients with advanced solid tumors will receive a lead-in of REGN7075 monotherapy every week for 3 weeks, followed by combination therapy with cemiplimab 350mg every 3 weeks. Planned dose levels (DL) of REGN7075 are 0.03, 0.1, 0.3, 1, 3, 10, 30, 100, 300, and 900mg. Primary objective is to assess safety and tolerability of REGN7075 in combination with cemiplimab.

Results As of the data cutoff date (May 6, 2022), 18 patients (median age, 53.5 years, 56% female) were treated in the dose-escalation phase (table 1), up to the 30mg DL for REGN7075 in combination with cemiplimab. Most patients (67%) were treated for microsatellite stable colorectal cancer. No patients experienced dose-limiting toxicities; maximum tolerated dose was not reached. Table 2 summarizes treatment-emergent adverse events (TEAEs) and treatment-related adverse events (TRAEs). The most frequent TEAEs (any grade) were increases in aspartate aminotransferase (AST), constipation, and fatigue (33% [n=6] each). The most frequent TRAEs (any grade) were fatigue (17% [n=3]), increases in AST, diarrhea, hypothyroidism, pyrexia, and rash (11% [n=2] each). One patient developed cytokine release syndrome which was characterized by isolated grade 1 fever without hypotension nor hypoxia. Five recorded deaths were not during study treatment and not attributed to study drug(s). Ongoing PK evaluation suggests possible target-mediated effects. T cell activation-associated cytokines were detected in monotherapy lead-in and combination dosing. Of all patients treated, 1 patient who received 1mg REGN7075 with cemiplimab for cervical cancer achieved an ongoing partial response.

Conclusions In this dose-escalation study, REGN7075 was safely administered up to the 30mg dose level in combination with cemiplimab without dose-limiting toxicities. Early data indicates that novel agent REGN7075 was generally well tolerated, with preliminary potential anti-tumor activity. Biomarker studies are ongoing. Clinical trial enrollment is ongoing; we are currently evaluating the 100mg cohort.

736 A CLINICAL STAGE ENGINEERED TOXIN BODY (ETB) TARGETING PD-L1 (MT-6402) INDUCES PERIPHERAL PHARMACODYNAMIC RESPONSES UNIQUE FROM PD-L1 MONOCLONAL ANTIBODIES

Swati Khanna, Rachael Orlandella, Elizabeth Saputra, Sydney Matthews, Lydia Navarrete-Galvan, Sara LeMar, Joseph Dekker*, Eric Poma, Chris Moore. *Molecular Templates Inc., Austin, TX, USA*

Background PD-L1 targeting mAbs have had success in the clinic for a variety of solid tumors and specific patient subsets. To date, all PD-L1 mAbs rely on blocking the PD-1/PD-L1 axis through steric hindrance for their activity. MT-6402 is a clinical stage ETB that binds to PD-L1, triggers receptor internalization, and induces cell death of PD-L1+ cells through ribosomal destruction. MT-6402 represents a wholly novel approach to targeting PD-L1 expressing immune and tumor cells built upon the clinical hypothesis that elimination rather than blocking of PD-L1+ tumor and immune cells could transform immune tolerant tumor microenvironments (TME) to immune augmenting phenotypes. To this end, MT-6402 also carries a CMVpp65 peptide capable of HLA-A*02 restricted antigen presentation designed to redirect CMV-specific cytotoxic T cells to tumor tissue. Thus far, MT-6402 has completed three dosage cohorts (n=16) in a phase 1 dose escalation trial. Here we show changes in serum vascular endothelial growth factor (VEGF) correlate with peripheral reductions in monocyte derived suppressor cells (MDSCs), both biomarkers of potential TME alterations and a unique peripheral effect not seen with αPD-L1 blocking mAbs.

Methods Peripheral blood mononuclear cells (PBMC) from MT-6402-dosed patients were stained with surface antibodies and acquired on a flow cytometer to identify CD11b+CD14+HLA-DR-/low Monocytic MDSCs. Luminex was used to quantify VEGF concentrations in patient matched serum.

Results A sawtooth pattern of peripheral VEGF levels emerged in 5/7 patients with higher pre-dose VEGF levels (>125pg/ml) following multiple doses of MT-6402 and indicative of a tumor remodeling response. A gradual VEGF increase in cohort 1 cycle 1 correlated with peripheral MDSC extravasation into tissue or TME. For cohorts 2 and 3, an inverse relationship between VEGF concentrations and MDSC frequencies emerged, where spikes in MDSCs correlated to sharp reductions in serum VEGF levels. Overall, PBMC phenotyping and cytokine data demonstrated an inverse correlation of MDSC frequencies and VEGF concentrations across dosage cohorts.

Conclusions PD-L1 expression on tumor and immune cells have non-redundant contributions to the maintenance of the TME and disease progression. Current PD-L1 antibodies physically inhibit PD-L1 and PD-1 interaction but do not fully inhibit PD-L1+ immune cell functions that contribute to TME maintenance (i.e., cytokine/chemokine secretion). Unlike PD-L1 antibodies, MT-6402 was designed to destroy PD-L1+ immune cells in a target-specific manner. We demonstrate here that MDSCs are depleted in the periphery of patients treated with MT-6402 and that this depletion appears related to peripheral changes in VEGF and alterations of the TME.

737 INTERIM RESULTS OF A FIRST-IN-HUMAN PHASE 1 DOSE-ESCALATION TRIAL OF TAK-102, A GLYPICAN-3 TARGETED ARMORED CHIMERIC ANTIGEN RECEPTOR T-CELL IMMUNOTHERAPY IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Takafumi Koyama*, [1]Toshio Shimizu, [2]Toshihiko Doi, [1]Noboru Yamamoto, [1]Shunsuke Kondo, [3]Abood Okal, [3]Aman Singh, [3]Janet Markman, [4]Takenori Akaike, [4]Hideaki Kagehara, [2]Yasutoshi Kuboki. *[1]National Cancer Center Hospital, Tokyo, Japan; [2]National Cancer Center Hospital East, Kashiwa, Japan; [3]Takeda Development Center Americas, Inc., Waltham, MA, USA; [4]Takeda Pharmaceutical Company Limited, Osaka, Japan*

Background Glypican 3 (GPC3) is a member of the glypican family of heparan sulfate (HS) proteoglycans that are attached to the cell surface by a glycosylphosphatidylinositol (GPI) anchor. High GPC3 expression rates are present in numerous cancer types with high unmet medical needs, including hepatocellular carcinoma, squamous non-small cell lung cancer, upper gastrointestinal cancers, cervical cancer, and undifferentiated sarcomas. TAK-102 is a GPC3-targeted, interleukin (IL)-7- and CC chemokine ligand 19 (CCL19)-expressing autologous chimeric antigen receptor (CAR) T-cell immunotherapy. The addition of IL-7 and CCL19 to the construct is expected to support the expansion of memory subsets and persistence of CAR T cells. This is hypothesized to help overcome the challenges associated with an immunosuppressive tumor microenvironment, one of the foremost pathogenic mechanisms likely limiting the activity of non-armored CAR T-cell therapies in solid tumors. In vivo antitumor activity of TAK-102 was confirmed in NOD scid gamma mice engrafted with GPC3-positive human HepG2 cells.

Methods The first-in-human, Phase 1 dose-escalation study is evaluating TAK-102 in patients with GPC3-expressing solid tumors who are refractory or intolerant to standard treatments. TAK-102 is administered via a single infusion on 3 dose cohorts after lymphodepleting chemotherapy (fludarabine and cyclophosphamide): Cohort 1 (starting cohort), $1x10^7$ CAR+ cells/body; Cohort 2, $1x10^8$ CAR+ cells/body; Cohort 3, $1x10^9$ CAR+ cells/body. Objectives include evaluation of safety, dose-limiting toxicity (DLT), recommended Phase 2 dose, cellular kinetic (CK) parameters, pharmacodynamic (PD) effects, and antitumor activity based on RECIST 1.1.

Results As of March 25, 2022, 4 patients were enrolled and infused with TAK-102 (Cohort 1: 3 patients, one each with gastric neuroendocrine carcinoma, liposarcoma, and hepatocellular carcinoma; Cohort 2: 1 patient with liposarcoma). No DLT, cytokine release syndrome, or neurotoxicity were observed in any of the patients. Two patients, one with hepatocellular carcinoma and the other with liposarcoma, achieved stable disease (SD). There was a dose-dependent increase in expansion and persistence based on peripherally measured TAK-102 transgene levels. Peripheral blood CK also trended with some of the cytokines' kinetics, including interferon-γ, IL-12/-23p40, and IL-10. Pre-/post-treatment paired tumor biopsies from a patient with hepatocellular carcinoma who was administered TAK-102 showed significant increase in endogenous T-cell infiltration and activation markers (CD69, granzyme B). The observed SD and accompanying changes in relevant tumor biomarker levels (alpha-fetoprotein, lactate dehydrogenase) are encouraging.

Conclusions TAK-102 is an autologous GPC3-targeted IL-7/CCL19 armored CAR T-cell immunotherapy. Preliminary data show an encouraging safety profile and CK/PD results. The dose-escalation study is ongoing (NCT04405778).

738 **INTERIM DOSE ESCALATION OF DAVOCETICEPT, A CONDITIONAL CD28 COSTIMULATOR AND DUAL CHECKPOINT INHIBITOR, IN COMBINATION WITH PEMBROLIZUMAB IN ADVANCED MALIGNANCIES (NEON-2)**

[1]Nehal Lakhani*, [2]Amita Patnaik, [3]Meredith McKean, [4]Justin Gainor, [5]Cathy Vo Buu, [5]Amanda Enstrom, [5]Rupert Davies, [5]Stacey Dillon, [5]Hany Zayed, [6]Michael Chisamore, [7]James Michael Pluda, [5]Allison Naumovski, [5]Stanford Peng. *[1]START Midwest, Grand Rapids, MI, USA; [2]START San Antonio, San Antonio, TX, USA; [3]Sarah Cannon Research Institute and TN Onc, Nashville, TN, USA; [4]Massachusetts General Hospital, Boston, MA, USA; [5]Alpine Immune Sciences, Seattle, WA, USA; [6]Merck and Co., Kenilworth, NJ, USA; [7]ICON Clinical Research, Blue Bell, PA, USA*

Background PD-1/PD-L1 inhibitors (PD-(L)1i) have improved outcomes for many patients with advanced malignancies; however, most do not respond, or fail to achieve durable anti-tumor immunity. PD-1-mediated inhibition of T-cell effector function works primarily by inactivating the CD28 costimulatory signal. While PD-(L)1i can remove such inhibition, active CD28 costimulation is likely still required for optimal T-cell activation. Davoceticept is a variant CD80 vIgD-Fc fusion protein, engineered to provide PD-L1-dependent CD28 costimulation, while inhibiting PD-1 and CTLA-4. In NEON-1 (NCT04186637), davoceticept monotherapy was well-tolerated up to 10mg/kg, Q3W, and showed evidence of clinical activity in papillary renal cell carcinoma (RCC). A davoceticept + PD-1i approach is supported by preclinical models where combination treatment yielded tumor volume reductions beyond those seen with either monotherapy. Further, PD-1 inhibition may up-regulate PD-L1 in the tumor and sensitize it to PD–L1-dependent CD28 costimulation by davoceticept.

Methods NEON-2 is an open-label dose escalation and expansion study of davoceticept + pembrolizumab in adults with advanced solid tumors or lymphoma (NCT04920383). Eligibility includes tumors for which single agent PD-(L)1i are standard of care, are refractory/resistant to standard therapies, or have no standard or curative treatments available. The study employs a standard 3+3 dose-escalation design with 2 schedules of intravenous (IV) davoceticept: Q1W and Q3W. Pembrolizumab is given per label at 400mg IV Q6W. Study objectives include evaluation of safety and tolerability, identification of the recommended phase 2 dose(s) (RP2D), pharmacokinetic, pharmacodynamic, exploratory biomarker analyses, and preliminary efficacy.

Results As of June 2022, 19 subjects have been treated with davoceticept in dose escalation at 0.1 and 0.3mg/kg, Q1W and Q3W. Seven subjects experienced a total of 9 Grade 3+ treatment–related adverse events, including one Grade 5 cardiogenic shock in the 0.3mg/kg, Q3W cohort. Gr3+ immune-related adverse events were more common in subjects receiving 0.3 vs. 0.1mg/kg regimens of davoceticept, at 27.3% and 12.5%, respectively. Of 14 evaluable subjects, 1 confirmed partial response has been observed in a nivolumab-experienced subject with clear cell RCC. Additionally, tumor reductions have been noted in a second ongoing RCC subject, and in subjects with prostate cancer and serous peritoneal carcinoma. Fifty percent of evaluable subjects achieved a best response of stable disease.

Conclusions The davoceticept + pembrolizumab combination has demonstrated preliminary anti-tumor activity in clear cell RCC, potentially by reversing resistance to PD-(L)1i. Dose escalation efforts will resume at 0.1mg/kg, Q1W and Q3W. Tumor-specific expansion cohorts will open once the RP2D/schedule of the combination treatment is identified.

739

A PHASE 1B/2, OPEN-LABEL, SAFETY, TOLERABILITY AND EFFICACY STUDY OF NC410 PLUS PEMBROLIZUMAB FOR PARTICIPANTS WITH IMMUNE CHECKPOINT INHIBITOR (ICI) REFRACTORY, OR MSS/MSI-LOW ICI NAÏVE ADVANCED OR METASTATIC SOLID TUMORS

[1]Han Myint, [2]Eric Christenson*, [3]Siqing Fu, [4]Martin Gutierrez, [5]Ashley Martz, [5]Stephanie Zeidan, [5]Megan Nelson, [5]Alina Barbu, [5]Aaron Morawski, [5]Chelsea Zhou, [5]Zachary Cusumano, [5]Rachel O'Neill, [5]Ron Copeland, [5]Dallas Flies, [5]Solomon Langermann, [6]Julia Cohen, [2]Dung Le. *[1]NextCure Inc, Beltsville, MD, USA; [2]Johns Hopkins Hospital, Baltimore, MD, USA; [3]MD Anderson Cancer Center, Houston, TX, USA; [4]John Theurer Cancer Center, Hackensack, NJ, USA; [5]NextCure, Beltsville, MD, USA; [6]Merck, West Point, PA, USA*

Background The tumor extracellular matrix (ECM) functions as a physical barrier to immune cell infiltration and acts to directly inhibit immune cells by interacting with the inhibitory receptor, Leukocyte Associated Immunoglobulin-Like Receptor-1 (LAIR-1). Several recent publications on pre-clinical studies have demonstrated this inhibition can be reversed by NC410, a recombinant form of the LAIR-2 protein, a naturally produced soluble decoy that normally functions to compete with LAIR-1 binding. NC410 is composed of LAIR-2 protein fused to a human Fc domain of the immunoglobulin (Ig) subtype IgG1.[1] More recently, in vivo modeling studies demonstrate that treatment with PD(L)-1 blockade in a murine lung model drives enhanced collagen production due to an increase in TGF-β signaling, resulting in resistance to treatment targeting the PD-L1 pathway. Genetically driven overexpression of LAIR-2, in this model was able to overcome resistance, sensitize tumors to PD(L)-1 blockade, reduce tumor growth, and increase local immune cell activation.[2] Extensive preclinical testing by NextCure and collaborators has demonstrated that the combination of NC410, and anti-PD(L)-1 leads to consistent reduction of tumor burden and enhanced survival in several animal models. A clinical trial of NC410 Phase 1 monotherapy in participants with advanced or metastatic solid tumors is currently on-going. Preliminary clinical and biomarker data has been presented,[3] supporting immune activation and mechanism of action proposed for NC410.

Methods This is an open-label, non-randomized, Phase 1b/2 study to determine the safety and tolerability of NC410 when combined with Pembrolizumab. This study will also assess the clinical benefit of combination therapy in participants with advanced unresectable and/or metastatic ICI refractory solid tumors (CRC MSI-H, Gastric including GE junction, Esophageal, Endometrial, and H&N cancer) in Cohort 1, and ICI Naïve, Microsatellite Stable or Microsatellite Instability Low (MSS/MSI-low) solid tumors (CRC, Gastric including GE junction and Ovarian) in Cohort 2. Key eligibility criteria include measurable disease based on RECIST v1.1 and being able to provide tissue samples at screening. Participants will receive pembrolizumab 400 mg on Day 1 of each 42-day cycle. NC410 will be given on Days 1, 15 and Day 29 of each 42-day cycle. Objective response rate (ORR) based on RECIST v1.1 will be the primary endpoint, while duration of response (DoR), disease control rate (DCR), progression-free survival (PFS), and overall survival will be evaluated as secondary endpoints. Several biomarker effects of NC410 in combination with pembrolizumab in peripheral blood and tumor tissue will be assessed.

740 **A FIRST-IN-HUMAN TRIAL OF HSTC810 (ANTI-BTN1A1 AB), A NOVEL IMMUNE CHECKPOINT WITH A MUTUALLY EXCLUSIVE EXPRESSION WITH PD-1/PD-L1, IN PATIENTS WITH RELAPSED/REFRACTORY SOLID TUMORS**

[1]Soohyeon Lee*, [2]Sangjoon Shin, [3]Lynn Howie, [4]Hyunjin Jung, [3,4]Steven Yoo, [5]David Hong. *[1]Korea University Anam Hospital, Seoul, Korea, Republic of; [2]Yonsei Cancer Center, Seoul, Korea, Republic of; [3]STCube Pharmaceuticals, Inc, Gaithersburg, MD, USA; [4]STCube, Inc, Seoul, Korea, Republic of; [5]MD Anderson Cancer Center, Houston, TX, USA*

Background Butyrophilin 1A1 (BTN1A1) is a novel immune checkpoint with a mutually exclusive expression with PD-1/PD-L1 and may offer a promising therapeutic target for tumors that are anti-PD-1/PD-L1 antibody refractory. BTN1A1 was identified as a potential stress-inducible candidate immune checkpoint using the STCube *in vivo* immune checkpoint target discovery platform. Murine studies demonstrated that the anti-BTN1A1 antibody exhibited antitumor activity as a single agent as well as when combined with anti-PD-1/PD-L1 or radiation therapy. A humanized anti-BTN1A1 antibody, hSTC810, was developed and evaluated in immunologically cold A549 tumors that are unresponsive to anti-PD-L1 treatment. hSTC810-treatd mice exhibited significantly reduced tumor volumes relative to hIgG4-treated control animals without any treatment-related toxicity. Humanized STC810 is currently being evaluated in a first in human study to identify hSTC810's maximally tolerated dose (MTD) and initial safety profile for patients with advanced solid tumors.

Methods A Phase I clinical study using a standard 3 + 3 escalation design to explore safety, tolerability, dose-limiting toxicities (DLTs), pharmacokinetics, define a recommended phase II dose (RP2D) and to evaluate preliminary efficacy in patients with advanced solid tumors is currently enrolling (NCT05231746). The study is a multi-site, non-randomized, open-label study with subjects ages >18 to be enrolled with various advanced solid tumors. Eligible patients receive hSTC810 intravenously (0.3mg/kg-15 mg/kg) once every 2-weeks as a single agent until disease progression or lack of tolerability. Dose expansion cohorts are planned at RP2D to further assess safety, pharmacokinetics (PK), pharmacodynamics and immunohistochemistry in pre-and post-treatment tumor tissue samples.

Results To date, 13 patients have been enrolled, and 2 dose levels have been completed. No DLTs have been observed and enrollment continues. Subject enrollment in the dose escalation cohorts is expected to be completed in the fourth quarter of 2022.

Conclusions Interim clinical data, including safety and tolerability and initial anti-tumor activity, from the ongoing Phase 1 dose-escalation study of STCube's hSTC810 in advanced solid tumors will be presented at the conference.

Trial Registration NCT05231746

Ethics Approval The study obtained ethics approval from Korea University Anam Hospital (2022AN008) and the other all participating institutions and a statement that participants gave informed consent before taking part.

Consent Written informed consent was obtained from the patient for publication of this abstract and any accompanying images. A copy of the written consent is available for review by the Editor of this journal.

741 **FIRST IN HUMAUN PHASE I TRIAL OF DT-9081, A SELECTIVE EP4 RECEPTOR ANTAGONIST IN PATIENTS WITH RECURRENT AND OR METASTATIC SOLIDS TUMORS**

[1]Jean-Pierre Delord, [2]Christophe Le Tourneau, [3]Nuria Kotecki, [4]Patricia Zerr, [4]Claire Jouffroy Zeller, [4]Samira El Farouk, [4]Asmaa Boudribila, [5]Jean-Pascal Machiels*. *[1]Institut Claudius Regaud, IUCT-Oncopole, Toulouse, France; [2]Department of Drug Development and Inn, Paris, France; [3]Institut Jules Bordet, Brussels, Belgium; [4]Domain Therapeutics, Strasbourg, France; [5]Cliniques Universitaires Saint Luc, Brus, Brussels, Belgium*

Background Overexpression of Prostaglandin E2 (PGE2) in tumour tissues suppresses anti-tumour immunity in the tumour microenvironment and can lead to disease progression. DT-9081 is small molecule, orally administered, highly selective antagonist of prostaglandin E receptor 4 (EP4R) developed to overcome the immune-suppressive effects of PGE2, and to reverse the resistance to immune checkpoint blockers.DT-9081 has recently demonstrated significant anti-tumor activity in vivo as monotherapy and in combination with immunotherapeutic agents in several mouse tumor models.

Methods This first-in-human phase 1, multicentre, open label trial is evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of DT-9081 in adult's patients with recurrent and/or metastatic solid tumours who failed standard of care therapies (EudraCT Number 2022-000092-40) Patients will be dosed orally once daily. The schedule might be adjusted in case of toxicities or based on PK parameters.

This Phase 1 consists of 2 parts. The first part will consist in an initial dose-escalation phase using a 3+3 designup to 6 dose escalation cohorts at increasing levels are planned. The primary objectives will be to determine the dose-limiting toxicities, maximal tolerated dose, and the toxicity profile (NCI CTCAE v5.0) to establish the recommended phase II dose (RP2D) as single agent. Adjustment of the doses will be based on toxicities, pharmacokinetics data and pharmacodynamics effects of DT-9081.

The second part will be an expansion phase at the RP2D in a homogeneous patient population to validate the dose/schedule of administration as well as to assess preliminary efficacy of DT-9081 according to RECIST1.1.

Ethics Approval UNDER REVEW

742 A MULTICOHORT PHASE 1B STUDY (STELLAR-002) OF XL092 IN COMBINATION WITH IMMUNOTHERAPY IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Bradley Mcgregor*, [1]Toni Choueiri, [2]Neil Shah, [3]Aung Bajaj, [4]Jad Chahoud, [5]Bert O'Neil, [6]Joel Michalski, [7]Benjamin Garmezy, [8]Lixian Jin, [9]Usman Aziz, [9]Fiona Xu, [2]Robert Motzer.
[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]Arizona Oncology, Tucson, AZ, USA; [4]Moffitt Cancer Center, Tampa, FL, USA; [5]Indiana University, Indianapolis, IN, USA; [6]Nebraska Cancer Specialists, Omaha, NE, USA; [7]Sarah Cannon Research Institute, Nashville, TN, USA; [8]Bristol Myers Squibb, Lawrenceville, NY, USA; [9]Exelixis, Inc., Alameda, CA, USA

Background XL092 is a novel, oral inhibitor of multiple receptor tyrosine kinases including MET, VEGFR2, AXL, and MER, which are implicated in tumor growth, metastasis, angiogenesis, and immune modulation. XL092 has a half-life of ~21h, convenient for daily dosing and managing tolerability. Preclinical studies of XL092 plus an immune checkpoint inhibitor (ICI) showed antitumor activity in tumor models. STELLAR-002 will evaluate the safety and clinical activity of XL092 alone and in combination with nivolumab ± ipilimumab in patients with advanced solid tumors. Presented here is the study design which includes a dose-escalation stage in solid tumors and a cohort-expansion stage in genitourinary cancers.

Methods This multicenter phase 1b, open-label study (NCT05176483) will enroll patients with unresectable advanced or metastatic solid tumors. The dose-escalation stage will determine recommended doses of XL092 (orally) in combination with nivolumab ± ipilimumab (intravenously) for the cohort-expansion stage. Dose escalation will enroll a total of ~24 patients into two cohorts using a rolling 6 design: Cohort A, XL092 + nivolumab (360 mg Q3W); Cohort B, XL092 + nivolumab (3 mg/kg Q3W × 4, then 480 mg Q4W) + ipilimumab (1 mg/kg Q3W × 4). The cohort-expansion stage will include six tumor-specific cohorts: clear cell renal cell carcinoma (ccRCC), first-line therapy; ccRCC, second-line therapy after one prior ICI regimen; metastatic castration-resistant prostate cancer (mCRPC), second-line therapy after one prior novel hormonal therapy; urothelial carcinoma (UC), second-line therapy after prior platinum-based regimen and ICI-naïve; UC, ICI-experienced, up to 2 prior lines of systemic therapy with prior platinum-based regimens allowed; non-clear cell RCC, first-line therapy. Cohort-specific randomization will include XL092 alone or in combination with nivolumab ± ipilimumab to evaluate the contribution of the individual agents to the combination regimens. Thirty patients will be enrolled in each XL092 alone arm and 40 patients in each combination arm. Preliminary efficacy, safety, and pharmacokinetics of XL092 alone or in combination with ICI will be assessed in each cohort. Primary endpoints include objective response rate per RECIST v1.1 by investigator, progression-free survival per Prostate Working Group 3 criteria by blinded review (mCRPC cohort only), and safety. The study is enrolling patients.

Trial Registration Trial registry is ClinicalTrials.gov NCT05176483

Ethics Approval The study will adhere to the principles outlined in "Guideline for Good Clinical Practice" (GCP) and remain consistent with the most recent version of the Declaration of Helsinki.

Consent Patients will be required to provide written informed consent.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0742

743 PHARMACOKINETIC AND PHARMACODYNAMIC PROFILE OF A FIRST-IN-HUMAN STUDY WITH MDNA11, AN ENGINEERED LONG-ACTING BETA-ONLY IL-2 AGONIST

[1]Minh To*, [1]Nina Merchant, [1]Melissa Coello, [1]Carole Galligan, [1]Kritika Mehta, [2]Victoria Atkinson, [1]Martin Bexon, [3]Jim Coward, [4]Jenny Lee, [5]Charlotte Lemech, [6]Peter Lloyd, [7]Jesus Antras, [8]Arash Yavari, [1]Fahar Merchant. *[1]Medicenna Therapeutics, Toronto, Canada; [2]Gallipoli Medical Research Foundation, Woolloongabba, Australia; [3]ICON Cancer Centre, South Brisbane, Australia; [4]Chris O'Brien Lifehouse, Camperdown, Australia; [5]Scientia Clinical Research, Randwick, NSW, Australia; [6]KinDyn Consulting Ltd, Warnham, West Sussex, UK; [7]Princess Margaret Hospital, Toronto, Canada; [8]University of Oxford, Oxford, UK*

Background MDNA11 is an engineered beta-only IL-2 albumin fusion protein with enhanced affinity and signalling via IL2-Rβg (CD122/CD132) and no binding to IL-2Rα (CD25). Consequently, MDNA11 preferentially stimulates immune effector cells to elicit effective tumor regression both, as monotherapy and in combination with immune checkpoint inhibitors in mouse syngeneic cancer models.[1] The ABILITY (**A B**eta-only **IL**-2 **I**mmuno**T**herap**Y**) trial is a first-in-human phase 1/2 study evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamic (PD) effects, and preliminary clinical activity of MDNA11 as monotherapy and in combination with an immune checkpoint inhibitor in patients with advanced solid tumors (NCT05086692).

Methods The ABILITY study comprises a dose-escalation monotherapy phase in a modified 3+3 Q2W design followed by monotherapy and combination expansion at the recommended phase 2 dose (RP2D) in specific-tumor cohorts. Key eligibility criteria are locally advanced or metastatic unresectable solid tumors with no more than 4 prior lines of therapy and measurable disease per RECIST v1.1. Dose levels (DL) 1-3 were administered at a fixed dose of 3, 10 or 30 ug/kg, respectively. A step-up dosing (SUD) strategy was implemented starting at DL4 in which patients received 2 priming doses of 30 ug/kg followed by a target dose of either 60 ug/kg (DL-4) or 90 ug/kg at DL-5 (enrolment initiated).

Results PK analysis showed dose-dependent increase in exposure as anticipated, with no evidence of anti-drug antibodies (ADA) based on consistent PK profile following each of 3 repeat dose administrations. Lymphocyte counts increased with each repeat dose administration and to date, there is no evidence of eosinophilia, associated with vascular leak syndrome (VLS) commonly observed with high dose IL-2. Immune profiling showed several-fold increases in Ki67 expression by peripheral CD8+ T and NK cell without stimulation of immune suppressive Tregs. Accordingly, CD8+ T and NK cell counts increased with each repeat dose (Q2W) of MDNA11 without eliciting any significant increase in Treg number. Increase in activation markers were also noted on CD8+ T cells without elicitation of similar markers on Tregs. Transient increase in some cytokines was observed. Analysis of paired biopsies is underway to examine local changes in the tumor micro-environment.

Conclusions Cumulative PD readouts to date are consistent with the anticipated pharmacological effect of MDNA11 demonstrating dose dependent activation of various biomarkers on effector cells without concomitant stimulation of immune suppression. Updated PK, PD and ADA data will be presented as dose escalation continues.

Acknowledgements We thank the patients participating in the ABILITY study.

744 INTERIM SINGLE-AGENT SAFETY AND ANTI-TUMOR ACTIVITY FROM DOSE ESCALATION PHASE OF ABILITY STUDY ON MDNA11, A LONG-ACTING BETA-ONLY IL-2 AGONIST

[1]Minh To, [1]Fahar Merchant*, [2]Victoria Atkinson, [1]Martin Bexon, [3]Jim Coward, [4]Jenny Lee, [5]Charlotte Lemech, [6]Jesus Antras, [7]Peter Lloyd, [8]Arash Yavari, [1]Melissa Coello, [1]Nina Merchant. *[1]Medicenna Therapeutics, Toronto, Canada; [2]Gallipoli Medical Research Foundation, Woolloongabba, Australia; [3]ICON Cancer Centre, South Brisbane, Australia; [4]Chris O'Brien Lifehouse, Camperdown, Australia; [5]Scientia Clinical Research, Randwick, NSW, Australia; [6]Princess Margaret Hospital, Toronto, Canada; [7]KinDyn Consulting Ltd, Warnham, West Sussex, UK; [8]University of Oxford, Oxford, UK*

Background High dose (HD) IL-2 has shown durable tumor response in a subset of metastatic melanoma and renal cell carcinoma (RCC), but its clinical utility is limited by need for frequent administration, undesirable activation of immune suppressive Tregs, and severe toxicities. MDNA11 is an albumin-fused long-acting engineered IL-2 agonist with enhanced affinity for IL-2Rbg with no binding to IL-2Ra, enabling Q2W administration, limiting Treg activation while potentiating anti-tumor CD8+ T and NK cells and reducing toxicities.[1]

Methods The objective of the dose-escalation phase of the ABILITY (**A** **B**eta-only **IL**-2 **I**mmuno**T**herap**Y**) study is to determine the safety and tolerability, define the recommended phase-2 dose (RP2D), and assess preliminary tumor response of MDNA11 in patients with advanced solid tumors. In this modified 3+3 dose escalation, patients received a fixed dose of 3 (dose level 1 or DL1), 10 (DL2) or 30 (DL3) ug/kg by intravenous (IV) infusion on a Q2W schedule. Step-up dosing (SUD) is implemented starting at DL4 where patients received 2 priming doses at 30 ug/kg (Q2W) prior to escalation to the target dose (Q2W) of 60 ug/kg (DL4) or 90 ug/kg (DL5; enrolling). Primary endpoints include incidence, nature and severity of adverse events (AEs). Secondary endpoints include assessment of pharmacokinetics, pharmacodynamics and tumor response per RECISTv1.1.

Results As of July 21, 2022, 14 patients have been dosed with MDNA11 (DL1 = 1, DL2 = 3, DL3 = 4, DL4 = 6). Tumor types enrolled were melanoma (n=7), RCC (n=1), pancreatic ductal adenocarcinoma (n=2), sarcoma (n=2), squamous cell carcinoma (n=1) and gastro-esophageal adenocarcinoma (n=1). PK analysis showed dose-dependent increase in MDNA11 exposure. MDNA11 has been well tolerated with no dose-limiting toxicities observed at up to DL4. The most common drug-related AEs were infusion related reactions (71%), pyrexia (35%), diarrhea (28%) and nausea (28%), and with a majority of these being Grade 1 or 2 and lasted less than 24 hours. Tumor responses were evaluated in 10 patients and 4 patients had not reached their first assessment. Single-agent activity based on RECISTv1.1 included stable disease (SD) observed in patients with melanoma (n=1), sarcomas (n=2) and pancreatic cancer (n=1).

Conclusions MDNA11 is well tolerated with no DLTs up to target dose of 60 mg/kg (DL4) and enrolment for 90 mg/kg (DL5) has initiated. There is dose-dependent increase in plasma exposure and evidence of single-agent anti-tumor activity in 4 of 10 (SD) patients.

Acknowledgements We would like to thank the patients for participating in the ABILITY study.

745 **IMP-MEL: A PHASE 1 FIRST-IN-HUMAN DOSE-FINDING STUDY OF A NOVEL INVARIANT NATURAL KILLER T-CELL AGONIST (INKT) IMM60 IN ADVANCED MELANOMA AND NON-SMALL-CELL LUNG CANCER (NSCLC)**

[1]Nicholas Coupe, [2]Ian Walters*, [2]Justin Fairchild, [3]Matthew Parkes, [3]David Thompson, [2]Robert Kramer, [3]Uzi Gileadi, [3]Mark Middleton. [1]*Oxford University Hospitals, Oxford, UK*; [2]*Portage BioTech, Westport, CT, USA*; [3]*University of Oxford, Oxford, UK*

Background Invariant natural killer T-cells (iNKTs) share features of innate cells (NK-like) and T-cells. The importance of this relatively rare lymphocyte subset has generated increased interest due to its dual ability to have a direct cytotoxic effect on CD1d-expressing tumors and its ability to induce long-lasting antitumor CD8 T-cell responses mediated by cross priming and licensing of dendritic cells. Various clinical approaches involving the use of allogeneic iNKT cells are in development; here we describe an initial clinical study with IMM60, a synthetically derived agonist of iNKT cells which is formulated in a liposome (PORT-2). In preclinical studies, IMM-60 treatment results in maturation of DCs and B cells and potent stimulation of iNKT cell-derived IFN-g. In efficacy studies, IMM60 demonstrated monotherapy activity in PD-1 resistant models, (e.g., B16-F10), and upregulation of PD-L1 expression on cancer cells as a consequence of its priming effect.

Methods IMP-MEL is an open-label first-in-human phase 1/2 study, currently enrolling adult subjects with advanced NSCLC and melanoma. IMM60-containing liposomes were administered IV Q3W at 3 escalating dose levels for 6 doses. The study seeks to assess the safety and efficacy of IMM-60 alone, as well as in combination with a PD-1 inhibitor. Pharmacodynamic analyses were performed, including circulating cytokines and flow cytometry.

Results Six patients with advanced melanoma (n=3) or NSCLC (n=3) have been enrolled in the monotherapy dose cohorts, having a median of 4.5 prior therapies (min 2, max 5). The drug was well tolerated with no treatment-related SAEs or Grade 3-5 adverse events to date. Cytokine analysis and flow cytometry of pre- and on-study blood samples revealed evidence of iNKT activation as well as NK and dendritic cell activation. [MP1] One patient achieved >50% reduction in select target and non-target lesions. The MTD has not been reached.

Conclusions This trial provides early proof of concept for using a small molecule iNKT agonist to promote both innate and adaptive immune responses. PORT-2 (liposomal IMM60) is well tolerated at 1 and 3 mg/m^2. Pharmacodynamic measurements support a broad immune mechanism. Once the Phase 2 dose is defined the trial is designed to accrue six Phase 2 arms testing PORT-2 alone or combined with a PD-1 inhibitor, compared to PD-1 inhibitor monotherapy. Further data on pharmacokinetics and biopsy analyses will be presented.

Ethics Approval This University of Oxford study has received ethical approval by a UK Research Ethics Committee, approval number 20/SC/0367. All participants provided informed consent before taking part in this clinical trial.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0745

746 **AFM24 AND ATEZOLIZUMAB COMBINATION IN PATIENTS WITH ADVANCED EPIDERMAL GROWTH FACTOR RECEPTOR-EXPRESSING (EGFR$^+$) SOLID TUMORS: INITIAL RESULTS FROM THE PHASE 1 DOSE-ESCALATION STUDY**

[1]Omar Saavedra Santa Gadea*, [2]Daniela Morales-Espinosa, [3]Juanita Lopez, [4]Eric Christenson, [5]Anthony El-Khoueiry, [6]Andrés Cervantes, [2]Christa Raab, [2]Ulrike Gärtner, [2]Kerstin Pietzko, [2]Laura Kohlhas, [2]Daniel Schütz, [2]Gabriele Hintzen, [2]Paulien Ravenstijn, [2]Michael Emig, [7]Pilar Nava-Parada. *[1]Vall D'Hebron University Hospital, Barcelona, Spain; [2]Affimed GmbH, Heidelberg, Germany; [3]Royal Marsden Hospital, London, UK; [4]John Hopkins University Hospital, Baltimore, MD, USA; [5]University of Southern California, Los Angeles, CA, USA; [6]Hospital Clínico, University of Valencia, Valencia, Spain; [7]Affimed Inc., New York, NY, USA*

Background AFM24 is an innate cell engager binding EGFR on tumor cells, and CD16A on natural killer cells and macrophages; AFM24 activates and redirects these cells to EGFR$^+$ tumors to enhance antibody-dependent cellular cytotoxicity and antibody-dependent phagocytosis, respectively. Atezolizumab, a PD-L1 inhibitor, has been approved in patients with solid tumors. Combining AFM24 with atezolizumab may synergistically enhance the innate and adaptive immune responses, respectively, to target EGFR$^+$ tumors.

Methods AFM24-102 (NCT05109442) is a Phase 1/2a open-label, non-randomized, multicenter, dose escalation, and expansion study evaluating AFM24 in combination with atezolizumab in patients with selected EGFR$^+$ advanced solid malignancies whose disease has progressed after treatment with previous anticancer therapies. Phase 1 will follow a 3+3 design to establish the maximum tolerated dose or recommended phase 2 dose of AFM24; patients will receive AFM24 IV QW at an escalating dose per cohort and 840 mg atezolizumab IV once fortnightly in a 4–week cycle until disease progression, intolerable toxicity, termination by the investigator, or patient withdrawal. Secondary endpoints include pharmacokinetic, pharmacodynamic, and immunogenicity analysis. A starting dose of 160 mg QW of AFM24 was selected based on data from an ongoing Phase 1/2a first–in–human trial of AFM24 monotherapy.

Results Four patients have been enrolled in the first dose cohort, with three completing the safety lead-in phase and receiving 160 mg AFM24 and atezolizumab. Patients are female with gastric (n=1) or pancreatic (n=3) adenocarcinomas (median [range] age was 60 years [50–73], number of prior therapies was 3.5 [3–4], with 90% EGFR expression [70–100%] by immunohistochemistry). All patients have European Cooperative Oncology Group scores of 0–1. Adverse events (AEs) (n≥2) included lymphopenia, anemia, neutropenia, and infusion-related reactions. No dose-limiting toxicities (DLTs) occurred. Serious AEs likely related to AFM24 treatment were one Grade 2 IRR and one Grade 1 medication error. In the patient with gastric cancer and skin metastases, who had rapidly progressed following four prior lines of therapy, including a PD-L1 inhibitor, an ongoing partial response has been confirmed after two cycles of AFM24 treatment. A still ongoing stable disease of 4+ months and symptomatic improvement has been observed in a patient with pancreatic adenocarcinoma that had rapid disease progression after three lines of previous therapy.

Conclusions AFM24 at 160 mg in combination with atezolizumab was adequately tolerated. No DLTs were reported. Clinical activity was observed in two patients. Dose escalation is proceeding at 480 mg and enrollment has begun.

747

A PHASE 1 TRIAL OF IO-202, AN ANTAGONIST ANTIBODY TARGETING MYELOID CHECKPOINT LILRB4 (ILT3), AS MONOTHERAPY AND IN COMBINATION WITH PEMBROLIZUMAB IN ADULT PATIENTS WITH ADVANCED RELAPSED OR REFRACTORY SOLID TUMORS

[1]Aung Naing, [2]John Powderly, [3]Meredith Pelster, [4]Alexander Spira, [5]Reva Schneider, [6]Paul Woodard, [6]Luke Chung, [6]Elizabeth Wieland, [6]Sydney Ray, [6]Kyu Hong, [6]Tao Huang, [6]X Charlene Liao, [6]Hong Xiang, [7]Heinz-Josef Lenz, [6]Wen Hong Lin*. *[1]MD Anderson Cancer Center, Houston, TX, USA; [2]Carolina BioOncology Institute, Huntersville, NC, USA; [3]Sarah Cannon Research Institute at Tennessee Oncology, Nashville, TN, USA; [4]Virginia Cancer Specialists, Fairfax, VA, USA; [5]Mary Crowley Cancer Institute, Dallas, TX, USA; [6]Immune-Onc, Palo Alto, CA, USA; [7]USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA*

Background Most patients with advanced solid tumors relapse after T-cell checkpoint blockade despite of immunotherapy becoming the mainstream with the approvals of T-cell checkpoint inhibitors. Myeloid checkpoint inhibition is a new approach to immunotherapy.

Leukocyte immunoglobulin-like receptor subfamily B member 4 (LILRB4) is a myeloid checkpoint with its expression restricted to monocytes or monocyte-derived cells[1,2,3] and in normal antigen presenting cells. LILRB4 functions as a negative regulator of immunity through interaction with its ligands, apolipoprotein E and fibronectin[1,2,4,5,6]. Blockade of LILRB4 has the potential to enhance anti-tumor T cell activities.

IO-202 is a IgG1 monoclonal antibody that binds to LILRB4 to block ligand interactions and inhibits the function of LILRB4. In vitro, IO-202 treatment of immune cells increases pro-inflammatory responses and enhances antigen presenting cell phenotypes. IO-202 has been studied at a first-in-human, phase1 study in acute myeloid leukemia and chronic myelomonocytic leukemia patients (IO-202-CL-001) up to 30 mg/kg IV Q2W with no observed dose limiting toxicity (DLT), which provided sufficient data supporting the starting dose of 250 mg.

Methods This trial (NCT05309187) is a Phase 1, dose-escalation, dose-expansion, safety, and pharmacokinetic (PK) evaluation of IO-202 alone and plus pembrolizumab in patients with advanced solid tumors. Up to 36 patients will be enrolled in the dose-escalation portion (Part 1) and up to 168 patients will be enrolled in the dose-expansion portion (Part 2). IO-202 will be administered IV Q3W, with a 21-day DLT evaluation period. In Part 1, patients will be treated with increasing doses of IO-202 alone and plus pembrolizumab using the modified Toxicity Probability Interval method; the combination cohorts will start once the 1st monotherapy dose has cleared the DLT window and be conducted independently. In Part 2, patients will be treated with IO-202 RP2D plus pembrolizumab 200 mg IV Q3W.

The primary objective is to assess safety and tolerability of IO-202 alone and plus pembrolizumab in patients with advanced solid tumors, to estimate the maximal tolerated dose or maximum administered dose and select the recommended phase 2 dose (RP2D). Secondary objectives include characterizing PK for IO-202 alone or plus pembrolizumab; and assessing efficacy of IO-202 plus pembrolizumab in various solid tumors. Biomarker evaluation includes changes in immune cell markers, LILRB4 expression and receptor occupancy.

Statistical analyses will be descriptive. Tabulations will be produced for appropriate disposition, demographics, baseline characteristics, safety, PK, pharmacodynamic, and clinical activity parameters. To date, one patient has been treated with IO-202 without DLT.

Trial Registration NCT05309187

748 **A PHASE 1/2, OPEN-LABEL, DOSE-ESCALATION, SAFETY AND TOLERABILITY STUDY OF NC762 IN SUBJECTS WITH ADVANCED OR METASTATIC SOLID TUMORS**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0748

[1]Han Myint, [2]Satish Shah*, [3]Martin Gutierrez, [4]Emese Zsiros, [5]Megan Nelson, [5]Stephanie Zeidan, [5]Nadia Myrthil, [5]Aaron Morawski, [5]Alina Barbu, [5]Jahangheer Shaik, [5]Chelsea Zhou, [5]Chrysi Kanellopoulou, [5]Ron Copeland, [5]Zachary Cusumano, [5]Dallas Flies, [5]Solomon Langermann, [6]Patricia Lorusso, [7]Kunle Odunsi. *[1]NextCure Inc, Beltsville, MD, USA; [2]Pennsylvania Cancer Specialists, Gettysburg, PA, USA; [3]John Theurer Cancer Center, Hackensack, NJ, USA; [4]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [5]NextCure, beltsville, MD, USA; [6]Yale Cancer Center, New Haven, CT, USA; [7]UFC Comprehensive Cancer Center, Chicago, IL, USA*

Background NC762 is a humanized IgG1κ monoclonal antibody that targets human B7-H4 (B7 homolog 4), a transmembrane protein, associated with the B7 family of molecules known for their immunomodulatory functions. While limited expression is observed on healthy tissue, B7-H4 is commonly expressed by several tumor types including ovarian, lung, renal, melanoma, prostate, pancreatic, and breast cancers and is often correlated with poor clinical outcome. Given differential expression of B7-H4 in healthy and cancerous tissue, B7-H4 presents itself as an attractive candidate for a targeted therapeutic monoclonal antibody (mAb) for oncology.

Preclinical data demonstrated that binding of NC762 to tumors expressing B7-H4 results in inhibition of tumor growth in vivo. The inhibitory effect on tumor growth is not dependent upon T cells and does not appear to be a predominant antibody-dependent cellular cytotoxicity (ADCC) mechanism. However, NC762 has been Fc engineered to enhance binding to CD16a and does demonstrate increased anti-tumor activity in the presence of NK cells.

Methods This is a multi-center, first in human, phase 1/2, open-label, single-armed study to determine the safety and tolerability, MTD, and pharmacologically active dose for NC762, as well as to assess preliminary efficacy, and explore predictive and pharmacodynamic biomarkers in subjects with advanced or metastatic solid tumors. The 3+3 dose escalation design in 5 cohorts is to establish recommended phase 2 dose (RP2D) (NCT04875806). Phase 1b and 2 study will select for patients expressing B7-H4+ in specific tumor types including ovarian.

Results As of 07/20/2022, a total of 14 patients (Median age 69; 5F, 9M) with 5 tumor types, have been enrolled, treated, and completed the DLT period. Median line of prior therapies was six. NC762 (up to 10mg/kg), was well tolerated, with no safety concerns, no infusion-related toxicities, nor any reported DLT. Clinical benefit is seen from the lowest dose cohorts with a few stable diseases beyond six months. PK and potential pharmacodynamic biomarkers continue to be evaluated as the phase 1 study continues to enroll and will be presented.

Conclusions Preliminary evaluation of NC762 in subjects with advanced or metastatic solid tumors appears to be safe and well-tolerated. Further evaluation will be performed with the final cohort at 20mg/kg and simultaneous expansion of 10mg/kg in B7-H4+ advanced solid tumors to confirm these initial findings.

Trial Registration NCT04875806

Ethics Approval This study has been approved by the IRB of all the participating institutions, and all participants have given informed consent before taking part in the study.

Consent Written informed consent was obtained from the patient for publication of this abstract and any accompanying images. A copy of the written consent is available for review by the Editor of this journal.

749 USE OF POSITRON EMISSION TOMOGRAPHY FOR THE DIAGNOSIS OF IMMUNE CHECKPOINT INHIBITOR MYOCARDITIS

Nicolas Palaskas*, Yang Lu, Rebecca Caldwell, Praise Oderinde, Gaspar Pina, Abdelrahman Ali, Khatera Shah, Cezar Iliescu, Syed Wamique Yusuf, Efstratios Koutroumpakis, Shaden Khalaf, Ihab Hamzeh, Bilal Siddiqui, Sumit Subudhi, Anita Deswal. *The University of Texas MD Anderson Cancer Center, Houston, TX, USA*

Background Myocarditis from immune checkpoint inhibitor (ICI) therapy has a reported mortality of 25 to 50%.[1] The gold standard for myocarditis diagnosis is endomyocardial biopsy (EMB).[1] The feasibility and diagnostic accuracy of fluorodeoxyglucose positron emission tomography (FDG PET) computed tomography (CT) has not been extensively evaluated compared to EMB in ICI myocarditis.

Methods This was a prospective observational study conducted at MD Anderson Cancer Center between March 2021 and May 2022. Patients were eligible if age $\geq$ 18 years, ICI was administered in single or combination therapy, and there was clinical or diagnostic suspicion of myocarditis. All patients had an EMB with at least 4 samples of the right ventricular septal wall. Prior to imaging with FDG PET CT, patients followed a 72-hour low carbohydrate, high fat diet. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of FDG PET CT were calculated.

Results There were 10 patients enrolled with FDG PET CT performed. The demographics were 68.9 years (median), 70% male, 70% Caucasian and 30% Hispanic. The most common malignancies were genitourinary (30%), melanoma (30%), lung (20%), liver (10%), and papillary thyroid (10%). The ICI use was 40% programmed cell death 1 (PD-1) inhibitor, 30% programmed cell death ligand 1 (PD-L1) inhibitor, and 30% combination PD-1 and cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) inhibition. The sensitivity of FDG PET CT was 75%, specificity 67%, PPV 60%, and NPV 80% (table 1). The time from admission to imaging with FDG PET CT was median 11 days. The time from admission to EMB was median 1 day. Reasons for delay in FDG PET CT included plasmapheresis being administered with glucose infusion (50%), inability to adhere to dietary protocol (20%), and clinical instability (20%) for imaging. One of the three patients EMB and FDG PET CT positive for ICI myocarditis had imaging uptake in the septal wall. Two patients FDG PET CT positive and EMB negative had imaging uptake in the lateral left ventricular wall and apex. Two of the FDG PET CT noted skeletal muscle FDG avidity and these patients had concomitant myositis.

Conclusions The feasibility of performing FDG PET CT is limited due to the use of plasmapheresis and the dietary protocol necessary for imaging. There is reasonable sensitivity and specificity for FDG PET CT in ICI myocarditis. There may be a role for identification of concomitant immune related adverse events also with the diagnosis of myositis.

750 **TWT-101: A FIRST-IN-CLINIC, PHASE 1/2 STUDY OF CFI-402411, A HEMATOPOIETIC PROGENITOR KINASE-1 (HPK1) INHIBITOR, AS A SINGLE AGENT AND IN COMBINATION WITH PEMBROLIZUMAB IN SUBJECTS WITH ADVANCED SOLID MALIGNANCIES**

[1]Kyriakos Papadopoulos, [2]Siqing Fu, [3]Erika Hamilton, [4]Alexander Spira, [5]Scott Laurie, [6]Judy Wang, [7]Brigette Ma, [8]Anna Spreafico, [9]Manish Sharma, [10]Quincy Chu, [11]Mark Bray, [11]Glenn Michelson, [11]Dih-Yih Chen, [11]Linh Nguyen, [11]Emily Roberts-Thomson, [12]Omid Hamid*. *[1]START, San Antonio, San Antonio, TX, USA; [2]MD Anderson Cancer Center, Houston, TX, USA; [3]SCRI/Tennessee Oncology, Nashville, TN, USA; [4]Virginia Cancer Specialists, Fairfax, VA, USA; [5]The Ottawa Hospital Cancer Center, Ottawa, Canada; [6]Florida Cancer Specialists/SCRI, Sarasota, FL, USA; [7]The Chinese University of Hong Kong, Sha Tin, Hong Kong; [8]Princess Margaret Cancer Centre, Toronto, Canada; [9]START Midwest, Grand Rapids, MI, USA; [10]Cross Cancer Institute, Edmonton, Canada; [11]Treadwell Therapeutics, Toronto, Canada; [12]The Angeles Clinic and Research Inst., Los Angeles, CA, USA*

Background CFI-402411 is a potent inhibitor of HPK1 (**H**ematopoietic **p**rogenitor **k**inase 1), a protein serine/threonine kinase that negatively-regulates T-cell activation. Following T-cell receptor engagement, HPK1 phosphorylates SLP-76, to down-regulate signals required for T-cell activation and proliferation[1,2]. CFI-402411 is expected to relieve HPK1-mediated inhibition of T-cell activation, facilitating an anti-tumor immune response.

Methods In this ongoing phase 1 study, part A evaluates CFI-402411 daily dose in dose escalation cohort (3+3 design) and dose expansion, part B evaluates CFI-402411 in combination with pembrolizumab in dose escalation (BOIN design) and dose expansion in pembrolizumab eligible tumors. Dose limiting toxicity (DLT) is any grade ≥3 toxicity in the first cycle of therapy (21d cycles). Starting dose was 80mg.

Results As of 14 May 2022 (data cutoff), 25 and 9 patients (pts) enrolled to A and B respectively. Median age was 62 (30-79). Median cycles of treatment were 3 (range: 0-20). Majority of patients were male (A, 60% and B, 78%). Median prior regimens were 2 (range: A, 1-4; B, 1-3). 6pts (A, 24%) and 5pts (B, 56%) received prior anti-PD-1/anti-PD-L1 inhibitor. Diagnoses in ≥2pts for A: colorectal (6pts), pancreatic (5pts); for B: small cell lung cancer (2pts). 8 dose levels (80 to 800 mg) have been studied in A, 2 dose levels (60 and 80 mg) in B. TEAEs occurring in ≥40% of A pts: diarrhea (n=17, 68%), nausea (n=11, 44%), decreased appetite (n=10, 40%); and B: vomiting (n=4, 44%). 19pts (76%) in A and 6pts (67%) in B experienced CFI-402411 related AEs. Immune-related AEs were reported in 1pt (A; 4% [ALT and AST increase]) and 2pts (B; 22% [febrile illness, flu-like symptoms]). Grade ≥3 AEs and serious AEs occurred in 14pts (56%) and 10pts (40%) in A; and 3pts (33%) and 4pts (44%) in B. DLTs occurred in 2pts (A [800mg]: diarrhea, spinal cord compression) and 1pt (B [80mg+pembro]: flu-like symptoms). No novel toxicity signals were seen. Disease control rates were 24% in A (6/25) and 44% in B (4/9). One B patient (11%), squamous head and neck cancer (H&N) previously treated with pembrolizumab, has confirmed partial response (PR) and remains on treatment, 8 cycles. An additional H&N patient treated with monotherapy CFI-402411 achieved unconfirmed PR after data cut.

Conclusions CFI-402411 is a well-tolerated, potent inhibitor of HPK1 with a manageable AE profile and initial evidence of activity. RP2D and additional safety and efficacy data will be reported at conference presentation.

Acknowledgements Treadwell Therapeutics would like to thank both the patients and the research staff at enrolling centers who have helped to bring this novel therapy to the clinic.

751 PMC-309, A HIGHLY SELECTIVE ANTI-VISTA ANTIBODY REVERSES IMMUNOSUPPRESSIVE TME TO IMMUNE-SUPPORTIVE TME

Cheon Ho Park, Sang Soon Byun*, Ki Dae Kim*, Hye Rim Han*, Weon Sup Lee. *PharAbcine Inc., Daejeon, Korea, Republic of*

Background The tumor microenvironment (TME) consists of blood & lymphatic vessels, stromal cells, and immune cells such as lymphocytes, macrophages, and APC cells. V-domain immunoglobulin suppressor of T cell activation (VISTA) is highly expressed in myeloid-derived cells and its blockade enhances antitumor immunity in multiple tumor models. Therefore, anti-VISTA agents may provide additional cancer immunotherapy and may work synergistically with PD1/PDL1 targeting drugs.

Methods Target cell analysis: human peripheral blood mononuclear cells (PBMC) containing lymphocyte and myeloid lineage cells were used for target cell analysis with flow cytometry.

T cell activity (ex vivo): human PBMC was employed for the evaluation of T cell activity (IRB #1041107-201703-BR-002-02) and CD3+ T cells and CD14+ monocytes were isolated from human PBMC and co-cultured in a 2.5 mg/ml anti-CD3 antibody-coated plate for 6 days in the presence of PMC-309 or other drugs. Culture media were harvested and evaluated the secreted levels of IFN-γ by ELISA.

MDSC suppression activity (ex vivo): MDSCs cells (5x10^4 cells) were cultured with CD3+ T cells (2x10^5 cells) in the presence of anti-CD3/28 bead with 10, 30, 100 μg/ml of PMC-309, or 100 μg/ml of anti-PD1, anti-PDL1, and anti-CTLA4 and for 3 days. IFN-g production was measured by ELISA.

In vivo study: MC38 bearing human VISTA knock-in (KI) mice were employed for the assessment of anti-tumor activity of PMC-309.

The tumor infiltrated immune cells: Immune cells in the TME were evaluated by immunohistochemistry (IHC) or flow cytometry (FACS) analysis.

Results PMC-309 binding to VISTA expressing cells is highly selective and the selectivity is maintained even in the low pH conditions that mimic TME. PMC-309 enhances the secretion of IFN-gamma, TNF-alpha, and IL-2 in T cell and monocyte co-culture settings. In addition, PMC-309 promoted monocyte differentiation into M1 macrophage that stimulates proinflammatory cytokine secretion of T cells. For the in vivo study, PMC-309 was intravenously administrated in VISTA-KI mice. The tumor growth rate was suppressed accompanied by a synergistic effect with an anti-PD1 antibody. The anti-tumor activity was associated with enhanced T cell activation, increased secretion of pro-inflammatory cytokines, and increased penetration of cytotoxic T cells, but lowing immune-suppressive MDSC cells into TME as demonstrated with IHC analysis.

Conclusions PMC-309 increased the number of T cell infiltration while a decrease of MDSCs in the TME. PMC-309 in combination with chemotherapy or other IO drugs could address highly medical unmet needs from patients with drug resistance to currently available IO treatment options.

753

A PHASE 1B/2 STUDY OF A NOVEL ANTI-CTLA-4 NEOBODY™ ADG116 MONOTHERAPY AND IN COMBINATION WITH TORIPALIMAB (TORI; ANTI-PD-1 ANTIBODY) IN PATIENTS WITH ADVANCED/METASTATIC SOLID TUMORS

[1]John Park, [2]Matthew Hsien, [3]Gary Richardson, [4]Anthony Tolcher, [5]Hong Jae Chon, [6]Sang Joon Shin, [7]Ho Yeong Lim, [3]Anis Hamid, [8]Daneng Li, [9]Kristine Shi, [9]Songmao Zheng, [9]Guizhong Liu, [9]Ai Li, [9]Lvyu Zhu, [9]Ruby Dai, [9]Wei Peng, [9]Dana Lowe, [9]Peter Luo, [9]Jiping Zha*. *[1]Macquarie University, Sydney, Australia; [2]National Cancer Centre, Singapore, Hospital Crescent, Singapore; [3]Cabrini Health, Melbourne, Australia; [4]Next Oncology, San Antonio, TX, USA; [5]CHA Bundang Medical Center, Seoul, Korea, Republic of; [6]Severance Hospital, Yonsei University, Seoul, Kosovo, Republic of; [7]Samsung Medical Center, Seoul, Korea, Republic of; [8]City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [9]Adagene, San Diego, CA, USA*

Background The anti-CTLA-4 immuno-oncology therapy (IO) is limited in clinical efficacy due to its on-target toxicities. ADG116 is a fully human IgG1 monoclonal antibody that targets a unique and highly conserved epitope of CTLA-4. ADG116 enables a controlled T cell activation via partial CD80/86 ligand blockade and promotes strong Treg depletion in the tumor microenvironment via enhanced ADCC. In preclinical studies, ADG116 has been shown to be more potent and better tolerated than ipilimumab. We believe ADG116 can offer a better therapeutic window for this class of molecules, especially when combined with anti-PD-1 therapies.

Methods ADG116 monotherapy [10 dose levels from 0.003 to 15 mg/kg (mpk)] and ADG116 (3 or 6 mpk) plus Tori (240 mg) combination therapy were administered Q3W intravenously. The primary endpoints are safety and tolerability; the secondary endpoints are PK, ORR per RECIST 1.1, and PFS.

Results As of July 14, 2022, 45 patients (pts) were treated with ADG116 monotherapy, among which 3, 4, 6, 18, and 3 pts received 1, 3, 6, 10, and 15 mpk dose, respectively. The median age was 62; 62% received $\geq$3 prior lines of therapies, and 31% progressed after prior IO therapies. Only 1 DLT [Grade (G) 4 hyperglycemia] was observed (10 mpk), and MTD was not reached. Only 3 pts showed G3 or above treatment-related AEs (TRAEs); common TRAEs (>10%) consisted of diarrhea, pruritis, and fatigue. Disease control rate is 35% across doses of ^{3} 1 mg/kg (range 30-80%). An initial partial response was observed from a patient with Kaposi's sarcoma (15 mpk). Dose expansion is ongoing at 10 mpk.

Nine pts received ADG116/Tori combination therapy. The median age was 59; 11% received > 3 prior lines of therapies, and none had prior IO therapies. At 6 mpk ADG116/Tori, two pts developed DLTs (2/3; G3 myocarditis & G3 diarrhea). At 3 mpk ADG116/Tori, 1 DLT (1/6, G3 diarrhea) was observed, and five pts are still on treatment (2-5 cycles). One pt with recurrent platinum-refractory HNSCC has a confirmed complete response (CR) and is still on the study (cycle 5). Detailed safety and efficacy data from this study will be reported.

Conclusions ADG116 monotherapy has cleared multiple dose levels including 15 mpk, a dose higher than any reported anti-CTLA-4 class agents in the repeat dose setting. ADG116 (3 mpk)/Tori (240mg) Q3W continuous dosing showed a manageable safety profile and encouraging efficacy including CR, supporting its further clinical evaluation.

754 A PHASE 1/2 STUDY OF ASP1570 IN PARTICIPANTS WITH LOCALLY ADVANCED OR METASTATIC SOLID TUMORS WHO HAVE PROGRESSED ON, OR ARE INELIGIBLE FOR, ALL AVAILABLE STANDARD THERAPIES

[1]Manish Patel*, [2]David Park, [3]Stefano Tarantolo, [4]Afshin Dowlati, [5]Daniel Olson, [6]Yuichiro Kaneko, [7]Mei Tang, [7]Serguei Soukharev, [6]Masaomi Takizawa, [6]Yohei Okada, [7]Christine Fredericks, [7]Derek Smith, [7]Teresa Flegel, [7]Tsubasa Watanabe, [7]Sue Lee, [8]Jason Luke. [1]*Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL, USA*; [2]*St Jude Crosson Cancer Institute, Fullerton, CA, USA*; [3]*Midwest Cancer Center, Omaha, NE, USA*; [4]*University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH, USA*; [5]*University of Chicago Comprehensive Cancer Center, Chicago, IL, USA*; [6]*Astellas Pharma, Inc., Northbrook, IL, USA*; [7]*Astellas Pharma Global Development, Inc., Northbrook, IL, USA*; [8]*UPMC Hillman Cancer Center, Pittsburgh, PA, USA*

Background Cancer immunotherapies target immune checkpoints and have been transformative in the treatment practices of oncology. However, only a subset of all patients in most cancer types effectively respond to these therapies. It has been established that approximately 60% to 70% of patients who receive anti–programmed cell death protein-1 (anti–PD-1) or anti-cytotoxic T-lymphocyte–associated antigen 4 (CTLA4) do not respond to treatment.[1] Furthermore, acquired resistance is common, causing some patients who initially responded to the therapy to later experience disease progression. Therefore, there is a significant opportunity for immunotherapy expansion in cancer treatment.

Diacylglycerol kinase (DGK) is a large enzyme family of 10 mammalian isoenzymes that catalyzes the conversion of diacylglycerol (DAG) to phosphatidic acid (PA). In T cells, DGK (such as DGKζ) inhibits DAG-mediated signals following T-cell receptor engagement by catalyzing the conversion of DAG to PA.[2] Even when PD-1 is blocked by anti–PD-1 antibodies, there may be partial inactivation by DGK. Therefore, DGK inhibitors have the potential to enhance DAG downstream signaling, leading to T-cell activation regardless of the PD-1 signal. ASP1570 is a novel inhibitor against DGKζ and has the potential to enhance DAG downstream signaling which can activate T cells regardless of PD-1 signaling and lead to tumor killing. ASP1570 restored T-cell functions suppressed by multiple immunosuppressive signals (PD-1, transforming growth factor beta, prostaglandin E2, and adenosine) and induced tumor growth inhibition in mice models of MC38 (anti-PD1 sensitive) and B16-F1 (tumor-infiltrating lymphocyte poor, anti–PD-1 insensitive). Taken together, ASP1570 treatment as a single agent and/or in combination with anti–PD-1 therapy for locally advanced or metastatic solid tumors may result in clinical benefit.

Methods This is a phase 1/2, open-label, multicenter, multiple-dose, dose-escalation/expansion study of ASP1570 in participants with locally advanced or metastatic solid tumors. The study will enroll approximately 168 participants into 2 phases, dose escalation and dose expansion, to assess safety, tolerability, efficacy, pharmacokinetics, and pharmacodynamics (figure 1). The study will consist of the following periods: screening, treatment with ASP1570 daily oral dosing in 21-day cycles, end of treatment, follow-up (safety and survival follow-up), and end of study (figure 2). The study is open for enrollment.

Background FT500, an allogeneic natural killer (NK) cell cancer immunotherapy derived from a clonal induced pluripotent stem cell (iPSC) line, is available off-the-shelf for on-demand administration to patients in multi-dose regimens. In preclinical studies, FT500 has been shown to recruit and activate T cells, increasing response to checkpoint inhibition for enhanced inflammatory cytokine production and tumor elimination. We report results from a Phase I clinical trial of patients with classical Hodgkin lymphoma (cHL) or non-small cell lung cancer (NSCLC) who were relapsed/refractory to prior anti-PD-1/L1 immune-checkpoint inhibitor (ICI) therapy and received FT500 combined with ICI therapy and IL-2.

Methods Treatment consisted of 2 days of outpatient conditioning chemotherapy (cyclophosphamide 300 mg/m^2 and fludarabine 25 mg/m^2), followed by two 29-day cycles of 3 once–weekly doses of 300 million FT500 cells/dose with subcutaneous IL-2 (6 MIU), and nivolumab, pembrolizumab, or atezolizumab administered at standard dose and schedule. Key endpoints included safety, tolerability, and anti-tumor activity.

Results As of 09 May 2022 data cutoff, 5 patients with cHL and 7 patients with NSCLC, with a median of 10 and 3 prior therapies, respectively, were treated. No events of cytokine release syndrome, neurotoxicity, or graft-versus-host disease were observed. Most common treatment-emergent adverse events (AEs) included lymphopenia and anemia. No FT500-related serious AEs were reported; only 1 Grade $\geq$3 FT500-related AE of lymphopenia was reported. For cHL, objective response by RECIL was reported in 4 patients (1 complete, 1 partial, 2 minor), with median peak tumor burden reduction of 24.9% (range 10.2, 72.4) and median response through 7.9 months (range 4.1, 12.0) from initiation of treatment, including an ongoing complete response subsequently lost to follow-up at 8.7 months. For NSCLC, tumor burden reduction was observed in 3 patients, with median peak reduction of 9.8% (range 6.3, 40); 1 patient refractory to 2 prior ICI-containing regimens had an ongoing partial response by iRECIST through 12.6 months from initiation of treatment, and 3 had stable disease with median duration of disease control of 7.7 months (range 3.4, 8.6).

Conclusions Six doses of 300 million FT500 cells with IL-2 and concurrent ICI therapy is safe and tolerable, with evidence of durable anti-tumor activity observed in heavily pretreated patients resistant to anti-PD1/L1 therapy. These results support the development of next-generation iPSC-derived NK cells engineered with synthetic functional elements designed to synergize with ICI therapy and enhance anti-tumor activity in solid tumors.

Ethics Approval This study is being conducted in accordance with the Declaration of Helsinki and was approved by all Institutional Review Boards from each clinical site participating in the study. Specific approval numbers can be provided upon request.

756 INCLINE-101, A PHASE 1/2, OPEN LABEL, DOSE ESCALATION AND EXPANSION STUDY OF TAC-001 (A TLR9 AGONIST CONJUGATED TO A CD22 ANTIBODY) IN PATIENTS WITH SELECT ADVANCED OR METASTATIC SOLID TUMORS

[1]Cesar Perez*, [2]Jason Henry, [3]Timothy Humphries, [4]Sunnie Kim, [5]Adi Diab, [6]Ons Harrabi, [6]Feng Jin, [6]Hong Wan, [6]Candy Bermingham, [7]Anthony El-Khoueiry. *[1]SCRI at Florida Cancer Specialists, Lake Nona, FL, USA; [2]SCRI at HealthONE, Denver, CO, USA; [3]Linear Clinical Research Ltd, Nedlands, WA, 6009, Australia; [4]University of Colorado Cancer Center, Aurora, CO, USA; [5]MD Anderson Cancer Center, Houston, TX, USA; [6]Tallac Therapeutics, Burlingame, CA, USA; [7]Norris Comprehensive Cancer Center, USC, Los Angeles, CA, USA*

Background Enrichment of memory B cells, plasma cells and tertiary lymphoid structure is a positive prognostic factor in patients with a variety of solid tumors.[1-3] Toll-like receptor 9 (TLR9) agonists generate both innate and adaptive immune responses. TLR9 activation in B cells has been shown to induce expression of co-stimulatory molecules, enhanced cross-presentation leading to T cell activation and proliferation, cytokine, chemokine and immunoglobulin secretion. Designed for systemic administration, TAC-001 is a Toll-like Receptor Agonist Antibody Conjugate (TRAAC) comprised of a potent and differentiated TLR9 agonist (T-CpG) conjugated to an antibody against CD22, a receptor restricted to B cells, including tumor-infiltrating B cells. In preclinical models, TAC-001 has demonstrated single agent anti-tumor activity in checkpoint inhibitor resistant and refractory tumor models, accompanied by increased B cell infiltration, T cell effector functions and modulation of suppressive myeloid cells within the tumor microenvironment.[4] INCLINE-101 is a Phase 1/2 study designed to evaluate the safety, efficacy, pharmacokinetics (PK) and biomarkers of TAC-001 in patients with select advanced or metastatic solid tumors.

Methods TAC-001 is being evaluated in an open-label, non-randomized, dose-escalation (Phase 1) study in patients with select advanced or metastatic solid tumors, and dose-expansion (Phase 2) in patients with select tumor types (NCT05399654). Eligible patients in Phase 1 must have histologically or cytologically-documented advanced, metastatic, unresectable or recurrent breast cancer, cervical squamous cell carcinoma, cholangiocarcinoma, colorectal carcinoma, cutaneous melanoma, endometrial carcinoma, gastro-esophageal adenocarcinoma, head and neck squamous cell carcinoma, hepatocellular carcinoma, Merkle cell carcinoma, non-small cell lung cancer, ovarian cancer, renal cell carcinoma, or urothelial carcinoma that have progressed on or are intolerant to standard therapy, including checkpoint inhibitor therapy if appropriate. Phase 1 study will explore ascending dose levels of TAC-001 monotherapy administrated intravenously every 2 weeks and utilize the Bayesian Optimal Interval (BOIN) design in order to identify the maximum tolerated dose (MTD) or maximum administered dose (MAD), and recommended Phase 2 dose (RP2D). Once RP2D is determined, the Phase 2 expansion in four specific tumor-type cohorts is planned. A 2-stage design will be utilized for Phase 2, and the Clopper-Pearson method to compute exact confidence limits for the response rates will be employed. The primary endpoints are safety and preliminary efficacy (overall response rate, duration of response, clinical benefit rate) per RECIST v1.1 and iRECIST. Additional endpoints include PK, immunogenicity, progression free survival, overall survival, and changes in relevant biomarkers. INCLINE-101 is enrolling in the USA and Australia.

Trial Registration NCT05399654

757 A PHASE 1/1B DOSE ESCALATION AND COHORT EXPANSION STUDY OF MGC018 IN COMBINATION WITH LORIGERLIMAB IN PATIENTS WITH ADVANCED SOLID TUMORS (AST)

[1]John Powderly*, [2]Patrick Kaminker, [2]Enxu Zhao, [2]Denise Casey, [3]Eugene Shenderov. *[1]Carolina BioOncology Institute, Huntersville, NC, USA; [2]MacroGenics, Inc., Rockville, MD, USA; [3]Johns Hopkins Medicine, Baltimore, MD, USA*

Background The immune checkpoint molecule B7-homolog 3 (B7-H3) is highly expressed in multiple solid tumors with limited expression in normal tissue, may play an immune suppressive role, and favors cancer growth. MGC018 is an investigational anti–B7-H3 IgG1 antibody-drug conjugate with a duocarmycin-based DNA-alkylating payload that can damage DNA in both dividing and nondividing cells, causing cell death.[1] As previously presented, Phase 1 testing of single-agent MGC018 (NCT03729596) demonstrated an acceptable safety profile with manageable toxicity in 115 patients and 25% objective response rate (ORR) among 32 evaluable patients in the NSCLC and mCRPC cohorts.[2,3] Lorigerlimab is an investigational bispecific, Fc-bearing (IgG4) DART® molecule that blocks PD-1 with enhanced CTLA-4 blockade on dual PD-1/CTLA-4–expressing tumor-infiltrating lymphocytes within the tumor microenvironment, and reduced CTLA-4 blockade in normal tissues.[4] Phase 1 testing of single-agent lorigerlimab (NCT03761017) demonstrated acceptable safety in 43 patients with advanced solid tumors and encouraging antitumor activity.[5] Coblockade of PD-1 and CTLA-4 with lorigerlimab combined with targeted delivery of a cytotoxic payload via MGC018 may improve antitumor activity in B7-H3+ cancers.
Methods This is a Phase 1/1b, open-label, multicenter, dose-escalation, and cohort-expansion study of MGC018+lorigerlimab in patients with relapsed/refractory, unresectable, locally advanced/metastatic solid tumors, including mCRPC, melanoma, pancreatic cancer, HCC, ovarian cancer, and RCC for whom there is no available therapy. Eligibility criteria include ECOG performance status ≤2 and having archival tumor or fresh biopsy specimens for B7-H3 and PD-L1 immunohistochemistry (IHC) analysis, although IHC results will not be used for patient selection. The primary objective is evaluation of safety/tolerability, dose-limiting toxicities, and the maximum-tolerated dose or maximum-administered dose for MGC018+lorigerlimab. Secondary objectives include assessment of pharmacokinetics, immunogenicity, and antitumor activity (ORR, DoR, progression-free survival, overall survival) of MGC018+lorigerlimab. MGC018 and lorigerlimab are administered as sequential infusions on Day 1 of each 28-day cycle, for up to 26 cycles. Dose escalation follows a 3+3 design with MGC018 escalating from 1.0-3.0 mg/kg and lorigerlimab fixed at 6 mg/kg. Cohort expansion of MGC018 +lorigerlimab follows a Simon's 2-stage design for each tumor-specific cohort. Safety assessments are based on AEs, graded by NCI CTCAE v5.0, occurring from the first dose until 30 days after the last dose or until starting another anticancer therapy. Tumor assessments are performed every 8 weeks for the first 6 months, then every 12 weeks until progressive disease. Response evaluation is determined using RECIST v1.1 or PCWG3 (for mCRPC). Enrollment ongoing.
Trial Registration Clinicaltrials. gov NCT05293496

758 A PHASE 1 DOSE ESCALATION AND EXPANSION STUDY OF THE ANTI-CD200R1 ANTIBODY 23ME-00610 IN PATIENTS WITH ADVANCED SOLID MALIGNANCIES

[1]Drew Rasco*, [2]Albiruni Razak, [3]Maike Schmidt, [3]Sariah Kell, [3]Dylan Glatt, [3]Erin Belshaw, [3]Sophia Majeed, [4]Shivaani Kummar. *[1]START San Antonio, San Antonio, TX, USA; [2]Princess Margaret Cancer Centre, Toronto, Canada; [3]23andMe, South San Francisco, CA, USA; [4]Oregon Health and Sciences University, Portland, OR, USA*

Background 23ME-00610 is a first-in-class, fully humanized monoclonal antibody that inhibits the CD200R1 immune checkpoint, a promising immuno-oncology target identified by the 23andMe genetic database.[1] 23ME-00610 binds with high affinity (K_D < 0.1 nM) to CD200R1 on immune cells and has been shown to block immunosuppressive signaling and enhance T cell-mediated killing of tumor cells that express its only known ligand in humans, CD200, in preclinical studies.[2] We hypothesize that blocking CD200R1 with 23ME-00610 will reverse immune cell tolerance in the microenvironment of tumors that are reliant on the CD200R1 pathway, leading to immune-mediated disease control.

Methods The safety and preliminary antitumor activity of 23ME-00610 is being evaluated in a Phase 1 dose escalation and expansion study in adults with locally advanced unresectable, or metastatic solid malignancies who have progressed on standard therapies with an ECOG score of 0 or 1; adolescents atleast 12 years, weighing atleast 40 kg with a Lansky play scale score of atleast 50 will be included in the expansion phase. The primary objectives in the dose escalation phase are determination of the maximum tolerated dose (MTD)/recommended phase 2 dose (RP2D), and safety and tolerability, measured by the incidence and severity of dose-limiting toxicities, treatment-emergent adverse events (AEs) and withdrawals due to AEs. Secondary objectives include pharmacokinetics, immunogenicity, and preliminary antitumor activity of 23ME-00610. The monotherapy activity of 23ME-00610 will be evaluated in indication-specific expansion cohorts (N~15/cohort), which include clear cell renal cell carcinoma; epithelial ovarian, fallopian tube or primary peritoneal carcinoma; neuroendocrine cancer; and microsatellite instability-high (MSI-H) or tumor mutational burden-high (TMB-H) cancers that have progressed on standard therapies. A cohort of adolescents with locally advanced unresectable, or metastatic solid malignancies will also be enrolled. These indications were selected based on the expression of CD200R1 and its ligand, CD200, T cell markers, and immune characteristics that may increase likelihood of response to CD200R1 inhibition. The primary objective of the expansion phase is objective response rate (ORR) based on RECIST 1.1. The pharmacodynamic profile of 23ME-00610, including markers of CD200R1 engagement, will be evaluated. Germline genotypic information collected from participants will be used to correlate genetic variants and polygenic risk scores with safety and efficacy outcomes. The statistical analyses will primarily be descriptive. Participants reflecting the characteristics for the indication-specific cohorts with regards to age, sex, race, and ethnicity, including those from the Black, Latinx/Hispanic and Indigenous communities, will be prioritized for enrollment.

Acknowledgements Dr. Jennifer Low and Dr. Adrian Jubb for providing guidance and review of the study design. Dr. Robin Bliss for providing statistics support.

759 PHASE 1B STUDY OF LNS8801 IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH SECONDARY RESISTANCE TO IMMUNE CHECKPOINT INHIBITORS

[1]Jordi Rodon*, [2]Marya Chaney, [3]Justine Cohen, [4]Tina Garyantes, [5]Jessica Lin, [6]Patricia Lorusso, [7]Alain Mita, [7]Monica Mita, [8]Carolyn Muller, [4]Christopher Natale, [9]Marlana Orloff, [10]Kyriakos Papadopoulos, [1]Sapna Patel. *[1]MD Anderson Cancer Center, Houston, TX, USA; [2]Merck and Co., Inc., Kenilworth, NJ, USA; [3]University of Pennsylvania, Philadelphia, PA, USA; [4]Linnaeus Therapeutics, Haddonfield, NJ, USA; [5]Mass General Hospital Cancer Center, Boston, MA, USA; [6]Yale Cancer Center, New Haven, CT, USA; [7]Cedars Sinai Medical Center, Los Angeles, CA, USA; [8]University of New Mexico Cancer Center, Albuquerque, NM, USA; [9]Sidney Kimmel Cancer Center, Philadelphia, PA, USA; [10]START San Antonio, San Antonio, TX, USA*

Background LNS8801 is an oral, selective, small molecule agonist of the G-protein coupled estrogen receptor (GPER). LNS8801 treatment results in reduced c-Myc protein levels in cancer cells, inhibition of proliferation, supressesion of invasion, and enhancement of immune recognition. In preclinical models, LNS8801 has demonstrated increased activity in combination with immune checkpoint inhibitors (ICIs). In the first-in-human dose escalation study, LNS8801 was safe and tolerable alone and in combination with pembrolizumab in patients with advanced solid tumors (NCT04130516).

Methods Patients who have secondary resistance to ICIs (CR/PR/>16w of SD followed by progression) and have measurable disease are enrolling in a Phase 1b cohort and receive LNS8801 (125 mg, QD, PO) and pembrolizumab (200 mg, Q3W, IV) (NCT04130516). The primary objective is safety and tolerability assessed according to NCI CTCAE v5.0. Secondary endpoints include pharmacokinetic, pharmacodynamics, objective response rate (ORR) and disease control rate (DCR, CR+PR+SD) per RECIST v1.1, and assessment of biomarkers including germline GPER genotype at the single nucleotide polymorphism (SNP) rs11544331.

Results As of 7/15/22, patients with secondary resistance to ICIs (n=18) were treated with LNS8801 and pembrolizumab, including those who entered the study directly after confirmed progression on ICIs (n=16). Cancer types include lung (n=5), cutaneous melanoma (n=2), mesothelioma (n=2), neuroendocrine, colorectal, vaginal, nasopharyngeal, uterine, pancreatic cancer, uveal melanoma, small-cell cervical, and sarcoma. 7 of 18 patients had AEs possibly related to study drugs (n=6 with grades 1-2 and n=4 with grade 3), with colitis, dyspnea, and fatigue appearing in more than 1 patient. Of the 15 patients evaluable for efficacy, 3 had partial responses and 6 had stable disease, resulting in an ORR of 20% and DCR of 60%. All patients with partial responses had confirmed progression on ICIs immediately prior to entering the study. 4 patients continued on treatment for >6 months. Germline GPER genotype of C/C at SNP rs11544331 was associated with improved outcomes in patients treated with LNS8801.

Conclusions The combination of LNS8801 and pembrolizumab demonstrates encouraging anti-tumor activity in patients with secondary resistance to ICIs, including patients who enrolled immediately after confirmed progression on ICIs. The combination is tolerable without unanticipated toxicities. Germline GPER genotype is a promising predictive biomarker that could be used to select patients in future studies. These data support further development of LNS8801 in combination with pembrolizumab as a therapeutic approach to treat patients with secondary resistance to ICIs.

Trial Registration NCT04130516

Ethics Approval LNS-101 uses Western Institutional Review Board (WIRB) as a central IRB for this study. WIRB serves as the IRB for Cedars-Sinai Medical Center, the University of New Mexico, University of Pennsylvania, and Thomas Jefferson University. WIRB also serves as the IRB for the Yale University School of Medicine–Yale Cancer Center, but this site must be responsible for submissions due to institutional policies. Three sites do not use WIRB as the central IRB. South Texas Accelerated Research Therapeutics (START) is required to use Advarra IRB due to institutional policies, Massachusetts General Hospital is required to use their local IRB due to institutional policies, and MD Anderson Cancer Center is required to use their local IRB due to institutional policies.

Participants gave informed consent before taking part.

760 **A PHASE I/II TRIAL INVESTIGATING SAFETY AND EFFICACY OF AUTOLOGOUS TAC T CELLS TARGETING HER2 IN RELAPSED OR REFRACTORY SOLID TUMORS**

[1]Benjamin Schlechter*, [2]Daniel Olson, [3]Samuel Saibil, [4]Mridula George, [1]Riemke Bouvier, [5]Jessica McKinley, [2]Brooke Pieke, [6]Jill Geisburger, [7]Nathan Ternus, [7]Kara Moss, [7]Deyaa Adib, [5]Ecaterina Dumbrava. *[1]Dana Farber Cancer Institute, Boston, MA, USA; [2]University of Chicago, Chicago, IL, USA; [3]Princess Margaret Cancer Center, Toronto, Canada; [4]Rutgers University, New Brunswick, NJ, USA; [5]MD Anderson Cancer Center, Houston, TX, USA; [6]Princess Margaret Cancer Center – UHN, Toronto, Canada; [7]Triumvira Immunologics, Austin, TX, USA*

Background Despite recent therapeutic developments for patients with advanced, metastatic, unresectable HER2 positive (HER2+) solid tumors, significant unmet medical needs still exist, especially in tumors other than breast and gastric cancers and in patients with HER2-low expression. The T cell antigen coupler (TAC) technology is a novel approach to modifying T cells, allowing them to recognize and treat HER2 + solid tumors. Mechanistically, the TAC receptor redirects T cells to tumor cells, and upon recognition, co–opts the natural T cell receptor (TCR) signaling action to yield safe anti-tumor responses. In preclinical studies, TAC T cells led to complete tumor clearance in various human HER2+ mouse models, without any TAC-related toxicities, and results superior to a similar 2nd generation chimeric antigen receptor (CAR) T cell.

In this ongoing clinical trial (NCT04727151), subjects undergo leukapheresis, bridging therapy while their TAC T cells are engineered (if needed), lymphodepletion chemotherapy (LDC), and finally TAC01-HER2 infusion.

Methods Dose escalation in Phase 1 is investigating the safety and tolerability of TAC01-HER2 single doses of 0.08, 0.3 (starting dose), 0.8, 3, 8 x 10^6 cells/kg in adult subjects with HER2+ solid tumors (1+, 2+ or 3+ by immunohistochemistry) who have progressed after $\geq$2 lines of systemic therapy. Dose limiting toxicities (DLTs) are being assessed up to 28 days after TAC01-HER2 infusion.

In Phase 2, dose expansion groups will further evaluate the safety, efficacy, and pharmacokinetics of the optimal TAC01-HER2 dose in HER2+ breast and other HER2+ tumor types, including: lung, pancreatic, colorectal, gastric, endometrial, and ovarian.

As of 20 July 22, eight subjects have been treated in Cohorts 1 and 2, with no DLTs or events of special interest, such as cytokine release syndrome or immune effector cell-associated neurotoxicity syndrome, being observed. Four subjects had 8 serious adverse events; all unrelated to TAC01-HER2 infusion and attributed to LDC or underlying malignancies. Preliminary safety results indicate single TAC01-HER2 treatments in a heavily pre-treated population have been well-tolerated, with the most frequent adverse events (AEs) being cytopenias related to LDC. Continued dose escalation of TAC01-HER2 is ongoing.

Following completion of each dose level, a Data Safety Monitoring Committee has met to review all AEs to approve or deny escalation to the next highest dose level

761 PHARMACOKINETIC AND PHARMACODYNAMIC DATA FROM A PHASE 1 STUDY OF CI-8993 ANTI-VISTA ANTIBODY IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Randolph Noelle*, [2]Melissa Johnson, [3]Jordi Rodon, [4]Marjorie Zauderer, [1]Lionel Lewis, [5]Mariano Severgnini, [5]Jefferson Parker, [5]Maureen Lane, [5]Reinhard von Roemeling, [6]Alex Martin, [7]Michael Molloy, [5]Robert Martell, [8]Tong Dai. *[1]Geisel School of Medicine at Dartmouth, Hanover, NH, USA; [2]Tennessee Oncology, Nashville, TN, USA; [3]MD Anderson Cancer Center, Houston, TX, USA; [4]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [5]Curis Inc, Lexington, MA, USA; [6]Curis Inc/Tufts Medical Center, Lexington, MA, USA; [7]ImmuNext Inc, Lebanon, NH, USA; [8]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA*

Background V-domain Ig suppressor of T-cell activation (VISTA) is a novel negative checkpoint ligand that suppresses T cell activation forcing cells into a quiescent state. In pre-clinical studies anti-VISTA monotherapy has been shown to promote anti-tumor immunity. The impact of anti-VISTA therapy within the tumor microenvironment (TME) resulted in upregulated antigen-presentation pathways, reduced myeloid mediated immune suppression, enhanced lymphocyte infiltration and, with the promotion of co-stimulatory genes, reduced regulators of T cell quiescence and reduced tumor growth. In this work, we present pharmacokinetic (PK) data, and describe pharmacodynamic (PD) changes in the immune system in patient samples from the Phase 1 CI-8993-101 study, open label, dose escalation study (NCT04475523) administering an IgG1 anti-VISTA antibody (CI-8993) to patients with solid tumors.

Methods Patients were enrolled into cohorts that are structured to receive step-dosing regimens before administering a single 'full dose" of CI-8993. Cytokine release related toxicities were successfully managed with initial step-dosing and corticosteroids. The CI-8993 full doses ranged from 0.15 mg/kg to 0.6mg/kg in three separate cohorts. Immune-related PD, and PK analyses were performed on blood/serum from 17 patients at time points following step-dose, and full dose administration of CI-8993.

Results Data indicates a rapid, but transient, increase in cytokines and chemokines (e.g., IL6, IL18, IP10, MCP1) ($P \leq 0.05$). Soluble markers (TNFα and MIP1β) present differences between cohorts 4 hours after treatment ($P \leq 0.05$) without a clear dose-response relationship. We observed changes in neutrophils and activated monocytes populations after 24 hours of initial treatment ($P \leq 0.05$). Activated T cells (CD8+CD69+), decreased CD16 on NK cells, and increased HLDR expression on monocytes were observed between cohorts ($P \leq 0.05$). A greater than dose-proportional exposure increased with higher doses of CI-8993.

Conclusions CI-8993 was well tolerated and no DLTs were observed in the cohorts studied. An increase in pro-inflammatory cytokines, and anti-cancer immune cell phenotypes was observed. The lack of a dose-response effect in cytokine concentrations between cohorts is likely related to the higher step-dose regimen in cohort 3 (0.6mg/kg) that is dampening the cytokine release following the first full dose. The increase in pro-inflammatory phenotypes and soluble mediators post-treatment suggests an early immune response with different anti-tumoral mechanisms. Saturation PK indicates a favorable drug bioavailability at higher doses with an increased half-life. This suggests the ability to saturate the VISTA sink consistent with pre-clinical studies.[1] Further evaluation of the immune system and PK properties of CI-8993 will be performed as we continue enrollment to determine the RP2D.

762 FIRST-IN-HUMAN PHASE 1A STUDY OF NG-641, A TUMOUR-SELECTIVE VECTOR EXPRESSING A FAP-TAC BISPECIFIC ANTIBODY AND IMMUNE ENHANCER MODULE, IN PATIENTS WITH METASTATIC/ADVANCED EPITHELIAL TUMOURS (STAR)

[1]George Simon*, [2]Vivek Subbiah, [3]Lee Rosen, [4]Heinz-Josef Lenz, [5]Haeseong Park, [6]Minesh Patel, [6]David Miles, [6]Stephanie Wallis, [6]Vladimir Evilevitch, [6]David Krige, [6]Mark Powell, [6]Tom Lillie. *[1]H Lee Moffitt Cancer Center, Tampa FL and Advent Health Research Institute, Celebration, Tampa, FL, USA; [2]MD Anderson Cancer Center, Houston, TX, USA; [3]UCLA Medical Center, Los Angeles, CA, USA; [4]USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA; [5]Washington University, St. Louis, MO, USA; [6]PsiOxus Therapeutics Ltd, Abingdon, Oxford, UK*

Background NG-641 is a tumour-selective adenoviral vector that expresses a fibroblast activation protein-directed bi-specific T-cell activator antibody (FAP-TAc) and potent immune cell enhancers (CXCL9/CXCL10/IFNα). FAP-TAc targets killing of immunosuppressive cancer-associated fibroblasts, while immune enhancers recruit and activate immune cells (e.g. CD8+ T cells and dendritic cells). NG-641 is stable in the bloodstream and has low immunogenicity, allowing for IV delivery. We report first-in-human dose-escalation results for this novel immunotherapy.

Methods STAR (NCT04053283) is a Phase 1 study of NG-641 in patients with metastatic/advanced epithelial tumours and no standard treatments. The primary objective was safety and tolerability of IV NG-641 monotherapy (one cycle with single doses on Days 1, 3 and 5; five increasing dose levels). Preliminary anti-tumour activity was a secondary objective.

Results As of June 2022, 20 heavily pre-treated patients (median 60 years; 55% male) with metastatic/advanced epithelial tumours (35% colorectal; 15% pancreatic; 10% liver) received NG-641. DLTs of hypertension and dyspnoea occurred in one patient at Dose Level [DL] 2. The first patient at DL5 (1×10^{12} vp on Day 1 and 1×10^{13} vp on Days 3 and 5) experienced a DLT of Grade 3 CRS following an innate response to viral particles. The NG-641 MTD was thus determined to be 6×10^{12} vp as part of a "low-high-high" dosing regimen. Overall, the NG-641 safety profile was consistent with acute reactions to viral particles, with no evidence of transgene-related toxicity (table 1). Dose-dependent, specific and sustained increases in serum IL-12, IFNγ and IL-17a were detected from ~Wk2-12 (last measurement). Similar elevations did not occur with the unarmed parent vector, suggesting a transgene driven effect. No systemic FAP-TAc transgene protein was detected at any dose level indicating a lack of spill over from tumour into systemic circulation. Among evaluable patients, increases in tumour CD8+ T-cell infiltration were seen in 3/7 patients, including one patient with pancreatic cancer and one with colorectal cancer. No objective responses occurred but 2/3 patients at DL3 had stable disease (DL4 under assessment).

Conclusions NG-641 demonstrated manageable tolerability, with no evidence of systemic transgene-related toxicity. The MTD of NG-641 was 6×10^{12} vp when given in a "low-high-high" dosing regimen. Consistent with the encoded immunostimulatory transgenes, NG-641 led to specific and sustained cytokine responses, without systemic spill over of transgene products from the tumour microenvironment. These results suggest that NG-641 drives local immunological tumour changes without systemic toxicity. A further trial (NEBULA, NCT05043714) examining NG-641 with nivolumab is ongoing.

763 **PHASE 1/2 DOSE ESCALATION AND DOSE EXPANSION STUDY OF TRANSCON TLR7/8 AGONIST ALONE OR IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH LOCALLY ADVANCED OR METASTATIC SOLID TUMOR MALIGNANCIES: INITIAL RESULTS FROM DOSE ESCALATION**

[1]Diwakar Davar*, [2]Morteza Aghmesheh, [3]Alain Algazi, [4]David Bajor, [5]Vinod Ganju, [6]Douglas Laux, [7]Alexander Spira, [8]Elizabeth Ahern, [9]Jaspreet Grewal, [10]Jamie Rand, [11]Randy Sweis, [12]Jens-Jakob Karlsson, [12]Mette Kriegbaum, [13]Yang Wu, [13]Tuan-Anh Tran, [13]Stina Singel, [14]Nashat Gabrail. *[1]University of Pittsburg Medical Center, Pittsburgh, PA, USA; [2]Southern Medical Day Care Centre, Wollongong, Australia; [3]University of California San Francisco, San Francisco, CA, USA; [4]University Hospitals Cleveland Medical, Cleveland, OH, USA; [5]Peninsula and Southeast Oncology, Frankston, Australia; [6]University of Iowa Hospital and Clinics, Iowa City, IA, USA; [7]Virginia Cancer Specialists, Fairfax, VA, USA; [8]Monash Health, Clayton, Australia; [9]Norton Cancer Institute, Louisville, KY, USA; [10]City of Hope, Duarte, CA, USA; [11]University of Chicago Medicine, Chicago, IL, USA; [12]Ascendis Pharma A/S, Copenhagen, Denmark; [13]Ascendis Pharma, Inc., Palo Alto, CA, USA; [14]Gabrail Cancer Center, Canton, OH, USA*

Background Resiquimod is a potent TLR7/8 agonist where systemic tolerability limits clinical use. TransCon TLR7/8 Agonist is an investigational prodrug of resiquimod with sustained release intended for intratumoral administration. It has the potential to overcome shortcomings of existing treatments by providing prolonged high local concentrations of resiquimod, promoting potent anti-tumoral responses while reducing systemic drug exposure and treatment related adverse events (TRAEs).[1] The primary objectives of the transcendIT-101 phase 1/2 trial are to evaluate safety and tolerability, and define the maximum tolerated dose and recommended phase 2 dose (RP2D) of TransCon TLR7/8 Agonist, alone or in combination with pembrolizumab.

Methods In dose escalation (3+3 design), patients aged ≥18 with advanced solid tumors receive TransCon TLR7/8 Agonist (dose levels: 0.3 and 0.5 mg/injected lesion) as monotherapy or in combination with pembrolizumab. Monotherapy patients receive dosing every 3 weeks (q3w). Combination therapy patients receive staggered dosing in cycle 1 where pembrolizumab is administered 7 days after TransCon TLR7/8 Agonist, then same-day dosing q3w at subsequent cycles. In expansion cohorts, TransCon TLR7/8 Agonist and pembrolizumab are administered same day q3w starting at cycle 1 day 1. Disease is assessed every 9 weeks using Response Evaluation Criteria in Solid Tumors version 1.1, supplemented by pathology, as available. Safety, pharmacokinetics (PK), and pharmacodynamics (PD) are evaluated.

Results As of 27th May 2022, 19 patients enrolled into dose escalation: 9 to monotherapy (3 at 0.3 mg, 6 at 0.5 mg) and 10 to combination therapy (3 at 0.3 mg, 7 at 0.5 mg). All 22 TRAEs were grade 1 or 2 (12 at 0.3 mg, 10 at 0.5mg) with most common TRAEs related to injection site reactions (59%) followed by fever (9%). Preliminary PK results showed low systemic resiquimod C_{max}, with mean systemic resiquimod half-life of 9 days, and no PK interaction with pembrolizumab. PD data from tumor biopsies were consistent with sustained intratumoral upregulation of type I interferon and TLR pathway genes that were comparable across the two dose levels. Preliminary antitumor efficacy was observed, including 1 confirmed partial response (melanoma, monotherapy at 0.3 mg).

Conclusions The transcendIT-101 trial indicates TransCon TLR7/8 Agonist has a well-tolerated safety profile as monotherapy and in combination with pembrolizumab. Results from PD studies demonstrated target engagement that correlates with observed antitumor activity. While enrollment continues, data support 0.5 mg/injected lesion as the projected RP2D.

764 **FIRST-IN-HUMAN, DOSE ESCALATION AND EXPANSION STUDY OF MT-6402, A NOVEL ENGINEERED TOXIN BODY (ETB) TARGETING PD-L1, IN PATIENTS WITH PD-L1 EXPRESSING RELAPSED/REFRACTORY ADVANCED SOLID TUMORS: INTERIM DATA**

[1]Brian Van Tine*, [2]Eugene Ahn, [3]John Powderly, [4]Herbert Duvivier, [5]Drew Rasco, [6]Rebecca Redman, [7]Steven Powell, [8]Agnes Rethy, [8]Chris Moore, [8]Amy Yuet, [8]Rachael Orlandella, [8]Swati Khanna, [9]David Spigel, [8]Angela Georgy, [8]Joseph Dekker. *[1]Washington University in St. Louis, St Louis, MO, USA; [2]Cancer Treatment Centers of America, Chicago, IL, USA; [3]Carolina BioOncology Institute, Huntersville, NC, USA; [4]CTCA-Atlanta, Atlanta, GA, USA; [5]START, San Antonio, TX, USA; [6]University of Louisville, Louisville, KY, USA; [7]Sanford Cancer Center, Sioux Falls, SD, USA; [8]Molecular Templates, Inc., Austin, TX, USA; [9]Sarah Cannon Research Institute, Nashville, TN, USA*

Background MT-6402 is a unique, potent PD-L1-targeted engineered toxin body capable of directly killing PD-L1 expressing tumor and immune cells by internalization of a de-immunized Shiga-like toxin A subunit (SLTA), which results in permanent SLTA-mediated ribosomal inactivation. Targeting PD-L1 expressing tumor cells may directly drive tumor regression, whereas targeting of PD-L1 expressing immune cells (IC) may release immunosuppression and drive immune recognition of the tumor. MT-6402 also delivers an HLA-A*02 restricted cytomegalovirus (CMV) class I antigen into PD-L1 expressing cells (antigen seeding) that can be recognized by existing CMV-specific cytotoxic T cells.

Methods A first-in-human dose escalation and expansion study (QW in 4-week cycles) was initiated in 2021.

Results 18 patients with PD-L1-expressing advanced solid tumors received $\geq$ 1 dose of MT-6402. 14 patients were eligible for Dose Limiting Toxicity (DLT) assessment in Cohorts 1 through 4. MT-6402 was well tolerated and no DLT was observed in Cohorts 1 and 3 (16 µg/kg and 32 µg/kg, respectively). 1 DLT of a Grade (G)2 maculopapular rash occurred in Cohort 2 (24 µg/kg). There was no G4 or G5 adverse events (AEs) or treatment-related discontinuations in the first 3 cohorts. Immune-related AEs of Infusion-related reaction (G1 and G2) and cytokine-release syndrome (G1 and G2) occurred, generally lasting 1-2 days.

2 patients in Cohort 1 had stable disease for 8 months. A significant reduction in CD14+ monocytes was observed after each administration, indicating HLA-independent pharmacodynamic effect. Dose dependent reduction of monocytes was observed across 3 cohorts and correlated with CCL2 and IL-8 modulation. PD-L1-negative peripheral monocytes and dendritic cell populations were spared, indicating on-target removal. Most patients display CD8 T cell expansion/activation and IL-2 and TNFα cytokine release, consistent with removal of PD-1/PD-L1 interaction.

One patient with high PD-L1 expression and osseous metastases who is HLA-A*02/CMV+ showed complete CMV-specific T-cell extravasation by C1D8, persisting until C6, and serum cytokine signatures consistent with antigen dependent responses and T cell mobilization. This patient had reduced tracer uptake of metastatic bone lesions with resolution of 3 lesions. 3 additional HLA-A*02/CMV+ patients with low PD-L1 expression followed a similar trend of extravasation of peripheral CMV-specific T cells.

Conclusions These results describe a novel approach to checkpoint modulation by MT-6402 with a potential to alter tumor immunophenotype particularly in patients with HLA-A*02/CMV positivity. Dose escalation is ongoing. These results provide compelling rationale for continued development of MT-6402, including in the R/R setting, possibly in combination with PD-1 inhibitors.

766 **PHASE I/II EVALUATION OF THE COMBINATION OF ENTINOSTAT, M9241 AND BINTRAFUSP ALFA IN PATIENTS WITH ADVANCED HPV RELATED MALIGNANCIES**

[1]Julius Strauss*, [1]Charalampos Floudas, [1]Danielle Pastor, [1]Jason Redman, [2]Deneise Francis, [2]Elizabeth Lamping, [1]Lisa Cordes, [1]Jennifer Marte, [1]Renee Donahue, [1]Caroline Jochems, [1]Sofia Gameiro, [1]Jeffrey Schlom, [1]James Gulley. *[1]Center for Immuno-Oncology, NCI, Bethesda, MD, USA; [2]Office of Research Nursing, NCI, Bethesda, MD, USA*

Background More than 630,000 cases of HPV related cancer (e.g. cervical, oropharyngeal, anal) occur worldwide annually. Unfortunately, only about 15-20% of cases respond to PD-(L) 1 inhibitors alone. Recent data with the triple combination of PDS0101 (a therapeutic vaccine targeting HPV 16 E6/E7), M9241 (a tumor-targeting IL-12 immunocytokine), and bintrafusp alfa (a bifunctional fusion protein targeting TGF-β and PD-L1) have shown early clinical activity in advanced checkpoint refractory HPV related cancers, with 45% of patients having disease reduction, including 27% with objective responses.[1] In addition, preclinical studies have shown that the triple combination of entinostat (histone deacetylase inhibitor), M9241, and bintrafusp alfa may also have promising anti-tumor activity in checkpoint refractory disease.

Methods 7 patients with advanced checkpoint refractory HPV positive cancers who had been previously treated with PDS0101, M9241 and bintrafusp alfa (NCT04287868) and progressed went on to be treated with the combination of entinostat, M9241, and bintrafusp alfa (NCT04708470). These patients received bintrafusp alfa at 300 mg IV q 2weeks, entinostat 3 mg po weekly including a 1 week lead in of entinostat alone, and M9241 at either 4 mcg/kg SC q 2 weeks or 8 mcg/kg SC q 4weeks (based on dose escalation cohort). Pts receiving M9241 at 8 mcg/kg did not receive entinostat on the week of M9241 treatment but did on all other weeks.

Results 7 patients with advanced checkpoint refractory HPV positive cancers (5 oropharyngeal, 1 anal, 1 neuroendocrine rectal) who had progressed on PDS0101, M9241 and bintrafusp alfa went on to receive entinostat, M9241, and bintrafusp alfa. After switching to the entinostat based triple combination, 2/7 patients had grade 3 treatment related AEs including grade 3 anemia in one patient and grade 3 leukopenia/lymphopenia in another. Otherwise, there were no grade 3 or greater treatment related AEs observed in patients switching to the entinostat based triple combination. 3/7 (43%) patients (2 oropharyngeal, 1 anal) have had tumor reduction of 28.8%, 38.3% and 42.6% by RECIST after switching to the entinostat based triple combination.

Conclusions Escalating doses of the triple combination of entinostat, M9241 and bintrafusp alfa continue to be evaluated in an ongoing phase I/II trial (NCT04708470). To date the triple combination appears to have a manageable safety profile along with encouraging clinical activity in patients with advanced checkpoint refractory HPV related cancers including in pts who have previously progressed on PD(L)1 inhibitor then on PDS0101, M9241 and bintrafusp alfa.

Background mRNA-2752 is a first-in-class mRNA-based therapeutic agent encoding T cell co-stimulator OX40L, and pro-inflammatory cytokines IL-23 and IL-36γ. Preclinical data demonstrated activity in a range of tumor microenvironments (TMEs), including immune checkpoint inhibitor (CPI)- refractory cancer models, and synergy when combined with α-PD-L1 antibodies. Data from the dose escalation phase of the study was previously reported and the recommended mRNA-2752 dose for expansion (RDE) was up to 8mg ITu.

Methods We evaluated the safety and efficacy of ITu mRNA-2752 administered as monotherapy (Arm A; previously reported ASCO 2020) and in combination with the PD-L1 inhibitor durvalumab (Arm B) in patients (pts) with tumors that were palpable or accessible with image guidance. Here we report preliminary data for the expansion cohorts in TNBC, CPI-refractory melanoma, and HNSCC. Biomarker analyses included IHC/F-IHC of immune status markers and whole transcriptome assessments of paired tumor biopsies. Protein quantification of IL-23, IL-36γ and other pro-inflammatory cytokines were performed in plasma and tumors.

Results As of 01JUL 2022, 88 pts were treated, 69 in Arm B with mRNA-2752 dosed by tumor size ranging from 0.25-8 mg. The most common treatment related adverse events occurring in ≥ 10% of pts in Arm B included grade 1/2 injection site erythema/pain/swelling, fever, chills, fatigue, nausea, and flushing. Grade 3 events included injection site pain/erythema, and fever. There were no grade 4/5 related events. Objective responses were observed in immune refractory tumors by RECIST and iRECIST, including a confirmed PR in a PD-L1 low TNBC and confirmed iCR in an immune checkpoint-refractory melanoma pt, respectively. Biomarker analyses of plasma and tumor show mRNA-2752 treatment was associated with elevated pro-inflammatory cytokines, including IL-23, IL-36γ, IFNγ, and TNFα. F-IHC of paired tumor biopsies showed increase in proliferating CD8+ T cells. Transcriptional profiling of the TME demonstrates a pronounced immune response including dendritic cell recruitment and T cell activation, which remained elevated in longitudinal samples. The greatest increases in immune response and markers of cytolytic activity were observed in pts deriving clinical benefit.

Conclusions ITu mRNA-2752 + IV durvalumab is safe, tolerable, and shows preliminary efficacy in immune refractory tumors, including TNBC and melanoma. Biomarker analyses indicate mRNA-2752 drives cytokine responses. Consistent with the expected mechanism of action, a productive and sustained inflammatory response is observed in the TME in response to treatment, including signatures of increased innate and adaptive immune cell abundance and effector response.

Acknowledgements We thank AstraZeneca for provision of durvalumab for this study.

768 **PERIPHERAL PHARMACODYNAMIC (PD) EFFECTS OF OCIPERLIMAB (OCI) IN COMBINATION WITH TISLELIZUMAB (TIS) IN PATIENTS WITH ADVANCED SOLID TUMORS: ADVANTIG-105 PHASE 1 DOSE-ESCALATION STUDY**

[1]Wei Tan*, [2]Yang Shi, [2]Han Yan, [2]Zhirong Shen, [3]Nageshwar Budha, [3]Ahsan Rizwan, [1]Ruiqi Huang, [3]Hao Zheng, [1]Rang Gao, [4]Sophia Frentzas, [5]Steven Kao, [6]Tarek Meniawy, [2]Yun Zhang. *[1]BeiGene (Shanghai) Co., Ltd., Shanghai, China; [2]BeiGene (Beijing) Co., Ltd., Beijing, China; [3]BeiGene (USA) Co., Ltd., San Mateo, CA, USA; [4]Monash Health, Melbourne, Australia; [5]Chris O'Brien Life House, Sydney, Australia; [6]Linear Clinical Research and University of Western Australia, Nedlands, Western Australia, WV, Australia*

Background OCI is a humanized monoclonal antibody (mAb) against T-cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domains (TIGIT) with high affinity and specificity, enabling Fc-mediated effector functions that induce antibody-dependent cellular cytotoxicity.[1] The Phase 1/1b open-label AdvanTIG-105 trial was designed to assess the safety and efficacy of OCI plus TIS (an anti-programmed cell death protein 1 mAb) in patients with advanced solid tumors (NCT04047862).[2] In the dose-escalation part, the combination was well tolerated, and preliminary antitumor responses were observed. Here, we report PD biomarker data from peripheral blood.

Methods Eligible patients had locally advanced/metastatic, unresectable solid tumors previously treated with standard systemic therapy or for which treatment was not available/tolerated, ECOG PS ≤1 and had received no prior anti-TIGIT therapy. Patients received five escalating doses of OCI (50–1800mg) intravenously (IV) on Cycle (C) 1 Day (D) 1 and TIS 200mg IV was initiated on C1D8. If tolerated, patients received OCI (50–1800mg) plus TIS 200mg on D29 (C2D1) and every three weeks thereafter until discontinuation. Peripheral blood samples were collected to monitor changes in total and TIGIT-expressing immune cell subsets pre- and post-treatment. Meso Scale Discovery V-plex panels were used to assess cytokine/chemokine release in plasma samples. Wilcoxon signed-rank test compared pre- and post-treatment cytokine/chemokine levels; p values are descriptive.

Results At data cutoff (09/01/2021), 32 patients had received ≥1 dose of OCI plus TIS. Total peripheral regulatory T cells (Tregs) decreased following OCI monotherapy (at C1D2 and C1D8) with doses of 900mg and 1800mg (not dose proportional), but not 450mg; the decrease was maintained with subsequent combination with TIS (at C1D15 and C2D1). CD4+ and CD8+ T-cell populations were not impacted at any OCI dose. TIGIT downregulation was observed on Tregs, CD4+, and CD8+ T cells at C1D8 with multiple OCI doses (not dose proportional); the reduction was sustained after combination with TIS. Plasma IL12/23p40 ($p<0.001$), CCL4 ($p<0.05$), and CXCL10 ($p<0.05$) were notably induced post-OCI (C1D8), and further elevated following combination with TIS ($p<0.001$, $p<0.001$, and $p<0.0001$, respectively) at C2D1. Plasma IFNγ and TNFα increased post-OCI at C1D8 and were dramatically induced post-combination at C2D1 ($p<0.0001$ and $p<0.001$, respectively).

Conclusions OCI, with or without TIS, led to Treg reduction at higher doses, TIGIT downregulation, and proinflammatory cytokine/chemokine release, reflecting the potential mechanism of action of OCI as an Fc-competent anti-TIGIT mAb.

769 **RESULTS FROM AN ONGOING OPEN-LABEL, MULTICENTER, PHASE 1 TRIAL OF CCX559, AN ORALLY ADMINISTERED SMALL MOLECULE PD-L1 INHIBITOR, IN PATIENTS WITH ADVANCED SOLID TUMORS**

[2]Gonzalo Tapia-Rico, [3]Joanne Lundy, [4]Gary Richardson, [1]Niky Zhao, [1]Karen Ebsworth, [1]Huibin Yue, [1]Shichiang Miao, [1]Emil deGoma, [1]Rita Jain, [1]Thomas Schall, [1]Kathleen Sullivan, [1]Penglie Zhang, [5]Paul de Souza, [1]Emil deGoma*. *[1]ChemoCentryx, San Carlos, CA, USA; [2]Icon Cancer Centre, Adelaide, Australia; [3]PASO Medical, East Bentleigh, Australia; [4]Cabrini Research, Melbourne, Australia; [5]Western Sydney University, Campbelltown, Australia*

Background The novel small molecule CCX559 is a highly potent and selective PD-L1 inhibitor that induces dimerization and internalization of cell-surface PD-L1. CCX559, when orally administered in animal models, demonstrated anti-tumor efficacy, including the ability to induce complete responses.[1] Initial results from a phase 1 study of CCX559 indicated on-target pharmacodynamic (PD) effects consistent with PD-L1 inhibition, including peripheral T cell activation and stimulation of cytokines.[2,3]

Methods This phase 1, first-in-patient, dose-escalation trial is evaluating safety, tolerability, pharmacokinetics (PK), PD, and preliminary anti-tumor activity of CCX559 in patients with advanced solid tumors. CCX559 is dosed orally once daily in repeated 21-day cycles with a starting dose level of 30 mg. PBMC and plasma samples are collected from patients over the first 2 cycles of treatment for PD assessments, including quantification of T cell proliferation and measurement of plasma cytokines and chemokines. Principal component analysis (PCA) was used to identify patient clusters with discrete cytokine/chemokine profiles.

Results As of July 12, 2022, a total of 17 patients were dosed with CCX559, including 13 patients across the 120 mg and 180 mg dose groups. No DLTs, treatment-related SAEs, or severe (Grade 3 or higher) treatment-related AEs were reported. The observed PK exposures were generally dose-proportional from 30 mg to 180 mg and in line with projections based on nonclinical data.

PD assays were performed with samples from the 30 mg (n=1), 60 mg (n=1), 120 mg (n=8) and 180 mg (n=2) cohorts. Patients in all four cohorts showed 1.5-fold or greater increases in peripheral CD4 and CD8 T cell proliferation starting in the first cycle (21 days) of treatment, as measured by Ki67 positivity. In patients treated with CCX559 120 mg or 180 mg, plasma levels of IFNγ, IFNγ-stimulated factors CXCL10 and CXCL11, and soluble PD-L1 were significantly increased ($p<0.05$) during the first treatment cycle, and changes in these factors were positively correlated with each other. PCA of the 120 mg cohort showed that patients with increased IFNγ-stimulated factors formed a cluster with a differentiated global cytokine/chemokine response, including upregulation of CXCL13, CXCL8, and IL-1β.

Conclusions Interim results from the phase 1 dose-escalation trial of CCX559 indicate on-target PD effects consistent with PD-L1 inhibition. Peripheral IFNγ-stimulated responses were observed in the 120 mg and 180 mg cohorts, consistent with the expected activity profile for immune checkpoint inhibitors. Additional PD data, together with the safety and PK profile, will be presented.

770 **SAFETY, EFFICACY, AND PHARMACOKINETIC RESULTS FROM A PHASE I FIRST-IN-HUMAN STUDY OF ABBV-151 WITH OR WITHOUT ANTI-PD1 MAB (BUDIGALIMAB) IN PATIENTS WITH LOCALLY ADVANCED OR METASTATIC SOLID TUMORS**

[1]Anthony Tolcher*, [2]Desamparados Roda-Perez, [3]Kai He, [4]Victor Moreno, [5]Carlos Gomez-Roca, [6]Jean-Pascal Machiels, [7]Albiruni Razak, [8]Mohammad Sahtout, [8]Xiaowen Guan, [8]Stacy Jaryno-Daly, [8]Rachel Leibman, [8]Martha Blaney, [8]James O'Brien, [9]Patricia Lorusso, [10]John Powderly, [11]Talia Golan, [12]Kathy Miller, [13]Jordi Bruix. *[1]NEXT Oncology, San Antonio, TX, USA; [2]The Institute of Cancer Research, London, UK; [3]The James Cancer Hospital, Columbus, OH, USA; [4]START Madrid-FJD, Madrid, Spain; [5]Institut Claudius Regaud/IUCT Oncopole, Marseille, France; [6]Institut Roi Albert II Cancer Centre, Brussels, Belgium; [7]Princess Margaret Cancer Center, Toronto, Canada; [8]AbbVie, Inc., North Chicago, IL, USA; [9]Yale Cancer Center, Yale University, New Haven, CT, USA; [10]Carolina Biooncology Institute, Huntersville, NC, USA; [11]Sheba Medical Center, Tel-Hashomer, Israel; [12]Indiana University School of Medicine, Indianapolis, IN, USA; [13]Hospital Clinic Barcelona, Barcelona, Spain*

Background Glycoprotein-A repetitions predominant (GARP) is expressed on regulatory T-cells and modulates release of active transforming growth factor β1 (TGFβ1), an immunosuppressive cytokine. ABBV-151 is a first-in-class monoclonal antibody (mAb) that binds to the GARP-TGFβ1 complex, blocking the release of active TGFβ1. Preclinical data demonstrate that blocking GARP-TGFβ1 and programmed cell death protein-1 (PD-1) improves antitumor efficacy compared with anti–PD-1 alone. Combining ABBV-151 with the anti–PD-1 mAb budigalimab may enable increased antitumor efficacy by reducing the immunosuppressive effects of TGFβ1. Herein, we report preliminary safety, efficacy, and pharmacokinetic (PK) results from a first-in-human, phase 1 study (NCT03821935) assessing ABBV-151 ± budigalimab in adult patients (≥18 years) with locally advanced/metastatic solid tumors. Results from the all-comer dose escalation (ESC) phase and two cohorts from the dose expansion (EXP) phase are available: anti-PD-1/PD-ligand (L)1 naïve hepatocellular carcinoma (HCC) and anti-PD-1/PD-L1 relapsed/refractory urothelial cancer (UC).

Methods ESC patients must be refractory/intolerant to existing effective therapies; EXP cohorts have tumor-specific eligibility requirements. The primary ESC endpoint is the recommended phase II dose of ABBV-151 ± budigalimab. The primary EXP endpoint is preliminary efficacy of ABBV-151 + budigalimab, assessed by objective response rate per Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1.

Results As of June 2022, 157 patients have been enrolled, 57 in ESC (23 ABBV-151 monotherapy; 34 combination therapy) and 100 in EXP (including 36 UC; 12 HCC). As of January 2022, safety data were available for 129 patients. Any-grade adverse events (AEs) were reported in 119/129 (92%) patients. Most commonly: fatigue (28%), pruritus (27%), and nausea (22%). Grade 3-4 AEs occurred in 66/129 (51%) patients, with drug-related grade 3-4 AEs in 18/129 (14%) patients. ABBV-151 showed dose proportional PK. No antitumor responses were reported for the ABBV-151 monotherapy ESC cohorts. In the combination ESC cohorts, there were 4 confirmed responses, 1 unconfirmed response, and 4 patients had stable disease (SD) ≥6 months. In the anti-PD-1/PD-L1 relapsed/refractory UC EXP cohort, there were 5 confirmed responses, 1 unconfirmed response, and 5 patients had a best response of SD. In the anti-PD-1/PD-L1 naïve HCC EXP cohort, there were 5 confirmed responses, including one response per immune RECIST, and 3 patients had a best response of SD.

Conclusions ABBV-151 ± budigalimab showed a manageable safety profile in patients with advanced solid tumors. Preliminary efficacy results demonstrate durable antitumor activity with ABBV-151 + budigalimab, including in anti-PD-1 relapsed/refractory UC and in anti-PD-1 naïve HCC.

771 A PHASE 1, FIRST IN HUMAN, OPEN-LABEL, DOSE ESCALATION AND DOSE EXPANSION STUDY OF TST005 IN PATIENTS WITH LOCALLY ADVANCED OR METASTATIC SOLID TUMORS

[1]Lei Chen, [2]Anthony Tolcher*, [3]Nashat Gabrail, [4]Minal Barve, [5]Xiaohua WU, [5]Jian Zhang, [1]Michael Shi, [1]Chuan Qi, [1]Steven Yu, [1]Jenny Yao, [1]Jianming Wang, [1]Christopher Cavanaugh. *[1]TRANSCENTA, Shanghai, China*; *[2]NEXT Oncology, San Antonio, TX, USA*; *[3]Gabrail Cancer, Canton, OH, USA*; *[4]Mary Crowley Cancer Research Centers, Dallas, TX, USA*; *[5]Fudan University Shanghai Cancer Center, Shanghai, China*

Background Anti-programmed death 1/ligand 1 (PD-1/PD-L1) therapies have been established as standard treatment for multiple tumor types. However, the key challenge of these therapies is resistance caused by immunosuppressive factors in the tumor microenvironment (TME). TGF–β is a multi-functional cytokine that is involved in the tight regulation of either anti-tumor immunity or tumor immunosuppression. TGF–β promotes an immune exclusion TME thus renders PD-L1 blockade ineffective. Therefore, dual targeting PD-L1 and TGF–β represents a rational synergistic strategy to enhance clinical outcome relative to each agent alone. TST005 is a novel bi-functional fusion protein combining a high affinity PD-L1 monoclonal antibody (mAb) in a fragment crystallizable (Fc) silenced immunoglobulin G1 (IgG1) backbone and a differentiated transforming growth factor beta (TGF–β) trap with improved stability. This study will investigate TST005's safety, tolerability and preliminary anti-tumor activity in solid tumors.
Methods This Phase 1, first in human (FIH) study is an open-label, multicenter trial that consists of a dose escalation phase in patients with advanced solid tumors who has failed prior therapy followed by a dose expansion phase in human papillomavirus (HPV) related malignancies that is not amenable to surgeryand have received prior standard therapy(ies). The primary objectives are to evaluate the safety and tolerability and determine the maximum tolerated dose or recommended Phase 2 dose(s) of TST005. Secondary objectives include pharmacokinetic, pharmacodynamic and preliminary anti–tumor activity of TST005. The dose escalation phase comprises five dose cohorts: accelerated titration of 1 subject in the starting dose cohort (1 mg/kg), and then four dose cohorts (3 mg/kg, 10 mg/kg, 20 mg/kg, 30 mg/kg) following classic 3+3 design. No more than one prior immune checkpoint inhibitor (ICI) treatment is allowed for eligible subjects. In the dose expansion phase, up to 30 patients with locally advanced or metastatic HPV+ malignancies, including cervical cancers, P16+ Oropharyngeal cancers, and other tumors that are known HPV+, and who are ICI treatment naive will be enrolled. Subjects will receive TST005 intravenous infusion every 3 weeks (Q3W) until disease progression per RECIST v1.1 and/or immune RECIST or unacceptable toxicity. Subjects may continue to receive TST005 beyond RECIST v1.1 defined progression at the discretion of the Investigator. This study is ongoing at 4 sites in the US and China. As of the 30 June, 2022, the first two dose cohorts evaluation has been completed and no DLT was observed. Clinical trial information: NCT04958434. Study Sponsor: Suzhou Transcenta Therapeutics Co., Ltd.

772 A PHASE 1/2 DOSE ESCALATION/EXPANSION STUDY EVALUATING THE SAFETY, PHARMACOKINETICS, PHARMACODYNAMICS, AND ANTITUMOR ACTIVITY OF E-602, A BI-SIALIDASE FUSION PROTEIN, IN ADVANCED CANCER (GLIMMER-01)

[1]Manish Sharma*, [2]Deanne Lathers, [3]Melissa Johnson, [4]Jason Luke, [5]Igor Puzanov, [6]Brendan Curti, [7]Christopher Chen, [8]Anthony El-Khoueiry, [9]Brian Henick, [10]Margaret Callahan, [11]Mario Sznol, [12]Sandip Patel, [2]Dawn Wilson, [2]Melissa Ricker, [2]Lizhi Cao, [2]Pushpa Jayaraman, [2]Jenny Che, [2]Li Peng, [2]David Feltquate, [2]Deanne Lathers, [13]Anthony Tolcher. *[1]START Midwest, Grand Rapids, MI, USA; [2]Palleon Pharmaceuticals, Waltham, MA, USA; [3]Sarah Cannon Research Institute, Nashville, TN, USA; [4]University of Pittsburgh Medical Center, Pittsburgh, PA, USA; [5]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [6]Providence Cancer Institute, Portland, OR, USA; [7]Stanford University Medical University, Palo Alto, CA, USA; [8]University of Southern California, Los Angeles, CA, USA; [9]Columbia University Medical Center, New York, NY, USA; [10]Memorial Sloane Kettering Cancer Center, New York, NY, USA; [11]Yale Cancer Center, New Haven, CT, USA; [12]University of California, La Jolla, CA, USA; [13]NEXT Oncology, San Antonio, TX, USA*

Background E-602 is a novel, first-in-class fusion protein of engineered human sialidases, neuraminidase (Neu)2, and the human IgG1 Fc region. The sialidase moieties of E-602 cleave terminal sialic acid residues from sialoglycans on diverse immune cell subsets and tumor cells. Sialoglycans are immunosuppressive in cancer, associated with poorer outcomes across numerous tumor indications, and have emerged as a critical glyco-immune checkpoint. In preclinical studies, sialidase-mediated cleavage of terminal sialic acids improves antitumor immunity by restoring the immune function of exhausted-like T cells and enhancing dendritic cell priming and naïve T cell activation.[1] In multiple syngeneic mouse tumor models, sialidase treatment has demonstrated antitumor activity as monotherapy[1] and additive antitumor activity when combined with anti-programmed death-1 (PD-1)/programmed death-ligand 1 (PD-L1) blockade. E-602 has a wide safety margin, is not an immune agonist and does not stimulate cytokine activation in an in vitro PBMC cytokine release assay.[1,2] In humans, E-602, via desialylation of tumor cells and immune cells, is expected to have antitumor activity either as monotherapy or in combination with an anti-PD-1 agent.

Methods A Phase 1/2, first-in-human, open label, dose escalation and expansion study of E-602 administered as monotherapy and in combination with an anti-PD-1 agent is ongoing to evaluate the safety, pharmacokinetics, pharmacodynamics, and antitumor activity in participants with advanced cancers. Phase 1 of the study consists of 4 planned dose escalation cohorts of E-602 monotherapy and 2 planned dose escalation cohorts of E-602 in combination with an anti-PD-1 agent. Phase 1 is treating eligible participants with advanced melanoma, ovarian, non-small cell lung, colorectal, pancreatic, breast, gastric/esophagogastric junction, head and neck, or urothelial cancers. Utilizing a modified 3+3 study design in Phase 1, the safety of the dose regimens is under evaluation to identify the maximum tolerated dose and/or recommended Phase 2 dose. Additional participants (backfill) may be enrolled in the Phase 1 cohorts to obtain additional safety, pharmacokinetic or pharmacodynamic data. Phase 2 will include up to 3 disease indications, evaluating E-602 as monotherapy and/or in combination with an anti-PD-1 agent utilizing a Simon's minimax 2-stage design. Pre and on-treatment biopsies to further explore the pharmacodynamic effects of E-602 are required for the Phase 1 backfill and Phase 2 participants.

Acknowledgements The authors would like to thank the clinical trial participants and their families for their willingness to participate in the study.

Trial Registration The study is registered on clinicaltrials.gov as NCT05259696.

773

A PHASE 1B/2, OPEN-LABEL, DOSE ESCALATION AND EXPANSION STUDY OF AN ANTI-CTLA-4 NEOBODY™ ADG116 IN COMBINATION WITH PEMBROLIZUMAB (ANTI-PD-1 ANTIBODY) IN PATIENTS WITH ADVANCED/METASTATIC SOLID TUMORS: A PRELIMINARY UPDATE

[1]Anthony Tolcher, [2]John Powderly, [3]Kristine Shi, [3]Songmao Zheng, [3]Guizhong Liu, [3]Jin Shang, [3]Xinwei Wang, [3]Wenda Li, [3]Dana Lowe, [4]Michael Chisamore, [3]Peter Luo, [3]Jiping Zha*. *[1]Next Oncology, San Antonio, TX, USA; [2]Carolina Biooncology Institute, Huntersville, NC, USA; [3]Adagene, San Diego, USA; [4]Merck, Kenilworth, NJ, USA*

Background CTLA-4 as an immunotherapeutic target that has been challenged with limited single agent efficacy and high-grade toxicities in the clinic. ADG116 is a fully human anti-CTLA-4 IgG1 monoclonal antibody that targets a unique and a highly conserved epitope of CTLA-4 using the NEObody™ technology platform. ADG116 enables a safer T cell activation via partial CD80/86 ligand blockade and enhances the Treg depletion in the tumor microenvironment via a stronger ADCC. Preclinical studies demonstrated that ADG116 is more potent and better tolerated than ipilimumab. In a Phase 1 dose escalation study, single agent ADG116 has been well-tolerated up to 10 mg/kg when dosed intravenously, once every 3 weeks (Q3W); target lesion size reduction and stable diseases were observed in multiple heavily pre-treated patients including those bearing "cold" tumors.[1] We propose that ADG116 in combination with pembrolizumab may enhance clinical antitumor activity through a simultaneous blockade of the PD-1/PD-L1 and CTLA-4 pathways while still maintaining a favorable safety profile.

Methods This is a Phase 1b/2, open label, multicenter, dose escalation and dose expansion study of ADG116 in combination with pembrolizumab in patients with advanced/metastatic solid tumors. During dose escalation, ADG116 and pembrolizumab are administered intravenously, Q3W. Primary endpoints are safety and tolerability. Secondary endpoints are PK, ORR per RECIST 1.1, and PFS.

Results As of June 30, 2022, 4 patients have been treated by ADG116 (3 mg/kg) + pembrolizumab (200 mg) combination therapy. Patients were 69 (47-74) years-old [median (range)] and have been heavily pre-treated before enrollment: all 4 (100%) had prior chemotherapy, 1 (25%) radiation therapy, 1 (25%) hormonal therapy; 2 (50%) received $\geq$ 3 prior lines of therapies, but none had been treated with an anti-PD-1/PD-L1, or an anti-CTLA-4 therapy. ADG116 + Pembro combination showed a manageable safety profile with no DLTs. Most common treatment-related adverse events were Grade 1 nausea (50%) and pruritis (50%). One Grade 3 AE (dehydration) was observed after repeated dosing in Cycle 3 (C3D12). Additional safety and efficacy data will be reported.

Conclusions The current safety data supports the regimen of ADG116 (3 mg/kg)/pembrolizumab (200 mg), Q3W for dose expansion, which is a higher dose than that approved for ipilimumab (1 mg/kg) when in combination with nivolumab for several cancer indications. Additional repeat dosing data are being generated to inform the safety, tolerability, and activity of ADG116 in combination with the anti-PD-1 therapy.

774 A PHASE 1 STUDY EXPLORING THE SAFETY AND TOLERABILITY OF THE SMALL MOLECULE PD-L1 INHIBITOR, INCB086550, IN PATIENTS WITH SELECT ADVANCED TUMORS

[1]Christophe Le Tourneau*, [2]Sarina Piha-Paul, [3]Hans Prenen, [4]Brant Delafontaine, [5]David Pinato, [6]Armando Santoro, [7]Rebecca Kristeleit, [8]Kristen Spencer, [9]Tara Gangadhar, [10]Howard Burris, [11]Nuria Kotecki, [12]Bristi Basu, [13]Donna Graham, [14]Anna Maria Di Giacomo, [15]Solmaz Sahebjam, [16]Massimo Di Nicola, [17]Carlos Gomez-Roca, [17]Pascale Tomasini, [18]Paolo Ascierto, [19]Giuseppe Curigliano, [20]Thomas Karasic, [21]Ryan Geschwindt, [21]Jeannie Daniel, [22]Eric Van Cutsem. *[1]Institut Curie, Paris, France; [2]University of Texas, Houston, TX, USA; [3]Universitair Ziekenhuis – Antwerpen, Antwerp, Belgium; [4]Drug Research Unit Ghent, Ghent, Belgium; [5]Imperial College London, London, UK; [6]Humanitas University, Rozzano-Milan, Italy; [7]Guy's and St Thomas NHS Foundation Trust, London, UK; [8]Perlmutter Cancer Center of NYU, Langone health and NYU Grossman School of Medicine, New York, NY, USA; [9]Abramson Cancer Center, Philadelphia, PA, USA; [10]Tennessee Oncology, Nashville, TN, USA; [11]Institut Jules Bordet, Brussels, Belgium; [12]University of Cambridge, Cambridge, UK; [13]The Christie NHS Foundation Trust, Manchester, UK; [14]University of Siena, Siena, Italy; [15]Moffitt Cancer Center, Tampa, FL, USA; [16]Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy; [17]Assistance Publique Des Hôpitaux de Marseille, Marseille, France; [18]Istituto Nazionale Tumori, Milan, Italy; [19]European Institute of Oncology, Milan, Italy; [20]Perelman School of Medicine, Philadelphia, PA, USA; [21]Incyte Corporation, Wilmington, DE, USA; [22]University Hospitals Gasthuisberg, Leuven, Belgium*

Background INCB086550 is an orally administered small-molecule inhibitor of programmed cell death ligand 1 (PD-L1). This is an ongoing phase 1, open-label, multicenter study.

Methods Eligible patients are aged ≥18 years with advanced solid tumors and Eastern Cooperative Oncology Group performance status of 0–1. Patients had disease progression after treatment with available therapies or were ineligible for or without access to standard treatment. Part 1 uses a modified 3+3 dose-escalation design to identify a maximum tolerated dose (MTD) of INCB086550. Multiple doses are expanded in additional cohorts: part 2 cohort A (tumors that progressed on previous PD-1 treatment), part 2 cohort B (immunotherapy-naive), part 3 (high microsatellite instability [MSI-H] or deficient mismatch repair), and part 4 (human papilloma virus–positive tumors). The primary endpoints were safety and tolerability measured by monitoring frequency and severity of adverse events (AEs) and to determine a pharmacologically active dose and/or MTD. Tumor response was evaluated per RECIST v1.1 or RANO.

Results As of April 1, 2022, 138 patients received INCB086550 treatment at doses ranging from 100 mg once daily to 800 mg twice daily (bid); median age was 65 years (range, 31–86), 60.9% were women, 80.4% were white. 78 patients (56.5%) had ≥2 lines of prior therapy. The most common tumor types were colorectal (13.8%), cervical (10.9%), and anal (10.9%). 121 patients (87.7%) discontinued treatment, 90 of whom discontinued for disease progression. Treatment-emergent AEs (TEAEs) occurring in >20% of patients were fatigue, nausea, decreased appetite, constipation, vomiting, and diarrhea. Serious TEAEs (SAEs) occurred in 50 patients (36.2%); SAEs occurring in >2 patients were small intestinal obstruction, abdominal pain, intestinal obstruction, and pneumonia. No dose-limiting toxicities (DLTs) occurred. Grade ≥3 treatment-related AEs occurred in 18 patients (13.0%), with aspartate aminotransferase increased, fatigue, immune-mediated neuropathy, and rash reported in >1 patient (n=2 each). Sponsor-defined immune-related TEAEs occurred in 41 patients (29.7%), 22 (15.9%) of which were peripheral neuropathies. Stepdown/intermittent dose regimens did not mitigate events of immune-mediated peripheral neuropathy. 16 patients (11.6%) had TEAEs that led to discontinuation of INCB086550. Two patients (1.4%) achieved a complete response (squamous cell anal cancer, 400 mg bid; MSI-H colorectal cancer, 400 mg bid); 10 patients overall (7.2%) achieved partial response.

Conclusions No DLTs occurred. Encouraging antitumor activity has been observed. INCB086550 has a safety profile consistent with monoclonal antibody immune checkpoint inhibitors, except for an observed increased rate of immune-mediated peripheral neuropathy.

Trial Registration NCT04629339

775 **INITIAL RESULTS FROM DOSE ESCALATION OF A PHASE 1/2 FIRST-IN-HUMAN, OPEN LABEL STUDY OF AU-007, A MONOCLONAL ANTIBODY THAT BINDS TO IL-2 AND PREVENTS ITS BINDING TO CD25, IN PATIENTS WITH SOLID TUMORS**

[1]James Vasselli*, [2]Paul de Souza, [3]Sophia Frentzas, [4]Andrew Weickhardt, [1]Timothy Wyant, [1]Jenny Tang, [5]Lori Richards, [1]Aron Knickerbocker, [6]Inbar Amit, [6]Yanay Ofran. *[1]Aulos Bioscience, San Francisco, CA, USA*; *[2]Southside Cancer Care, Campbelltown, Australia*; *[3]Monash Cancer Center, Melbourne, Australia*; *[4]Austin Health, Heidelberg, VT, Australia*; *[5]Aulos Biosciences, Oakland, CA, USA*; *[6]Biolojic Design, Rehovot, Israel*

Background AU-007 is a computationally designed monoclonal antibody that binds IL-2 on its CD25 binding epitope. AU-007 bound IL-2 (A/IL-2) cannot bind to trimeric (CD25, CD122, CD132) IL-2 receptors (IL-2R) on Tregs and vascular endothelium, but leaving IL-2's binding to dimeric IL-2Rs (CD122, CD132) on T effector and NK cells unhindered. Therefore AU-007 redirects endogenous or exogenous IL-2 (aldesleukin) towards T effector and NK cell activation, while diminishing Treg activation and vascular leak. Unique in the IL-2 field, AU-007 can bind and redirect endogenous IL-2 generated from A/IL-2 driven T cell expansion in vivo, converting a Treg-mediated autoinhibitory loop into an immune-stimulating loop. Additionally, A/IL-2 is expected to substantially prolong the 90-minute T1/2 of IL-2, potentially allowing the use of endogenous IL-2 (as A/IL-2) alone to initiate an anti-tumor response. In non-human primates, AU-007 bound IL-2 with a similar affinity to human IL-2 and increased IL-2 serum concentrations in a dose- dependent manner while demonstrating an excellent safety profile.

Methods Phase 1 of this Phase 1/2 study (**NCT05267626**) consists of 3 dose escalation arms. Each Arm begins with one 1+2 escalation cohort followed by 3+3 escalation cohorts. In Arm 1A, escalating doses of monotherapy AU-007 (Q2W) are evaluated in sequential cohorts. In Arm 1B, AU-007 (Q2W) is evaluated in combination with a single low-dose of aldesleukin with the first AU-007 dose. The AU-007 dose will be fixed with escalating aldesleukin doses in sequential cohorts. In Arm 1C, AU-007 is evaluated in combination with escalating low-doses of aldesleukin, both given Q2W. The AU-007 and aldesleukin dose and schedule for Phase 2 cohort expansion in selected solid tumor types will be based on safety, objective signs of efficacy and PD parameters including increases of IL-2 concentration (as A/IL-2), total lymphocytes, CD8+ T cells, IFN-γ, and soluble CD25.

Results As of July 2022, two patients enrolled into dose escalation Arm 1A, 1 patient on 0.5 mg/kg (First In Human starting dose) and one patient into the second cohort (1.5 mg/kg). AU-007 was well tolerated with no drug related adverse events in the ongoing dose escalation.

Conclusions At this early data cut, AU-007 monotherapy given 0.5 mg/kg Q2W or 1.5 mg/kg Q2W was safe and well tolerated. Data from additional patients are expected to be presented in the poster.

776 **ITIL-306–201: A MULTICENTER, FIRST-IN-HUMAN PHASE 1A/1B STUDY OF ITIL-306, AN ENGINEERED AUTOLOGOUS TUMOR-INFILTRATING LYMPHOCYTE (TIL) CELL THERAPY PRODUCT, IN ADULTS WITH ADVANCED SOLID TUMOR**

[1]Jeffrey Ward*, [1]Armin Ghobadi, [2]John Liao, [3]Adam Schoenfeld, [2]Scott Tykodi, [4]Yizhou Jiang, [4]John Le Gall, [4]Ruben Alvarez-Rodriguez, [4]Marika Sherman, [4]Tiffany Singson, [4]Jeffrey McLeroy. *[1]Washington University School of Medicine and Siteman Cancer Center, Saint Louis, MO, USA; [2]University of Washington and Fred Hutchinson Cancer Center, Seattle, WA, USA; [3]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [4]Instil Bio, Inc., Dallas, TX, USA*

Background Pioneering work in advanced melanoma has prompted investigation of TIL cell therapy in other immunogenic solid tumor indications.[1-3] Although TILs encompass a broad diversity of antitumor reactivities with an unrestricted T-cell receptor (TCR) repertoire, their activity may be limited in certain tumors.[4] Addition of synthetic costimulation improves T-cell functional activity while maintaining the diverse antigen specificity of TILs (figure 1).[5] In a murine model with a human solid tumor xenograft, the anti-folate receptor alpha (FRα) costimulatory antigen receptor (CoStAR) significantly enhanced T-cell proliferation, persistence, and antitumor activity without exogenous IL-2 support, resulting in enhanced tumor control and prolonged survival.[6] ITIL-306 is an engineered autologous TIL cell therapy that supplements native TCR-specific antigen recognition with synthetic costimulation upon engagement with FRα. ITIL-306-201 is a multicenter, single-arm, phase 1a/1b dose escalation and expansion study evaluating the safety and feasibility of ITIL-306 in adult patients with advanced epithelial ovarian cancer (EOC), non-small cell lung cancer (NSCLC), and renal cell carcinoma (RCC) who relapsed from or are refractory to ≥1 prior line of systemic therapy.

Methods Eligible patients are aged ≥18 years with histologically confirmed EOC, NSCLC, or RCC that has progressed during or after ≥1 prior line of systemic standard-of-care therapy, have ECOG performance status 0-1, and have viable tumor tissue that is suitable to resect with ≥2 grams for TIL harvest. Patients will be enrolled in phase 1a (dose escalation in a standard 3+3 design; n≈6-18) or 1b (expansion; n≈15 in each of 3 cohorts, 1 for each tumor type; **Figure 2**). Following tumor resection for TIL harvest, patients must have ≥1 remaining measurable lesion per RECIST v1.1.[7]Patients will receive a reduced dose of lymphodepleting chemotherapy followed by a single, intravenous fixed-dose of ITIL-306 in phase 1a (1 of 3 dose levels) or 1b (dose selected in the phase 1a portion) and no post-infusion IL-2. The phase 1a primary endpoint is incidence of dose-limiting toxicities. The phase 1b primary endpoint is frequency and severity of treatment-emergent adverse events (AEs), serious AEs, and AEs of special interest. Secondary endpoints include manufacturing success rate, objective response rate per modified RECIST v1.1,[7] disease control rate, best overall response, time to response, duration of response, progression-free survival, and overall survival. Key exploratory endpoints include association of biomarkers with response (eg, tumor FRα expression) and characterization of ITIL-306 activation, trafficking, persistence, and phenotype. The study is open (NCT05397093).

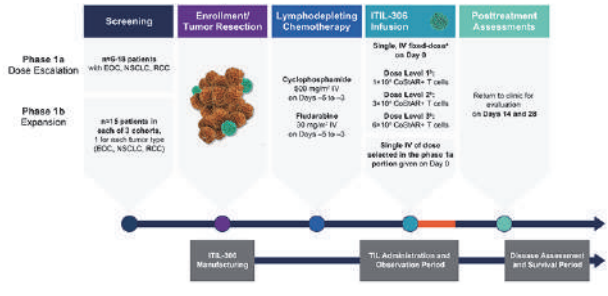
Abstract 776 Figure 1 CoStAR Platform Overview
The novel CoStAR platform is engineered to enhance TIL functional activity. Similar to unmodified T cells, CoStAR TILs require specific antigen recognition via the native TCR for activation. CoStAR ligand engagement also provides T cells with synthetic costimulatory signals that enhance antitumor responses. Therefore, CoStAR-expressing T cells supplement tumor-specific antigen recognition via TCR with a robust costimulatory signal delivered via CoStAR.
CoStAR, costimulatory antigen receptor; FRα, folate receptor alpha; scFv, single-chain variable fragment; TCR, T-cell receptor; TIL, tumor-infiltrating lymphocyte; TME, tumor microenvironment.



Abstract 776 Figure 2 ITIL-306-201 Phase 1a/1b Treatment Schema
ITIL-306-201 is a phase 1a/1b dose escalation and expansion study evaluating the safety and feasibility of ITIL-306 in adult patients with advanced EOC, NSCLC, and RCC who relapsed from or are refractory to ≥1 prior line of systemic standard-of-care therapy.
[a] Enrollment at the next dose level will be based on the incidence of dose-limiting toxicities observed within each dose level. Enrollment into

dose levels will continue sequentially until a maximum-tolerated dose is reached, or all dose levels have been tested. If the dose-limiting toxicity threshold is not met at the highest dose level, then dose level 3 will be selected for testing in phase Ib.

[b] ± 20% target dose.

EOC, epithelial ovarian, fallopian tube, and peritoneal carcinomas; IV, intravenous; NSCLC, non-small cell lung cancer; RCC, renal cell carcinoma; TIL, tumor-infiltrating lymphocyte.

777 INITIAL CLINICAL CHARACTERIZATION OF NOVEL PROXIMAL BIOMARKERS FOR NX-1607, A FIRST-IN-CLASS ORAL CBL-B INHIBITOR, IN PATIENTS WITH ADVANCED MALIGNANCIES

[1]Sarah Whelan*, [1]Christopher Karim, [1]Jordan Ye, [1]Timothy Ingallinera, [1]Ganesh Cherala, [1]Katherine Jameson, [2]Anja Williams, [3]Adam Sharp, [4]Matthew Krebs, [5]Simon Pacey, [6]Sarah Blagden, [7]Ruth Plummer, [8]Daniel Hochhauser, [9]Jeff Evans, [10]Johann De Bono, [1]Janine Powers. *[1]Nurix Therapeutics, Inc., San Francisco, CA, USA; [2]Sarah Cannon Research Institute UK, London, UK; [3]Royal Marsden NHS Foundation Trust, Sutton, UK; [4]The Christie NHS Foundation Trust, Manchester, UK; [5]University of Cambridge, Cambridge, UK; [6]University of Oxford, Oxford, UK; [7]Newcastle University Centre for Cancer, Newcastle-upon-Tyne, UK; [8]University College Hospital, London, UK; [9]CR-UK Beatson Institute, Glasgow, UK; [10]Institute of Cancer Research, London, UK*

Background Casitas B-lineage lymphoma proto-oncogene B (CBL-B) is an E3 ubiquitin ligase expressed in multiple immune cell lineages and is a master regulator of the immune response. NX-1607 is a first-in-class oral small molecule inhibitor of CBL-B that has demonstrated potent anti-tumor activity in animal models by reversing T cell dysfunction and overcoming suppressive signaling in the tumor microenvironment.[1] Nurix has identified and characterized novel proximal biomarkers of CBL-B inhibition that correlate with anti-tumor activity in syngeneic tumor models. Assays for these biomarkers characterize the activity of NX-1607 in a first-in-human clinical trial (NCT05107674).

Methods Agnostic screening campaigns utilizing flow cytometry protein phosphorylation signals and mass spectrometry-based methods to measure direct ubiquitination substrates identified multiple proprietary proximal biomarkers of CBL-B inhibition in activated T cells. Validation of these biomarkers in mouse and non-human primate (NHP) *in vivo* models, coupled with allometric scaling of pharmacokinetic (PK) profiles, were used to inform clinical dose selection. PK and pharmacodynamic (PD) data are currently being monitored in a Phase I trial with daily oral dosing in 21-day cycles.

Results Phosphorylated hematopoietic lineage cell-specific protein 1 (pHS1), a regulator of T cell-receptor signaling, was identified as a robust and reproducible biologically relevant proximal biomarker for monitoring pharmacologic inhibition of CBL-B in whole blood. Validation of proximal biomarkers *in vivo* demonstrated target engagement with dose-dependent increases of pHS1 in CD8+ T cells in both mice and NHP dosed orally with NX-1607. As of June 16, 2022, 10 patients have enrolled on study at 4 ascending oral dose levels (5, 15, 25 and 50 mg once daily). Dose-proportional increases of pHS1-expressing T cells were observed in cycle 1. Preliminary PK data suggest a half-life of 4 to 9 hours and dose-proportional exposures with no apparent accumulation. Together these data are consistent with preclinical human dose projections and compare to pHS1 levels associated with anti-tumor activity in mouse models.

Conclusions NX-1607 is a first-in-class oral CBL-B inhibitor displaying linear PK, dose-dependent target engagement as measured by the validated proximal biomarker, pHS1, and downstream signals of T cell engagement. PK and PD data derived from non-clinical and clinical studies have shown remarkable concordance with biomarker levels observed in the clinic corresponding to those levels associated with potent anti-tumor activity observed in mouse models. The study continues to enroll, and updated PK and PD data will be presented.

Background Botensilimab (BOT) promotes optimized T cell priming, activation and memory formation by strengthening antigen presenting cell/T cell co-engagement. As an Fc-enhanced next-generation anti-CTLA-4 antibody, BOT also promotes intratumoral Treg depletion and reduces complement fixation. We present results from patients with metastatic solid tumors treated with BOT±balstilimab (BAL; anti-PD-1) in an expanded phase IA/B study; NCT03860272.

Methods Patients received either BOT monotherapy at 0.1-3 mg/kg every 3 weeks (Q3W), BOT monotherapy 1 or 2mg/kg every 6 weeks (Q6W), BOT 0.1-2mg/kg Q6W+BAL 3 mg/kg every 2 weeks, or a fixed-dose of BOT 150mg Q6W+BAL 450mg Q3W. Unconfirmed responses are included. Of the 44 BOT monotherapy patients, 13 crossed over to combination.

Results 142 patients (98 combination, 44 monotherapy [13 crossover]) were evaluable for efficacy/safety (treated as of April 7, 2022 with ≥1 Q6W tumor-imaging assessment). Patients had immunologically cold and/or immunotherapy resistant tumors and were heavily pretreated: 61% received ≥3 prior lines of therapy including 34% prior immunotherapy. Median follow-up was 6.1 months.

Disease-specific combination therapy cohorts are being expanded with BOT at 1 or 2mg/kg or 150mg+BAL (including 4 crossover patients): (1) microsatellite stable (MSS) colorectal cancer (n=44, ORR 25%), (2) platinum resistant ovarian cancer (n=18, ORR 28%), (3) sarcoma (n=12, ORR 42%, and (4) PD-(L)1 relapsed/refractory non-small cell lung cancer (n=3, ORR 67%).

The ORR was 22% (22/98; 3 CR/19 PR) with median duration of response [DOR] not reached (range,1.4+ to 19.5 + months) in all combination patients (BAL+BOT 0.1-2 mg/kg or 150 mg); 13/22 responses are ongoing. In addition, 15% (2/13) monotherapy patients achieved PR after crossing over to combination therapy. The ORR was 11% (5/44; 1 CR/4 PR) in all monotherapy patients (BOT 0.1-3 mg/kg). Responses were independent of PD-L1 expression and tumor mutation burden. Further evaluation of biomarkers is ongoing including paired biopsies (before/during treatment).

Grade 1/2, 3 or 4 treatment-related adverse events (TRAE) occurred in 88%, 29%, 2% respectively. Diarrhea/colitis (19%) was the only grade 3/4 TRAE occurring in ≥5% of patients. There were no cases of hypophysitis or myocarditis. Pneumonitis occurred in 4 patients (3%). Two patients had grade 5 TRAEs (enterocolitis, colonic perforation).

Conclusions BOT±BAL demonstrates remarkable activity in heavily pretreated patients with solid tumors historically unresponsive to immunotherapy. The safety profile is consistent with the mechanism of action of BOT. Randomized studies in MSS CRC, pancreatic cancer, and melanoma are planned to open this year.

Trial Registration NCT03860272

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0778

779 **A PHASE I, DOSE ESCALATION AND EXPANSION STUDY OF PT199, A NEXT GENERATION CD73 MONOCLONAL ANTIBODY, ADMINISTERED ALONE AND IN COMBINATION WITH A PD-1 INHIBITOR IN ADULT PATIENTS WITH ADVANCED SOLID TUMORS**

Ramzi Melhem*, Harold Wright, Hui Zou, Claudia Ramos, Jack Li, Ming Wang. *Phanes Therapeutics, San Diego, CA, USA*

Background PT199 is an anti-CD73 monoclonal antibody (mAb) with a differentiated mechanism of action. PT199 is designed to counter the adenosine-mediated immunosuppressive tumor microenvironment, rendering antitumor immune cells more responsive to checkpoint immunotherapies, such as PD-1/PD-L1 inhibitors. PT199 fully inhibits both soluble and membrane-bound CD73, unlike some other CD73 inhibitors which may inhibit only one form of enzyme or exhibit incomplete inhibition. Moreover, at higher concentrations no loss of inhibition or "hook effect" is observed with PT199, unlike with some other CD73 inhibitors in clinical development. Hence, PT199 addresses the limitations of current CD73 inhibitors and is expected to increase antitumor immune activation, especially in combination with PD-1 pathway inhibition, and thus offers a new treatment option for cancer patients.

Methods This study is evaluating the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary efficacy of PT199 alone and in combination with a PD-1 inhibitor, in patients with locally advanced or metastatic solid tumors that have progressed after all available standard therapy or for which standard therapy has proven to be ineffective, intolerable, or is considered inappropriate. Approximately 32-38 patients will be enrolled. The study consists of 3 parts: Monotherapy Dose Escalation, Combination Therapy Dose Escalation, and Combination Dose Expansion. The dose escalation study of PT199 will be guided by a standard 3+3 dose escalation study design to determine the maximum tolerated dose (MTD) and/or the dose recommended for dose expansion (DRDE). The MTD and/or DRDE will be further evaluated in a dose expansion cohort and a recommended phase II dose (RP2D) may be determined based on the totality of the safety, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy data obtained from both dose escalation and expansion cohorts. Each enrolled patient will receive PT199 as a monotherapy (10, 20, or 30 mg/kg QW) as an intravenous infusion continuously in 21-day cycles or in combination with a PD-1 inhibitor.

Results The primary endpoints are Dose Limiting Toxicity and MTD, if reached, and RP2D of PT199 as a single agent and/or in combination with a PD-1 inhibitor. PD assessments will include measurements of CD73 enzyme activity and cytokines in serum and CD73/PD-L1 expression in tumor tissues.

Conclusions The study is currently enrolling. Preliminary safety and efficacy data is anticipated the middle of next year.

Trial Registration NCT05431270

Ethics Approval The study obtained ethics approval through a central IRB (Advara IRB: Pro00063442). All participants have given informed consent before taking part in this trial.

780 **SRK-181, A LATENT TGFβ1 INHIBITOR: SAFETY, EFFICACY, AND BIOMARKER RESULTS FROM THE DOSE ESCALATION PORTION OF A PHASE I TRIAL (DRAGON TRIAL) IN PATIENTS WITH ADVANCED SOLID TUMORS**

[1]Timothy Yap*, [2]Justin Gainor, [3]Meredith McKean, [3]Melissa Johnson, [4]Bruno Bockorny, [5]Minal Barve, [6]Randy Sweis, [7]Ulka Vaishampayan, [8]Ahmad Tarhini, [9]Deepak Kilari, [10]Yawen Ju, [10]Si-Tuen Lee-Hoeflich, [10]Stephen DeWall, [10]Lan Liu, [10]Nisha Shah, [10]Ann Marie Kennedy, [10]Lu Gan. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Massachusetts General Hospital Harvard Medical School, Boston, MA, USA; [3]Sarah Cannon Research Institute, Nashville, TN, USA; [4]Beth Israel Deaconess Medical Center, Boston, MA, USA; [5]Mary Crowley Cancer Research, Dallas, TX, USA; [6]University of Chicago, Chicago, IL, USA; [7]University of Michigan, Ann Arbor, MI, USA; [8]Moffitt Cancer Center, Tampa, FL, USA; [9]Medical College of Wisconsin, Milwaukee, WI, USA; [10]Scholar Rock, Inc., Cambridge, MA, USA*

Background Transforming growth factor-beta 1 (TGFβ1) plays an important role in mediating the primary resistance to PD-1/PD-L1 [PD-(L)1] blockade. SRK-181 is a fully human, selective anti-latent TGFβ1 IgG4 monoclonal antibody under investigation as a monotherapy or in combination with anti-PD(L)1 therapy in patients with solid tumors. Compared to broad TGFβ inhibitors, SRK-181 was observed to have improved safety profile (no cardiotoxicities) in four-week GLP nonclinical toxicology studies.

Methods The DRAGON trial (NCT04291079) is an ongoing open-label, phase 1 study. Part A followed a 3+3 dose escalation design to evaluate SRK-181 in patients with advanced solid tumors at 80-3000mg every three weeks (q3w) and 2000mg q2w in Part A1, and SRK-181+anti-PD-(L)1 in patients who did not respond to prior anti-PD-(L)1 therapy at 240-2400mg q3w in Part A2. In Part B (expansion phase), SRK-181 (1500mg q3w or 1000mg q2w)+anti-PD-(L)1 are administered in anti-PD-(L)1-resistant patients with non-small cell lung cancer (NSCLC), urothelial carcinoma, melanoma, clear cell renal cell carcinoma (ccRCC) or other advanced solid tumors. The level of circulatory TGFβ1 was assessed as a target engagement biomarker.

Results As of 2 June 2022, Part A1 and Part A2 enrolled 19 and 15 patients, respectively, with median prior lines of therapies of 4 (range 1-10). No dose limiting toxicity (DLT) were observed in Part A. In Part A1, the most common treatment-related AEs (TRAEs, >10%) of any grade were fatigue (16%, n=3), decreased appetite and nausea (each: 11%, n=2). Eight patients had stable disease (SD) as best response (3/colorectal, 3/ovarian, 1/pancreatic, and 1/testicular). The three patients with ovarian cancer were stable for 25 to 42 weeks. In Part A2, the TRAEs (>10%) of any grade were pruritus, rash and rash maculo-papular (each: 20%, n=3), diarrhea (13%, n=2). One confirmed RECIST1.1 partial response (PR) was observed at 800mg in a patient with anti-PD-1 resistant RCC who stayed on study for 30 weeks. Nine patients had best response of SD and five of them were stable for more than 16 weeks (2/head and neck, 1/melanoma, 1/skin squamous cell carcinoma, 1/RCC). SRK-181 treatment resulted in increased levels of circulatory TGFβ1, which suggested target engagement. Part B enrollment is ongoing.

Conclusions As of 2 June 2022, SRK-181 has been tolerated as monotherapy and in combination with anti-PD-(L)1. No DLT was observed up to 3000mg q3w/2000mg q2w as monotherapy and up to 2400mg q3w as combination treatment. Early evidence of efficacy was observed with prolonged stable disease and a confirmed PR.

781 DELTA-2: A PHASE 1, OPEN-LABEL, MULTICENTER STUDY OF ITIL-168, AN AUTOLOGOUS TUMOR-INFILTRATING LYMPHOCYTE (TIL) CELL THERAPY, WITH PEMBROLIZUMAB IN PATIENTS WITH ADVANCED SOLID TUMORS

[1]Oladapo Yeku*, [2]Daniel Olson, [3]Jeffrey Ward, [4]Sandip Patel, [5]Jeff Aycock, [5]Amber Donahue, [5]Yizhou Jiang, [5]John Le Gall, [5]Zachary Roberts, [5]Rubén Alvarez-Rodríguez, [5]Judy Seng, [5]Tong Shen, [5]Nishi Kothari. *[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA; [2]The University of Chicago Medical Center, Chicago, IL, USA; [3]Washington University School of Medicine and Siteman Cancer Center, Saint Louis, MO, USA; [4]University of California San Diego, La Jolla, CA, USA; [5]Instil Bio, Inc., Dallas, TX, USA*

Background Despite the benefits of immune checkpoint inhibitors (ICIs) in solid tumors, additional treatment options are needed for patients with primary or acquired resistance.[1] TILs are present in various solid tumors, and TIL therapy has demonstrated efficacy and durable responses in some advanced solid tumors due to its antitumor reactivity and broad T-cell repertoire.[2-4] Additionally, preclinical data suggest ICIs may further support the persistence of TILs in immunogenic tumors.[5] Here, we describe a study that will explore the safety, feasibility, and preliminary efficacy of an autologous TIL therapy, ITIL-168, in combination with pembrolizumab in patients with cervical cancer (CC), head and neck squamous-cell carcinoma (HNSCC), or non-small cell lung cancer (NSCLC).

Methods DELTA-2 (NCT05393635) is an ongoing phase 1, multicenter, multicohort, open-label trial evaluating ITIL-168 with pembrolizumab in previously treated patients with advanced solid tumors. Patients will be enrolled in 1 of 3 cohorts (n≈9-15 patients per cohort): advanced CC (Cohort 1), HNSCC (Cohort 2), or NSCLC (Cohort 3). Eligible patients must have progressed during or following ≥1 prior line of chemotherapy along with an ICI. EGFR mutations or ALK translocations in NSCLC are included in Cohort 3, and patients are required to have progressed on targeted therapy but not ICI. Eligibility criteria across all cohorts include ECOG PS ≤1, adequate organ function, resectable tumor lesion(s), and ≥1 remaining measurable lesion per RECIST v1.1 post-tumor resection. Bridging therapy is allowed but must be discontinued at least 2 weeks or 5 half-lives before baseline imaging. Patients with prior cell therapy treatment, symptomatic and/or untreated central nervous system metastases, or requiring chronic steroids are ineligible. Treatment will include lymphodepleting chemotherapy (the dosage of cyclophosphamide and fludarabine will be adjusted based on cohort and patient comorbidities) followed by a single infusion of ITIL-168 and up to 8 doses of high-dose IL-2 (figure 1). Patients will receive pembrolizumab at baseline before ITIL-168 infusion, day 21 postinfusion, and then every 6 weeks for ≤48 weeks or until disease progression or intolerable toxicity. An interim and a primary analysis for each cohort will be conducted. The primary endpoint is the frequency and severity of ITIL-168 treatment-emergent adverse events (AEs) per Common Terminology Criteria for AEs version 5.0. Secondary endpoints include manufacturing success rate, objective response rate per modified RECIST v1.1, duration of response, progression-free survival, and overall survival. The study opened in July 2022 and is currently recruiting patients.

Abstract 781 Figure 1 DELTA-2 Treatment Schema
DELTA-2 is a phase 1 trial evaluating the safety, feasibility, and preliminary efficacy of ITIL-168 in combination with pembrolizumab in patients with select advanced solid tumors with progressive disease during or after 1 prior line of treatment.
*Tumor resection occurs within 30 days after patient consent, followed by optional bridging therapy.
†Baseline visit occurs within 14 days prior to lymphodepleting chemotherapy, followed by pembrolizumab (200 mg).
‡Cohorts 1/3 will receive lymphodepleting chemotherapy on days –7 to –3; Cohort 2 will receive lymphodepleting chemotherapy on days –5 to –3.
§Pembrolizumab is administered once on day 21 (200 mg), followed by every 6 weeks from weeks 6 to 48 (400 mg).
D, day; HD, high-dose; IL-2, interleukin-2; Q6W, every six weeks; W, week.

INTRATUMORAL SOTIGALIMAB WITH PEMBROLIZUMAB ACTIVATES ANTIGEN-PRESENTING CELLS AND INDUCES LOCAL AND DISTANT ANTI-TUMOR RESPONSES IN FIRST-LINE METASTATIC MELANOMA: RESULTS OF A PHASE I/II STUDY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0782

Background Checkpoint inhibitors (CPI) provide significant clinical benefits for patients with metastatic melanoma (MM). However, the majority of patients do not respond or develop resistance after initial tumor regression. In this ongoing phase I/II study, we assessed intratumoral sotigalimab, a CD40 agonistic antibody in combination with systemic pembrolizumab in CPI treatment naïve MM.

Methods As of May 15, 2022, thirty-two patients were enrolled. Patients received sotigalimab every 3 weeks for a total of 4 doses. The primary objectives include safety and tolerability, determination of the recommended phase 2 dose (RP2D), and assessment of the overall response rate (ORR) by RECIST v1.1. Biomarker analyses of blood and tumor samples were performed to measure immune activation using imaging mass cytometry, TCR sequencing, and a cross-cohort comparison of gene expression data (sotigalimab plus pembrolizumab versus anti-PD-1 monotherapy). Single-nucleus ATAC and RNA sequencing are being performed to determine cell-type-specific chromatin accessibility and transcriptional profiles associated with clinical response.

Results The combination therapy has been well-tolerated, and there were no study discontinuations or death due to treatment-related adverse events, most common treatment-related adverse events were injection-site reactions. Efficacy analysis of thirty patients with disease evaluations demonstrated an ORR of 50% in distant lesions and a disease control rate of 67%. The ORR at the RP2D of 10 mg is 55% (12/22). Responses were observed in PD-L1 negative patients and those with elevated LDH. Multi-omics analysis of peripheral blood mononuclear cells and tumor biopsies demonstrate that sotigalimab effectively engaged CD40 pathway. In comparison to anti-PD-1 monotherapy, the combination therapy significantly increased expression of genes associated with antigen presentation and effector T-cells in local lesions accompanied by an increase in T cell activation genes at distant lesions. Additionally, combination therapy resulted in an increase in clonality with expansion of new clones shared between local and distant lesions. All these immunologic changes were correlated with clinical response. Findings were recapitulated in B16 melanoma preclinical model, which demonstrated that intratumoral CD40 activation synergizes with systemic anti-PD-1 therapy and suppress tumor growth. Therapeutic efficacy was associated with increases in intratumoral conventional type 1 dendritic cells (cDC1), $CD8^+$ T cells, and an increased ratio of intratumoral $CD8^+$ T cells to myeloid-derived suppressor cells.

Conclusions This combination therapy is well tolerated and has a notable clinical response rate, accompanied by broad innate and adaptive immune activation at both local and distant lesions. More biomarker and clinical response data are anticipated in November.

Trial Registration NCT02706353

Ethics Approval The study was approved by FDA and the Institutional Review Board

783 TRIAL IN PROGRESS: A PHASE 1/2 OPEN-LABEL STUDY (IOV-GM1–201) OF TALEN-MEDIATED PD-1–INACTIVATED AUTOLOGOUS TUMOR-INFILTRATING LYMPHOCYTES (TIL; IOV-4001) IN PATIENTS WITH ADVANCED MELANOMA AND NSCLC

[1]Allison Betof*, [2]Trisha Wise-Draper, [3]Kai He, [4]Amod Sarnaik, [5]Jonathan Thompson, [6]Friedrich Finckenstein, [6]Parameswaran Hari, [6]Madan Jagasia, [6]Anjali Desai, [6]Akiko Suzuki, [6]Xiao Wu, [7]Jason Chesney. *[1]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]University of Cincinnati Cancer Center (UCCC), Cincinnati, OH, USA; [3]Ohio State University, Columbus, OH, USA; [4]H. Lee Moffitt Cancer Center, Tampa, FL, USA; [5]Medical College of Wisconsin, Froedtert Hospital Cancer Center, Milwaukee, WI, USA; [6]Iovance Biotherapeutics, Inc., San Carlos, CA, USA; [7]James Graham Brown Cancer Center, University of Louisville, Louisville, KY, USA*

Background Adoptive cell therapy with TIL has demonstrated efficacy in patients with advanced solid tumors, both as monotherapy in melanoma,[1] NSCLC,[2] and cervical cancer,[3] and in combination with anti–PD-1 therapy in melanoma, head and neck cancer, and cervical cancer.[4] IOV-4001 is a TALEN®-mediated *PDCD-1* knockout autologous TIL cell therapy product. Preclinical studies suggest that PD-1 inactivation by *PDCD-1* gene knockout may enhance TIL cell therapy efficacy, with similar quality attributes and phenotypes to those of non-edited TIL.[5]

Methods This first-in-human phase 1/2, open-label, nonrandomized, multicenter study (NCT05361174; open to enrollment) will enroll ~53 adult patients. During the phase 1 portion, enrollment and dose level decisions will be based on emerging safety and tolerability data in a 28-day dose-limiting toxicity (DLT) observation period.

Cohort 1 will include patients with unresectable/metastatic melanoma that has progressed during/within 12 weeks of last anti–PD-1/PD-L1 dose (patients must have also received a BRAF ± MEK inhibitor if *BRAF V600* mutation-positive). Cohort 2 will include patients with advanced NSCLC who have received ≤3 prior therapies and whose disease progressed either: (1) during/within 12 weeks after last anti–PD-1/PD-L1 dose (patients without oncogene driver mutations) or (2) during/after ≥1 targeted therapy and either platinum doublet chemotherapy or during/within 12 weeks after last anti–PD-1/PD-L1 dose (patients with oncogene-driven tumors). Patients must have ECOG performance status ≤1, ≥1 resectable lesion(s) (≥1.5 cm), ≥1 remaining RECIST-measurable lesion(s) and recovered from prior surgery/anticancer treatment-related adverse events (AEs; grade ≤1). IOV-4001 is generated from resected tumor in a centralized GMP process. The regimen includes nonmyeloablative lymphodepletion, IOV-4001 infusion, and a short course of high-dose IL–2.

The primary endpoints of phases 1 and 2 are safety (DLTs and AEs) and objective response rate per RECIST v1.1, respectively. Secondary endpoints include complete response rate, duration of response, disease control rate, progression-free survival, overall survival, feasibility, and additional safety.

Pirogov, Saint Petersburg, Russian Federation; [13]Charité Medical University, Berlin, Germany*

Background CV8102 is a non-coding, non-capped RNA complexed with a carrier peptide activating the innate (via TLR7/8, RIG-I) and adaptive immune system.[1, 2] An ongoing expansion of a phase I trial is investigating the intratumoral (i.t.) administration of CV8102 in patients with advanced cutaneous melanoma (cMEL), either as a single agent or in combination with systemic anti-PD-1 antibody therapy. In the initial dose escalation part, the recommended dose for subsequent cohort expansion and phase II was defined as 600 mg. Here we report preliminary immune profiling results.

Methods For the expansion cohorts, 30 anti-PD-1 refractory Melanoma patients received CV8102 in combination with Pembrolizumab or Nivolumab and 10 patients as single agent. Eight i.t. injections of CV8102 were administered over a 12-week period, with optional continuation in case of clinical benefit.

Blood samples for flow cytometry-based immune cell phenotyping and next-generation RNA sequencing (RNAseq) were collected at baseline and multiple time points during the treatment period. For characterization of the tumor microenvironment (TME), core needle biopsies of injected and/or non-injected lesions were taken before, during and after treatment. Changes on various tumor-infiltrating immune cells were assessed by multiplex immunofluorescence (MultiOmyx < sup >TM</sup >) and immune-related gene expression profiling using nCounter® Pan Cancer IO360< sup >TM</sup > panel (NanoString).

Results Blood RNAseq analysis showed increase in several transcripts related to systemic immune response activation like interferon alpha and gamma after the first dose.

Paired serial biopsies showed changes in the TME, not only in the immune cell infiltration but also in gene expression profiling.

Comprehensive results of blood RNAseq, immune cell phenotyping, and tissue analysis for the expansion cohorts will be presented, including examples of individual patients.

Conclusions Intratumoral injection of CV8102 activated several pathways of immune response detectable in peripheral blood after the first dose and showed immunological changes in the tumor microenvironment, with increased parameters of immune infiltration in a group of patients.

785 A PHASE I STUDY OF INTRALYMPHATIC (IL) ADMINISTRATION OF IPILIMUMAB (IPI) WITH INTRAVENOUS NIVOLUMAB (NIVO) USING THE SOFUSA® DOSECONNECT™ DEVICE IN PATIENTS WITH ADVANCED MELANOMA

Anastasios Dimou*, Vera Suman, Kristina Denic, Lisa Kottschade, Heather Montane, Heidi Finnes, Kristina Franta, Jill Schimke, Yiyi Yan, Robert McWilliams, Matthew Block, James Jakub, Joel Reid, Svetomir Markovic. *Mayo Clinic, Rochester, MN, USA*

Background Pre-clinical studies of Sofusa® DoseConnect™ (DC) have shown that IL infusion of antineoplastic medications results in higher lymph node concentrations, more efficient tumor growth inhibition and less systemic exposure when compared to conventional systemic administration. We conducted a Phase I clinical trial to assess the safety of IL infusion of ipilimumab with DC followed by nivolumab IV in patients with advanced melanoma.

Methods A 3+3 phase I clinical trial was conducted to assess the safety of IL infusion of IPI by DC over 12-24 hours followed by NIVO 3 mg/kg IV among patients with advanced melanoma. A maximum of four 21 day cycles were administered. Cycle 1 IPI was administered by DC; cycles 2-4 IPI were administered at 1 mg/kg IV. Dose levels (DL) of cycle 1 IPI included: DL1: 1 mg/kg; DL-1: 0.75 mg/kg; and DL-2: 0.5 mg/kg. All DL were given at 0.5 mL/hour. Dose limiting toxicities included the following if they were at least possibly related to DC: inability to administer at least 75% of the protocol-specified dose due to DC dislodgement, $\geq$ grade 4 hematologic toxicity, $\geq$ grade 3 non-hematologic toxicity or $\geq$ grade 3 infusion site reaction or infusion related reaction that does not resolve to Grade 0-1 within 2 weeks. IPI pharmacokinetics were characterized in all patients who participated in the study.

Results Six patients (3 males and 3 females) were enrolled in this trial at DL1. The median number of prior therapies for metastatic disease was 1 (range 1-3). The most common sites of metastatic disease were distant lymph nodes and lung. No dose limiting toxicities were observed. Cycle 1 toxicities reported included grade 2 hypophysitis (N=1) and grade 2 abdominal pain (N=1). No adjustments to the DC flow rate were required. Two severe, DC unrelated, immune-related toxicities were reported: grade 3 maculopapular rash and grade 3 colitis (same patient, cycle 1 causing discontinuation). Four patients progressed on treatment (1-cycle 2; 3-cycle 4). One patient completed 4 cycles of treatment. The mean IPI serum concentrations at the end of the infusion and 15 days after the DC infusion in Cycle 1 were 4.13 ug/mL and 4.88 ug/mL, respectively.

Conclusions IL administration of IPI with the DC device on the first cycle was well tolerated with no dose limiting toxicities. Safety and secondary efficacy of IL infusion of IPI through all 4 cycles will be assessed next.

Trial Registration ClinicalTrials. gov: NCT04967196

Ethics Approval This study was performed in line with the principles of the Declaration of Helsinki. Approval was granted by the Ethics Committee of Mayo Clinic.

Pirogov, Saint Petersburg, Russian Federation; [13]Curevac AG, Frankfurt, Germany*

Background CV8102 is a non-coding, non-capped RNA complexed with a carrier peptide activating the innate (via TLR7/8, RIG-I) and adaptive immune system. An ongoing phase I trial (CV-8102-008) is investigating intratumoral administration of CV8102 either as a single agent or in combination with systemic anti-PD-1 antibodies in patients with advanced cutaneous melanoma (cMEL), squamous cell carcinoma of the skin (cSCC) or head and neck (hnSCC) and adenoid cystic carcinoma (ACC). Recruitment of the expansion part in melanoma patients is completed and preliminary results from this part are reported here.

Methods Study CV-8102-008 is an open-label, cohort-based, dose escalation and expansion phase I study. Eight intratumoral injections of CV8102 are being administered initially over a 12-week period. The trial consists of two parts, a dose escalation part and an expansion part. Primary objective of the expansion part is to obtain additional safety data as well as initial estimates of efficacy in patients with advanced melanoma in a single agent cohort and patients with advanced melanoma patients refractory to anti-PD-1 therapy receiving CV8102 in combination with anti-PD-1 antibodies. In the expansion part, CV8102 was administered at a dose level of 600µg which has been determined as recommended phase 2 dose during the dose escalation part.

Results As of January 2022 10 patients have been treated with CV8102 as a single agent and 30 patients have received CV8102 in combination with anti-PD-1 antibodies within the expansion part. Most frequent treatment emergent adverse events were mild to moderate fever, chills and asthenia. Regression of injected and distant noninjected lesions was observed (including 4 PR per RECIST 1.1. in the combination cohort). Preliminary safety and efficacy as well as selected biomarker results from the expansion cohorts will be presented.

Conclusions The acceptable safety profile already observed during the dose escalation part could be confirmed in the expansion part. Preliminary evidence of clinical efficacy in the expansion cohorts was seen in combination with anti-PD-1-antibodies.

787 DELTA-1: A GLOBAL, MULTICENTER, PHASE 2 STUDY OF ITIL-168, AN UNRESTRICTED AUTOLOGOUS TUMOR-INFILTRATING LYMPHOCYTE (TIL) CELL THERAPY, IN ADULT PATIENTS WITH ADVANCED CUTANEOUS MELANOMA

[1]Brian Gastman*, [2]Amod Sarnaik, [3]Donald Lawrence, [4]Anthony Olszanski, [5]Bartosz Chmielowski, [6]Jose Lutzky, [7]Marcus Butler, [8]Omid Hamid, [9]Pippa Corrie, [10]Evidio Domingo-Musibay, [11]Sajeve Thomas, [12]Fiona Thistlethwaite, [13]Gregory Daniels, [14]Thomas Evans, [15]Andrew Furness, [16]Geoffrey Gibney, [17]Mark Harries, [18]Theresa Medina, [19]Daniel Olson, [20]Lalit Pallan, [21]Eric Whitman, [22]Melissa Wilson, [23]Jeff Aycock, [23]Robert Hawkins, [23]Yizhou Jiang, [23]Audrey Kennedy, [23]Paul Robbins, [23]Zachary Roberts, [23]John Le Gall. *[1]Cleveland Clinic, Cleveland, OH, USA; [2]Moffitt Cancer Center, Tampa, FL, USA; [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA; [4]Fox Chase Cancer Center, Philadelphia, PA, USA; [5]University of California Los Angeles, Los Angeles, CA, USA; [6]University of Miami, Miami, FL, USA; [7]Princess Margaret Cancer Centre, Ontario, Canada; [8]The Angeles Clinic and Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA, USA; [9]Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK; [10]University of Minnesota, Masonic Cancer Center, Minneapolis, MN, USA; [11]Orlando Health Cancer Institute, Orlando, FL, USA; [12]The Christie NHS Foundation Trust and University of Manchester, Manchester, UK; [13]University of California San Diego, Moores Cancer Center, La Jolla, CA, USA; [14]University of Glasgow, Beatson West of Scotland Cancer Centre, Glasgow, UK; [15]The Royal Marsden NHS Foundation Trust, London, UK; [16]MedStar Georgetown University Hospital, Washington, DC, USA; [17]Guy's and St. Thomas' NHS Foundation Trust, London, UK; [18]University of Colorado, Denver, CO, USA; [19]University of Chicago, Chicago, IL, USA; [20]University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [21]Atlantic Health System, Morristown, NJ, USA; [22]St. Luke's University Health Network, Easton, PA, USA; [23]Instil Bio, Inc., Dallas, TX, USA*

Background Investigational autologous TIL cell therapies have shown promise in patients with advanced cutaneous melanoma and persistent disease after checkpoint inhibitor therapy, a population with a high unmet medical need.[1,2] Made from autologous digested and cryopreserved tumor, ITIL-168 is a TIL cell therapy manufactured to offer an unrestricted T-cell receptor repertoire. DELTA-1 (NCT05050006) is a global, multicenter, phase 2 study evaluating efficacy and safety of ITIL-168 in patients with cutaneous melanoma relapsed or refractory to a PD-1i, patients intolerant to a PD-1i, and patients with stable disease on a PD-1i.

Methods Adult patients with histologically confirmed advanced cutaneous melanoma and ECOG performance status 0-1 will be enrolled in 1 of 3 cohorts. Cohort 1 (n≈80) will include patients who relapsed after or were refractory to ≥1 prior line of systemic therapy, including a PD-1i and, if *BRAF*-mutated, a BRAFi ± MEKi. Cohorts 2 and 3 (n≈25 each) will include patients intolerant to PD-1i and those with stable disease after ≥4 doses of PD-1i, respectively. After tumor harvest, patients must have ≥1 measurable lesion per RECIST 1.1. Noncutaneous melanoma, certain prior therapies, and patients with symptomatic and/or untreated central nervous system metastases are ineligible. Patients will receive 5 days of lymphodepleting chemotherapy (cyclophosphamide ×2 days overlapping with fludarabine ×5 days) followed by a single ITIL-168 infusion and supportive IL-2. The primary endpoint is objective response rate (ORR) per central review. Secondary endpoints include duration of response, progression-free survival, overall survival, disease control rate, TIL persistence, and safety. Hypothesis testing of ORR will be performed for cohort 1. The primary analysis will occur ≥6 months after the first posttreatment disease assessment of patients in the cohort 1 modified intent-to-treat population. Enrollment has expanded into Canada and Europe.

788 A PHASE 1B STUDY TO EVALUATE THE SAFETY, TOLERABILITY, PHARMACOKINETICS AND ANTI-TUMOR ACTIVITY OF NEOADJUVANT USE OF PH-762 ADMINISTERED INTRATUMORALLY IN SUBJECTS WITH ADVANCED MELANOMA

[1]Simon Fricker*, [2]Caroline Robert, [3]François-Xavier Danloss, [3]Emilie Routier, [1]Benjamin Cuiffo, [1]James Cardia. *[1]Phio Pharmaceuticals, Marlborough, MA, USA; [2]Gustave and Paris-Saclay University, Villejuif-Paris, France; [3]Gustave Roussy, and Paris-Saclay Univers, Paris, France*

Background Immunotherapy with antibodies targeting PD-1 and CTLA-4 has shown significant benefit in late-stage melanoma. However, as response is limited to approximately 60%, and with emergence of resistance, further improvements in therapeutic options are still required. Two approaches for improving the outcome of immunotherapy with checkpoint inhibitors are neoadjuvant treatment and local intratumoral (IT) injection. Neoadjuvant immunotherapy can induce significant pathological responses that seem to be associated with a decrease in the risk of relapse. Currently there is no neoadjuvant standard of care for patients with resectable, advanced melanoma. IT immunotherapy uses the tumor as its own vaccine to activate the immune system, priming an anti-tumor immune response and minimizing systemic exposure and off-target toxicities. PH-762 is a potent RNAi molecule targeting PD-1 that contains structural and chemical modifications conferring rapid and efficient tissue uptake suitable for IT administration. In pharmacology studies PH-762 provided robust silencing of PD-1 associated with T cell activation, and dose-dependent inhibition of tumor growth in *in vivo* syngeneic tumor models with on-target PD-1 silencing-associated with immunostimulatory effects in the tumor microenvironment.

Methods The primary objective of this first-in-human study is to evaluate the safety of neoadjuvant use of PH-762 administered by IT injection. Secondary objectives include PK after IT injection, potential immunologic and pathologic tumor responses, and determination of the recommended Phase 2 dose. Subjects must have histologically confirmed stage IIIB/IIIC/IIID or IV oligometastatic cutaneous melanoma with at least one resectable lesion that is large enough to allow IT injection, and that can undergo repeated biopsy. Subjects with brain metastases, leptomeningeal disease, uveal melanoma, and auto-immune disease are excluded. PH-762 is administered IT into one designated tumor lesion once weekly for 4 weeks prior to surgical excision at 5-6 weeks after the initial injection. The dose of PH-762 is normalized to tumor volume to ensure an equivalent local dose (tumor tissue concentration). Post tumor excision, subjects are followed-up for 6 weeks. Primary endpoint is determination of a safe dose of PH-762 assessed by incidence of dose limiting toxicities (DLT) prior to tumor resection. Bayesian optimal interval (BOIN) design will be employed to evaluate escalating doses of PH-762 with up to 5 dose levels in cohorts of 3 or more subjects. Tumor changes will be evaluated per RECIST criteria (version 1.1 and iRECIST adapted for IT therapy) and pathological response. Secondary endpoints include immunological response in tumor tissue and blood. The first cohort has been enrolled.

Background Despite improved outcomes in advanced (unresectable or metastatic) melanoma, many patients progress after ICI,[1-3] and have low response rates to subsequent therapy.[4-7] Lifileucel, a one-time autologous TIL cell therapy, demonstrated an investigator-assessed ORR of 36% in Cohort 2 (C2), which enrolled 66 patients who progressed post-ICI and appropriate targeted therapy.[8,9] We now report outcomes of 153 patients enrolled across C2 and C4 (NCT02360579), representing the largest phase 2 study of cell therapy in melanoma.

Methods Eligibility criteria were identical for C2 and C4. Patients had ≥1 lesion(s) resected (~1.5 cm in diameter post-resection) and shipped to a central GMP facility for 22-day lifileucel manufacturing. All patients received a nonmyeloablative lymphodepletion (NMA-LD) regimen, a single lifileucel infusion, and up to 6 doses of high-dose IL-2. Primary endpoint was IRC-assessed ORR (RECIST v1.1).

Results The full analysis set included 153 patients (C2: n=66; C4: n=87) treated with lifileucel, with a median of 3 prior lines of therapy (range: 1-9) and substantial baseline disease burden (>3 target and non-target lesions: 76%; median target lesion SOD: 97.8 mm; LDH >ULN: 54%). ORR was 31% (95% CI: 24.1%-39.4%) (C2: 35%; C4: 29%), with 8 CRs and 40 PRs (figure 1). At median study follow-up of 27.6 months, median DOR was not reached (NR). Forty-two percent of responses extended ≥18 months, and 40% (19/48) of responses were ongoing at time of datacut (figure 2). In multivariable analyses adjusted for ECOG PS, elevated LDH and target lesion SOD >median were independently correlated with ORR (p=0.008); normal LDH and SOD < median were associated with higher odds of response than either (OR=2.08) or both (OR=4.42) risk factors. The median OS was 13.9 months (95% CI: 10.6-17.8. In an analysis of survival by response at first assessment (1.5 months post-lifileucel infusion), median OS in responders was NR (95% CI: 22.5 months-NR). The most common (≥30%) G3/4 TEAEs were thrombocytopenia (77%), anemia (50%), and febrile neutropenia (42%). TEAEs were consistent with known safety profiles of NMA-LD and IL-2, and their incidence decreased within the first 2 weeks post-lifileucel infusion, characteristic of one-time treatment.

Conclusions Lifileucel demonstrated clinically meaningful and durable activity (ORR: 31%; mDOR: NR) in heavily pretreated patients with advanced melanoma and high tumor burden after ICI (and targeted therapy, where appropriate). Favorable safety profile and sustained responses support the potential benefit of one-time lifileucel TIL cell therapy as a novel treatment option for patients without approved therapies post-ICI.

790 PHASE I CLINICAL TRIAL ON INTRATUMORAL ADMINISTRATION OF AUTOLOGOUS CD1C (BDCA-1)$^+$/ CD141 (BDCA-3)$^+$ MYELOID DENDRITIC CELLS PLUS IPILIMUMAB AND AS01$_B$ IN COMBINATION WITH INTRAVENOUSLY ADMINISTERED NIVOLUMAB

[1]Jens Tijtgat*, [1]Julia Katharina Schwarze, [1]An-Sofie Vander Mijnsbrugge, [1]Steven Raeymaeckers, [1]Ivan Van Riet, [2]Xenia Geeraerts, [2]Latoya Stevens, [2]Sandra Tuyaerts, [1]Bart Neyns. [1]*UZ Brussel, Jette, Belgium*; [2]*Vrije Universiteit Brussel, Jette, Belgium*

Background The presence of CD1c (BDCA-1)$^+$ (cDC2) and CD141 (BDCA-3)$^+$ (cDC1) conventional dendritic cells (myDC) in the tumor microenvironment (TME) is a necessary prerequisite to induce an effector CD8$^+$ T cell response and for response to immune checkpoint blockade (ICB).[1-4] AS01$_B$ is an adjuvant component of a commercialized prophylactic shingles vaccine which induces adaptive immunity through recruitment and activation of cDC1 and cDC2.[5-6] Previously, intratumoral (IT) administration of ipilimumab and autologous myDC has shown promising antitumoral activity.[7]

Methods In this phase Ib clinical trial, patients with metastatic melanoma refractory to ICB and BRAF/MEK inhibitors (in case of BRAF V600-mutant melanoma) were recruited. Patients underwent a leukapheresis followed by immunomagnetic bead isolation of CD1c (BDCA-1)$^+$/CD141 (BDCA-3)$^+$ myDC. Patients received an intravenous (IV) administration of low dose nivolumab (10mg d1 and q2w) plus an IT administration of ipilimumab 10 mg (d1 and q2w). The isolated myDC were injected (palpation or ultrasound-guided) as a single injection into a metastatic lesion on day 2; together with AS01$_B$0.5 ml (d2 and q2w). Response assessment was performed by PET/CT q12w. Blood and tissue samples were collected each treatment cycle. Translational research including gene expression profiling, TCR analysis and multiplex immunohistochemistry is ongoing. (figure 1)

Results Between July 2021 and May 2022, 8 patients were recruited (all female) with a median age of 63 years (range 33-83). All patients had been treated with ICB as well as BRAF/MEK inhibitors when applicable. Median number and range of treatment administrations was 4 (range 1-7) for IT and 4.5 (range 1-15) for IV. Three patients remained on treatment at data cutoff date. Median PFS was 10.1 weeks (95% CI 5.193-15.007), median OS has not been reached. One patient obtained a complete remission on PET/CT 6 months after the start of study treatment. One patient obtained a pathological complete response 4 weeks after start of study treatment. One patient obtained a complete remission of injected lesions but progressed in non-injected lesions. Three patients died due to progressive disease. Treatment was well tolerated. There were no unexpected adverse events. One patient had G3 pyrexia, leading to prolongation of hospital stay with 1 day.

Conclusions In this clinical trial, IT injection of CD1c (BDCA-1)$^+$/CD141 (BDCA-3)$^+$ myDC in combination with repeated IT administration of ipilimumab and AS01$_B$ and systemic low dose nivolumab has shown promising early results and no unexpected safety signals, deserving further clinical investigation. Translational investigations are ongoing.

Combination Immunotherapies

791 IMMUNE CHECKPOINT BLOCKADE ENHANCES CYCLOPHOSPHAMIDE INDUCED ANTI-TUMOR IMMUNITY IN A PRECLINICAL MELANOMA MODEL

Mariam George*, Allison Betof, Taha Merghoub, Linda Hamadene, Daniel Hirschhorn, Alan Houghton, Jedd Wolchok. *Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background Immune Checkpoint Blockade (ICB) with anti-programmed cell death protein (PD)-1 and anti-cytotoxic T lymphocyte associated protein (CTLA)-4 have had immense success in cancer treatment. However, primary and acquired resistance to these therapies limits their clinical benefit. Accumulating evidence indicates that chemotherapeutic agents such as Cyclophosphamide (CTX) can induce anticancer immunity and improves the efficacy of ICBs when used in combination. A combination strategy to reorchestrate the anti-tumor immune response could magnify the clinical benefit of ICBs. CTX is an alkylating chemotherapeutic agent which is directly tumoricidal and induces immunomodulatory properties. CTX preferentially depletes T cell subsets (such as T regulatory cells) and leads to homeostatic proliferation of T cells. We hypothesized that the addition of ICBs to CTX treatment will augment the immunomodulatory changes induced by CTX including but not limited to the homeostatic proliferation of T cells which will reset the T cell receptor (TCR) repertoire to favor tumor antigen-specific T cells. The murine melanoma tumor model, B16-F10, is known to be refractory to treatment with ICBs, particularly anti-PD-1, as it only modestly slows tumor growth.

Methods Mice were given a single dose of CTX one day prior to starting an ICB (anti-PD-1 and/or anti-CTLA-4) regimen.

Results The treatment slows tumor progression of B16-F10 compared to CTX or ICB alone and significantly prolongs the survival of mice. Further, the combination of CTX with anti-PD-1 and anti-CTLA-4 increased the number of activated and proliferating CD8+ tumor infiltrating lymphocytes (TILs). This increase in cytotoxic T cells was accompanied by a decrease in Tregs, which further augments the tumor control. Additionally, we observed a significant increase in a highly cytolytic population of CD4+ CD8+ double positive TILs. The depletion of CD8+ cells but not CD4+ cells abrogates the therapeutic effect of the triple combination suggesting that the anti-tumor effect is CD8+ T cell dependent. The tumor control effect of the triple combination (CTX+ anti- PD-1 + anti-CTLA-4) extends to other murine tumor models namely, MC38 (colon adenocarcinoma) and 4T1 (mammary carcinoma).

Conclusions Our results suggest that the combination of CTX with ICBs, anti- PD-1 and anti-CTLA-4, is a potent combinatorial approach that can prime an anti-tumor response and promote robust control of tumor growth. These findings form the basis for further investigations in understanding the mechanisms of combinatorial cancer therapies in tumor models that are refractory to ICB therapies and can inform the design of future therapeutic interventions that combine ICB with chemotherapy.

792 **NATURAL KILLER T CELL IMMUNOTHERAPY COMBINED WITH FUSOGENIC ONCOLYTIC VIRUS AND PD-1 BLOCKADE ENHANCES SURVIVAL IN A MOUSE MODEL OF SPONTANEOUS LUNG ADENOCARCINOMA**

Jordan Lukacs*. *Dalhousie University, Halifax, Canada*

Background Non-small cell lung cancer (NSCLC) is a leading cause of cancer deaths, with a 5-year survival rate of 19%. Improvements in treatment are crucial for reducing both morbidity and mortality. In this study, we examined the therapeutic benefit of combining oncolytic vesicular stomatitis virus (VSV) expressing reovirus-derived fusion-associated small transmembrane (FAST) proteins (p14 or p15), PD-1 checkpoint blockade, and natural killer T (NKT) cell immunotherapy in a genetic mouse model of lung adenocarcinoma.

Methods Mice containing a tamoxifen-inducible Cre recombinase gene driven by the (Club cell-secretory protein) CCSP promoter, were crossed with mice containing a Lox-Stop-Lox $KRAS^{G12D}$ mutation and a floxed *p53* allele. CCSP-KP mice were treated with VSV-GFP, VSV-p14, or VSV-p15 on days 40, 42, and 44, followed on day 45 by treatment with α-galactosylceramide-loaded dendritic cells to activate NKT cells. Anti- PD-1 (ip. 300 μg) was given once a week for a total of 4 doses (days 48, 55, 62, and 69). MTT assays were performed to examine the oncolytic potential of the VSV-FAST constructs (VSV-p14, -p15, -p14delta, -p14endop15, -p10 ARV, -p10 NBV) in comparison to UV-inactivated VSV and VSV-GFP controls in murine (LLC, CMT-167) and human lung cancer cell lines (A549).

Results MTT cell viability assays demonstrate that VSV-FAST constructs VSV-p14, -p15, and chimeric -p14endop15 have increased tumor cell killing ability when compared to VSV-GFP in both mouse and human lung cancer cells. CCSP-KP mice receiving combinatorial treatment of VSV-p14 or VSV-p15, NKT cell activation, and PD-1 blockade exhibited increased overall survival in comparison with untreated or VSV-GFP combination therapy treated mice CCSP-KP mice. Furthermore, signs of morbidity (heavy or labored respirations, hunched posture, weight loss, etc.) were considerably delayed in treated mice.

Conclusions Our study demonstrates that VSV-FAST constructs are effective at killing lung cancer cells and when combined with NKT cell immunotherapy and immune checkpoint blockade, can prolong survival in a mouse model of NSCLC.

793 TREATMENT OF ANTI-SIRPα IN COMBINATION WITH ANTI-TAA EXERTS SUPERIOR ANTI-TUMOR ACTIVITY

Xiaofeng Niu, Chunnian Wang, Jinfeng Zhao, Haiying Wang, Li Zhang, Jiahui Hu, Jingfeng Yu, Yefeng Lu, Xiaoli Guo, Haixia Jiang, Rui Gao, Zhihao Wu, Yangsheng Qiu, Quan Qiu, Zheng Song, Dawei Sun, Hongtao Lu*. *Elpiscience Biopharma, Shanghai, China*

Background Signal-regulatory protein alpha (SIRPα), is an inhibitory receptor expressed on myeloid cells and dendritic cells. Ligation of CD47 to SIRPα delivers a "don't eat me" signal to suppress phagocytosis. Tumor cells frequently overexpress CD47 to evade macrophage-mediated destruction. Currently, agents targeting CD47 have proceeded to clinical trials and demonstrated promising anti-tumor results. However, these agents have been associated with hemolytic anemia and thrombocytopenia. In addition, universal expression of CD47 causes antigen sink, which leads to reduced efficacy. We therefore consider targeting CD47 receptor SIRPα to achieve improved efficacy with better safety profile. We have developed a pan-allele anti-SIRPα competitive functional antibody ES004-B5 that potently potentiates antibody dependent cellular phagocytosis (ADCP) activity of antibodies against tumor associated antigens (TAAs) *in vitro* and *in vivo*.

Methods Pan-allele SIRPα reactivities, SIRP family homologue binding properties, and cross-species reactivity were evaluated by ELISA and FACS. Antigen binding affinity was determined by surface plasmon resonance system (Biacore). Blocking activity was determined by competition assay and SHP-1 recruitment assay. *In vitro* functional activity was determined by phagocytosis assay. The impact on T cell function was evaluated by mixed lymphocyte reaction (MLR). *In vivo* efficacy was evaluated in a syngeneic mouse tumor model with human CD47/human SIRPα double knock-in mice. Epitope analysis was performed by competitive ELISA and hydrogen deuterium exchange mass spectrometry (HDX-MS). Lead clone was humanized via CDR grafting and back mutation screening. Non-human primates (NHPs) models were used to assess the safety and pharmacokinetics of the humanized candidate.

Results ES004-B5 recognizes pan-allele human SIRPα with high affinity, and cross reacts well with cynomolgus SIRPα It binds a unique epitope on SIRPα that is distinct from known competitor molecules. Although ES004-B5 binds to SIRPγ expressed on T cell surface, it doesn't cause negative impact on T cell activation. ES004-B5 potently blocks CD47-SIRPα interaction as well as CD47 mediated SHP-1 recruitment to phosphorylated SIRPα intracellular tail. Through blocking CD47-induced inhibitory "don't eat me" signals, ES004-B5 potently potentiates ADCP activity of anti-TAA antibodies like rituximab and cetuximab. In a syngeneic mouse tumor model, the combination of ES004-B5 plus anti-Claudin18.2 significantly inhibited tumor growth *in vivo*. ES004-B5 has favorable pharmacokinetics and safety profile in NHPs.

Conclusions In summary, the functional anti-SIRPα mAb ES004-B5 has great potential to be used in combinations with multiple anti-TAA antibodies in cancer treatment. We are currently advancing the development of ES004-B5 into clinical candidate.

794 **TKM-011, ANTI-CD20 ANTIBODY CONFERS MULTI-PROPERTIES AGAINST BURKITT'S LYMPHOMA IN COMPARABLE EFFICACY TO RITUXIMAB AND OBINUTUZUMAB**

Jutatip Panaampon*, Seiji Okada. *Kumamoto University, Kumamoto, Japan*

Background Burkitt's lymphoma (BL), an aggressive non-Hodgkin B-cell lymphoma needs an intensive chemotherapy regimen for the treatment. Immunotherapy plays significant roles in the treatment of BL. Rituximab (RTX) treatment regimens display the correlation with a positive prognosis. Yet, there is the subset of patients failed to respond to RTX treatment or became the resistance to RTX treatment. Newer generation of monoclonal anti-CD20 antibodies such as Obinutuzumab (OBI) have shown to inhibit B cell malignancies. TKM-011, the novel anti-CD20 antibody that binds to different CD20 epitope has been established. In this study, we studied the efficacy of TKM-011, RTX, and OBI against BL cell lines both *in vitro* and *in vivo*.

Methods We screened the antibody-dependent cytotoxicity (ADCC) and antibody-dependent cell phagocytosis (ADCP) by using the luciferase effector bioassay-based Jurkat cells with the expression of Fc receptor to evaluate ADCC and ADCP activities of RTX, TKM-011, and OBI. Raji and Ramos cell lines were used as the target cells. Flowcytometric analysis was performed to confirm ADCC by using KHYG-1 ($CD16^-$) and N6 (CD16 transduced KHYG-1) NK cell lines. In order to determine ADCP, we generated monocyte-derived macrophages from healthy donors and performed ADCP assay. Moreover, we also tested the efficacy of these antibodies *in vivo* model by using Raji cells xenografted-immunodeficient mice.

Results TKM-011 exerted ADCC and ADCP activities in the similar levels compared to that of RTX and OBI. Moreover, TKM-011 also showed a potent CDC activity against BL cells. By performing MTT assay, all 3 antibodies presented an induction of cell death. The results of an *in vivo* experiment demonstrated an equivalent inhibitory level of tumor growth by the three tested antibodies.

Conclusions TKM-011 shows multi-activities against BL cell lines. The efficacy of TKM-011 reaches the level of standard RTX antibody. Considering the different binding epitopes in CD20, TKM-011 can be an alternative antibody therapy for the treatment of BL.

795 STAT3 SIGNALING AS A CHECKPOINT FOR TLR9-DRIVEN EPIGENETIC REPROGRAMMING OF ACUTE MYELOID LEUKEMIA INTO ANTIGEN-PRESENTING CELLS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0795

Dongfang Wang, Priyanka Duttagupta, Yu-Lin Su, Haiqing Li, Mingye Feng, Bin Zhang, Ya-Huei Kuo, Guido Marcucci, Marcin Kortylewski*. *Beckman Research Institute at City of Hope, Duarte, CA, USA*

Background Cultured AML blasts can differentiate into antigen-presenting cells, however, stimulating leukemic cell differentiation and immunogenicity in patients has not translated into therapeutic effects. We previously demonstrated that eliminating STAT3 signaling in *Cbfb/MYH11/Mpl* (CMM) leukemia using siRNA or decoy DNA strategies permits TLR9-induced AML cell differentiation and thereby leads to potent adaptive immune responses and leukemia regression.[1,2]

Methods Here, we interrogated cellular and molecular underpinnings of leukemic cells differentiation following STAT3-inhibition and TLR9-activation (STAT3i/TLR9a).

Results Our whole genome and single-cell transcriptomic analyses combined with immunophenotyping revealed that the combined STAT3i/TLRa had a dramatic effect on CMM cell differentiation. The treatment induced heterogenous leukemia cell clusters at different stages of myeloid cell differentiation towards macrophage and antigen-presenting cell phenotype. These were characterized by decreasing gene signatures of proliferation/survival genes with appearance of signature of leukocyte activation, antigen presentation, and in case of more differentiated AML-derived clusters, type I and type II IFNs. The more differentiated clusters 6, 12 and 15 were characterized by markers of antiviral/antimicrobial responses with pronounced expression of type I and II IFNs. The transcriptional profiling of CMM cells isolated from mice treated using inducible *STAT3* gene silencing or decoy STAT3 in combination with TLR9 stimulation, revealed the increased expression of genes regulating myeloid cell differentiation such as *Irf8, Cebpa, and Cebpe* with decreased expression of leukemia-promoting *Runx1*. The combination treatment also increased expression of genes regulating antigen-presentation such as *Gadd45A, Ciita, Il12a,* and *Ifng* in leukemic cells. We further confirmed that IRF8 expression is required for AML cell differentiation as shown by conditional *Irf8* silencing. The AML cell reprogramming was likely regulated epigenetically as indicated by the reduced gene methylation profile of crucial myeloid cell differentiation genes such as *Irf8*. These changes were associated with reduced expression of DNMT1 and DNMT3ab, known STAT3 target genes.

Conclusions Our studies suggest that eliminating STAT3 checkpoint allows for TLR9-mediated reprogramming of leukemic cells into antigen-presenting cells capable of stimulating adaptive T cell immune responses against AML. Furthermore, these findings support further development of CpG-STAT3 inhibitors as a new bi-functional agent for AML immunotherapy.

796 REPURPOSING NSAIDS FOR CANCER IMMUNOTHERAPY: MECHANISMS BEYOND COX INHIBITION

[1]Gang Zhou*, [1]Nada Aboelella, [1]Md Gazi, [2]Gary Piazza. *[1]Augusta University, Augusta, GA, USA; [2]Auburn University, Auburn, AL, USA*

Background Adoptive cell therapy (ACT) using genetically modified T cells has evolved into a promising treatment option for patients with cancer. However, even for the best-studied and clinically validated CD19-targeted chimeric antigen receptor (CAR) T-cell therapy, many patients face the challenge of lack of response or disease relapse. There is increasing need to improve the efficacy of ACT so that durable, curative outcomes can be achieved in a broad patient population.

Methods Here we investigated the impact of non-steroidal anti-inflammatory drugs (NSAIDs) on the efficacy of ACT in multiple preclinical models. Mice with established B-cell lymphoma received various combinations of preconditioning chemotherapy, infusion of suboptimal dose of tumor-reactive T cells, and administration of eithor indomethacin (indo, a COX-inhibitory NSAID) or ADT-030 (a non-COX-inhibitory novel NSAID). Donor T cells used in the ACT models included CD4+ T cells expressing a tumor-specific T cell receptor (TCR) and T cells engineered to express CD19CAR. Mice were monitored for tumor growth and survival. The effects of indo on donor T cell phenotype and function were evaluated. The molecular mechanisms by which the selected NSAID shapes the outcome of ACT were investigated.

Results ACT coupled with indo administration led to improved tumor growth control and prolonged mouse survival. Indo did not affect the activation status and tumor infiltration of the donor T cells. Moreover, the beneficial effect of indo in ACT did not rely on its inhibitory effect on the immunosuppressive COX2/PGE2 axis. Instead, indo-induced oxidative stress boosted the expression of death receptor 5 (DR5) in tumor cells, rendering them susceptible to donor T cells expressing TNF-related apoptosis-inducing ligand (TRAIL). Furthermore, the ACT-potentiating effect of indo was diminished against DR5-deficient tumors, but was amplified by donor T cells engineered to overexpress TRAIL.

Conclusions Our results demonstrate that the pro-oxidative property of NSAIDs can be exploited to enhance death receptor signaling in cancer cells, providing rationale for combining NSAIDs with genetically modified T cells to intensify tumor cell killing through the TRAIL-DR5 axis.

Ethics Approval All animal experiments and procedures were performed in accordance with the institutional protocol and were approved by the Institutional Animal Care and Use Committee (IACUC) of Augusta University.

797 **REAL-WORLD TREATMENT DURATION OF ATEZOLIZUMAB+CARBOPLATIN+ETOPOSIDE AMONG OLDER PATIENTS WITH EXTENSIVE-STAGE SMALL CELL LUNG CANCER (ES-SCLC) AND THE IMPACT OF PERFORMANCE STATUS AND BRAIN METASTASES**

[1]Husam Albarmawi*, [2]Scott Robinson, [2]Kevin Dietz, [2]Kris Norris, [1]Nindhana Paranthaman, [1]Sarika Ogale, [2]Taylor Schwartz. *[1]Genentech, South San Francisco, CA, USA; [2]Inovalon, Bowie, MD, USA*

Background Previous real-world studies of first-line (1L) atezolizumab+carboplatin+etoposide for ES-SCLC in the US community oncology setting showed similar treatment durations (medians: 4.9;5.7 months) as in the IMpower133 trial (median: 4.7 months) although the real-world populations had higher proportions of patients with poor ECOG performance status (PS) and brain metastases.[1,2] This study measured treatment duration in an older ES-SCLC population initiating 1L atezolizumab+carboplatin+etoposide and the impact of ECOG PS and brain metastases at baseline on treatment duration.

Methods This retrospective cohort study utilized the 100% sample of Medicare Fee-For-Service enrollment and Parts A/B claims from January 1, 2018 to June 30, 2021. Beneficiaries with ≥2 claims with an ICD-10-CM code for lung cancer and claims for atezolizumab+carboplatin+etoposide were identified. Index was 1L treatment initiation occurring between October 11, 2018 to December 31, 2019. ECOG PS at baseline was approximated using a claims-based measure that classifies individuals as good (ECOG 0-1) or fair/poor (ECOG≥2) based on healthcare utilization in the 12-month pre-index period.[3] Baseline brain metastases were identified from diagnosis to 30 days post-index based on ICD-10-CM codes. 1L treatment duration was measured from index to a gap in treatment claims of ≥60 days, initiation of a new anti-cancer regimen or death. Kaplan-Meier curves were utilized to examine the differences for patients stratified by brain metastases (Y/N) and binary ECOG PS.

Results A total of 2,470 patients older than 65 years (median age: 73 years) were included in the study with a median follow-up of 8.4 months. 62% had a proxy for fair/poor ECOG PS and 22% had baseline brain metastases. Median 1L duration for the full cohort was 5.4 months (95% CI: 5.2-5.6). Median 1L treatment duration was 5.1 months for patients with poor/fair ECOG PS (95% CI: 5.1-5.3) and 5.8 months (95% CI: 5.6-6.0) for patients with good ECOG PS (figure 1) (Log-Rank p<0.0001). Median 1L treatment duration for patients with brain metastases was 5.0 months (95% CI: 4.6-5.3) and 5.5 months (95% CI: 5.3-5.7) for patients without brain metastases (figure 2) (Log-Rank p=0.2488).

Conclusions Despite the older age of the study population and the worse baseline ECOG PS and brain metastases status, 1L treatment duration with atezolizumab+carboplatin+etoposide was similar to those observed in IMpower133 and in previous real-world community oncology studies. Based on descriptive comparisons, treatment duration was longer in patients with a proxy for good ECOG PS (statistically significant) and patients without brain metastases (not statistically significant).

REAL-WORLD OVERALL SURVIVAL AMONG PATIENTS RECEIVING FIRST-LINE (1L) PEMBROLIZUMAB IN THE TREATMENT OF RECURRENT/METASTATIC HEAD AND NECK SQUAMOUS CELL CARCINOMA (R/M HNSCC) IN THE UNITED STATES

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0798

Christopher Black*, Liya Wang, Karthik Ramakrishnan, Gleicy Hair, Daisuke Goto. *Merck and Co., Inc., Rahway, NJ, USA*

Background KEYNOTE-048 has demonstrated extended survival benefit of pembrolizumab in 1L R/M HNSCC. This study aims to assess real-world overall survival (rwOS).

Methods A retrospective cohort study was conducted using the Flatiron Health Advanced Head and Neck database. The study cohort included adult R/M HNSCC patients, who initiated 1L pembrolizumab monotherapy (P) or combination with chemotherapy (P+C) between 07/01/19 – 6/30/21 with follow-up until 12/31/21. Patients were excluded if they received prior platinum treatment ≤6 months of 1L pembrolizumab therapy, had other primary cancers before R/M HNSCC diagnosis, or were treated with a clinical study drug. rwOS was assessed using Kaplan-Meier methods, and a multivariate Cox proportional hazard model assessed the effects of age (>=75 vs <75), gender, race, primary tumor site, staging at diagnosis, HPV status, smoking, ECOG PS, and CPS score.

Results A total of 513 patients initiated 1L pembrolizumab therapy, [P (n=337), P+C (n=176)]. The median rwOS was 13.0 months (95%CI 10.0-15.3) for P and 12.8 months (95% CI 9.0-21.1) for P+C (figure 1), consistent with the results of the KEYNOTE-048 trial [P: 11.5 months (10.3 – 13.5) P+C: 13.0 months (10.9 – 14.7)]. Survival rates at 24 months (P: 33.3% (26.2 – 40.6) and P+C: 40.3% (31.3- 49.2) were greater in the real-world compared to KEYNOTE-048. The Cox proportional- hazards model found that older age (>=75 years vs <75) and higher ECOG PS (2+ vs 0-1) were unfavorable predictors of rwOS survival (HR=1.4 , 95% CI 1.03-1.90, HR: 1.5, 95%C 1.08-2.1). This analysis further showed no significant differences in rwOS between P and P+C populations.

Conclusions Overall survival among patients treated with pembrolizumab in the real-world were consistent with results from KEYNOTE-048. We found that age and ECOG were predictive of rwOS even after removing the effects of other common predictors, such as race, HPV status, and staging at diagnosis.

Real-World Overall Survival of Pembrolizumab Regimens

799 REAL-WORLD USE OF PEMBROLIZUMAB COMBINATION REGIMENS IN FIRST-LINE RECURRENT/METASTATIC HEAD AND NECK SQUAMOUS CELL CARCINOMA

Christopher Black*, Liya Wang, Karthik Ramakrishnan, Daisuke Goto. *Merck and Co., Inc., Rahway, NJ, USA*

Background Based on KEYNOTE-048 results, pembrolizumab was approved for use as monotherapy and in combination with platinum+5FU in the first-line (1L) treatment of patients with recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC). Taxanes can help expand the available treatment options in the 1L R/M HNSCC, in place of 5-FU. NCCN guidelines recommend pembrolizumab + platinum + taxane as another treatment option for R/M HSCC patients. This study assessed the real-world treatment patterns of patients receiving pembrolizumab combination regimens in 1L R/M HNSCC.

Methods This retrospective cohort study assessed data from a US based de-identified EHR-derived database (Flatiron Health Advanced H&N database) of patients initiating pembrolizumab + platinum + taxane or platinum + 5-FU regimens between 07/01/19 – 6/30/21 with follow-up until 12/31/21. Real-world time on treatment (rwToT) was defined as length of time between first and last documented administration date pembrolizumab and assessed using Kaplan-Meier method.

Results A total of 225 patients received pembrolizumab combination therapy (Platinum+5-FU:176, Platinum+Taxane:49). Patient characteristics (age, gender, ECOG PS) were similar; differences were noted in oropharyngeal HPV+ cancer (50.0% vs 75.0%), and% treated at an academic center (6.3% vs 34.7%) between pembrolizumab with platinum + 5-FU and platinum + taxane, respectively (table 1). Carboplatin use was similar among pembrolizumab + platinum + 5-FU (84.8%) and platinum + taxane (87.8%) patients, where paclitaxel was the most used taxane (87.8%). Patients remained on treatment longer with pembrolizumab + platinum + taxane compared to pembrolizumab + platinum + 5-FU .

Conclusions Substituting 5-FU with a taxane resulted in a longer median rwToT of 2.4 months. These results support guideline recommendations for the pembrolizumab + platinum + taxane combination as another treatment option for 1L R/M HNSCC patients.

Abstract 799 Table 1

	Pembrolizumab+Platinum+5-FU (N = 176)	Pembrolizumab+Platinum+Taxane (N = 49)
Discontinued, N (%)	132 (75.0)	28 (57.1)
Median Follow Up, months (range)	8.5 (0.1 - 29.1)	8.3 (0.0 - 29.2)
Median ToT, months (95% CI)	5.0 (3.9 - 6.0)	7.4 (4.2 - 20.0)
On-treatment rate (95% CI)		
6 months	42.3% (34.8 - 49.7)	55.8% (40.5 - 68.6)
12 months	20.2% (14.0 - 27.3)	36.8% (21.0 - 52.7)
18 months	16.3% (10.5 - 23.3)	36.8% (21.0 - 52.7)
24 months	14.3% (8.3 - 21.7)	27.6% (10.5 - 47.9)

Real-World Time on Treatment Results

800 CLINICOPATHOLOGICAL AND MOLECULAR PREDICTIVE FACTORS OF SURVIVAL IN NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH FIRST-LINE IMMUNOTHERAPY WITH OR WITHOUT CHEMOTHERAPY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Alessandro Di Federico*, Francesco Gelsomino, Andrea De Giglio, Francesca Sperandi, Barbara Melotti, Andrea Ardizzoni. *IRCCS Azienda Ospedaliero-Universitaria Di Bologna, Bologna, Italy*

Background The majority of advanced non-small cell lung cancer (NSCLC) patients derives modest benefit from immunotherapy (IO) alone. For some of them, adding chemotherapy (CT) may significantly improve the outcomes, but the reliability of PD-L1 expression as the only biomarker to identify patients that might need concomitant CT is unsatisfactory.[1,2]

Methods A systematic research of articles using PubMed/MEDLINE, and the Cochrane Database of Systematic Reviews and Central Register of Controlled Trials was performed, last updated April 11th, 2022. Abstract from main oncology congresses were also searched, including ASCO 2022. Eligible studies were randomized controlled clinical trials (RCT) investigating IO, alone or combined with CT, versus CT alone in previously untreated advanced NSCLC patients. The objective was to detect clinicopathological and molecular predictive factors of survival (progression-free survival and overall survival). Study characteristics and outcome estimates (hazard ratio and 95% CI) were extracted. Random-effects meta-analyses were performed to investigate IO alone versus CT, and IO plus CT versus CT. Random-effects meta-regression analyses were performed to provide a comparison of IO alone versus IO plus CT.

Results a total of 14367 patients with advanced NSCLC in 25 RCT was included (table 1).[3-48] Squamous histology, male gender, current/former smoker status, PD-L1 expression >=50%, and high TMB correlated with improved survival with IO alone compared to CT. Conversely, female gender, absence of smoking history, negative PD-L1 expression, and low TMB correlated with unsatisfactory outcomes with IO alone versus CT (figure 1), but not with IO plus CT versus CT (figure 2). IO plus CT improved survival versus IO alone in female patients [HR for PFS: 1.65, 95% CI, 1.25-2.18, p=0.0004; HR for OS: 1.31, 95% CI, 1.01-1.71, p=0.044], never smokers [HR for PFS: 3.59, 95% CI, 1.62-7.94, p=0.0016; HR for OS: 1.28, 95% CI, 0.95-1.72, p=0.10], in those having a PD-L1 expression >=1% [HR for PFS: 1.88, 95% CI, 1.55-2.28, p<0.0001; HR for OS: 1.28, 95% CI, 1.11-1.48, p=0.0007] or a low TMB [HR for PFS: 2.08, 95% CI, 1.61-2.70, p <0.0001; HR for OS: 1.43, 95% CI, 1.12-1.82, p=0.004], and in patients with central nervous system metastasis [HR for PFS: 1.51, 95% CI, 1.01-2.25, p=0.045; HR for OS: 1.32, 95% CI, 0.85-2.06, p=0.22] (figure 3).

Conclusions Certain clinicopathological and molecular features may add predictive value to PD-L1 expression in the selection of the most appropriate first-line treatment for advanced NSCLC patients.

801 THE ANTI-TUMOR EFFICACY OF IMMUNOGENIC CHEMOTHERAPY IS ENHANCED BY THE DUAL $A_{2A}R$/$A_{2B}R$ ANTAGONIST ETRUMADENANT, RELIEVING THE NECESSITY FOR AN EXTENDED CHEMOTHERAPY REGIMEN

Daniel DiRenzo*, Dana Piovesan, Ferdie Soriano, Livia Yamashiro, Janine Kline, Dillon Miles, Ehesan Sharif, Manmohan Leleti, Matthew Walters. *Arcus Biosciences, inc., Hayward, CA, USA*

Background Generation of extracellular adenosine is a hallmark of cancerous tissue and drives immunosuppression that facilitates tumor growth/survival. Chemotherapy releases adenosine triphosphate into the tumor microenvironment, where it is rapidly converted into adenosine, primarily by the ectoenzymes CD39 and CD73. Recent studies have demonstrated that certain chemotherapies can enhance the expression of tumoral CD73, suggesting that inhibition of adenosine generation and/or signaling might enhance the immune-activating and anti-tumor effects of those chemotherapeutic agents. Indeed, our preclinical studies with the dual $A_{2a}R/A_{2b}R$ antagonist etrumadenant (etruma) have shown a marked ability to suppress mouse syngeneic tumor growth and enhance intratumoral T cell infiltration when combined with immunogenic chemotherapies. Various etruma/chemotherapy combinations are currently being studied in clinical trials. We have investigated the capacity of etruma to drive enhanced tumor control and immune activation in mouse tumor models, in combination with lower chemotherapy doses or reduced dosing regimens.

Methods Mice were inoculated with either AT3-OVA or 4T1 syngeneic cancer cell lines. Mice with established tumors were dosed with oxaliplatin or doxorubicin, alone or in combination with etruma and the effects of the various treatments on tumor growth were assessed. Tumors were removed for histologic analysis or analysis of immune cell infiltration by flow cytometry.

Results Etruma increased anti-tumoral activity and tumor infiltration of antigen-specific $CD8^+$ T cells across a dose range of oxaliplatin using the AT3-OVA mammary cancer model. Similar results were also found using the 4T1 model, a strongly $CD73^+$ tumor, in which a combination of etruma with doxorubicin showed a reduction in both primary tumor growth and metastatic tumor burden. Following these results, we investigated whether a shorter course of chemotherapy could provide similar therapeutic benefit in combination with etruma. Using the AT3-OVA model, etruma significantly enhanced the efficacy of doxorubicin at both low and higher doses (3 vs 5 mg/kg). Interestingly, a shorter course of doxorubicin (2 doses) in combination with etruma provided similar efficacy and was statistically indistinguishable from the full course of chemotherapy (4 doses), indicating that the greatest therapeutic benefit of chemotherapy, when combined with etruma, may result from the initial, priming, doses of chemotherapy.

Conclusions These findings demonstrate a clear benefit for etruma combinations with chemotherapeutic agents in preclinical models. Furthermore, our most recent studies suggest that a truncated course of immunogenic chemotherapy plus etruma may be sufficient to enhance immune activation and yield similar anti-tumor effects as a full course of chemotherapy.

802

ELICITING CALRETICULIN-MEDIATED "EAT ME" PHAGOCYTIC SIGNAL IS ADDITIVE/SYNERGISTIC WITH CD47 BLOCKADE IN ENHANCING TUMOR ASSOCIATED MACROPHAGE PHAGOCYTOSIS OF TUMOR CELLS AND DECEASING XENOGRAFT TUMOR GROWTH IN EWING SARCOMA

[1]Wen Luo*, [1]Mitchell Cairo, [1]Janet Ayello, [2]Timothy Cripe, [2]Kevin Cassady, [1]Hai Hoang. *[1]New York Medical College, Valhalla, NY, USA; [2]Nationwide Children's Hospital, Columbus, OH, USA*

Background Tumor associated macrophages (TAM) are abundant in Ewing sarcoma (ES),[1] a malignant pediatric bone and soft tissue tumor. Macrophages are known to harbor phagocytic activity against cancer cells,[2] yet they fail to phagocytose ES cells and confer a poor prognosis.[1] Cancer cells may utilize dual mechanisms, up-regulation of "don't eat me" signal mediated by CD47 and down-regulation of "eat me" signal mediated by cell surface calreticulin (csCRT), to resist TAM-mediated phagocytosis. To overcome TAM resistance, both enhancing csCRT expression and blocking CD47 signal will be required. Chemotherapy is known to enhance translocation of CRT to the cell surface during the process of apoptosis. Magrolimab is a humanized, monoclonal antibody that blocks CD47 and is currently in phase III trials for AML/MDS.

Methods Expression of CD47 and csCRT on ES cells was examined by flow cytometry and western blotting. To elucidate whether csCRT increase is associated with apoptosis of ES cells, annexin V assays were carried out. Macrophages were derived from human peripheral blood. In vitro phagocytosis assays were performed to evaluate the efficacy of doxorubicin (DOX) and magrolimab, generously provided by Gilead, alone or in combination, in enhancing macrophage phagocytosis of ES cells. The efficacy of DOX combined with magrolimab in limiting ES tumor growth and prolonging animal survival in-vivo was assessed in an ES xenograft NSG mouse model.

Results We found that most of the tested ES cell lines (A673, EWS502, SKNMC, RDES, TC32 and TC71) express high levels of CD47 and low levels of csCRT. The csCRT levels in A673, TC32, and EWS502 cells were increased by DOX treatment in a dose dependent manner (figure 1) and this increase in csCRT level was associated with apoptosis. DOX or magrolimab alone significantly enhanced, and the combination of the two further significantly enhanced, phagocytosis of ES cells by macrophages. The increased phagocytosis induced by magrolimab was due to CD47 blockade because CD47 KO rendered ES cells resistant to magrolimab induced increase in phagocytosis (figure 2). In ES xenografted NSG mice, DOX alone had no effect while magrolimab alone had a moderate effect on decreasing ES xenograft tumor growth. Importantly, DOX combined with magrolimab had an additive/synergistic effect on decreasing ES tumor growth and significantly prolonged animal survival compared to control and single agent treatment (figure 3).

Conclusions Our data demonstrate an additive/synergistic effect of DOX and magrolimab in-vitro and in-vivo against ES and provide a rationale to move this combinatorial therapy to clinical investigation.

803 ENHANCEMENT OF ANTI-TUMOR EFFICACY OF IMMUNE CHECKPOINT BLOCKADE BY ALPHA-TOCOPHERYLOXACETIC ACID-LYSINE

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0803

[1]Emmanuel Akporiaye*, [2]William Redmond, [2]Melissa Kasiewicz. [1]*Veana Therapeutics Inc, Portland, OR, USA*; [2]*Providence Cancer Institute, Portland, OR, USA*

Background While much success has been achieved with immune checkpoint blockade (ICB)-targeted therapies, curative responses occur in only a fraction of patients. Adjuvant chemotherapy, which frequently consists of DNA targeting agents, while necessary, can contribute to additional acute toxicity and side effects to the immune-related toxicictes inherent in the use of immune checkpoint. These limitations can negatively impact the quality of life of patients during and after treatment and highlight the need for safer, less toxic anti-cancer agents that can be used in combination with ICB to improve patient outcomes. Alpha-Tocopheryloxy acetic acid-Lysine (a-TEA-LS) is a scalable salt form of alpha-TEA that exhibits tumor cytotoxicity by preferentially targeting dysregulated tumor cell mitochondria to generate toxic reactive oxygen species that trigger immunogenic cell death (ICD). This activity causes release of ”danger signals” including heat shock proteins, ATP, Calreticulin and HMGB-1 and generates antigen-containing autophagosomes which stimulate cross-presentation within dendritic cells leading to antigen-specific T cell priming.
Methods Mice bearing establsihed 4T1 mammary tumors were treated with alpha-TEA-lysine salt in combination with the immune checkpoint blockade antibodies anti-PD-1, anti-PD-L1, and anti-CTLA4 and monitored for tumor growth suppression, and overall survival. The combination treatment group that was not effective in controlling 4T1 tumor growth was evaluated for anti-tumor activity against MMTV-PyMT and Eph4 1424 mammary tumors.
Results Combination therapy consisting of alpha-TEA-Lys+anti-PD-1 or alpha-TEA-Lys+anti-CTLA4 but not of alpha-TEA-LS +anti- PD-L1 controlled tumor growth in the 4T1 tumor model. Anti-PD-L1 which had no impact on growth of 4T1 tumors inhibited tumor growth and increased overall survival in MMTV-PyMT and Eph4 1424 tumor models. When compared with an immunogenic cell death inducing agent, Doxorubicin, a-TEA-LS+anti-PD-L1 treatment, both treatments were effective in controlling tumor growth but the alpha-TEA-LS +anti-PD-L1 treatment was better tolerated than Doxorubicin +anti-PD-L1 treatment. Mice on the alpha-TEA/anti-PD-L1 therapy demonstrated no weight loss whereas mice in the Doxorubin/aanti-PD-L1 treatment group demonstrated ruffling, were hunched and experienced significant weight loss.
Conclusions The data demonstrate that the efficacy of ICB therapy is dependent on the mammary tumor model and on the type of ICB antibody used. Based on the safety profile of a-TEA-LS and the enhanced anti-tumor efficacy demonstrated by a-TEA-LS+ICB in these pre-clinical mammary tumor models, a-TEA-LS has the potential to be used as an adjuvant therapeutic to improve the effectiveness of ICB in human breast cancer. Experiments are underway to interrogate the immune tumor microenvironment to find out what role they may play in the different responses observed.

804 NOVEL AI-DERIVED APPROACH TO IDENTIFY LOMITAPIDE AS AN ANTICANCER AGENT INDUCING AUTOPHAGIC CELL DEATH IN COLORECTAL CANCER

Seung Ju Park*, Seulgi Lee, Boah Lee. *ERSTEQ Co., Ltd., Daejeon, Republic of Korea*

Background Identifying therapeutic approaches to treat cancer is laborious, expensive, and often inefficient. Drug repurposing or repositioning in oncology refers to the application of drugs, which are already approved for other medical applications, in treating cancer.[1] Moreover, in order to enhance therapeutic benefits, repurposed drugs are often combined with frequent administrations of low-dose chemotherapy/immunotherapy. Recent advancements in artificial intelligence (AI) technology have led to the development of in silico drug discovery approaches. Therefore, therapeutic discovery through a drug repurposing strategy aided by these technological advancements can potentially accelerate studies into clinical trials more rapidly compared to that using newly developed drugs.

Methods In this study, we employed an AI driven structure-based model (ERSTE-Explorer) to identify an mTOR inhibitor candidate. Using in vitro biochemical and cellular experiments as well as transcriptome sequencing analyses, we identified lomitapide, an inhibitor of hepatic microsomal triglyceride transfer protein (MTTP) approved for the homozygous familial hypercholesterolemia (HoFH) is an mTOR inhibitor.[2] To validate anticancer effect of lomitapide in vivo, we used tumor xenograft model and patient-derived colorectal cancer organoids for clinical relavance. Furthermore, potential synergistic effects were confirmed by combining of lomitapide and immune checkpoint blocking antibodies to inhibit tumor growth in murine MC38 or B16-F10 preclinical syngeneic tumor models.[3]

Results Autophagy is a biological process that maintains cellular homeostasis and regulates the internal cellular environment. Hyperactivating autophagy to trigger cell death has been a suggested therapeutic strategy for cancer treatment.[4, 5] Mechanistic target of rapamycin (mTOR) is a crucial protein kinase that regulates autophagy; therefore, we identified lomitapide, a cholesterol-lowering drug, as a potential mTOR complex 1 (mTORC1) inhibitor (figure 1). Our results showed that lomitapide directly inhibits mTORC1 in vitro (figure 1) and induces autophagy-dependent cancer cell death by decreasing mTOR signaling (figure 2), thereby inhibiting the downstream events associated with increased LC3 conversion in various cancer cells (e.g., HCT116 colorectal cancer cells) (figure 3) and tumor xenografts (figure 4). Lomitapide also significantly suppresses the growth and viability along with elevated autophagy in patient-derived colorectal cancer organoids (figure 5). Furthermore, a combination of lomitapide and immune checkpoint blocking antibodies synergistically inhibits tumor growth in murine MC38 or B16-F10 preclinical syngeneic tumor models (figure 6).

Conclusions Our results elucidate the direct, tumor-relevant immune-potentiating benefits of mTORC1 inhibition by lomitapide, which complement the current immune checkpoint blockade. This study highlights that the U.S. FDA-approved drug, lomitapide, can be potentially repurposed for the treatment of cancer.

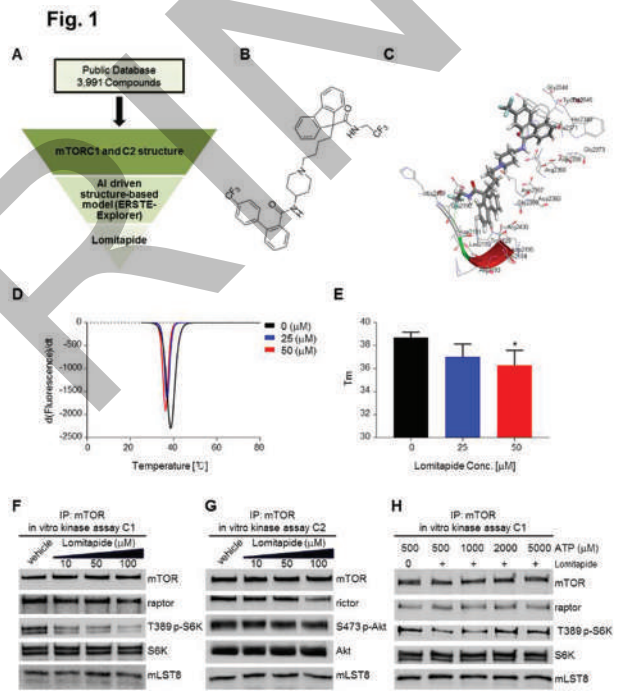
Ethics Approval All mice were housed in a pathogen-free animal facility at KAIST Laboratory Animal Resource Center. The animals were maintained in a temperature/humidity-controlled room on a 12 h light/12 h dark cycle and fed a standard chow diet. All experiments involving animals were conducted according to the ethical policies and procedures approved by the Committee for Animal Care at KAIST.



Abstract 804 Figure 1 Identification of lomitapide as a mTORC1 inhibitor

a Flowchart of in silico virtual screening. b Structure of lomitapide. c The docking pose of lomitapide within the ATP-binding core of human mTORC1. d, e The thermal denaturation of recombinant mTOR kinase domain was measured in the absence and presence of varying lomitapide concentrations, as indicated. Representative derivative (dF/dT) curves are shown for untreated and treated with varying ligand concentrations (d). Midpoint temperatures of the protein-unfolding transition (Tm) are presented as bars (e). Values are mean ± SD of at least three independent measurements (*P < 0.05). f In vitro kinase assays were performed in the absence or presence of lomitapide using mTOR immunoprecipitates prepared from HEK293T cell lysates. mTORC1 kinase activity was assessed via immunoblotting of T389 S6K1 phosphorylation. g mTORC2 kinase activity was assessed based on S473 Akt phosphorylation. h In vitro mTORC1 activity was assayed in the presence of 50 μM lomitapide and increasing concentrations of ATP. T389 phosphorylation of S6K1 was measured via immunoblotting.

805 MULTIPLE COMBINATIONAL STRATEGIES OF IMMUNOTHERAPY FOR UROTHELIAL CARCINOMA IN ONE INSTITUTION

[1]Jo-Pai Chen*, [2]Sung-Hsin Kuo, [2]Wei-Chen Lu. [1]*National Taiwan University Hospital, Yun-lin Branch, Yun-lin, Taiwan*; [2]*National Taiwan University Hospital, Taipei, Taiwan*

Background Urothelial cancers are immunogenic and may benefit from anti-PD1/PDL1 no matter in front-line cisplatin-ineligible patients(IMvigor210) or 2nd line setting(KN45). Avelumab maintenance after 1st line platinum-based chemotherapy(JAVELIN Bladder 100) in 1st line setting has offered survival benefits. Antibody drug conjugates(like enfortumab vedotin and sacituzumab govitecan) have shown encouraging efficacy in later lines and tried to be combined with anti-PD1/PDL1 in front-line setting. Furthermore, in the era of precision medicine, FGFR inhibitors, HER2 targeting agents, and PARP inhibitors may be introduced to urothelial cancers alone or in combination with anti-PD1/PDL1. Although lenvatinib combined with pembrolizumab(LEAP11) had failed to get survival benefit compared with chemotherapy in frontline setting, cabozantinib is used for (1)maintenance therapy alone or with avelumab after 1st line chemotherapy; (2)combination with atezolizumab for later line treatment.

Methods From early 2016 to 2022, 55 advanced urothelial cancers patients had ever received immunotherapy-containing regimens in Yun-lin Branch of National Taiwan University Hospital. We have reviewed basic characteristics and therapeutic regimens of these patients to find out treatment outcomes of combinational strategies of immunotherapy and special characters of responders.

Results Immunotherapy-based combinations have brought objective response rates in 73% (40/55) and clinical benefits in 91% (50/55). Front-line Gemcitabine (11) or Taxane (7) and cisplatin with bevacizumab and ateozolizumab (12) or pembrolizumab (6) were administered to 18 patients and 94% objective response rate was got. In one of these patients, HER2 amplification was noted by NGS analysis and atezolizumab with Herceptin & afatinib maintenance was given thereafter. Only 5/55(9%) of the toal patients had received NGS studies (No FGFR derangements seen, 1 HER2 amplification, 2 BRCA2 mutation). Olaparib was not given for these 2 BRCA2 mutation patients.12 patients with ureter cancers received 2nd line immunotherapy combinations (Pembrolizumab 9, Nivolumab 1, Nivolumab with CT 1, low dose nivolumab 20 mg per 2 weeks with metronomic cyclophosphamide 1) and objective response rate was 58% (7/12). 18 patients with ureter cancers (Avastin 200 mg per 3 weeks, Atezolizumab, & CT in 13; Avastin, Pembrolizumab, & CT in 2; low dose nivolumab with metronomic cyclophosphamide 3) received front-line immunotherapy-containing regimens and objective response rate was 94%. 7 patients with single kidney received neoadjuvant ateozolizumab monotherapy (5) or low dose nivolumab with metronomic cyclophosphamide (2) and objective response rate was 57% (4/7) with clinical benefits in 100%. Total 30 patients with ureter cancers have received immunotherapy-based combinations and 80% (24/30) ORR was got. Low dose nivolumab with metronomic cyclophosphamide was administered in 4 ureter cancers (1 2nd line, 3 1st line, 2 cisplatin-ineligible) and the response rate was 75% with 100% clinical benefits. No avelumab maintenance was given in our series.

Conclusions In Taiwan, urothelial cancers are still a health burden due to smoking and aristolochic acid in Chinese medicines. In our institution, bevacizumab and anti-PD1/PDL1 with platinum-based chemotherapy has shown encouraging efficacy in nearly all UC patients, esp. for high tumor burden with rapid progression, and may be a potentially front-line treatment in the future deserving further clinical trial development focusing on bevacizumab and ateolizumab maintenance. Most ureter cancers have responded to immunotherapy-containing regimens, esp. in front-line combinations. Metronomic dose cyclophosphamide(suppress Treg) with low dose nivolumab could be an exciting regimen for CT-unfit or cisplatin-ineligible patients with economic concerns.

807 **SELECTIVE DEPLETION OF TUMOR-SPECIFIC REGULATORY T CELLS IN COMBINATION WITH LOW DOSE CHEMOTHERAPY WITH OR WITHOUT PD-1 BLOCKADE IMPROVES ANTI-TUMOR T CELL RESPONSES IN SOLID TUMORS**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0807

Dorothèe Saddier Axe, Michelle Kuhne, Renu Jain, Brian Weist*. *Gilead Sciences, Foster City, CA, USA*

Background Lack of effector T cell activity in solid tumors can be attributed to suppressive mechanisms utilized by regulatory T cells (Tregs) within the tumor microenvironment. An outstanding question in the field is how to selectively deplete intratumoral Tregs to avoid the severe autoimmunity triggered by systemic depletion. CCR8 is a chemokine receptor expressed at high levels on the surface of tumor infiltrating Tregs, but not on peripheral Tregs, nor effector T cells. CCR8 targeting antibodies, which lead to rapid depletion of intratumoral Tregs in mouse models and human explant systems, are currently in the clinic as monotherapy and in combination with checkpoint inhibitors. Chemotherapy has the potential to trigger immunogenic cell death and lead to enhanced T cell priming. We hypothesized that chemotherapy treatment may combine with a Treg depleting agent such as anti-CCR8 and lead to improved outcomes. In this study, we tested the ability of an anti-CCR8 antibody to augment tumor specific effector T cell responses when paired with low doses of chemotherapy with or without an anti-PD-1 mAb in mouse syngeneic tumor models.

Methods The 4T1, Panc02, B16F10, and LLC mouse syngeneic tumor models were used in this study. Following implantation, mice were randomized and grouped out when tumors reached 80-120 mm^3, and administered a single dose of anti-CCR8 antibody in combination with a suboptimal dose of Cisplatin, Gemcitabine, or Docetaxel with or without an anti-PD-1 mAb. Tumor growth inhibition and analysis of intratumoral lymphocyte populations were performed to assess the combination potential of Treg depletion and chemotherapy.

Results In multiple syngeneic tumor models with varying levels of Treg and CD8 infiltration, a single suboptimal dose of chemotherapy treatment administered at the beginning of the study did not result in meaningful tumor growth inhibition. When selective Treg depletion via CCR8 was paired with low dose chemotherapy, both 4T1 and Pano2 tumor models demonstrated significant tumor growth inhibition. Complete responses were observed in 50% of mice treated with a combination of Gemcitabine and anti-CCR8 in the Panc02 model. On the contrary, in relatively cold tumor models including B16F10 and LLC, no single agent or combination effect was observed. Finally, addition of anti-PD-1 mAb to low dose chemotherapy and Treg depletion in the LLC model led to 72% tumor growth inhibition in the triple combination group.

Conclusions Tumor Treg depletion demonstrates the potential to augment anti-tumor activity when paired with low dose chemotherapy in cold tumor models.

Ethics Approval Procedures involving the care and use of animals in the study were reviewed and approved by the Stony Brook University Institutional Animal Care and Use Committee (Protocol # 748435-3/2015-2182-NF-MI- 5.18.18) prior to conduct. During the study, the care and use of animals was conducted in accordance with the principles outlined in the Guide for the Care and Use of Laboratory Animals, 8th Edition, 2010 (National Research Council).

808 BLOCKING "DON'T-EAT-ME" SIGNAL OF CD47-SIRPα BY ANTI-SIRPα ANTIBODY ENHANCES ANTI-TUMOR EFFICACY OF TRASTUZUMAB DERUXTECAN

Mayumi Sue*, Takuya Tsubaki, Yoko Ishimoto, Shinko Hayashi, Saori Ishida, Yoshitaka Isumi, Jun Ishiguro, Reimi Kawaida, Toshiaki Ohtsuka, Teiji Wada, Toshinori Agatsuma, Norihito Kawasaki. *Daiichi Sankyo, Tokyo, Japan*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0808

Background CD47-Signal-regulatory protein alpha (SIRPα) pathway is an emerging target for cancer immunotherapy. Preclinically, CD47-SIRPα blockers have been shown to enhance anti-tumor function of macrophages such as antibody-dependent cellular phagocytosis (ADCP). While in blood cancer patients, several CD47-SIRPα blockers have shown encouraging monotherapy activity, the monotherapy efficacy in solid tumors seems less promising, suggesting the need for combination drugs to fully exploit the myeloid immune checkpoint. We have established DS-1103a, a humanized IgG4 antibody against human SIRPα, and in this study we assessed whether trastuzumab deruxtecan (T-DXd; DS-8201a), a HER2-targeting antibody-drug conjugate (ADC), is a potential combination drug for DS-1103a. The antibody portion of T-DXd is a human IgG1, an ADCP-enabling Fc, which might show a combination benefit with DS-1103a.

Methods The binding of DS-1103a to human SIRPα and the inhibitory potency on CD47-SIRPα interaction was assessed by a cell-based binding assay. To test whether the combination of DS-1103a with T-DXd augments ADCP activity of macrophages, human monocyte-derived macrophages were co-cultured with JIMT-1 cells, HER2-expressing human breast cancer cells. The anti-tumor activity of T-DXd or trastuzumab in combination with MACK-8260a, an anti-mouse SIRPα antibody, was evaluated in a syngeneic mouse model bearing HER2-expressing mouse cancer cells.

Results DS-1103a successfully bound to human SIRPα and inhibited CD47-SIRPα interaction. In our ADCP assay, T-DXd induced modest ADCP (9.267% ± 1.249% of JIMT-1 cells were phagocytosed) of macrophages, compared to a control IgG-ADC (5.156% ± 0.571%, $P = 0.0242$). When combined, DS-1103a significantly enhanced the ADCP (40.860% ± 8.319%) compared to T-DXd monotherapy described above ($P = 0.0025$). Further, in our syngeneic mouse model with HER2-expressing CT26.WT cells, the combination of T-DXd with MACK-8260a prolonged the overall survival of animals compared to those of the monotherapy. By day 35 from the treatment initiation, 7/15, 13/15, and 15/15 of mice reached humane endpoint in the combination therapy, T-DXd, and MACK-8260a monotherapy group, respectively ($P = 0.0232$, combination vs T-DXd; $P = 0.0006$, combination vs MACK-8260a). Interestingly, trastuzumab failed to show such combination effect with MACK-8260a, suggesting that T-DXd is a better combination drug for DS-1103a than trastuzumab.

Conclusions Our *in vitro* and *in vivo* studies demonstrated that blocking CD47-SIRPα pathway by anti-SIRPα antibody enhances antitumor efficacy of T-DXd, warranting future clinical trials of the combination to assess the potential of DS-1103a to further enhance the efficacy of T-DXd.

Ethics Approval All the in vitro studies employing human blood obtained from healthy volunteers were approved by and conducted in accordance with the guidelines of Daiichi Sankyo Research Ethics Committee. All animal studies were approved by the Institutional Animal Care and Use Committee of Daiichi Sankyo.

809 ANTI-CLDN18.2 ANTIBODY ZL-1211 ENHANCES ANTI-TUMOR ACTIVITIES IN COMBINATION WITH CHEMOTHERAPY IN GASTRIC CANCER MODELS

Anthony Cao, Qiuping Ye, Karl Hsu, Hua Gong, Haiying Zhou, Jiaqing Yi*, Xinyan Tang. *Zai Lab, Menlo Park, CA, USA*

Background CLDN18 is a member of the claudin family transmembrane proteins expressed at the epithelial tight junctions to establish a paracellular barrier to control the flow of ions and solutes between cells. Localization of the CLDN18.2 isoform is strictly confined to and buried within tight junctions in the gastric mucosa in healthy individuals. During malignant transformation however, CLDN18.2 is overexpressed in up to 60% of gastric cancers, and ectopically expressed in 50% of pancreatic and 30% of esophageal cancers. Anti-CLDN18.2 has shown the potential to inhibit tumor growth alone or in combination with standard of care chemotherapies in gastric cancer.

Methods In vitro antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cellular phagocytosis (ADCP), and complement-dependent cytotoxicity (CDC) assays were used to measure ZL-1211 efficacy. SNU601 xenograft gastric cancer model was used in BALB/c Nude mice to measure the efficacy of ZL-1211 in combination with standard of care (SoC) chemotherapy. RT-qPCR and western blot were used to measure CLDN18.2 expression levels, and ELISA was used to measure cytokine levels.

Results ZL-1211 is an anti-CLDN18.2 IgG1 that possesses enhanced Fc-dependent effector functions to enable potent ADCC, ADCP, and CDC. ZL-1211 increased therapeutic benefit over the most advanced anti-CLDN18.2 antibody benchmark with greater than 10-fold induction of immune effector functions under tested conditions. Chemotherapy, such as gemcitabine, increased CLDN18.2 mRNA and protein expression levels in cancer cells and sensitized tumor cells to ZL-1211-mediated ADCC. Furthermore, ZL-1211 in combination with SoC chemotherapies, oxaliplatin + capecitabine (CAPOX), enhanced anti-tumor efficacy in SNU601 gastric cancer xenograft model. Additionally, ZL-1211 in combination with chemotherapy treatment induced remarkable pro-inflammatory cytokine release, which might associate with its deeper and durable anti-tumor responses.

Conclusions These data provide rationale to combine ZL-1211 with SoC chemotherapy in gastric cancer. Currently, a phase I dose escalation study is underway to assess the safety, tolerability, pharmacodynamics, and pharmacokinetics of ZL-1211 in patients with advanced solid tumors (NCT05065710).

810 NOVEL RENAL CELL CARCINOMA IMMUNOTHERAPY COMBINING TLR9-TARGETED STAT3 ANTISENSE OLIGONUCLEOTIDE WITH PD-1 BLOCKADE

[1]Marice Alcantara*, [1]Alexander Chehrazi-Raffle, [2]Nazli Dizman, [1]Wilson Tang, [1]Luis Meza, [1]Zeynep Zengin, [1]Dongfang Wang, [1]Dayson Moreira, [3]Alan Horsager, [1]JoAnn Hsu, [1]Sumanta Pal, [4]Marcin Kortylewski. *[1]City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [2]Yale University School of Medicine, New Haven, CT, USA; [3]Duet Therapeutics, Pasadena, CA, USA; [4]Department of Medical Oncology and Therapeutics, Duarte, CA, USA*

Background Novel therapy combinations utilizing PD-1 immune checkpoint inhibition have improved outcomes in patients with RCC; however, positive clinical responses are limited to select individuals.[1] Various studies indicate resistance is mediated partly through STAT3 induced activity and a concomitant accumulation of tumor infiltrating myeloid derived suppressor cells and tumor promoting M2 macrophages capable of suppressing anti-tumor responses independent of PD-1 signaling.[2] Indeed, in a separate study, we observed an increase in cytokines IL-6, IL-8 and persistent STAT3 activity within myeloid cells in RCC patients with resistance to anti-PD-1/CTLA-4 therapy. In this preclinical study, we investigated a novel treatment strategy combining anti-PD-1 therapy with our original CpG-STAT3ASO oligonucleotide strategy to knockdown STAT3 specifically within TLR9-positive myeloid cell populations associated with RCC tumors.

Methods 6-8 week female Balb/C mice were injected subcutaneously with 500,000 Renca cells in Matrigel. Mice were treated using CpG-STAT3ASO (IV, 5mg/kg) together with anti-PD-1 (IP, 200 ug), each of the two reagents alone, IgG control or only PBS. Immune alterations in tumors and tumor-draining lymph nodes were assessed via spectral cytometry. Statistical significance was determined using two-way ANOVA or Wilcoxon signed ranked test with SEM.

Results CpG-STAT3ASO with anti-PD-1 significantly inhibited growth of syngeneic Renca tumors compared to either treatment alone or negative controls. To elucidate the immune-mediated mechanisms underpinning this efficacy, we undertook spectral cytometry analysis of tumor and tumor draining lymph nodes. In comparison to PBS, IgG and anti-PD-1 alone, combination CpG-STAT3ASO and anti-PD-1 treatment induced maturation and activation of intratumoral dendritic cells (DCs) and macrophages, including a decrease in immunosuppressive M2 macrophages, with a concomitant increase in anti-tumor M1 macrophages and an increase in intratumoral CD8+ T cells, decrease in CD4+ Tregs and increase CD8+ T cell to Treg ratios. In fact, anti-PD-1 alone treated cohorts was shown to have high percentages of alternatively activated (pro-tumor) M2 macrophages in comparison to combination treated cohorts where an increase in anti-tumor M1 macrophages was observed. This suggests anti-PD-1 alone efficacy may be limited by its failure to induce maturation/activation of myeloid cells.

Conclusions Our results indicate that combination of PD1 blockade with systemic administration of CpG-STAT3ASO significantly improves antitumor efficacy against the tested kidney cancer model in comparison to each treatment alone. The improved treatment efficacy is likely related to more potent activation and reprogramming of tumor-associated myeloid cells, particularly macrophages. Our results warrant further investigation into myeloid cell specific STAT3 silencing in combination with Anti-PD-1 in RCC.

811 PD1 AND LAG3 SYNERGIZE ON CD8$^+$ T CELLS TO HINDER IFNγ-DEPENDENT ANTI-TUMOR IMMUNITY

Lawrence Andrews*, Carly Cardello, Jian Cui, Creg Workman, Dario Vignali. *University of Pittsburgh, Pittsburgh, PA, USA*

Background Overcoming immune-mediated resistance to PD1 blockade remains a challenge, however enhanced efficacy has now been demonstrated in metastatic melanoma patients with a combinatorial regimen of nivolumab and relatlimab, an anti-LAG3 targeting antibody recently FDA approved. Despite this success, little is known about how PD1 and LAG3 synergize to hinder anti-tumor immunity, particularly on CD8$^+$ T cells, which is the dominant LAG3-expressing intratumoral population signifying highly dysfunctional exhausted T (T_{EX}) cells regulated by the transcription factor TOX.

Methods To understand the cellular and mechanistic basis for PD1/LAG3 synergy, conditional knock-in mice "surgically dissect" *Pdcd1* and/or *Lag3* floxed alleles restricted to CD8$^+$ T cells expressing E8I$^{Cre.GFP}$. These mice were crossed with the pMEL transgene to assess PD1 and/or LAG3-sufficient or deficient gp100-specific CD8$^+$ T cell populations adoptively transferred into mice harboring a B16-gp100-overexpressing tumor. Single-cell RNAseq analysis was performed, identifying both effector and IFNγ-stimulated genes up-regulated in PD1/LAG3-deficient pMEL. The IFNγ signaling pathway was further interrogated by retroviral transduced knockdown of IFNγR in pMEL.

Results While little therapeutic benefit was observed with a prophylactic adoptive transfer (AT; d-1) of wild-type CD8$^+$ pMEL cells into mice, there was reduced B16-gp100 tumor growth in mice receiving PD1-deficient CD8$^+$ pMEL cells, which was further enhanced in mice receiving PD1/LAG3-deficient CD8$^+$ pMEL cells with long-term tumor-free survival. Likewise, therapeutic AT (d6) of PD1/LAG3-deficient CD8$^+$ pMEL cells showed initial therapeutic benefit, with enhanced survival, that was not demonstrated with AT of PD1 or LAG3-deficient, or wild-type, counterparts.

PD1/LAG3-deficient CD8$^+$ T cells were shown to be more proliferative and more functional, with increased IFNγ and GzmB observed by flow cytometry. Interestingly, PD1 and LAG3 were demonstrated to synergize together to modulate the T_{EX}program by restraining the expression of TOX and promoting a more terminally-exhausted phenotype defined by expression of TIM3 and Ly108.

As this population was shown to be transcriptionally distinct by transcriptomic analysis, we interrogated whether enhanced IFNγ signaling was responsible for the phenotypes observed. Retroviral knockdown of IFNγR reversed the therapeutic benefit observed with AT of PD1/LAG3-deficient pMEL. In addition, other IFN-responsive genes upregulated in PD1/LAG3-deficient pMEL, such as CCL5, were reduced with IFNγR knockdown.

Conclusions Overall PD1 and LAG3 limit antitumor immune effects as PD1/LAG3-deficient pMEL AT resulted in reduced tumor growth and enhanced survival due to increased functionality, dependent on IFNγ signaling. These results provide mechanistic insight for the success seen with the clinical development of anti-LAG3 agents in combination with anti-PD1.

812 DEVELOPMENT OF BCMA-TARGETED IMMUNOTHERAPY USING VACCINE-INDUCED ANTIGEN-SPECIFIC MEMORY CD8$^+$ T CELLS FOR TREATING PATIENTS WITH MULTIPLE MYELOMA

Jooeun Bae*, Derin Keskin, Yueyi Huang, Sean Rowell, Sarah Nikiforow, Gerry MacDonald, Jerome Ritz, Nikhil Munshi, Kenneth Anderson. *Dana Farber Cancer Institute, Boston, MA, USA*

Background Multiple myeloma (MM) is a largely incurable cancer of the plasma cells. Despite remarkable recent advances in treatment using novel therapeutics, MM remains incurable. Previously, we reported a vaccination strategy that induced antigen-specific memory CD8$^+$ T lymphocytes (CTL) against XBP1 (X-box binding protein 1), CD138 (Syndecan-1) and CS1 (SLAMF7), which are highly expressed in MM cells. Clinical trials on patients with smoldering MM have proven this multi-peptide vaccine's safety and immunogenicity, and larger clinical trials are ongoing. We further developed a translational research strategy to combine vaccination with the *ex vivo* expansion and infusion of vaccine-induced antigen-specific memory T cells. As a first step, we focused on targeting the B cell maturation antigen (BCMA), as it is specifically and highly expressed on the MM cells, and developed a protocol to efficiently isolate and expand BCMA-specific memory CTL *ex vivo*.

Methods In conjunction with our proposed immunogenic heteroclitic BCMA peptide-based vaccine, we have developed a protocol to efficiently isolate and expand the antigen-specific memory CD8$^+$ CTL *ex vivo* as a supplemental immunotherapy against MM.

Results We developed a feasible and efficient method to secure antigen-specific T cells following the induction of MM-specific CTL using immunogenic heteroclitic $BCMA_{72\text{-}80}$ (YLMFLLRKI) peptide. The resulting CD8$^+$ CTL show specific upregulation of various costimulatory molecules including CD28, 4-1BB, CD40L and OX40. Among the different conditions we evaluated, anti-CD3/CD28 (clinical grade) stimulation produced the greatest expansion of BCMA-specific CTL within 2 weeks and specifically induced the proliferation of antigen-specific central memory CTL (47% with anti-CD3/CD28 treatment vs. 6% without anti-CD3/CD28). To further enhance the efficacy of the final cell product, functionally active BCMA-specific IFN-g$^+$ CTL were sorted and expanded with anti-CD3/CD28, IL-2 (200 units/ml) and IL-15 (10 ng/ml). Under the conditions, we found a significant and continuous expansion (day 3: 2-fold, day 14: 22-fold, day 21: 55-fold) of BCMA-specific CTL with high Th1 cytokine (IL-2, TNF-a) production and anti-tumor activity (CD107a upregulation) against MM, which were both the BCMA epitope-specific and HLA-A2-restricted.

Conclusions BCMA-specific CD8$^+$ CTL can be effectively expanded using clinical grade anti-CD3/CD28 and IL-2/IL-15 to yield MM-specific memory CTL with robust poly-functional anti-tumor activities. These results provide the framework for combining BCMA-peptide vaccination and the specific cellular therapy using the vaccine-induced IFN-g$^+$ memory T cells to further enhance anti-MM immunity and improve MM patient outcome.

813 CANCER VACCINE TRIPLE SYNERGISTIC COMBINATION IMMUNOTHERAPY ENHANCES ANTI-CANCER EFFICACY

[1,2]Jay Berzofsky*, [2]William Becker, [2]Purevdorj Olkhanud. [1]*NIH, Bethesda, MD, USA*; [2]*National Cancer Institute, Bethesda, MD, USA*

Background The discovery of checkpoint inhibitors (CPIs) has revolutionized cancer treatment, but many cancers remain resistant. In many cases, resistant tumors are considered "cold" because they lack infiltrating T cells that can be reinvigorated by the CPIs. Cancer vaccines may overcome this resistance by inducing the needed T cell immune response against the tumor. Conversely, cancer vaccines may not be effective alone if immunoregulatory mechanisms inhibit the immune response. Overcoming such regulatory mechanisms by CPIs or other immunomodulatory agents can improve vaccine efficacy. Thus, these complementary therapies can synergize

Methods Here we used a B6 mouse tumor model, TC1, expressing HPV16 E6 and E7 oncogenes, and utilized a vaccine consisting of an E7 synthetic long peptide 43-77 combined with alpha-galactosylceramide (a potent NKT cell agonist) and GM-CSF as adjuvants. We examined combinations of CPIs with the vaccine for increased efficacy in control of TC1 tumor growth.

Results We found triple synergy among the E7 vaccine, anti-TIGIT, and anti-PD-L1, more effective than any pairwise combination. Further, whereas the protection was dependent on CD8 T cells, depletion of CD4 T cells surprisingly improved the vaccine response, suggesting it was removing a suppressive CD4 T cell. Experiments are in progress to determine whether this putative suppressive cell is a Foxp3+ Treg cell. The triple therapy enhanced the number of E7-specific T cells infiltrating the tumors by tetramer staining. Further, the triple therapy was effective, although slightly less so, in aged mice as in young mice, suggesting it may be effective in older humans in whom cancer is more frequent.

Conclusions These studies show proof-of-concept for use of a synergistic combination of cancer vaccine immunotherapy to generate tumor-specific T cells and multi-checkpoint inhibitor therapy to overcome resistance in order to inhibit tumor growth and improve survival in mouse cancer models that is translatable to human cancer patients.

Ethics Approval This study was approved by the NCI Animal Care and Use Committee under ACUC Protocol METB-033.

814 DT-9081, A SELECTIVE EP_4 RECEPTOR ANTAGONIST WHICH SYNERGIZES WITH IMMUNE CHECKPOINT INHIBITORS TO INDUCE COMPLETE RESPONSES IN SYNGENEIC MURINE CANCER MODELS

[1]Anne-Laure Blayo*, [1]Claire Jouffroy-Zeller, [1]Nathalie Lenne, [2]Imane Nafia, [1]Patricia Zerr, [1]Stéphan Schann*, [1]Xavier Leroy*. *[1]Domain Therapeutics, Illkirch, France; [2]Explicyte Immuno-Oncology, Bordeaux, France*

Background Elevated levels of Prostaglandin E_2 (PGE_2), an eicosanoid synthesized by the cyclooxygenase-2 (COX-2), exert strong immunosuppressive effects in the tumor microenvironment (TME). COX-2-positive solid tumors have the ability to use this pathway as a resistance mechanism, especially to escape from the host immune system, thus limiting the anti-tumor effects of immune checkpoint inhibitors (ICI). These immunosuppressive effects are largely mediated by the EP_4 receptor, expressed on multiple immune cells. DT-9081, a selective EP_4 receptor antagonist, has been designed to counteract the PGE_2-immunosuppressive effects in the TME and to synergize with ICI.

Methods DT-9081 has been evaluated in 2 syngeneic murine cancer models in combination with ICI. DT-9081 was first tested at 30 and 60 mg/kg, as single agent or in combination with anti-CTLA-4 antibody, in the CT26 colorectal cancer model. DT-9081 was then tested at 30 mg/kg as single agent, or at 3, 10 or 30 mg/kg in combination with an anti-PD-1 in the MCA205 sarcoma model. In both studies, tumor growth, survival and type of response were evaluated. Complete responders were additionally submitted to a tumor rechallenge study to evaluate the immune system memory.

Results In the CT26 colorectal cancer model, combination of DT-9081 at both doses with anti-CTLA-4 antibody enabled a significant tumor growth inhibition and a noticeable increase in survival as compared to the anti-CTLA-4 antibody treatment alone. Moreover, 3 and 2 complete responses over 10 mice were observed in the groups treated with 30-mg/kg and 60-mg/kg DT-9081 in combination with the anti-CTLA-4 antibody, compared to none in the anti-CTLA-4 antibody treatment alone group.

In the MCA205 sarcoma model, combination of DT-9081 at the 3 tested doses with anti-PD-1 antibody enabled significant tumor growth inhibition and increase in survival, with a maximum anti-tumor efficacy from 10-mg/kg DT-9081. 5, 9 and 10 complete responses over 15 mice were observed in the groups treated with 3-, 10- and 30-mg/kg DT-9081, respectively, in combination with the anti-PD-1 antibody, compared to a single one in the anti-PD-1 antibody treatment alone group.

Complete responders from both studies were additionally assessed to address their response to a new challenge with the corresponding tumor cells. No tumor growth was observed indicating a long lasting tumor immune control.

Conclusions DT-9081 demonstrates strong anti-tumor effects in multiple syngeneic mouse tumor models, and synergizes with immune checkpoint inhibitors to induce long lasting complete responses. DT-9081 has completed regulatory development and will enter in clinical development by the end of 2022.

815 CRB-601, A SELECTIVE INTEGRIN AVβ8 BLOCKING ANTIBODY, EXHIBITS POTENT ANTI-TUMOR ACTIVITY IN ANTI-PD-1 RESISTANT MODELS

Daqing Wang*, Vaishali Shinde, Maneesh Singh, Rachael Brake, Andrew Kolodziej. *Corbus Pharmaceuticals, Norwood, MA, USA*

Background Transforming growth factors-beta (TGFβ) is a promising immunotherapeutic target in cancer given its association with increased signaling in the tumor microenvironment (TME) immune exclusion, resistance to checkpoint inhibitors (CPI), and poor clinical outcomes. TGFβ is expressed as a latent form (L-TGFβ) and presented on cell surfaces by L-TGFβ binding proteins (e.g. GARP and LTPB1) as part of the large latent complex (LLC) whereupon it is activated by binding to integrins. Integrin $a_v\beta_8$ binds to and activates L-TGFβ, specifically the TGFb1 and TGFb3 isoforms. Corbus Pharmaceuticals is developing a humanized monoclonal antibody, CRB-601, that binds with high specificity and affinity to integrin $a_v\beta_8$ and blocks its critical interaction with L-TGFβ.

Methods Mice bearing subcutaneously implanted murine colon carcinoma MC38 or orthotopically implanted murine breast cancer EMT6 and 4T1 were treated with avβ8-blocking antibody CRB-601, anti-mouse PD-1 or the combination. These models demonstrate differential sensitivity to CPI treatment and are thought to reflect an immune inflamed (MC38), excluded (EMT6) or desert (4T1) tumor immune phenotypes. To determine the impact of disease establishment on sensitivity of these models to CRB-601 treatment both early (tumor volume = 50-80 mm^3) and late (tumor volume > 200 mm^3) intervention studies were conducted. Tumor growth, immune cell populations, and biomarkers of response (e.g. TGFb levels) were evaluated.

Results CRB-601 as a single agent, significantly inhibited growth of both MC38 and EMT6 models in both early and late intervention studies. In combination with anti-PD-1, CRB-601 not only enhanced anti-PD-1 therapy efficacy in early- and late-stage immune inflamed MC38, but also overcame resistance to PD-1 therapy in late-stage immune excluded EMT6 model. Notably, in the 4T1 model, an anti-PD-1 resistant desert tumor, combination therapy with CRB-601 and anti-PD-1 resulted in significant tumor growth inhibition even though there was negligible effect of each single agent. Analysis of tumor infiltrating lymphocytes in treated EMT6 tumors, showed TME remodeling, marked by increased infiltration of T cells, NK cells and M1-like macrophages in animals receiving CRB-601 or the combination. Biomarkers of response were consistent with Integrin $a_v\beta_8$ target engagement.

Conclusions CRB-601 is a potent and selective integrin αvβ8 blocking monoclonal antibody that can overcome tumor immune exclusion and enhance the activity of immune checkpoint inhibitors *in vivo*. Investigational New Drug (IND) enabling studies are currently underway.

816 BLOCKADE OF SIRPα ON MACROPHAGES TO ENHANCE CAR T ACTIVITY AGAINST GLIOBLASTOMA

Rebecca Brock*, Alesandra Echeandia-Marrero, Matthew Dysthe, Robin Parihar, Nabil Ahmed, Meenakshi Hegde. *Baylor College of Medicine, Houston, TX, USA*

Background The tumor microenvironment in glioblastoma (GBM) is highly immune suppressive, largely due to tumor-associated macrophages (TAMs) signaling. TAMs utilize several checkpoint inhibitors including SIRPα to regulate T cell function through the induction of apoptotic signaling and reduced activation. These also pose a challenge for engineered T cell therapies such as chimeric antigen receptor (CAR) T cells. While previous work has investigated blockade of either SIRPα or its ligand CD47, showing a temporal increase in trafficking of endogenous T cells to the tumor, understanding of the potential impact of such treatments on CAR T cells is lacking. We hypothesize that blocking the interaction of SIRPα with CD47 can improve the trafficking and functional activity of CAR T cells against glioblastoma.

Methods HER2-specific second generation CAR T cells were generated from primary human T cells using a retroviral transduction method. Primary human monocytes were harvested from peripheral blood and differentiated in vitro using M-CSF and IL-4 into M2-skewed macrophages. Macrophages, HER2+ GBM cell lines, and CAR Ts were co-cultured together with and without an anti-human SIRPα blocking monoclonal antibody. Cell surface expression of phenotypic macrophage markers, T cell activation markers, and SIRPα were assessed at baseline and post-treatment by flow cytometry. Supernatant from co-cultures was assessed for the presence of chemokines and cytokines using a custom multiplex panel and analyzed for differences in immunosuppressive signaling. CAR T cytolytic activity was determined by live-cell imaging using GFP-containing LN229-GBM.

Results We observed that TAM-like macrophages altered the cytokine release in CAR T and GBM co-cultures, promoted tumor cell growth, and increased CAR T apoptotic signaling resulting in delayed tumor cell lysis. In the presence of a SIRPα blocking antibody, we noted decreased surface expression of endogenous SIRPα and increased expression of M1-related marker CD86 on the macrophages at 24 hours of co-culture. The expression of several chemokines including MCP-1 was increased. At high ratios of CD28ζ CAR T cells, down-regulation of SIRPα induced by the antibody blockade was not sustained.

Conclusions Macrophages cultured with GBM cells in vitro can alter the immune milieu, leading to CAR T cell apoptosis and hinder tumor-directed cytotoxicity. Blockade of SIRPα favorably alters the cytokine and chemokine production and may facilitate lymphocyte trafficking while reducing inhibitory receptor expression on macrophages. However, these effects can be countered by potent pro-inflammatory CAR T cell signaling, underscoring the need for more robust SIRPα disruption strategies.

Ethics Approval This study was approved by Baylor College of Medicine's Ethics Board; approval number H-15280.

817 ENGINEERED TOXIN BODY TARGETING CTLA-4 (MT-8421) DEPLETES TREGS IN THE TUMOR MICROENVIRONMENT AND SYNERGIZES WITH αPD-1 TO ENHANCE T CELL IMMUNITY

Lauren Byrne, Swati Khanna*, Rebecca Martin, Caleigh Howard, Lilia Rabia, Michaela Sousares, Jay Zhao, John Majercak, Eric Poma, Chris Moore. *Molecular Templates Inc., Austin, TX, USA*

Background Despite being approved for clinical use over a decade ago, CTLA-4 mAbs remain encumbered by a narrow therapeutic window and relatively severe adverse event (AE) profile. Increasing data support that CTLA-4 mAb efficacy is primarily driven by depletion of CTLA-4+ T regulatory cells (Tregs) in the tumor microenvironment (TME), while AEs have been linked to an overzealous peripheral T cell response mediated by prolonged CTLA-4 blockade. It has been postulated that a more selective approach directly targeting TME-associated Treg cell depletion, while reducing peripheral T cell effects, might improve the tolerability of this class of immune checkpoint inhibitors, yet no CTLA-4 targeted mAb has achieved this. MT-8421 is a potent CTLA-4-targeted engineered toxin body (ETB) that can preferentially deplete high CTLA-4 expressing Tregs in the TME while sparing low CTLA-4 expressing peripheral T cells. In addition, MT-8421 was well-tolerated in a non-GLP non-human primate (NHP) study at doses hundreds-fold higher (450ng/mL) than the IC50 on CTLA-4 expressing cells. Here we demonstrate that MT-8421 synergizes with αPD-1 mAb in a Treg/T cell primary cell co-culture to stimulate T cell proliferative responses through direct Treg cell depletion.[1] Results from animal models including a GLP-NHP study will be described.

Methods T cells and Tregs were isolated from PBMCs of healthy donors and were stained to track T cell proliferation. T cells were co-cultured with autologous Tregs at various ratios. Anti-CD3/CD28 was used to drive proliferation of T cells in the presence of 4,000ng/mL of MT-8421, inactive MT-8421, or αPD-1 mAb (20μg/mL) to test for monotherapy activity. In addition, cells were treated with αPD-1 mAb followed by MT-8421 to evaluate combination effects. After 4 days, cells were stained with surface antibodies and analyzed by flow cytometry.

Results Co-cultures treated with MT-8421 alone demonstrated release of Treg-mediated CD8 T cell suppression compared to the untreated or inactive MT-8421. In addition, while αPD-1 treatment alone expectedly increased CD4+ and CD8+ T cell proliferation, when followed by MT-8421 treatment, the effects on T cell proliferation were greater than with either treatment alone.

Conclusions MT-8421 is a novel approach to CTLA-4 targeting: a potent depletion of TME CTLA-4+ Tregs without long-lasting CTLA-4 blockade in the periphery. This approach may allow for enhanced efficacy over current antibody approaches through the elimination of Tregs in the TME. The lack of prolonged peripheral CTLA-4 blockade may reduce toxicity as seen with antibody approaches to CTLA-4. Clinical studies are expected to start in 2023.

818 COMBINATION THERAPY WITH ANTI-PD1 AND ANTI-LAG3 LEADS TO UNIQUE PERIPHERAL AND INTRATUMORAL CD8+ T CELLS SIGNATURES IN PATIENTS WITH METASTATIC MELANOMA

[1]Anthony Cillo*, [1]Carly Cardello, [1]Lilit Karapetyan, [1]Feng Shan, [2]Cindy Sander, [2]Elizabeth Rush, [3]Aofei Li, [3]Arivarasan Karunamurthy, [1]Sheryl Kunning, [1]John Kirkwood, [1]Tullia Bruno, [1]Dario Vignali. *[1]University of Pittsburgh, Pittsburgh, PA, USA; [2]UPMC Hillman Cancer Center, Pittsburgh, PA, USA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA, USA*

Background CD8+ T cell exhaustion, characterized by co-expression of multiple inhibitory receptors, limits antitumor immunity. Combination therapy with anti-PD1 and anti-LAG3 synergistically improves CD8+ T cell function in murine models of cancer and has recently demonstrated improved progression-free survival versus anti-PD1 alone in metastatic melanoma. However, the mechanisms underlying improved efficacy of this combination therapy have yet to be fully elucidated.

Methods A phase 2 clinical study was designed to assess the antitumor efficacy of anti-PD1 or anti-LAG3 alone versus anti-PD1 with anti-LAG3 in combination in patients with advanced melanoma naïve to prior immunotherapy. Peripheral blood mononuclear cells (PBMC) and tumor biopsies were obtained prior to and at four weeks following therapy. Single-cell RNA-seq (scRNAseq) was performed using 5'-based chemistry (10X Genomics) on live FACS-sorted immune cells from blood and tumors. scRNAseq data was normalized across patients using scVI, and CD8+ T cells from PBMC and tumors were bioinformatically isolated for detailed analyses. miloR was used to identify CD8+ T cell transcriptional signatures that would distinguish effects associated with each treatment arm.

Results We identified a total of 33,646 CD8+ T cells from PBMC and tumor infiltrating leukocytes (TIL) from 22 patients. Using miloR to define subpopulations of CD8+ TIL, we found that each treatment arm led to a distinct CD8+ T cell transcriptional signature at just four weeks post-treatment. Using a gene set derived from genes upregulated in CD8+ TIL following combination therapy, we found that melanoma patients from The Cancer Genome Atlas with high enrichment of this anti-PD1 plus anti-LAG3 combination signature had improved overall survival (HR=0.39,p<0.001), indicating that this signature is associated with antitumor immunity. We also found that CD8+ T cells from PBMC of patients receiving combination therapy had higher levels of T cell receptor (TCR) and interferon gamma (IFNg) signaling, suggestive of peripheral signatures of pharmacodynamic response to combination therapy. Notably, TCR and IFNg signaling were correlated between CD8+ T cells in PBMC and TIL at week 4 (rho=0.67,p=0.020 for TCR; rho=0.59,p=0.046 for IFNg), demonstrating that peripheral CD8+ T cells may serve as a surrogate for intra-tumoral responses.

Conclusions The anti-PD1, anti-LAG3, and anti-PD1 plus anti-LAG3 treatment arms each led to unique CD8+ TIL signatures. A transcriptional signature derived from combination therapy was associated with favorable prognosis in patients from an independent cohort. Functional signatures expressed by CD8+ T cells in PBMC were reflective of signatures occurring within tumors during therapy.

819 INTRATUMORAL ADMINISTRATION OF HIGH-CONCENTRATION NITRIC OXIDE AND ANTI PD-1 TREATMENT LEADS TO HIGHER TUMOR REGRESSION RATES AND PROLONGED SURVIVAL IN CT26 TUMOR-BEARING MICE

[1]Hila Confino*, [1]David Greenberg, [1]Selena Chaisson, [1]Jedidiah Mercer Monson, [2]Steve Lisi, [1]Amir Avniel, [3]Ido Wolf, [1]Yana Epshtein. *[1]Beyond Cancer, Beyond Air Inc., Rehovot, Israel; [2]Beyond Cancer, Beyond Air Inc., Garden City, NY, USA; [3]Tel Aviv Sourasky Medical Center, Tel Aviv Yafo, Israel*

Background Immune checkpoint inhibitors have shown dramatic activity transforming clinical oncology.[1] Yet, their activity is limited to a subset of highly sensitive tumors (e.g., melanoma). Even then response is observed in only 50% of patients.[2]

Nitric Oxide (NO) is a signaling molecule in multiple diseases, including cancer and has been shown to activate anti-tumor immune responses.[3] Previously, we reported that treatment of CT26 tumor-bearing mice with high-concentration NO (UNO) stimulated anti-tumor immune responses leading to the rejection of a secondarily-induced tumor. More specifically, a significant increase of tumor-infiltrating T-cells and blood and spleen B and T-cells were observed 14-21 days post-UNO treatment.

In this study we investigated the ability of UNO to improve the efficacy of anti-PD-1 antibody.

Methods Day zero, 5.0 X 10^6 CT26 cells were injected to the right flank of Balb/c mice (n=15-16 per group). Day six, CT26 cells were injected to the contralateral flank and anti-PD1 injections (5mg/kg mouse, q2d, x 5) commenced.

Day eight, tumors (average size 71.9±37.2mm^3) were treated intratumorally with UNO (50,000 ppm, 5 or 10 minutes, flow rate ~0.2 liter per minute). Post-treatment tumor volume and survival were monitored thereafter.

Results Complete regression of the primary tumor occurred in 9/15 (60%) of mice treated with combination 10-minute NO and anti-PD-1, post-treatment day 26. This compared to 4/16 (25%) of controls treated with anti-PD-1 alone (p=0.13) and 0/15 (0%) treated with UNO alone (p=0.0027).

Survival was drastically increased in the 10-minute UNO/anti-PD-1 combination arm compared to anti-PD-1 alone (p<0.05), post-treatment day 32.

Secondary, contralateral flank tumor take in the anti-PD-1 alone arm was 21.4% but reduced by 38% to 13.3% in the 10-min combination arm and reduced by 67% to 7.14% in the 5-min combination arm, post-treatment day 19.

Survival was significantly improved for both the 5- and 10-minute combination arms compared to the 5- and 10-minute UNO controls (p=0.02 and p<0.0001, respectively).

Conclusions Combination of UNO with anti-PD-1 significantly improved outcomes compared with UNO or anti-PD-1 alone. A strong possibility is that high-concentration NO assists the immune system in overcoming anti-PD-1 resistance. Thus, the combination of high-concentration NO and immune checkpoint inhibitors such as anti-PD-1 can be a breakthrough therapy with important clinical implications.

820 LINEAR DNA AMPLICONS AS A NOVEL ANTIVIRAL AND CANCER VACCINE STRATEGY

[1]Luigi Aurisicchio*, [2]Antonella Conforti, [3]Mirco Compagnone, [1]Erika Salvatori, [1]Lucia Lione, [1]Eleonora Pinto, [4]Clay Shorrock, [4]James Hayward, [4]Brian Viscount, [3]Fabio Palombo, [4]Yuhua Sun, [4]Ben Minghwa Liang. [1]*Takis Srl, Rome, Italy*; [2]*Evvivax Srl, Rome, Italy*; [3]*Neomatrix Srl, Rome, Italy*; [4]*ADNAS, Stony Brook, NY, USA*

Background DNA-based vaccines represent a simple, safe and promising strategy for harnessing the immune system to fight infectious diseases as well as various forms of cancer and thus are considered an important tool in the cancer immunotherapy toolbox. Nonetheless, the manufacture of plasmid DNA vaccines has several drawbacks, including long lead times and the need to remove impurities from bacterial cultures. Here we report the development of polymerase chain reaction (PCR)-produced amplicon expression vectors as DNA vaccines and their *in vivo* application to elicit antigen-specific immune responses in animal cancer models.[1]

Methods Plasmid DNA and amplicon expression was assessed both *in vitro*, by Hela cells transfection, and *in vivo*, by evaluating luciferase expression in mice through optical imaging. Immunogenicity induced by DNA amplicons was assessed by vaccinating mice, cats and ferrets against SARS-CoV-2 Spike protein. Similarly, amplicons encoding a tumor-associated antigen (Telomerase Reverse Transcriptase, TERT) and neoantigens were tested to evaluate the antitumoral effect of DNA amplicons in murine cancer models in combination with immune-checkpoint inhibitors (ICIs).

Results Amplicons encoding Spike Receptor Binding Domain (RBD) were strongly immunogenic in all models and were able to confer antiviral effects. DNA vaccines encoding tumor-associated-antigens, such as telomerase reverse transcriptase or neoantigens expressed by murine tumor cell lines were able to elicit antigen-specific immune responses and proved to significantly impact tumor growth when administered in combination with ICIs.

Conclusions These results strongly support the further exploration of the use of PCR-based amplicons as an innovative immunotherapeutic approach to viral diseases and cancer treatment.

821 **THE POTENTIAL CLINICAL USAGE OF FC-OPTIMIZED ANTI-CCR8 THERAPEUTIC ANTIBODIES AS A MONOTHERAPY OR COMBINED WITH OTHER PROMISING IMMUNE-MODULATING AGENTS BEYOND PD-1/L1**

[1]Shuang Dai, [1]Weifeng Huang, [1]Longjun Yan, [1]Shaogang Peng, [1]Shihui Zhou, [2]Zhijun Yuan, [2]Chao Wang, [2]Chuan-Chu Chou*, [2]Andy Tsun, [1]Tianhang Zhai. *[1]Biotheus (Suzhou) Co., Ltd., Suzhou, China; [2]Biotheus Inc., Zhuhai, China*

Background FOXP3$^+$ Regulatory T cells (Tregs) play a critical role in mediating tolerance to self-antigens but can repress anti-tumor immunity through multiple mechanisms. TGF-β is a potent immunosuppressive cytokine that acts as an essential factor during the differentiation of Treg cells. Therefore, targeted depletion of tumor-promoting Tregs is warranted to promote effective anti-tumor immunity while preserving peripheral homeostasis. CCR8 is a chemokine receptor that has recently been identified as a specific marker for tumor-infiltrating Tregs. Preclinical mouse tumor models have shown that the depletion of CCR8+ Tregs by anti-CCR8 monoclonal antibodies (mAbs) and FcγR engagement, but not ligand blockade, enables effective and long-lasting anti-tumor immunity in combination with PD-1 blockade. Several ADCC function-enhanced anti-CCR8 mAbs have been approved for clinical study both as a monotherapy and combined with PD-1 blockade. However, whether ADCP function enhancement would further potentiate anti-CCR8-mediated Treg depletion is still unknown. Here, we reveal an Fc-optimized anti-CCR8 mAb, which shows stronger ADCC and ADCP function than a wild-type IgG1 control. To explore potential combination strategies in the clinic, we also investigated the synergistic potential of combining the anti-CCR8 mAb with an anti-PD-L1 mAb fused to the extracellular domain of the human TGF-β receptor II (TGFβRII) via a flexible linker, to neutralize TGF-β (anti-PD-L1-β trap).

Methods Effector function-optimized anti-CCR8 mAbs were generated by the mutation of Fc residues plus expression in a *fut8*$^{-/-}$ CHO cell line. ADCC and ADCP function was detected in both luciferase reporter cell line and primary cells. *In vivo* efficacy studies using anti-muCCR8-mG2a combined with an anti-PD-L1-β trap was conducted in a CT-26 colon carcinoma model.

Results Fc-optimized anti-CCR8 mAb showed stronger ADCC and ADCP function than the version containing wildtype IgG1 Fc in *in vitro* assays. The combination of anti-CCR8 mAb and anti-PD-L1-β trap more effectively controlled *in vivo* tumor growth compared to both monotherapies. We hypothesize that this potent anti-tumor immune response is propagated by the synergy of activating tumor infiltrating lymphocytes and the depletion of tumor-infiltrating Treg cells.

Conclusions We successfully generated an Fc-optimized anti-CCR8 mAb with both ADCC and ADCP enhancement. We also highlight the potential clinical combination benefit of anti-CCR8 mAbs with agents simultaneously blocking the PD1/L1 and TGF-β pathways.

Ethics Approval All mice were maintained under specified pathogen-free conditions, and all studies were approved by the Animal Care and Use Committee of HUST-Suzhou Institute for Brainsmatics.

822 OVERCOMING THE SUPPRESSIVE TUMOR MICROENVIRONMENT WITH A LIVE BACTERIAL IMMUNOTHERAPY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0822

Andrew Scott, Matthieu Besneux, Oluwatobiloba Oke, Mary Chol, Claudia Prevosto, Nicholas Glanville, Livija Deban*. *Prokarium Limited, London, UK*

Background Tumor-infiltrating myeloid cells supress anti-tumor immunity within the tumor microenvironment (TME) through direct and indirect inhibitory mechanisms. However, inherent myeloid plasticity offers the opportunity for treatments to reprogramme these cells. One class of agents with potential to reprogramme myeloid cells are bacteria and their products, which act locally on suppressive cell populations, but also induce long-lasting systemic reprogramming of myeloid cells, a process termed trained immunity. Prokarium is developing a live attenuated *Salmonella enterica* serovar Typhi strain (ZH9) to be the next cancer immunotherapy and sought to establish whether *Salmonella* reprograms myeloid cells and enhances anti-tumor immune function.

Methods The effects of *Salmonella* on established suppressive myeloid cell phenotypes was assessed by flow cytometry staining, cytokine release and T cell suppression assays using M2 polarised human macrophages. The effects of *Salmonella* on unpolarised myeloid cells was investigated after oral *Salmonella* infection of healthy mice by phenotyping splenic myeloid cells using flow cytometry and assessing their cytokine production after *ex vivo* re-stimulation. Anti-tumor activity of *Salmonella* treatment was measured in syngeneic subcutaneous colon (MC38) and experimental metastasis (4T1) models. Finally, potential synergy with established therapies was assessed utilising a co-culture system of human monocyte-derived M2 macrophages treated with *Salmonella* and autologous T cells, with or without checkpoint inhibitor antibodies.

Results *Salmonella* treatment repolarized human M2 macrophages towards an anti-tumor phenotype, upregulating costimulatory molecules, increasing secretion of pro-inflammatory cytokines and relieving suppression of co-cultured T cells. Oral *Salmonella* treatment of mice induced long-term phenotypic and functional myeloid changes, including upregulation of costimulatory and MHC molecules on systemic dendritic cells, monocytes and macrophages, and increased responsiveness of CD11c+ splenocytes to secondary stimuli, suggesting *Salmonella* also affects unpolarised myeloid cells. Oral treatment with *Salmonella* as a monotherapy was able to suppress tumour growth in subcutaneous and experimental metastasis models, indicating this *Salmonella*-induced myeloid phenotype may translate to changes in the myeloid compartment of the TME. Finally, *Salmonella* complemented other cancer therapies both *in vitro* and *in vivo*. *In vitro, Salmonella*-trained human monocytes overcame the suppressive phenotype induced by subsequent culture in M2-polarizing conditions to synergize with checkpoint inhibitors in driving T-cell proliferation. *In vivo*, oral *Salmonella* treatment synergized with anti-PD-L1 in supressing growth of subcutaneously implanted MC38 tumors.

Conclusions *Salmonella* immunotherapy can both reverse established suppressive myeloid phenotypes and systemically prime myeloid cells, likely rendering them resistant to immunosuppression in the TME and ultimately leading to improved efficacy of existing cancer immunotherapies.

Ethics Approval All animal studies were conducted under authority of United Kingdom Animals (Scientific Procedures) Act 1986 project license number PP8366809.

823 IMM20059, A NOVEL ANTI-EPN1 ANTIBODY, IN COMBINATION WITH ATEZOLIZUMAB SIGNIFICANTLY ENHANCES TUMOR REGRESSION IN THE B16.F10 SYNGENEIC MELANOMA MODEL COMPARED TO ANTI-PD-L1 MONOTHERAPY

John Dowling*, Pavel Nikitin, Cezary Swider, Chris Nicolescu, Halley Shukla, Jamie Bingaman-Steele, Nirja Patel, Eden Sikorski, Benjamin Harman, Jillian DiMuzio, Karen Lundgren, Yumi Ohtani, Michael Morin, Matthew Robinson, Fang Shen. *Immunome, Inc., Exton, PA, USA*

Background Immune checkpoint inhibitors (ICI), such as anti-PD-L1 and anti-PD-1 antibodies, have exhibited remarkable efficacy in the clinic. However only a small subset of patients will ultimately respond to therapy and there is a dire need for expanding the patient population who will benefit from ICI treatments. Immunome's proprietary platform allows the interrogation of the memory B cell population for potential therapeutic antibodies, including those that may enhance ICI responses.

Methods In this study, IMM20059, an antibody discovered using Immunome's proprietary platform, is assessed for target specificity using immunoprecipitation/mass spectrometry (IP/MS), surface plasmon resonance (SPR), and epitope mapping. Tumor cell binding is evaluated via flow cytometry. Anti-tumor efficacy of IMM20059 in combination with anti-PD-L1 is evaluated in the syngeneic B16.F10 melanoma model in C57BL/6 mice and intra-tumoral chemokines are assessed by Luminex.

Results IMM20059 selectively binds to the N-terminal domain of epsin 1 (EPN1), an adapter protein involved in clathrin-mediated endocytosis, as compared to other epsin family members. Although expressed in multiple tissues, EPN1 is specifically upregulated in multiple cancer types, including lung, breast, and prostate cancers. Strikingly, while this expression is largely restricted to the intracellular compartment in normal cells, EPN1 appears to be ectopically expressed on the cell surface in multiple cancer cell lines, allowing for tumor specific targeting. The selectivity of IMM20059 and surface expression of EPN1 was confirmed by knockout of EPN1 and competition with recombinant protein. IMM20059 cross reacts with murine EPN1, exhibits a favorable pharmacokinetic profile *in vivo*, and exhibits a good tolerability profile in C57BL/6 mice. In the B16.F10 melanoma syngeneic model, combination treatment of IMM20059 and anti-PD-L1 (Atezolizumab) induced significant tumor regression compared to IMM20059 or Atezolizumab treatment alone, suggesting a combinatorial effect between the two pathways. Furthermore, this combination treatment significantly enhanced production of intratumoral chemokines, including MIP-1α, MIP-1β, and RANTES.

Conclusions This study suggests that EPN1 is a promising tumor target. Combination treatment of IMM20059 and anti-PD-L1 could enhance the efficacy of anti-PD-L1 therapy by boosting intratumoral chemokines and attracting immune cells to the immunologically cold tumor microenvironment.

824 **NX-1607, A SMALL MOLECULE INHIBITOR OF THE CBL-B E3 UBIQUITIN LIGASE, PROMOTES T AND NK CELL ACTIVATION AND ENHANCES NK-MEDIATED ADCC IN A MOUSE LYMPHOMA TUMOR MODEL**

Marilena Gallotta*, Jennifa Gosling, Austin Tenn-McClellan, Serena Ranucci, Jose Gomez Romo, Frederick Cohen, Gwenn Hansen, Arthur Sands, Cristiana Guiducci, Ryan Rountree. *Nurix Therapeutics, San Francisco, CA, USA*

Background The E3 ubiquitin ligase Casitas B-lineage lymphoma B (CBL-B) is expressed in leukocytes and regulates signaling pathways in T and NK cells, significantly limiting their antitumor effector function. In T cells CBL-B attenuates activation initiated by TCR engagement, in part by mediating the requirement for CD28 co-stimulation, thus setting the threshold for T cell activation. In NK cells, CBL-B functions downstream of TAM receptors and negatively regulates cytokine production and cytotoxicity.

Methods Here we describe the effects of NX-1607, an orally bioavailable intramolecular glue inhibitor of CBL-B, on primary human T and NK cells and assess NX-1607 in combination with Rituximab in a murine xenograft model of Non-Hodgkin's Lymphoma (NHL).

Results Previously, we showed that NX-1607 enhances IL-2 and IFN-g secretion in human T cells following TCR stimulation. Regulatory T cells (Tregs) produce multiple cytokines in the tumor microenvironment (TME) that work to counteract the antitumor response by suppressing T-cell activation. Proliferation of CD4+ effector T cells activated by anti-CD3/CD28 was suppressed when cultured 1:1 with Tregs or TGF-b. Addition of NX-1607 recovered the proliferative capacity of CD4 + effector T cells to levels equivalent to that of anti-CD3/CD28 stimulation alone. Therefore, in addition to enhancing T-cell activation, NX-1607 renders T cells resistant to Treg and TGF-β-mediated suppression.

In an *in vitro* ADCC assay, addition of NX-1607 significantly enhanced TNF-α and IFN-γ production in human primary NK cells. The efficacy of NX-1607 in combination with Rituximab was evaluated in a Raji NHL model where Raji cells were administered by IV to establish disseminated tumors followed by treatment with NX-1607 (30 mg/kg QD) and/or Rituximab (10 mg/kg). Both NX-1607 and Rituximab given as monotherapy provided a significant survival benefit. Combination of NX-1607 and Rituximab significantly enhanced tumor growth inhibition and stable rejections when compared to single agent activity. Importantly, the survival benefit provided by NX-1607 was abrogated by depletion of NK cells. Therefore, NX-1607 augments NK cell activity both in human NK cells and in mouse tumor models.

Conclusions These studies provide insight into the antitumor activity of this novel, small molecule inhibitor of CBL-B, demonstrating that NX-1607 enhances both innate and adaptive immune responses, both of which are important for overcoming a suppressive TME. These studies also provide support for clinical development of NX-1607 as a monotherapy or in combination with antibody therapeutics to enhance ADCC antitumor effects. We have initiated a clinical trial with NX-1607 in patients with advanced solid tumors NX-1607-101 (NCT05107674).

826 IL7R TME EXPRESSION CORRELATES WITH IMMUNOTHERAPY RESPONSE AND IS ASSOCIATED WITH T-CELL STEMNESS WITH DECREASED APOPTOSIS

Nicolas Poirier*, Isabelle Girault, Aurore Morello, Justine Durand, Margaux Seite. *OSE Immunotherapeutics, Nantes, France*

Background Anti-PD(L)1 therapy can reinvigorate exhausted Tcells by inducing a proliferative burst of PD1+TCF7+ stem-like Tcells but, Tcells rapidly undergo exhaustion and death, limiting efficacy of therapy. IL7 induces survival and homeostatic proliferation of Tcells. IL7R is associated with memory-stem-like Tcells subset but, the effect of IL7 on cancer-specific TILs remains unknown. We studied gene expression of the IL7/IL7R pathway on single cell transcriptomic analysis in multiple datasets of anti-PD1/PDL1 responder's and non-responders' patients.

Methods RNAseq of bulk tumor and scRNAseq of TILs and tumor-specific clonotypes datasets were analyzed prior checkpoint inhibitors treatment from different clinical studies representing a total of 1036 patients for RNAseq analysis and 39 patients for scRNAseq analysis: Melanoma (aPD1+/-aCTLA4), TNBC (Chemotherapy+PDL1), NSCLC (aPD1) and Ovary (*Ex vivo* aPD-1 response).

Results IL7R and IL7R pathways gene expression on tumor bulk is significantly correlated with better OS or PFS across multiple cancers, as analyzed by PanCancer TCGA and iATLAS datasets ($p<0.02$; $p<0.0001$). In Melanoma, NSCLC, Ovarian, TNBC, HNSCC and/or Kidney cancers, we demonstrated a significant higher expression of IL7R and/or IL7R pathway signatures of future ICI responders versus non-responders and confirmed this data by scRNAseq analysis specifically on TILs and tumor-specific Tcell clonotypes.[1-5] TILs over-expressing IL7R show upregulation of genes related to stemness and downregulation of genes related to exhaustion. In addition, IL7RHigh TILs are less apoptotic and express significant higher level of BCL2 anti-apoptotic molecule. As TCF7 gene is described as key marker for stemness and anti-PD(L)1 response, we also analysed impact of IL7R+/-TCF7 expression. TCF7 or IL7R expression only are not sufficient to predict ICI response, while the coexpression is predictive to ICI response in Melanoma. scRNAseq and FACs analyses of chronically stimulated human Tcells *in vitro* show that IL7 significantly promotes long-term survival (up to 5 weeks) and proliferation of stem-like Tcells (TCF7+Tcells), whereas IL2 or IL15 promotes proliferation of Tcells with exhausted phenotype dying after >10 days of culture.

Ex-vivo, IL7 fused to an anti-PD1 mAb reinvigorates TILs (IFNg secretion) in human 3D-tumoroids from both anti-PD1 sensitive or not patients.

Conclusions Altogether, our data show that IL7R pathway expression in TILs and tumor-specific Tcell clonotypes are predictive of long-term ICI clinical response. Redirecting IL7 on PD1+Tcells provides stemness, proliferative and survival signals to tumor-specific Tcells capable to induce durable response.

827 **THE ROLE OF COMBINATION IMMUNE CHECKPOINT INHIBITORS AS SALVAGE THERAPY FOR PD-1/PD-L1-RESISTANT MERKEL CELL CARCINOMA**

Tarek Haykal*, Georgia Beasley, April Salama, Brent Hanks. *Duke University, Durham, NC, United States*

Background Merkel cell Carcinoma (MCC) is a rare but aggressive cutaneous neuroendocrine malignancy that often presents as locally advanced or metastatic disease. MCC has a high risk of relapse, morbidity, and mortality that can be challenging to manage. The PD-1/PD-L1 inhibitors, pembrolizumab and avelumab, have recently been shown to benefit approximately 50% of metastatic MCC patients, indicating that a significant fraction of these patients are in need of alternative therapeutic options. There is currently no standard salvage treatment regimen for anti-PD-1-refractory MCC patients. We sought to explore our clinical experience at Duke University with combination immune checkpoint inhibitors (ICIs), ipilimumab and nivolumab, after progression on PD-1/PD-L1 inhibitors for patients with metastatic or locally advanced MCC.

Methods A comprehensive electronic database search was conducted for all metastatic and locally advanced MCC patients that were treated with PD-1/PD-L1 therapies between years 2015 and 2022, at Duke University. Patients that were treated with combination ICIs were included. Patients treated with surgery, radiation, and chemotherapy were not excluded. The primary outcome was objective response rates (ORR), as assessed by utilizing Response Evaluation Criteria in Solid Tumors (RECISTv1.1) as well as immune-related Response Evaluation Criteria in Solid Tumors (irRECIST). Secondary outcomes were progression free survival (PFS), overall survival (OS), and immune-related adverse events (irAEs) at the longest follow-up.

Results Our search yielded 6 patients with metastatic or locally advanced MCC that were treated with ipilimumab and nivolumab after progression on PD-1/PD-L1 inhibitor therapies. The patients' mean age was 69.6 years with a male percentage of 66.66%. ORR was 50%, where 2 patients had a complete response and one had a partial response. Of the other 50% of patients, 2 patients had progression of disease and one had stable disease at their week 12 restaging scans. Mortality rate was 50% and all deaths were cancer-related. Median PFS was 7 months and median OS was 13 months. 50% of patients suffered an irAE while 33% experienced a grade 3 or higher irAE.

Conclusions Our study highlights that the use of combination ICIs with ipilimumab and nivolumab as salvage therapy for patients with metastatic or locally advanced MCC resistant to PD-1/PD-L1 therapy can be effective and is relatively well-tolerated. These data indicate that this treatment regimen is worthy of further exploration in a larger cohort of MCC patients.

828 COMBINATION OF FLT3L AND STING AGONISM SENSITIZES NON-T CELL-INFLAMED TUMORS TO CHECKPOINT BLOCKADE THERAPY

Emily Higgs*, Thomas Gajewski. *University of Chicago, Chicago, IL, United States*

Background STING agonists have been pursued as a strategy to trigger innate immune activation within the tumor microenvironment, which can lead to adaptive immunity and tumor regression in mice. However, clinically activity of STING agonists has been less impressive. We hypothesized that a low response rate clinically could be because most patients have non-T cell-inflamed (cold) tumors. We hypothesized that non-T cell-inflamed tumors may lack the required $CD103^+$dendritic cell (DC) subset for T cell priming, thus failing to make the bridge to adaptive immunity. To investigate this notion, we turned to a B-catenin-driven genetically engineered mouse melanoma model, which is non-inflamed and known to lack $CD103^+$ DCs. We evaluated whether recruitment of $CD103^+$ DCs via Flt3L might cooperate with a STING agonist to promote tumor control, alone or in combination with checkpoint blockade antibodies.

Methods We used the BRAF-activated, PTEN-deleted, B-catenin-stabilized (BPC) genetic melanoma model. Our laboratory previously showed that these tumors lack spontaneous $CD103^+$ DC and T cell infiltration and have low expression of the chemokines known to recruit these cells, which closely resembles the biology of many non-T cell-inflamed human cancers. To recruit and activate $CD103^+$ DCs to these tumors, we injected intratumoral Flt3L alone, the STING agonist DMXAA alone, and both in combination.

Results Intratumoral DMXAA injection led to significant increases in $CD8^+$ T cells in BPC tumors five days post injection. However, the $CD103^+$ DC numbers in these tumors were not increased. Moreover, T cells recruited following DMXAA treatment were unable to control tumors alone or with anti-PD-L1 + anti-CTLA-4. This led us to adopt an additional strategy aimed at promoting $CD103^+$ DC accumulation directly. A single injection of Flt3L was able to drive $CD103^+$ DC accumulation in BPC tumors. However, Flt3L alone or with a subsequent DMXAA injection had minimal effects on tumor growth. Excitingly, Flt3L and DMXAA injection followed by anti-PD-L1 + anti-CTLA-4 mAB therapy led to significant tumor control.

Conclusions Injection of Flt3L + DMXAA supported intratumoral accumulation of both $CD8^+$ T cells and $CD103^+$ DCs. This enabled subsequent therapeutic activity of anti-CTLA-4 + anti-PD-L1 mAb therapy in this very challenging cold tumor model. Inasmuch as tumors in this model fail to respond to vaccination, adoptive T cell therapy, and checkpoint blockade strategies, the activity of this regimen is highly significant. Clinical investigation of intratumoral Flt3L + STING agonists should be prioritized for future study in anti-PD-1-refractory patients.

Ethics Approval This study obtained ethics approval by the Institutional Animal Care and Use Committee (IACUC) at the University of Chicago as outlined in the animal protocol #71621. The IBC protocol number is IBC1309(3).

829 IN SITU VACCINATION UTILIZING INTRATUMORAL ELECTROPORATION OF PLASMIDS EXPRESSING IL-12 AND CD40 LIGAND (CD154) HAS EFFICACY AGAINST MURINE TUMORS

Gregory Ho*, Steven Fiering. *Dartmouth College, Lebanon, NH, United States*

Background Although the human body generates tumor-specific T cells, tumor-mediated immunosuppression protects tumors from antitumor immunity. Any immunotherapy must overcome this local/systemic immunosuppression. One strategy is *in situ* vaccination (ISV), where an immunostimulant is applied directly to an established tumor to disrupt the local immunosuppression, generating a robust local antitumor immunity, slowing or potentially eliminating the treated tumor. In addition, the rapid expansion of tumor-specific T cells induces antitumoral effects on distant, non-treated tumors known as the abscopal effect. While there are many therapeutic options under development for ISV, the optimal combination of immunostimulants needed for different tumor types remains unclear. Reported here are studies to express specific proteins by plasmid electroporation as ISV therapy.[1,2] Previous studies have reported the benefit of expressing different molecules from plasmids in tumors, particularly IL-12, which has also been tested in phase II clinical trials.[3] CD154 expression, (ligand for CD40), can mature antigen-presenting cells, lead to changes in cytokine expression, and support antigen presentation. We find that intratumoral CD154 electroporation has potent local antitumor effects and those effects are increased when CD154 is combined with IL-12. Presented studies will include abscopal effects on established but untreated tumors.

Methods Plasmids encoding for either CD154, IL-12, or control (Bgeo) were transformed into competent *E.coli* and inoculated into LB Miller cultures. Plasmid DNA was isolated and purified using Qiagen Plasmid Mega kit. Mice were anesthetized and injected with 2 x 10^5 B16F10 cells into the right flank intradermally prior to electroporation treatment into C57BL6 mice. 50ug of each plasmid was injected intratumorally twice one week apart. Immediately following injection, mice were electroporated for 6 pulses at 1500v/cm for 6 pulses at 100us durations using BTX Harvard Gemini X2 electroporator.

Results We find that intratumoral CD154 electroporation has potent local antitumor effects and those effects are increased when CD154 is combined with IL-12. With the addition of the IL-12 plasmid, we are able to generate significant abscopal effects on established, untreated tumors.

Conclusions The addition of CD40 ligand expression in combination with IL-12 induces a tumor clearance on the treated tumor. CD154 and IL-12 plasmid electroporation combination therapy provides superior protection on the treated tumor, in addition to providing protection on distant, untreated tumors.

830 TARGETING B CELL SUPPRESSION TO IMPROVE THE EFFICACY OF IMMUNOTHERAPIES IN BRAIN CANCER

[1]David Hou*, [2]Brandyn Castro, [1]Andrew Zolp, [1]Mark Dapash, [1]Victor Arrieta, [3]Jana Biermann, [3]Johannes Melms, [1]Maciej Lesniak, [3]Benjamin Izar, [1]Jason Miska, [3]Junfei Zhao, [1]Catalina Lee-Chang. *[1]Northwestern University, Chicago, IL, United States; [2]University of Chicago, Chicago, IL, United States; [3]Columbia University, New York, NY, United States*

Background Immunotherapy is a promising approach to treat brain tumors, but several factors, especially the suppressive tumor microenvironment (TME), make translation of immunotherapies difficult. Studies in several other solid tumors have revealed the accumulation of germinal-center-like B-cells as a critical survival predictor of immune-checkpoint-blockade (ICB) therapy, suggesting a central of B-cell immunity in driving ICB therapeutic impact.[1,2] However, the harsh TME of brain tumors such as glioblastoma (GBM) suppress B-cell activity. We seek to better understand mechanisms of TME-driven immunosuppression and leverage B-cell immunity to enhance immunotherapy effectiveness in brain tumors.

Methods Single-cell and single-nuclei transcriptomic sequencing were used to analyze human GBM and melanoma brain metastasis tumor samples, as well as CT2A murine glioma models. Spatial multiplex analysis and single-cell transcriptomic analysis were used to characterize B-cell interactions within the TME of GBM samples to identify pathways of B-cell immunosuppression.

Results We characterized tumor infiltrating B-cells as activated but suppressed, with expression of coinhibitory checkpoint molecules such as CD22, CD72, and CD32 that inhibit effector functions such as plasmablast differentiation and antibody production (figure 1). Single-cell transcriptomic and spatial multiplex analysis highlighted the TGF-ß receptor 2 (TGFBR2) as a key regulator of tumor B-cell suppression with tumor associated myeloid cells (TAMCs) and tumor cells being main producers of TGF-ß1 cytokine (figure 2). TGF-ß1 signaling directly inhibited B-cell proliferation and plasmablast differentiation, and induced expression of checkpoint molecules *in-vitro*. Murine and tumor models with conditional knock-outs of TGFBR2 or TGF-ß1, showed significant increased efficacy of PD1 blockade compared to wild type controls (figure 3). The TME of these animals had expanded germinal-center-like proliferating intratumoral B-cells, production of tumor-reactive antibodies, and T-cell activation, and these animals showed increased survival. We also blocked aVß8 integrin, which has tumor-B-cell specificity and activates TGF-ß1, and found that our treatment promoted PD1 blockade efficacy and long-term survival benefit. Combining aVß8 and PD1 blockade eradicated gliomas in nearly 60% of treated mice and promoting immunological memory against tumor rechallenge (figure 4). This robust therapeutic effect depended on B-cell immunity as mice lacking B-cells (B-cell deficiency or intratumoral B-cell depletion using rituximab) failed to prevent tumor growth. After dual treatment, analysis of the TME showed robust cellular proliferation and differentiation into plasmablasts and effector T-cells (figure 5).

Conclusions Our results highlight the importance of B-cells in anti-tumor response, and that promoting Bcell function is a novel approach to boosting the effects of checkpoint blockade in brain tumors.

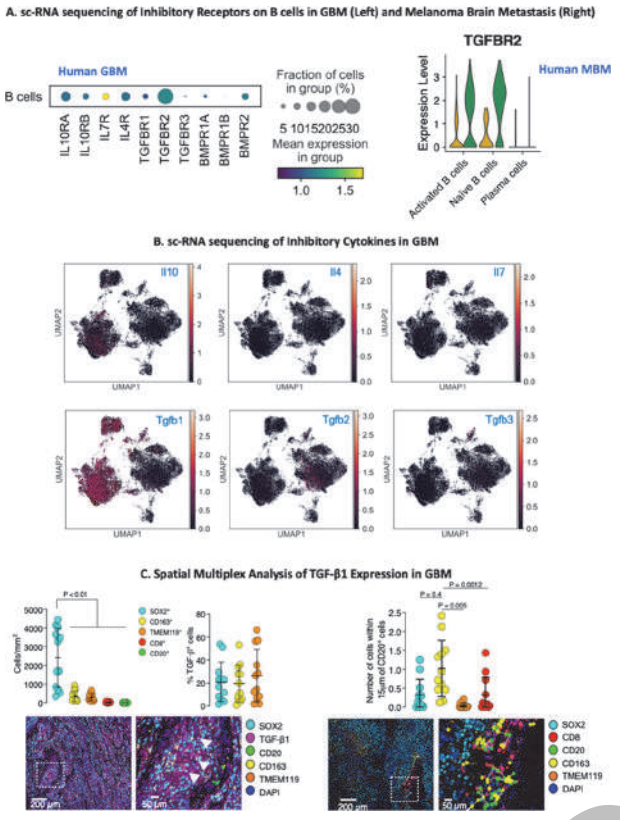
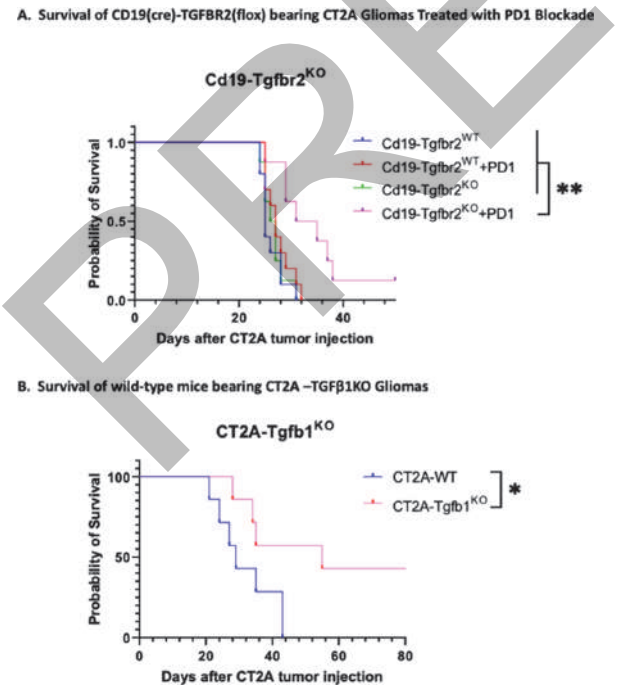
All models show elevated expression of coinhibitory checkpoint molecules CD22, CD72, and CD32

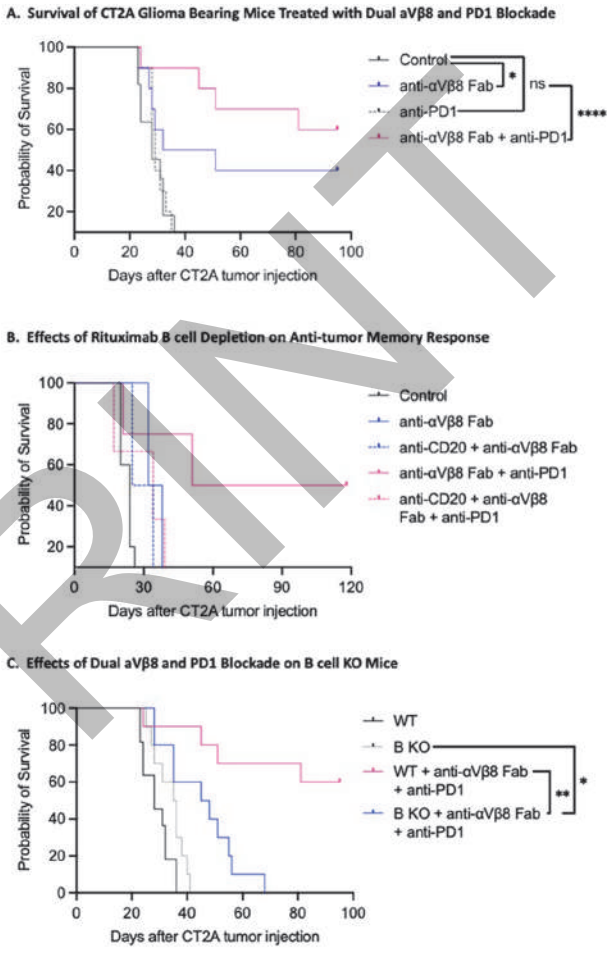


Abstract 830 Figure 2 TGFb1-TGFb-R2 Pathway Mediates B cell Suppression
(A) Tumor B cells express high levels of TGFb-R2 in both GBM (left) and MBM (right) samples as well as murine CT2A model. (B) scRNAseq shows that the TME of GBM has high levels of TGFb1 cytokine. (C) Spatial multiplex analysis shows TAMCs and tumor cells are key producers of TGFb1 in the TME

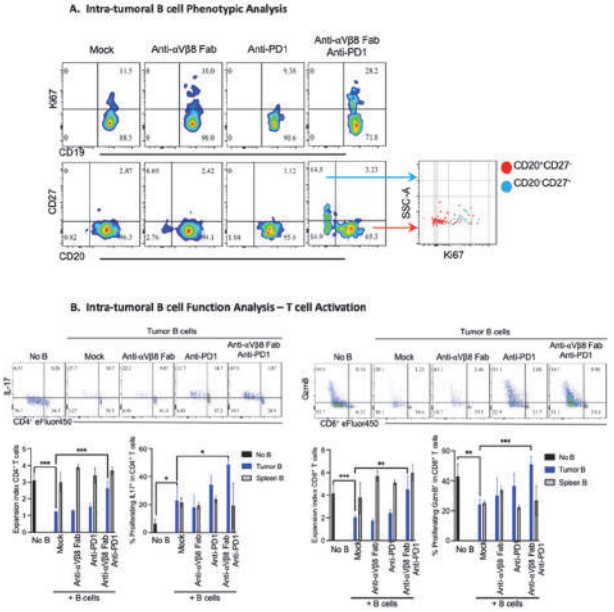


Abstract 830 Figure 3 Inhibiting TGFb Signaling on B cells Increases Survival

(A) We generated conditional knockouts of TGFb-R2 from B cells. These animals had an improved response to PD1 therapy ($p<0.01$). (B) Wild type mice with CT2A-TGFb1KO tumors had improved survival compared to those with CT2A-wild type tumors ($p<0.5$). B cells in these mice also had improved proliferation and function



Abstract 830 Figure 4 aVb8 Integrin Blockade Improves PD1 Blockade Efficacy
(A) CT2A bearing mice were treated with dual or single aVb8 and PD1 blockade. Dual treated animals showed significantly improved survival benefit (n=10 animals/group, $p<0.0001$). (B) Animals were re-challenged with CT2A tumors in the contralateral hemisphere. Those that also received B cell depletion via rituximab were not able to mount a memory response. (C) Dual aVb8 and PD1 blockade did not exhibit the same therapeutic benefit in B cell KO mice compared to wild type mice ($p<0.01$).



Abstract 830 Figure 5 Dual aVb8 and PD1 blockade Improves B cell Functionality
(A) Phenotypic analysis of B cells after treatment show increased proliferation and plasmablast differentiation. (B) Functional analysis of B cells show increased activation and proliferation of CD4 and CD8 T cells as determined via induction of IL17 and granzyme B

831 TARGETING TUMOR OXIDATIVE METABOLISM TO OVERCOME HYPOXIA-INDUCED IMMUNOTHERAPY RESISTANCE IN PROSTATE CANCER

[1]Priyamvada Jayaprakash*, [1]Michael Curran, [1]Brittany Morrow, [1]Joseph Marszalek, [1]Krithikaa Rajkumar Bhanu, [1]Meghan Rice, [1]Jason Gay, [1]Christopher Vellano, [2]Benjamin Cowen, [2]Dean Welsch. [1]*The University of Texas MD Anderson Cancer Center, Houston, TX, United States*; [2]*Immunomet, Houston, TX, United States*

Background Immunotherapy is successful in "hot" tumors with pre-existing immune infiltrates. However, "cold" tumors like prostate cancers remain unresponsive.[1,2,3] Murine prostate tumors harbor hypoxic regions, islands of immune privilege, excluding T cells while promoting recruitment and suppressive polarization of myeloid-derived suppressor cells (MDSC). Targeting hypoxia using the hypoxia-activated prodrug, TH-302 (Evofosfamide) reduced MDSC driven suppression, enhanced T cell function, improving sensitivity to immune checkpoint blockade (ICB).[4] In a Phase I clinical trial, combining Evofosfamide with Ipilimumab (anti CTLA-4) elicited both objective responses and prolonged disease stabilization in late-stage "cold" tumor patients. However, Evofosfamide reduces, but does not eliminate hypoxia and patients resistant to Evofosfamide/Ipilimumab combination exhibited hyper-metabolic tumors.[5] Targeting tumor oxidative metabolism reduced hypoxia and improved sensitivity to PD-1 blockade.[6,7] We hypothesized that targeting tumor oxidative metabolism using mitochondrial complex I inhibitors might diminish tumor hypoxia, and act synergistically with Evofosfamide to sensitize unresponsive tumors to immunotherapy. Since oxidative phosphorylation (OxPhos) is also crucial to T cell function, we tested multiple doses of two complex I inhibitors to determine a regimen with optimal capacity to compromise tumor oxygen metabolism while sparing T cell metabolic fitness.

Methods Utilizing the transplantable TRAMP-C2 prostate tumor model, we investigated the capacity of two complex I inhibitors to reduce tumor oxidative metabolism, diminish myeloid suppressive capacity and improve T cell immunity, alone and in combination with Evofosfamide and ICB. We assessed tumor burden, evaluated immune composition using flow cytometry and characterized metabolism using Seahorse XFe96 analyzer.

Results While Evofosfamide or OxPhos inhibition alone did little to inhibit prostate cancer progression, combination acted synergistically to reduce tumor burden and augment tumor-specific CD8 and CD4 effector T cell proliferation. Complex I inhibition reduced TRAMP-C2 tumor cell proliferation and MDSC suppressive polarization, but improved function of previously activated T cells. Consequently, neither prior, nor concurrent, complex I inhibition diminished efficacy of CTLA-4/PD-1 blockade in TRAMP-C2 . Used in combination, complex I inhibition and ICB promoted tumor-infiltrating T cell proliferation, activation and cytotoxicity while reducing dysfunction/exhaustion markers.

Conclusions Tumor hypoxia and associated immune suppressive programming can be reduced through both restoration of oxygen supply through vascular remodeling (i.e. Evofosfamide) and limitation of tumor oxygen metabolism (e.g. complex I inhibition). OxPhos inhibition selectively inhibits tumor and myeloid function, while sparing T cell function and responsiveness to ICB. Coordinated remodeling of tumor oxygen metabolism with existing drugs can compromise hypoxia-associated T cell suppression without compromising intrinsic T cell metabolic potential.

832 ANTIGEN SPREAD MEDIATED BY ONCOLYTIC ADENOVIRUS DELTA-24-RGDOX DURING INTRATUMORAL ADOPTIVE T CELL THERAPY IN IMMUNOCOMPETENT MICE WITH DISSEMINATED TUMORS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0832

Hong Jiang*. *MD Anderson Cancer Center, Houston, TX, United States*

Background Tumor relapse due to antigen escape is an essential problem in adoptive T cell therapy (ACT) with limited antigen targets, such as CAR T cells. This is especially true for solid tumors since they are more heterogeneous than hematological malignancies. Moreover, systemically delivered T cells infiltrate poorly into the solid tumors and are susceptible to the immune suppressive tumor microenvironment (TME) ("cold tumor"). On the other hand, oncolytic viruses, such as oncolytic adenovirus Delta-24-RGDOX developed by our group, can turn "cold tumor" into immune active "hot tumor" and induce immune response against a variety of tumor-associated antigens (TAAs). Thus, we hypothesize that Delta-24-RGDOX potentiates the effect of ACT through activating TME and antigen spread.

Methods We used B16-OVA-C57BL/6 subcutaneous (s.c.)/s.c. melanoma model[1] to assess systemic therapeutic effect in disseminated tumors. gp100-TCR CD8+ T cells were injected into the first tumor, followed by three injections of Delta-24-RGDOX into the same tumor. Leukocytes from the tumors were profiled for surface markers with flow cytometry. Activity of splenocytes against specific TAAs and tumor cells was measured with ELISA.

Results Delta-24-RGDOX injections following gp100-TCR CTLs in the first tumor increased total CD8+ leukocyte presence within both tumors. Further analysis revealed that treatments with either agents or combination dramatically downregulated CD62L whose expression kept at low levels in adopted gp100-TCR and endogenous OVA-specific CTLs. Moreover, although Delta-24-RGDOX significantly upregulated PD-1, TIM3 and LAGs in CD8+ leukocytes, its effect on these immune inhibitors was different in gp100-TCR or OVA-specific CTLs. The overall levels of these inhibitors in OVA-specific CTLs were remarkably higher than in gp100-TCR CTLs or CD8+ leukocytes. The virus slightly increased the inhibitors in the gp100-TCR CTLs from the treated tumor and decreased the inhibitors in the gp100-TCR CTLs from the untreated tumor. Importantly, PD-1 levels in OVA-specific CTLs were significantly downregulated in OVA-specific CTLs from both treated and untreated tumors although the other two inhibitors kept at a steady lower level. As a result, Delta-24-RGDOX drastically increased the density of OVA-specific CTLs in both tumors and the combination synergistically enhanced the effect. Consistently, the splenocytes from the combination group showed significant stronger response against other TAAs (OVA and TRP2) than gp100, leading to higher activity against tumor cells.

Conclusions Our data demonstrate that localized treatment with intratumoral ACT followed by Delta-24-RGDOX enhances global immune activation and antigen spread to expand antitumor T cell repertoire, leading to efficacious systemic anti-tumor immunity.

833 BLOCKADE OF HUMAN LILRB4/ILT3 INHIBITS THE FORMATION OF LUNG METASTASIS IN MELANOMA MODEL

[1]Darya Khantakova*, [1]Martina Molgora, [2]Julie Roda, [2]Geoffrey Stone, [1]Susan Gilfillan, [1]Tihana Trsan, [1]Marina Cella, [2]Alan Kutach, [2]Daniel Kaplan, [2]Jer-Yuan Hsu, [1]Marco Colonna. [1]*Washington University School of Medicine, St. Louis, MO, United States*; [2]*NGM Biopharmaceuticals, South San Francisco, CA, United States*

Background Targeting the immunosuppressive tumor microenvironment to enhance or recover anti-tumor functions is a promising strategy to favor tumor regression and response to checkpoint immunotherapy. LILRB4 is an inhibitory immune receptor, also named ILT3, that is primarily expressed in myeloid cells. We previously showed with *in vitro* assays that ILT3 is highly expressed in tumor-associated macrophages (TAMs) and binds fibronectin (Fn), which is ubiquitously expressed in the extracellular matrix and enriched in various primary tumor tissues and metastatic sites.[1] Therefore, targeting ILT3 can be a promising therapeutic strategy to reprogram TAMs and promote tumor control.

Methods Transgenic mice (LILR-T) that carry the human LILR cluster comprising the ILT3 gene were generated. A recombinant anti-human ILT3 monoclonal antibody (an NGM831 surrogate antibody) that blocks the interaction between ILT3 and Fn was produced. The anti-tumor efficacy and immune profile were investigated in the B16 lung metastasis model in LILR-T mice treated with anti-ILT3 antibody.

Results Analysis of ILT3 expression in the LILR-T mouse showed a consistent expression pattern with that in humans across different tissues. We found that ILT3 blockade has beneficial effects on anti-tumor immune responses in B16 lung metastasis *in vivo* and promotes metastasis control.

Conclusions These results suggest that ILT3 blockade could be an effective approach to reprogram tumor myeloid infiltrates and promote tumor control. Our study further elucidates the role of ILT3 in the tumor immune cell composition.

834 INTEGRIN αVβ8 INHIBITOR IMPROVES IMMUNE CHECKPOINT THERAPY IN ADVANCED OVARIAN CANCER MODEL AND ITS ACTIVITY CAN BE MONITORED IN BLOOD

[1]Natalia Reszka-Blanco*, [1]Megan Krumpoch, [1]Huidong Chen, [1]Lia Luus, [1]Michaela Mentzer, [1]Aleksey Molodtsov, [1]Adrian Ray, [1]Vinod Yadav, [2]Matthew Clark, [2]Ian Gerken, [2]Justin Snider, [1]Blaise Lippa, [1]Bruce Rogers, [1]Gerard Bain. *[1]Morphic TX, Waltham, MA, United States*; *[2]Labcorp Drug Development, Ann Arbor, MI, United States*

Background Ovarian cancer (OC) is the most lethal gynecologic malignancy. Despite the initial high response rate to chemotherapy, most patients relapse. Immunotherapy offers potential for long-term remission but single checkpoint inhibition benefits less than 15% of patients. Growing evidence suggests that immune-checkpoint blockade (ICB) is enhanced when combined with therapies that target tumor tolerance. Transforming growth factor beta (TGF-β) is associated with resistance to immunotherapy and tumor tolerance. Integrin αvβ8 controls cell-type-specific activation of TGF-β and αvβ8 antagonism promotes anti-tumor immunity leading to tumor regression in ICB refractory tumors.[1,2] We explored the impact of αvβ8 inhibition to restore ICB response in a murine ovarian carcinoma model and performed blood cytokine profiling to search for pharmacodynamic markers of response to treatment.

Methods Bioinformatic analysis on bulk and single-cell levels of public OC datasets was performed to evaluate ITGB8 and TGF-β-related gene signatures. qPCR was used for the detection of TGF-β and ITGB8 expression in ID8, a murine ovarian carcinoma model (ID8-Luc-mCh-Puro.TD1). ID8 tumors unresponsive to PD-1/L1 inhibition were established to mimic advanced-stage disease. The efficacy of αvβ8 mAbs in combination with PD-L1 blockade was evaluated. Mice were evaluated for survival for 65 days. Blood samples were harvested before treatment and on days 1,8 and 14. Plasma was analyzed via Luminex for a total of 30 cytokines. Transcriptomic analyses of MC38 and EMT6 mouse tumors were performed by bulk RNA seq.

Results In high-grade serous OC, ITGB8 expression is associated with shorter overall survival and increased gene signatures of TGF-β1/3 pathways. The ID8 murine ovarian carcinoma model is unresponsive to PD-1/L1 inhibition and expresses Itgb8 together with TGF-β 1/3. The combination of αvβ8 and PD-L1 mAbs led to complete tumor regression in 9/10 mice relative to 0/10 in the PD-L1 group, resulting in superior survival (P=0.0001) (Fig 1 A, B). The combination therapy led to upregulation of blood granzyme B (P=0.05), IL-27(P=0.03), and IL-1a (P= 0.008) at 14-day post-treatment and transient upregulation of CCL3 (P<0.0001) and CCL7 (P= 0.0005) at 8-day post-treatment. Cross-analysis of tumor tissues from the colon and breast syngeneic models after treatment showed similar transcript upregulation for cytokines.

Conclusions Inhibition of αvβ8 renders advanced ID8 tumors sensitive to immune checkpoint therapy, leading to tumor eradication and superior survival. These data provide evidence that a treatment modality targeting αvβ8-mediated TGF-β 1/3 pathways may enhance patients' sensitivity to checkpoint therapies. Plasma blood-based biomarkers serve as a non-invasive method for response assessment to αvβ8-based therapy.

835 AZD4820 ONCOLYTIC VACCINIA VIRUS ENCODING IL-12 MEDIATES ANTI-TUMOR ACTIVITY THROUGH ONCOLYSIS AND TUMOR-SPECIFIC IMMUNITY

[1]Cheyne Kurokawa, [1]Sonia Agrawal, [1]Abhisek Mitra, [1]Elena Galvani, [1]Shannon Burke, [1]Ankita Varshine, [1]Raymond Rothstein, [2]Johann Foloppe, [2]Nathalie Silvestre, [2]Eric Quemeneur, [1]Puja Sapra, [1]Carl Barrett, [1]Scott Hammond, [1]Jason Laliberte, [1]Nicholas Durham, [1]Michael Oberst*, [1]Maria Broggi. *[1]Astrazeneca, Gaithersburg, MD, United States; [2]Transgene, Illkirch-Graffenstaden, France*

Background While vaccinia virus (VACV) has demonstrated robust oncolytic activity, we sought to enhance therapeutic efficacy by engineering VACV to express interleukin-12 (IL-12), a potent NK and T cell activating cytokine that reprograms the tumor immune microenvironment. AZD4820 is an oncolytic VACV engineered to express IL-12 with viral thymidine kinase and ribonucleotide reductase deleted to enhance tumor cell-specific replication. We evaluated the oncolytic activity of AZD4820 and enhancement of anti-tumor immunity in combination with immune checkpoint inhibitors (ICIs).

Methods The oncolytic activity of VACV was evaluated in 47 primary patient derived xenograft (PDX) models representing 9 tumor indications. Replication, oncolytic activity, and IL-12 transgene production of AZD4820 was evaluated in cultured human tumor cell lines, normal human cells, primary human dissociated tumor cells (DTCs) and tumor tissue slice cultures (TSCs). The anti-tumor activity and mechanism of action for AZD4820 was evaluated in syngeneic rat tumor models, as well as MC38 and CT26 syngeneic mouse tumor models with or without ICI targeting PD-L1. Specific anti-tumor immunity in the CT26 model was assessed in mice treated with AZD4820 alone or in combination with anti-PD-L1 mAb by interferon-γ (IFNγ) ELISpot assays after stimulating splenocytes with tumor-specific peptides.

Results Oncolytic VACV demonstrated anti-tumor activity (disease stabilization, partial or complete responses) in 35 of 47 PDX models tested. AZD4820 was highly oncolytic in human tumor cells relative to normal cells, both *in vitro* (EC_{50} range 0.0005 to 0.86) and *in vivo*. To evaluate AZD4820 in human tumor samples, we showed that AZD4820 resulted in production of IL-12 in DTCs (19/19 samples) and TSCs (22/22 samples). A surrogate virus expressing murine IL-12 demonstrated anti-tumor activity in both the MC38 and CT26 syngeneic models. In the CT26 syngeneic tumor model, delivery of AZD4820 significantly upregulated IFNγ relative to control VACV-Luciferase treated mice. In this study, 6/10 mice had a complete response following treatment with AZD4820, while the control VACV-Luciferase treated mice had 0/10 complete responders. Next, we demonstrated in the CT26 tumor model that treatment with AZD4820 in combination with an anti-PD-L1 blocking antibody augmented tumor-specific T cell immunity relative to monotherapies.

Conclusions AZD4820 is an oncolytic VACV expressing IL-12 in vitro and in vivo which replicates preferentially in tumor cells compared to normal cells. A surrogate of AZD4820 demonstrated activity in pre-clinical syngeneic mouse tumor models in combination with anti-PD-L1 mAb, supporting its use in combination with ICIs in patients with cancer.

836 ACTIVATING THE ANTIGEN PRESENTING CELLS TO IMPROVE VIROTHERAPY EFFICACY IN DIFFUSE MIDLINE GLIOMAS

[1]Sara Labiano*, [1]Reyes Hernández-Osuna, [1]Virginia Laspidea, [1]Marc Garcia-Moure, [1]Javier Marco-Sanz, [1]Iker Ausejo, [1]Montserrat Puigdelloses, [2]Oren Becher, [1]Ana Patiño-Garcia, [3]Candelaria Gomez-Manzano, [3]Juan Fueyo, [1]Marta Alonso. *[1]University of Navarra, Pamplona, Spain; [2]Mount Sinai Kravis Children's Hospital, New York, NY, United States; [3]MD Anderson Cancer Center, Houston, TX, United States*

Background Within Diffuse Midline Gliomas, Diffuse Intrinsic Pontine Glioma (DIPG) is the principal cause of non-accidental pediatric deaths. Although gold-standard treatments have improved, the outcome for children with DIPGs remains poor pointing to the need for alternative therapies. In this sense, we have previously demonstrated that the oncolytic adenovirus Delta-24-RGD (which has already shown safety and feasibility in DIPG patients) is able to recruit T cells into the tumor. However, such as T-lymphocyte infiltration rapidly acquires an exhausted phenotype that prevents from achieving long-term anti-tumor responses. Therefore, we decided to improve this therapy by combining the Delta-24-RGD with the activation of the costimulatory receptor CD40, which is known to increase antigen presentation and enable T-cell priming.

Methods To determine anti-tumor efficacy, we treated immunocompetent and immunodeficient mice bearing orthotopic DIPG tumors with an intratumoral injection including the Delta-24-RGD and a CD40 agonistic monoclonal antibody. Survival and toxicity were monitored after treatment and the changes in the tumor immune microenvironment were analyzed by flow cytometry, immunofluorescence, and RNA sequencing. Long-term survivors were rechallenged with primary tumor cells to study the development of anti-tumor immunological memory.

Results The combination therapy is safe and extends survival of immunocompetent treated mice as compared to single treatments or non-treated mice, resulting in 40% of complete responses. In addition, mice that rejected the tumor were able to control the growth of a rechallenge with the primary cells indicating the development of long-term anti-tumor immunity. This, together with the lack of effect observed in immunodeficient mice evidences a key role of the adaptive immune system in the anti-tumor response. We found that the combination remodels the tumor context towards a proinflammatory scenario with an increase of proinflammatory chemokines, proliferating T lymphocytes and activated dendritic cells, which express high levels of the CD40 receptor. In addition, the blocking of CSF1R (mainly expressed by microglia/macrophages) avoids the recruitment of dendritic cells into the tumor and abrogates the anti-tumor effect observed upon the combination of Delta-24-RGD and anti-CD40.

Conclusions Our results show that the combination of Delta-24-RGD with the stimulation of CD40 is safe, has a potent and long-term anti-tumor effect and promotes a proinflammatory tumor microenvironment. We believe that these results can be translational and open the door for a future innovative clinical trial.

Ethics Approval The study was approved by the University of Navarra's Ethics Committee for Animal Experimentation (CEEA), approval number 068-20

837 REDIRECTING IL-7-INDUCED BYSTANDER TUMOR-INFILTRATING LYMPHOCYTES BY BISPECIFIC T-CELL ENGAGER AUGMENTS ANTITUMOR RESPONSE

[1]Kun-Joo Lee student*, [2]Nara Tae, [1]Yeon-Woo Kang, [1]Dain Moon, [1]Youngsik Oh, [1]Ji-Hae Kim, [3]Minji Lee, [2]Ha Won Song, [2]Sun Shim Choi, [3]Donghoon Choi, [2]Dae Hee Kim, [1]Seung-Woo Lee*. *[1]Pohang University of Science & Technology (POSTECH), Pohang, Republic of Korea; [2]Kangwon National University, Chuncheon, Republic of Korea; [3]Research Institute of NeoImmuneTech, Pohang, Republic of Korea*

Background rhIL-7-hyFc (efineptakin alfa, NT-I7) is a long-acting form of recombinant human IL-7 and is currently under clinical trials for various cancers in combination with immune checkpoint inhibitors (ICI). We have previously shown that rhIL-7-hyFc monotherapy increases tumor-infiltrating lymphocytes (TILs); however, the majority of $CD8^+$ TILs is $PD\text{-}1^-$ bystander T cells that lack tumor-specific activity.[1] Therefore, we hypothesized that bispecific T-cell engagers (TCE) composed of two single-chain variable fragments simultaneously targeting CD3ϵ and tumor antigens, including PD-L1, can redirect and activate IL-7-induced bystander TILs to kill tumor cells resulting in enhanced antitumor response

Methods We conducted scRNA-seq paired with TCR-seq of $CD8^+$ TILs isolated from tumors after rhIL-7-hyFc treatment to evaluate transcriptomic changes of both tumor-reactive and bystander T cells. We generated various TCEs targeting mouse or human CD3ϵ and tumor antigens. The efficacy of antitumor responses by combination treatment of rhIL-7-hyFc and TCE was evaluated in immunogenic and non-immunogenic murine tumor models. To address the activation of bystander TILs, we analyzed the expression of effector molecules and cytotoxicity of $PD\text{-}1^-$ $CD8^+$ TILs after co-culturing with TCE and tumor cells. We determined the antitumor response of bystander $CD8^+$ T cells with an adoptive transfer experiment in $RAG1^{-/-}$ mice.

Results scRNA-seq analysis of $CD8^+$ TILs revealed that rhIL-7-hyFc attenuates the dysfunctional (or exhaustion) process of tumor-reactive cells and recruits bystander cells with the characteristics of cytokine-primed central memory phenotype. TCE can activate $CD8^+$ T cells when it simultaneously binds to tumor antigen. The combination of rhIL-7-hyFc and TCE enhanced the antitumor responses by upregulating $CD8^+$ TILs in MC38, B16F10, and CT-26 models. In addition, IL-7-induced bystander $CD8^+$ TILs are TCR-activated to gain a cytotoxic activity to tumor cells. Lastly, we observed the antitumor response of IL-7-primed bystander $CD8^+$ T cells when redirected in vivo by TCE in $RAG1^{-/-}$ mice.

Conclusions Our data suggest that bispecific T-cell engagers are promising candidates to augment the antitumor activity of rhIL-7-hyFc by redirecting bystander $CD8^+$ TILs

838 COMBINATION MRX0518 AND ANTI-PD-1 OVERCOMES CHECKPOINT INHIBITOR RESISTANCE VIA MYELOID MODULATION

[1]June Li*, [1]Karen Millerchip, [1]Carlos Ramos, [1]Edwin Parra, [1]Luisa Solis, [2]Alex Stevenson, [2]Aurelie Couturier, [2]Gayle Fyvie, [3]Michael Chisamore, [4]Rahul Parikh, [5]Eric Bernicker, [6]Diwakar Davar, [7]Arvind Chaudhry, [1]Nizar Tannir, [1]Shubham Pant, [1]Cara Haymaker. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX, United States; [2]4D Pharma Research Ltd., Leeds, UK; [3]Merck & Co., Inc., Kenilworth, NJ, United States; [4]University of Kansas Medical Center Research Institute, Kansas City, KS, United States; [5]The Methodist Hospital Research Institute, Houston, TX, United States; [6]UPMC, Pittsburgh, PA, United States; [7]Medical Oncology Associates, Spokane, WA United States*

Background The gut microbiome is a known modulator of response to checkpoint inhibitors.[1-4] MRx0518 is a strain of *Enterococcus gallinarum* that was isolated from a healthy human fecal sample. Administration of MRx0518 in pre-clinical cancer models results in anti-tumor effects and immune system modifications potentially contributing to therapeutic effects of checkpoint inhibitors. We hypothesized that a PD-1 checkpoint inhibitor in combination with MRx0518 would decrease suppressive myeloid cells and increase T-cell activation

Methods

Study design: Patients who had developed resistance to checkpoint inhibitors received MRx0518 (1×10^{10} to 1×10^{11} CFU) PO BID and 200mg pembrolizumab IV Q3W for up to 2 years or disease progression. Responders are defined as patients achieving clinical benefit (CR, PR or SD $\geq$ 6months per RECIST v1.1).

Flow cytometric analysis: PBMCs from baseline (BL) and cycle 4 day 1 (C4D1) were subjected to immune profiling. Normal donor (ND, n=9) PBMCs serve as controls for non-responder (NR, n=33) and responder (R, n=11) BL samples.

Circulating biomarker assay: Cytokines were assessed in plasma collected at BL (n=27) and C4D1 (n=27) using a kit from Meso Scale Discovery.

Statistical tests: Non-parametric ANOVA and Mann-Whitney test or Wilcoxon matched-pairs signed rank test were utilized for flow cytometry data and paired T-test for cytokine analysis.

Results At BL, expression of HLA-DR on mDC is reduced and the frequency of HLA-DR negative monocytes is increased in patients ($p<0.05$) suggesting a higher degree of suppressive myeloid cells prior to combination therapy. Expression of PD-L1 and PD-L2 on mDC and monocytes is higher in patients at BL ($p<0.05$). Checkpoint receptor expression and activation markers on T cells (both CD4+ and CD8+) is higher in patients at BL, including CTLA4 ($p<0.01$), PD-1 ($p<0.05$), Tim3 ($p<0.05$), OX40 ($p<0.001$) and Ki67 ($p<0.05$). CTLA4, PD-1, and Tim3 ($p<0.05$) expression on NK cells are higher in patients at BL. Overall, the circulating immune microenvironment is immuno-suppressed in patients at BL irrespective of subsequent clinical outcome.

Upon treatment, HLA-DR+ myeloid cells are increased, PD-L1 expression on HLA-DR+ myeloid cells is consistently reduced, and the frequency of CD8+ T cells is increased in R patients ($p<0.05$). IL-6 and MIP-1α are increased in circulation in NR upon treatment ($p<0.05$).

Conclusions Immune activation was recovered in R patients with MRx0518 and anti-PD-1 combination therapy. Immune changes associated with improved outcome include: 1) increased expression of HLA-DR and decreased PD-L1 expression on myeloid cells and 2) increased CD8+ T-cell frequencies in circulation.

839 SELECTIVE TARGETING OF GARP-LTGFß AXIS IN THE TUMOR MICROENVIRONMENT AUGMENTS PD-1 BLOCKADE VIA ENHANCING CD8+ T CELL ANTI-TUMOR IMMUNITY

[1]Anqi Li*, [1]Yuzhou Chang, [1]No-Joon Song, [1]Xingjun Wu, [1]Dongjun Chung, [2]Brian Riesenberg, [1]Maria Velegraki, [1]Hyunwoo Kwon, [1]Karthik Chakravarthy, [1]Chelsea Bolyard, [1]Yi Wang, [1]Qin Ma, [1]Zihai Li,. *[1]The Ohio State University, Columbus, OH, United States*; *[2]University of North Carolina, Chapel Hill, NC, United States*

Background Immune checkpoint blockade (ICB) targeting programed cell death protein 1 (PD-1) and its ligand has revolutionized cancer immunotherapy. Unfortunately, while some cancer patients experience robust and lasting remission following treatment, most fail to respond clinically. Accumulation of transforming growth factor b (TGFß) in the tumor microenvironment (TME) can induce an immunosuppressive milieu and therapeutic resistance. TGFß drives cancer immune evasion by inducing regulatory T cells (Tregs) and limiting $CD8^+$ T cell function within the TME. Glycoprotein-A repetitions predominant (GARP; encoded by *LRRC32*) is a cell surface docking receptor for all isoforms of latent TGFß (LTGFß) and is expressed by effector Tregs, cancer cells, and platelets.

Methods We studied the role of *LRRC32* expression in human cancer patients by mining the existing bulk transcriptomic databases. Then, we generated, characterized, and humanized an anti-GARP monoclonal antibody (called 'PIIO-1'). Lastly, anti-tumor efficacy and its underline mechanism was investigated by murine tumor models.

Results We found that the overexpression of *LRRC32* in human cancers correlates with unfavorable immune TME and poor responsiveness to ICB, indicating that targeting GARP may improve cancer immunotherapy. Therefore, we established our anti-GARP antibody PIIO-1 with a unique characterization that specifically binds to the ligand-interacting domain of free GARP and blocks the recognition by all LTGFß isoforms. PIIO-1 antibody does not induce thrombocytopenia in our human *LRRC32* knock-in mice due to the lack of recognition of GARP-LTGFß complex on platelets. It obtains the anti-tumor efficacy against both $GARP^+$ and $GARP^-$ tumors in a mono- or combo- therapeutic strategies with PD-1 blockade. Mechanistically, PIIO-1 preferentially distributes to the TME and dLNs and inhibits canonical TGFß pathway in their infiltrating immune cells. In addition, PIIO-1 treatment prevents $CD8^+$ T cell exhaustion and improves its migration into TME in a CXCR3-dependent manner.

Conclusions GARP overexpression in cancer patients contributes to immune suppression as well as ICB resistance. Targeting GARP by using PIIO-1 antibody blocks LTGFß activation *in vivo* effectively and safely. PIIO-1 is responsible for the improvement of function and trafficking in tumor-infiltrating $CD8^+$ T cells and synergizing anti-PD-1 efficacy. Therefore, PIIO-1 is potent for the clinical development of cancer immunotherapy.

840 TRIPLE-DRUG ORAL IMMUNOTHERAPY TARGETING MYELOID CELLS FOR TREATMENT OF METASTATIC OSTEOSARCOMA EVALUATED IN SPONTANEOUS CANINE MODEL

[1]Cheryl London, [2]Dan Regan*, [2]Lyndah Chow, [2]Kristen Weishaar, [3]Heather Gardner, [2]Doug Thamm, [2]Steven Dow. *[1]Tufts University Veterinary College, Grafton, MA, United States; [2]Colorado State University, Ft Collins, CO, United States; [3]Tufts University, Grafton, CO, United States*

Background We reported recently in a spontaneous canine model of metastatic osteosarcoma (OS) that oral treatment with two repurposed agents targeting monocyte migration (losartan) and MDSC and Tregs (toceranib) induced partial responses in 4/16 dogs (25%) with another 4 dogs experiencing durable stable disease (SD), for a clinical benefit rate of 50%. In the current study, we evaluated the utility of incorporating ladarixin (an orally bioavailable allosteric CXCR1/2 antagonist) into the losartan/toceranib regimen in 15 dogs with OS metastatic to the lungs.

Methods The effects of treatment on lung metastases, circulating cytokine concentrations, and gene expression profiles in PBMC were assessed in this new study. Studies are also ongoing to determine whether this same approach has activity in the adjuvant setting in dogs with appendicular OS treated prior to and continuously following amputation, in lieu of standard cytotoxic adjuvant chemotherapy. To date, 18 animals have been enrolled in the adjuvant trial, and analysis of the impact on MFI and OST are ongoing as data matures.

Results Of enrolled dogs with greater than 60 days of follow up, 1 dog underwent a complete response (400+ days) and another 4 dogs experienced PR, for an objective response rate of 36%; another 5 dogs exhibited durable SD, for an overall clinical benefit rate of 71%. The 3-drug protocol was generally well-tolerated, with no adverse events other than those associated with toceranib alone (gastrointestinal signs). Transcriptomic analysis of PBMCs from 8 dogs on days 0 and 14 using Nanostring revealed significant downregulation of 30 immune genes, including IRF2, IRF8, CTLA4, NFKB, and CCR2, and upregulation of 176 genes, including IL21, CCL19, B7-H3, IL17A/B. Pathway analysis demonstrated significant downregulation of IFN-γ and IFN-α response pathways, and upregulation of β-catenin signaling pathways.

Conclusions In summary, these findings in a canine spontaneous osteosarcoma model indicate that the combined losartan/ladarixin/toceranib immunotherapy protocol is biologically active and can effectively modify the immune suppressive tumor microenvironment to generate spontaneous antitumor activity in dogs with advanced OS lung metastases.

841 XTX202, A TUMOR-SELECTIVE PROTEIN-ENGINEERED IL-2, EXHIBITED ENHANCED ANTI-TUMOR ACTIVITY IN COMBINATION WITH CHECKPOINT INHIBITION IN MICE

Wilson Guzman*, Uli Carl Bialucha, Hanumantha Rao Madala, Haley Duprey, Manoussa Fanny, Stephanie Hsiao, Parker Johnson, Jake Taylor, Rebekah O'Donnell, Magali Pederzoli-Ribeil, Benjamin Nicholson, Jennifer O'Neil, Caitlin O'Toole. *Xilio Therapeutics, Waltham, MA, United States*

Background High-dose recombinant human interleukin-2 (IL-2, aldesleukin) is approved for the treatment of renal cell carcinoma (RCC) and melanoma based on durable responses. However, use of aldesleukin is limited due to treatment-related life-threatening toxicities. With the goal of overcoming these toxicities and improving the therapeutic index of IL-2, we employed protein engineering (Geographically Precise Solutions) to generate XTX202, a masked, non-alpha tumor-selective IL-2. XTX202 is designed to bias its binding towards beta/gamma IL-2 receptors and be pharmacologically inactive until unmasked by proteases that are enriched in the tumor microenvironment, resulting in activation and IL-2 signaling.

Methods The in vitro bioactivity of masked and proteolytically unmasked XTX202 was compared using STAT-5 phosphorylation in human CD8+T (CD8) and regulatory T (Treg) cells. Dissociated cells from primary human tumor tissues or patient plasma were incubated with XTX202, and % of cleaved XTX202 was measured by Western blot. Tumor growth was monitored after treatment with XTX202 alone and in combination with checkpoint inhibition in human FcRn transgenic mice bearing syngeneic MB49 tumors.

Results XTX202 has attenuated IL-2 receptor signaling in CD8 and Treg cells, as compared to its unmasked control XTX200. Upon activation by proteases, XTX202 had comparable activity in CD8 and Treg cells to that of its unmasked control XTX200. Unlike recombinant IL-2, unmasked XTX202 has similar potency on CD8 and Treg cells, rather than higher potency on Treg cells. XTX202 was cleaved by a broad range of human primary solid tumors (29-100% of samples tested were cleaving XTX202). XTX202 was not significantly activated by plasma from healthy control donors, and RCC patients. In vivo data indicated that single-agent dosing with XTX202 resulted in anti-tumor activity in the MB49 murine bladder carcinoma model. Combining XTX202 with checkpoint inhibition further enhanced the anti-tumor activity.

Conclusions XTX202, a tumor-selective IL-2, was proteolytically activated by a broad range of solid primary human tumors and minimally cleaved in plasma. In the syngeneic mouse bladder MB49 model, XTX202 as a single agent showed significant tumor-growth inhibition, and no evidence of toxicity or peripheral immune activation was observed, thus demonstrating tumor-selective activity in this model. The combination of XTX202 with immune checkpoint blockade demonstrated further enhancement in the anti-tumor activity in MB49 tumor bearing mice. Clinical testing of XTX202 is ongoing (NCT05052268).

Ethics Approval All animal procedures were either approved by an Institutional Animal Care and Use Committee and conducted in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals.

842 DEVELOPMENT OF A MULTIPLEX TEST FOR PREDICTING RESPONSE TO COMBINED IMMUNOTHERAPIES IN PATIENTS WITH METASTATIC MELANOMA

[1]Gabriele Madonna, [2]Pedro Machado Almeida*, [1]Mariaelena Capone, [1]Vito Vanella, [1]Lucia Festino, [2]Antonio Sorrentino, [2]Marco Cassano, [2]Benjamin Pelz, [2]Diego Dupouy, [1]Paolo Ascierto. *[1]Istituto Nazionale Tumori IRCCS Fondazione "G. Pascale", Napoli, Italy; [2]Lunaphore Technologies, Tolochenaz, Switzerland*

Background In recent years, advanced melanoma treatment has improved dramatically thanks to the advent of immunotherapy. Particularly immune checkpoint inhibitors (ICI), in some patients, have demonstrated to improve long-term outcomes associated with limited toxicity. However, only a small population of patients achieve a durable response to therapy, owing to the lack of clinically validated predictive biomarkers (reviewed in[1]). The availability of improved predictive biomarkers may allow the identification of patients who will most benefit from ICI treatment and those who may be susceptible to immune-related adverse events. This difficulty in obtaining clinically relevant predictive biomarkers underscores the complexity of the immune system and the heterogeneity of the tumor microenvironment. In the present study, we take the first steps towards stratification of advanced melanoma patients who received a combination of ICI. We studied the predictive value of a multi-parameter spatial signature composed of lymphocyte-activation gene-3 (LAG-3), programmed death-ligand 1 (PD-L1) and cluster of differentiation 8 (CD8) in a retrospective cohort of patients with metastatic melanoma treated with a combination of ICI.

Methods In this retrospective study, from the biobank of the Istituto Nazionale Tumori IRCCS Fondazione G. Pascale, we recovered FFPE skin metastasis samples obtained from 10 melanoma patients with AJCC 8th edition stage IV[2] subsequently treated with combined ICI, enrolled from September 2016 to November 2017. According to the Response Evaluation Criteria in Solid Tumors (RECIST 1.1),[3]4 patients achieved response to the treatment, while 6 patients were non-responders. A single FFPE tumor tissue of each patient was stained using LabSat® platform (Lunaphore Technologies) performing a Tyramide Signal Amplification multiplex immunohistochemistry staining for PD-L1, CD8, and LAG-3 expression, followed by DAPI counterstaining and whole slide fluorescent scanning. Single cell segmentation, phenotyping and quantification were performed in QuPath (0.3.0). The workflow is depicted in figure 1.

Results Responder patients showed a statistically significant increase in CD8+ single-positive cell frequency compared to non-responders (figure. 2A and 2C). Non-responder patients displayed a statistically significant increase of PD-L1+ single-positive cell frequency, as well as statistically significant increased frequency of double CD8+PD-L1+ positive cells, previously found to be a poor prognostic in multiple cancer types,[4,5] and triple positive cells (figure 2B and 2C).

Conclusions We show here preliminary evidence of the predictive value of a spatial biomarker signature in patients who underwent combined ICI therapy for advanced melanoma. To further demonstrate clinical relevance, a more detailed analysis using larger retrospective and prospective cohorts is ongoing.

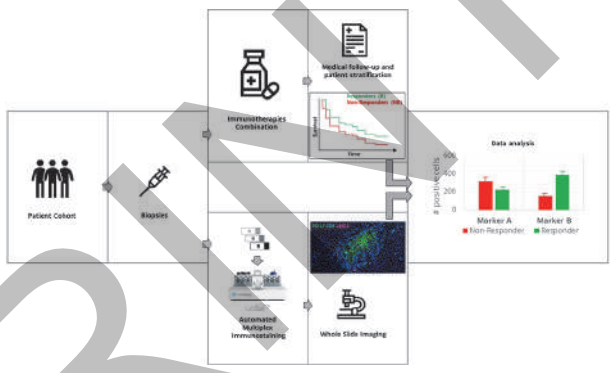
Ethics Approval This study was conducted in accordance with the guidelines of the Declaration of Helsinki, and approved by the Institutional Review Board of the Istituto Nazionale Tumori IRCCS Fondazione "G. Pascale" (Naples, Italy) (protocol code 33/17oss, approved on 10 January 2018).



Abstract 842 Figure 1 Visual representation of the study presented here. A cohort of 10 advanced melanoma patients underwent biopsies of skin metastasis (left panels). The cohort then followed a full course of combined immune-checkpoint inhibitor immunotherapies (upper middle panels). Based on their clinical response to the combined treatment, the cohort was subdivided in Responders (R) and Non-Responders (NR) (note: disease free survival chart for representation purpose only, not based on real data analysis from this our study). In parallel (bottom middle panels), a single FFPE tissue sample slide from tissue collected prior the start of the treatment underwent automated multiplex immunohistochemistry staining for LAG-3, programmed death-ligand 1 (PD-L1) and cluster of differentiation 8 (CD8) on a LabSat® (Lunaphore) instrument. All samples underwent whole slide imaging (WSI). Finally, a retrospective data analysis quantified the number of positive cells for given markers from the WSI to determine relevant biomarkers discriminating R to NR patients. This strategy is now being scaled up with a larger cohort and a larger panel of markers.

843 LAG3 BLOCKADE IN COMBINATION WITH GITR IMPROVES ANTI-TUMOR IMMUNE RESPONSES IN A PRECLINICAL MELANOMA MODEL

[1]Rachana Maniyar*, [2]Roberta Zappasodi, [1]Yuval Elhanati, [1]Samantha St Jean, [1]Sebastian Carrasco, [1]Benjamin Greenbaum, [1]Jedd Wolchok, [1]Taha Merghoub. *[1]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [2]Weill Cornell Medical Center, New York, NY, United States*

Background Immune checkpoint blockade (ICB) therapies anti-PD1 and anti CTLA-4 have had tremendous successes in clinic. However, many patients are either inherently resistant or acquire resistance to these therapies. Appropriately activating co-stimulation pathways of T cells together with blocking immune checkpoints can provide substantial anti-tumor responses. Glucocorticoid induced TNFR Related protein (GITR), is a costimulatory molecule whose engagement with agonist antibodies leads to proliferation, cytokine production and survival of cytotoxic T cells, and destabilization and depletion of suppressive T regulatory cells in the tumor microenvironment, making it an attractive target for cancer immunotherapy. GITR agonism as a monotherapy in murine models of advanced melanoma leads to increased effector T cell dysfunction with a marked upregulation in expression of exhaustion markers PD-1 and Lag3, making them rational targets to combine with GITR agonism.

Methods C57BL/6 mice were implanted with B16-F10 melanoma and were treated with a single dose of GITR Agonism with or without anti Lag3 on Day 7 post tumor implant, followed by anti Lag3 every 3 days. Spectral flow cytometry and immunohistochemistry was used to study immune cell repertoires. Splenic B cell repertoire was studied using BCR IgH sequencing.

Results We show that combining GITR agonism with Lag3 ICB therapy, leads to better tumor control, and improved survival in mice with advanced ICB resistant B16 melanoma. Additionally, mice treated with GITR agonism monotherapy show a marked increase in activated B cells infiltrating the tumor microenvironment. This infiltration is further increased when GITR agonism is combined with Lag3 blockade therapy. These tumor-infiltrating B cells are highly activated with an increased expression of activation markers CD86, MHC-II, and CD38. The spleens from mice treated with GITR agonism in combination with Lag3 blockade demonstrate increased hyperplasia, and an increase in size and number of germinal centers. B cell receptor sequencing from the spleens of these mice revealed an increased clonality and reduced entropy in mice treated with GITR agonism + Lag3 blockade therapy.

Conclusions Increased B cell activity observed in these mice warrants further investigation into the role and mechanism of action of a GITR/Lag3 combination therapy. Our results suggest that combining GITR agonism with Lag3 blockade is a safe and potent therapeutic strategy to overcome ICB resistance in mice with advanced melanoma.

Ethics Approval This study was approved by the Institutional Animal Care and Use Committee (IACUC) and Memorial Sloan Kettering Cancer Center

844 COMBINED IMMUNOTHERAPY EFFICACY ON A MULTIFOCAL HEPATOCELLULAR CARCINOMA MODEL BASED ON HYDRODYNAMIC ONCOGENE TRANSFER

[1]Maria Ochoa*, [2]Sandra Sanchez-Gregorio, [3]Alvaro Teijeira, [3]Saray Garasa, [2]Carlos De Andrea, [2]Maria Villalba, [3]Inaki Etxeberria, [3]Ignacio Melero. *[1]CIBERONC, Pamplona, Spain; [2]Clinica Universidad de Navarra, Pamplona, Spain; [3]CIMA Universidad de Navarra, Pamplona, Spain*

Background Immunotherapy based on checkpoints inhibitors has become a conventional treatment of advanced hepatocellular carcinoma (HCC) and is under clinical investigation as a strategy to improve the efficacy of locoregional interventions such as transarterial chemoembolization and radiofrequency. In advanced disease, the combination of nivolumab and ipilimumab has resulted in more frequent and durable objective responses as compared to nivolumab monotherapy. Important aspects are pending for these developments, such as reliable and predictive preclinical models, as well as biomarker discovery.

Methods A model based on mice bearing multifocal HCC as a result of hydrodynamic gene transfer to hepatocytes of c-myc and CRISPR/CAS9 disruption of p53 was used. This model was sophisticated to induce coexpression of luciferase, EGFP and the melanosomal antigen gp100 to permit incisive immunological mechanistic experimentation. This genetic approach attains traceability of the tumor and sufficient levels of antigenicity in order to test immunotherapy agents such as anti-CTLA-4, antiPD-1 and anti-CD137 monoclonal antibodies, IL-2 or adoptive Pmel-1 $CD8^+$ T cell therapy and their combinations. Survival assays, as well as multiplex immunofluorescence and intravital microscopy were performed to study the efficacy and mechanism of action of the therapies.

Results In this tumor setting, combinations of anti-CTLA-4 + anti-PD1 mAbs attained partial efficacy that was markedly augmented by combination with either recombinant IL-2 or an anti-CD137 mAb to deploy triplet regimens. As shown by multiplex tissue immunofluorescence and intravital microscopy, treatments enhanced T-cell infiltration and antitumor immune responses.

Conclusions We provide a relatively simple, reproducible and reliable spontaneous HCC mouse model that enabled us to test various immunotherapies. With it, we have investigated clinically feasible combinatorial regimens including triplets.

Ethics Approval All animal procedures were approved by the animal experimentation ethics committee of the regional government of Navarra (protocol 108-19).

845 IDENTIFYING PATIENT SUBSETS FOR CTLA4 AND GITR DEPLETION STRATEGIES IN POORLY T CELL INFILTRATED TUMORS

Arjun Mittal*, Jason Luke, Riyue Bao. *University of Pittsburgh, Pittsburgh, PA, United States*

Background Many combination immunotherapies have been investigated however identifying subsets of patients who will benefit from each combination has been challenging. While immunotherapy combinations have to date centered on therapeutic targets on immune cells, the expression of immuno-oncology (IO) targets on cancer cells has not been well studied. We investigated the gene expression landscape across human solid tumors for seven existing IO targets (CTLA4, GITR, CSF1R, IDO1, LAG3, TIM3, and FOXP3) in conjunction with PDL1 to evaluate tumor-intrinsic patterns and potential for IO combinations in specific patient populations.

Methods We used a hierarchical approach on samples from the Cancer Genome Atlas (TCGA). Normalized RNAseq data was converted to quartile rank to define patient populations of PDL1 high/low in combination with high/low from one of the IO targets. Genes differentially expressed between groups were identified by limma voom (fold change >1.5, FDR 0.05). Upstream regulators were predicted by causal networks from Ingenuity Pathway Analysis (z-score >1.95).

Results Patients with PDL1 high expression showed high expression in all seven genes, and those of PDL1 low showed low expression in all genes, consistent with the literature. We identified a unique subset of patients in the PDL1 low setting, however, that demonstrated high CTLA4 or GITR expression, composing 14% and 21% of all tumor samples, respectively. Subsequent analysis of the CTLA4-high/PDL1-low subset indicated that high CTLA4 expression in PDL1 low tumors may represent an intermediate-T cell-inflamed tumor microenvironment (TME) with activated upstream regulators of Type-I IFNγ pathways (IFNG, AHR, TNF, STAT1, NFKB1, IFNA1), which comprised 12% of cervical squamous cell carcinoma, 15% of head and neck squamous cell carcinoma, and 17% of liver hepatocellular carcinoma. Analysis surrounding GITR suggested that high GITR expression in PDL1 low tumors may also represent an intermediate-T cell-inflamed TME. 14% of skin cutaneous metastatic melanoma, 20% of liver hepatocellular carcinoma, 20% of sarcoma, and 11% of testicular germ cell tumor samples fell in GITR-high/PDL1-low group and demonstrated intermediate activation of IFNG, TNF, CD28, AHR, NFKB1, and MYD88. These analyses were not impacted when adjusted by tumor mutational burden across cancer types.

Conclusions High CTLA4 or GITR in the context of low PDL1 may represent an intermediate-T cell-inflamed TME and/or tumor cell-intrinsic expression. Stratification of tumors by T cell-inflamed gene signature, or PDL1 status, as well as expression of a specific therapeutic target may identify patient populations who could benefit from CTLA4 or GITR depletion strategies in IO combination therapies.

846 TRASTUZUMAB, AN ANTI-HER2 ANTIBODY MODULATES CYTOTOXICITY AGAINST CHOLANGIOCARCINOMA (CCA) VIA MULTIPLE MECHANISMS

Seiji Okada*, Jutatip Panaampon. *Kumamoto University, Kumamoto, Japan*

Background Trastuzumab (Tras) monoclonal antibody targets the extracellular domain of human epidermal growth factor receptor 2 (HER2). FDA approved Tras for the treatment of HER2 positive breast cancer. Cholangiocarcinoma (CCA) is a cancer forms in the bile ducts. Several CCAs are multifocal and cannot be completely removed by surgery and are incurable. Combination of gemcitabine and cisplatin is a standard first line therapy for patients with advanced CCA. Nowadays, the precision medicine and immunotherapy has been playing remarkable roles for cancer treatment. In this study, we found that HER2 expression is relatively high in CCA PDX and cell lines from Thailand. We hypothesized and speculated that Trastuzumab could be a promising antibody immunotherapy for CCAs.

Methods We examined surface HER2 expression on 5 CCA cell lines (M213B, D068, D113, RBE, YSCCC) and patient-derived cell (PDC) by Flowcytometry. We defined the activities of antibody-dependent cytotoxicity (ADCC) and antibody-dependent cell phagocytosis (ADCP) by using FcR-bearing recombinant Jurkat T cell expressing firefly luciferase gene under the control of NFAT response elements. ADCC was then confirmed by using CD16-transduced NK cell line (KHYG-1) and NK cells from a healthy donor. Rabbit and human serum were administered to test CDC activity of Tras. To clarify ADCP activity, we used mouse peritoneal macrophages and monocyte-derived macrophages from healthy donor as effector cells. Moreover, we performed MTT assay to investigate the direct effect of Tras. Finally, we evaluated the efficacy of Tras *in vivo* xenograft and PDX model.

Results Flowcytometric analysis and immunohistochemistry revealed high expression of HER2 in CCA cells. Tras conferred ADCC, ADCP, CDC, and direct effect to induce CCA cell death. Tras demonstrated potent *in vivo* inhibitory effect using PDX model.

Conclusions

Tras indicates multi-activities against CCA. Tras can be considered as a promising antibody immunotherapy for the treatment of HER2 expressing CCA.

Ethics Approval The use of human materials is approved by Kumamoto University's ethical committee (ID: 30-78-20-20201119). Animal experiments are approved by Kumamoto Univeristy's animal ethics committee (ID: A2021-053)

CF33-CD19T ONCOLYTIC VIRUS (ONCARLYTICS) IN COMBINATION WITH OFF-THE-SHELF ALLOGENEIC CYCART-19 T CELLS TARGETING DE NOVO CD19+ SOLID TUMORS

[1]Anthony Park*, [1]Isabel Monroy, [1]Colin Cook, [2]Shuyang He, [2]Kathy Karasiewicz, [3]Monil Shah, [3]Nimali Withana, [3]Leslie Chong, [2]Robert Hariri, [1]Yuman Fong, [1]Saul Priceman.
[1]City of Hope, Duarte, CA, United States; [2]Celularity, Warren, NJ, United States; [3]Imugene, Sydney, Australia

Background Autologous chimeric antigen receptor (CAR) T cell therapy has shown impressive clinical responses against CD19+ B-cell hematological malignancies and is being actively explored in the treatment of solid tumors. However, several barriers have precluded therapeutic responses in solid tumors, including limited tumor-restricted CAR targets and the immunosuppressive tumor microenvironment. We have recently reported the successful combination immunotherapy using a novel chimeric vaccinia-based oncolytic virus (OV), called onCARlytics (Imugene Limited), that is engineered to express a non-signaling, truncated CD19 (CD19t) antigen for tumor-selective delivery, enabling de novo targeting of tumor cells by autologous CD19-CAR T cells. One of the field's unanswered questions is whether treatment-naïve allogeneic CAR T cells are superior to cancer patient-derived T cells for product manufacturing to improve overall responses against solid tumors.
Methods Here, we evaluated this combination strategy using two allogeneic CAR T cell products generated from peripheral blood mononuclear cells (PBMC) and placental T cells, respectively. PBMC-derived CAR-T cells were manufactured from normal, healthy donors. CYCART-19 (Celularity, Inc.) cells were derived from postpartum human placental T cells that are genetically modified to express the CD19 CAR followed by CRISPR-Cas9- mediated knockout of the endogenous TCR and expanded to produce multiple doses of allogeneic "off the shelf" treatment. For preclinical testing, we utilized *in vitro* co-culture assays. We evaluated tumor cell killing and T cell activation using flow cytometry and cytokine assays. Xenograft mouse models were used to evaluate anti-tumor activity of the combination *in vivo*.
Results CYCART-19 T cells induced potent cytolytic activity against solid tumor cells infected with onCARlytics. Interestingly, while we observed comparable anti-tumor activity between PBMC-derived CD19-CAR T cells and CYCART-19, significant differences in cytokine secretion were detected. This warrants the possibility that the placental-derived CAR T product may elicit reduced CRS potential in patients with maintained or improved efficacy. This combination approach demonstrated impressive in vivo anti-tumor response in human tumor xenograft models.
Conclusions In summary, our results have demonstrated that further development of this combination immunotherapy for the potential treatment of a wide array of solid tumors is warranted.

IMPACT OF IMMUNOTHERAPY TIME-OF-DAY INFUSION ON OVERALL SURVIVAL IN PATIENTS WITH METASTATIC RENAL CELL CARCINOMA

[1]Jimmy Patel*, [1]Amber Draper, [2]Yena Woo, [2]Layla Dhabaan, [1]Pretesh Patel, [1]Ashesh Jani, [1]Bradley Carthon, [1]Viraj Master, [1]Haydn Kissick, [1]Mehmet Bilen, [1]Zachary Buchwald, [1]David Qian. *[1]Emory Winship Cancer Institute, Atlanta, GA, United States; [2]Emory University, Atlanta, GA, United States*

Background Our prior study demonstrated that the time-of-day of immune checkpoint inhibitor (ICI) infusion influences clinical outcomes including overall survival (OS) for Stage IV melanoma patients. Similar results have subsequently been shown in lung cancer. In this study, we hypothesized that the time-of-day of ICI infusion may impact OS for patients with stage IV renal cell carcinoma (RCC).

Methods The treatment records of all patients with stage IV RCC who underwent ICI therapy within a multi-center academic hospital system between 2015 and 2020 were reviewed. Association between OS and proportion of ICI infusions received prior to 13:00 (cutoff to denote morning infusions) was evaluated using Cox proportional hazards regression.

Results In this study, there were 201 patients with stage IV RCC (28% female) who were administered ICIs and followed over a median of 18 months (IQR 5–30). Median age at the time of starting ICI treatment was 63 years (IQR 56–70). Initial ICI agents consisted of pembrolizumab (8%), nivolumab (61%), and dual nivolumab/ipilimumab (31%); table 1. The 119 patients (59%) who received at least a quarter of their ICI infusions in the morning had significantly longer OS (median 58 vs. 34 months, HR 0.51, 95% CI 0.29–0.89, P=0.017), independent of age, sex, RCC histology, liver and brain metastases, pre-treatment LDH, and choice of initial ICI; table 2, figure 1.

Conclusions Patients with metastatic RCC may benefit from earlier time-of-day ICI infusions. Our findings are consistent with established mechanisms of chrono-immunology, as well as with preceding analogous studies in melanoma and lung cancer. Additional prospective randomized trials are warranted.

849 NT-I7, A NOVEL LONG-ACTING INTERLEUKIN-7, IMPROVES ENGRAFTMENT OF PATIENT IMMUNE CELLS AND EFFICACY OF ANTI-PD-1 THERAPY IN A PRECLINICAL HUMANIZED MELANOMA MODEL

[1]Yee Peng Phoon*, [1]Kang Kai, [2]Alexandra Wolfarth, [2]Sara Ferrando-Martinez, [2]Byung Ha Lee, [1]Brian Gastman. *[1]Cleveland Clinic, Cleveland, OH, United States; [2]NeoImmuneTech, Inc., Rockville, MD, United States*

Background Although immune checkpoint inhibitors (ICIs) have led to significant massive improvements in melanoma survival, half of these patients fail to benefit, necessitating the discovery of novel strategies. There is a pivotal need for the development of preclinical models to evaluate 'next-generation' immunotherapies prior to clinical investigation.

In this study, we developed and optimized our all-autologous humanized melanoma mouse model for the study of NT-I7 (efineptakin alfa), a long-acting recombinant human IL-7. Because NT-I7 has been shown to enhance T cell proliferation and survival in both humans and mice, we hypothesized NT-I7 would both improve the engraftment of patient immune cells and the efficacy of anti-PD-1 therapy in our humanized mouse model.

Methods Both tumor cells and peripheral blood lymphocytes (PBLs) were collected from melanoma patients to establish our autologous humanized melanoma mouse model. Tumor-bearing NSG mice were infused with matched melanoma PBLs prior to receiving 10 mg/kg NT-I7. Optimization of the model was performed and evaluated by measuring engraftment of the patient immune cells via flow cytometry and comparing tumor growth. The optimized autologous melanoma model was then used to test the efficacy of NT-I7 combined with anti-PD-1 therapy.

Results NT-I7 was well tolerated in the preclinical humanized melanoma mouse model. The optimal dosing of NT-I7 was determined to be two subcutaneous injections of 10 mg/kg NT-I7 1-2 weeks apart after infusing unexpanded PBLs. NT-I7 dramatically increased engraftment of patient PBLs in the spleen and infiltration of the tumor, with a majority of T cells being $CD4^+$. NT-I7 also enhanced the anti-tumor response with decreased tumor growth compared to vehicle control. In combination with anti-PD-1, NT-I7 continued to boost immune cell engraftment, with a majority of T cells still being $CD4^+$. While NT-I7 and anti-PD-1 displayed a similar modest anti-tumor effect as monotherapies, combination treatment significantly decreased tumor growth compared to control.

Conclusions Our all-autologous humanized melanoma mouse model allows us to evaluate novel immunotherapies in the context of matched patient immune and tumor cells. NT-I7 dramatically improves engraftment of patient PBLs. When combining NT-I7 and anti-PD-1 therapy, tumor control was significantly improved. In sum, we have developed a platform to feasibly design NT-I7 combination therapies to identify optimal strategies that can be translated into clinical investigations.

Ethics Approval All human tissue was obtained at the Cleveland Clinic under a protocol approved by the institutional review board with written informed consent obtained from each patient. Animal studies were performed in accordance with the guidelines of and approved by the Institutional Animal Care and Use Committee at the Cleveland Clinic.

850 INTERIM RESULTS FOR PHASE 1B DOSE EXPANSION OF MTL-CEBPA IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH ADVANCED SOLID TUMOUR MALIGNANCIES

[1]Ruth Plummer, [2]Mikael Sodergren*, [3]Brid Ryan, [3]Ilian Tachkov, [3]Vikash Reebye, [4]Tim Meyer, [2]David Pinato, [5]Debashis Sarker, [6]Bristi Basu, [7]Sarah Blagden, [8]Natalie Cook, [9]Jeff Evans, [10]Jeffrey Yachnin, [11]Cheng-Ean Chee, [12]Daneng Li, [13]Anthony El-Khoueiry, [14]Maria Diab, [15]Kai-Wen Huang, [2]Antonio D'Alessio, [2]Claudia Fulgenzi, [16]Marcus Noel, [17]Bridget Keenan, [18]Devalingam Mahalingam, [3]Nina Raulf, [3]Rose Hogson, [3]Choon Ping Tan, [2]Joanna Nicholls, [3]Alison Adderkin, [3]Julia Vassiliadou, [3]Robert Habib, [19]John Rossi, [3]Nagy Habib. *[1]Newcastle University, Newcastle-upon-Tyne, UK; [2]Imperial College London, London, UK; [3]MiNA Therapeutics Ltd, London, UK; [4]University College London, London, UK; [5]Kings College London, London, UK; [6]University of Cambridge, Cambridge, UK; [7]Univeristy of Oxford, Oxford, UK; [8]The Christie NHS Foundation Trust, Manchester, UK; [9]University of Glasgow, Glasgow, UK; [10]Karolinska University Hospital, Stockholm, Sweden; [11]National University Cancer Institute, Singapore, Singapore; [12]City of Hope Comprehensive Cancer Center, Duarte, CA, United States; [13]University of Southern California, Los Angeles, CA, United States; [14]Emory University, Atlanta, GA, United States; [15]National Taiwan University Hospital, Taipei, Taiwan; [16]Medstar Georgetown University Hospital, Washington, WA, United States; [17]University of California San Francisco, San Francisco, CA, United States; [18]Northwestern University, Chicago, IL, United States; [19]Beckman Research Institute, City of Hope, CA, United States*

Background Most cancer patients do not benefit from currently approved immune checkpoint inhibitors (ICI), suggesting that additional immunomodulation is required to improve outcomes. MTL-CEBPA is a novel immunotherapy targeting the myeloid cell lineage that has shown promising clinical activity in hepatocellular carcinoma, and preclinical activity in models of solid tumour cancers in combination with ICIs. We previously reported dose escalation data for MTL-CEBPA in combination with ICI from TIMEPOINT, an ongoing multi-centre phase 1/1b study (NCT-04105335) evaluating the safety, PK, immunomodulation and clinical activity of MTL-CEBPA in combination with pembrolizumab in patients with anti-PD(L)1 naïve advanced solid tumours for whom no standard therapy is available.[1]

Methods In the dose expansion part of TIMEPOINT, patients were treated at RP2D 130mg/m2 MTL-CEBPA QW for 3 consecutive weeks and 1 week off (28-day cycle) and 200mg pembrolizumab Q3W. Analysis was undertaken of plasma cytokine and complement profiles; gene expression (qPCR and Nanostring I/O 360) and immune landscape (multiplex IHC) from core tumour biopsies taken at baseline and cycle 2. Adverse events (AEs) were assessed by CTCAEv5.0. Clinical activity was assessed by RECIST v1.1/iRECIST.

Results At data cut-off 15 March 2022, 50 patients across a wide range of tumour types reported to have primary resistance to anti-PD(L)1 therapy have been enrolled. Patient demographics, clinical characteristics are in table 1. The most frequent AEs in at least 5 patients (10%) are listed in table 2. 20 patients (40%) experienced an AE Gr $^{3}3$, 1 pt (2%) had a Gr4 AE, and there were no Gr 5 AEs. 7 pts (14%) had a SAE, however there were no AEs leading to dose modification or treatment discontinuation of MTL-CEBPA. Pharmacokinetic profile of MTL-CEBPA was not affected by pembrolizumab. Cytokine/complement analysis did not suggest cytokine release syndrome. Paired tumour biopsies during treatment suggested significant increase in Immunosign21 (figure 1) and proliferation of granzyme-producing T cells. 4 (10%) patients had confirmed PR (table 1). A 30-year-old NET patient with primarily lung involvement (failed 3 prior lines of therapy) achieved PR (43% reduction) in cycle 4, associated with a transformation from cold to hot TME (Immunosign21 from 2/21 to 19/21).

Conclusions MTL-CEBPA in combination with pembrolizumab is safe and well tolerated, with encouraging early signs of activity in heavily pre-treated patients across multiple tumour types. Treatment was associated with intratumoural changes supporting the hypothesis of immunomodulation by MTL-CEBPA and further investigation in combination with ICI is warranted.

851 VOYAGER V1 (VV1) ONCOLYTIC VIRUS COMBINED WITH IMMUNE CHECKPOINT THERAPY BOOSTS CTL RESPONSES TO MULTIPLE TUMOR ANTIGENS AND CORRESPONDINGLY DEEPENS TUMOR RESPONSES IN MURINE MODELS OF MELANOMA, LUNG AND COLON CANCER

[1]Priyanka Ram, [1]Navpreet Tung, [1]Himani Sharma, [1]Ben Fulton, [2]Kah-Whye Peng, [2]Stephen Russell, [1]Markus Mohrs, [1]Gavin Thurston, [1]Christos Kyratsous, [1]Alina Baum, [1]Jessica Kirshner, [1]John Lin, [1]Saida Dadi-Mehmetaj*. *[1]Regeneron Pharmaceuticals, Tarrytown, NY, United States*; *[2]Vyriad, Rochester, MN, United States*

Background There is a need for novel immunotherapies to address patient populations resistant or refractory to immune checkpoint inhibitors (CPI). VV1 is an oncolytic vesicular stomatitis virus engineered to express interferon beta (IFNβ) to enhance anti-tumor immune responses and tumor selectivity. Phase 1 studies demonstrated VV1 anti-tumor activity in certain clinical settings either alone or in combination with a CPI. The current preclinical study aimed to identify dosing and scheduling regimens that maximize the efficacy of VV1 in combination with CPIs.

Methods Immune-competent mice bearing syngeneic tumor models MC38 (colorectal), B16F10 (melanoma) and CMT64 (lung adenocarcinoma) tumors were dosed to test combinations of VV1 delivered intravenously with anti-PD-1 and anti-CTLA4 antibodies. Treatment was started once tumors were established, and T cell responses in the tumor and peripheral lymphoid organs were analyzed using flow cytometry and ELISPOT assays.

Results Potent anti-tumor efficacy was observed following intratumoral or intravenous administration of VV1 combined with anti-CTLA4 and anti-PD-1. A comparison of single dose versus repeat administration of anti-CTLA4 in combination with VV1 plus continuous anti-PD-1 showed that a single dose was sufficient to maximally enhance the depth and durability of tumor response. This effect was observed consistently in multiple tumor models, including anti-PD-1 sensitive (MC38) or anti-PD-1 resistant tumor models (B16F10 and CMT64). Remarkably, the triple combination boosted T cell priming against the B16F10 and CMT64 neo-antigen peptides in TILs and tumor-draining lymph nodes. ELISPOT and multimer staining showed that, in contrast to doublet therapy using virus and a single CPI, triplet combination therapy strongly boosted CTL responses against a broad array of B16F10 and CMT64 neoepitopes, detected both in the tumor and in tumor-draining lymph nodes. This was associated with increased infiltration of CD8 T cells in the tumor, but the number of regulatory T cells was not impacted, indicating that the enhancing effect of anti-CTLA4 was not a consequence of Treg depletion.

Conclusions Intratumoral or intravenous VV1 virotherapy combined with anti-CTLA4 and anti-PD-1 checkpoint antibodies synergistically enhances tumor control in multiple syngeneic mouse tumor models. The triple combination seems to promote a tumor-vaccination effect, by inducing a polyclonal anti-tumor T cell response and boosting anti-tumor CTL responses. This triplet combination approach will soon be evaluated clinically in patients with advanced melanoma (after progression on an anti-PD1) and first line NSCLC patients. (ClinicalTrials.gov Identifier: NCT04291105).

852 INVESTIGATING THE FUNCTIONAL ROLE OF GPNMB IN GLIOBLASTOMA AND THE TUMOR IMMUNE MICROENVIRONMENT AND ITS TARGETED ELIMINATION USING CAR-TS

[1]Neil Savage*, [2]Franz Zemp, [3]Nick Mikolajewicz, [3]Hong Han, [1]Chitra Venugopal, [1]Chirayu Chokshi, [1]Nazanin Tatari, [4]Thomas Kislinger, [3]Jason Moffat, [2]Doug Mahoney, [1]Sheila Singh. *[1]McMaster University, Hamilton, Canada*; *[2]University of Calgary, Calgary, Canada*; *[3]University of Toronto, Toronto, Canada*; *[4]Princess Margaret Hospital, Toronto, Canada*

Background Glioblastoma (GBM) is the most common primary malignant brain tumor in adults. Due to GBM displaying extreme heterogeneity and immune suppression, prognosis remains dismal. Glycoprotein nonmetastatic melanoma protein B (GPNMB) has previously been identified as a clinically relevant target in GBM while being absent in normal brain tissues and shown to be active in the tumor immune microenvironment.[1,2] Chimeric Antigen Receptor T-cells (CAR-Ts) fail clinical trials because multiple antigens will be required to eliminate all GBM subpopulations.[3,4] We previously proved CD133 to be an effective CAR-T target in GBM models.[5]

Methods Immunohistochemistry was performed on patient derived xenograft (PDX) brains and tissue microarrays of 16 patient matched primary/recurrent GBMs as well as 23 normal organ tissues. Whole cell proteomics was performed on 43 matched primary/recurrent GBM samples. Flow cytometry measured surface expression levels of CD133 and GPNMB to confirm CAR-T accessibility. CRISPR/Cas9 was used to eliminate expression in GBM lines to measure proliferation and mouse survival times. GPNMB knockout clones were generated in GL261 and engrafted in immunocompetent mice to examine single cell transcriptomes using sciRNAseq at endpoint. A second-generation CAR-T was developed to target GPNMB-expressing populations, and efficacy was interrogated using standard *in vitro* assays and PDX models.

Results GPNMB detected in residual tumors of PDX brains treated with CD133 CAR-Ts revealed it as a targetable subpopulation. Tissue microarrays and proteomics found GPNMB to be upregulated in recurrent GBMs compared to primary ($p=0.0349$ and $p=0.0033$ respectively), particularly in macrophage populations while being absent in normal tissues. Eliminating GPNMB in cell lines decreased proliferation ($P\leq0.001$) and prolonged survival times in all mouse models ($P\leq0.01$) indicating its functional relevance. GPNMB knockout clones displayed downregulation of hallmark signalling pathways of GBM such as PDGFR, TGF-beta, Integrins and Stats, as well as decreased innate/adaptive immune activation. CAR-T cytotoxicity and activation was observed *in vitro* and *in vivo* resulting in decreased tumor burden ($P\leq0.001$) and increased survival times ($P\leq0.001$). Ultimately a CD133+ population was observed in residual tumors of GPNMB treated mice at endpoint. Surface expression of CD133 and GPNMB revealed co-expression and distinct populations.

Conclusions We show GPNMB influences tumor intrinsic biology of GBM and is active in the tumor immune microenvironment. By targeting GPNMB along with CD133, combinatorial therapeutic regimens could target the cancer stem cell hierarchy and its supportive niche. We therefore plan to administer both CAR-T cells to provide better cytotoxic coverage and increase efficacy.

853 **NOVEL CEAXCD47 (NILK-2401) AND CEAXCD3 (NILK-2301) KL BISPECIFIC ANTIBODIES FOR MULTIMODAL IMMUNOTHERAPY OF CEA-EXPRESSING SOLID CANCER**

[1]Anja Seckinger*, [2]Vanessa Buatois, [2]Valéry Moine, [2]Lise Nouveau, [2]Bruno Daubeuf, [2]Sara Majocchi, [2]Ulla Ravn, [2]Nicolas Bosson, [2]Krzysztof Masternak, [2]Yves Poitevin, [2]Giovanni Magistrelli, [2]Pauline Malinge, [2]Limin Shang, [2]Nicolas Fischer, [1]Klaus Strein, [2]Walter Ferlin, [1]Dirk Hose. *[1]LamKap Bio, Pfaeffikon SZ, Switzerland; [2]Light Chain Bioscience – Novimmune SA, Geneva, Switzerland*

Background We present here our novel macrophage-directed CEAxCD47 bispecific antibody (bsAb) NILK-2401 alone and in combination with the CEAxCD3 T-cell retargeting bsAb NILK-2301 for multimodal treatment of CEA-expressing solid malignancies, e.g., gastrointestinal or lung carcinomas.

Methods BsAbs are generated using LCB's fully human κλ body platform based on a common heavy chain and on one κ and one λ light chain, determining specificity and affinity. Binding, inhibition of CD47-SIRPα interaction, antibody-dependent cellular phagocytosis (ADCP) and antibody-dependent cellular cytotoxicity (ADCC) were assessed *in vitro* using colorectal (n=3), lung (n=2), and gastric (n=2) cancer cell lines. Human monocyte-derived macrophages (MDMs) or peripheral blood mononuclear cells (PBMCs) were used as effector cells. Combination activity ("mixed killing assay") of NILK-2401 and NILK-2301 was assessed by flow cytometry, incubating both effector cell populations with tumor cells. *In vitro* safety data include binding to other CEACAM-members, ADCP of CEA-negative cells (n=3), cytokine release in whole blood, erythrophagocytosis, and platelet activation. *In vivo*, NSG-mice were co-engrafted SC with PBMCs, MDMs, and LS-174T tumor cells, and exposed to 10 mg/kg NILK-2401 IV once weekly vs. control. Pharmacokinetics and tolerability were assessed in cynomolgus monkeys and Tg32 human FcRn mice.

Results NILK-2401 has a functional IgG1 Fc part and shows low nM binding-affinity to CEA and high nM binding-affinity to CD47, enabling tumor specific blockade of the CD47-SIRPα interaction. Elimination of CEA-expressing cell lines by ADCP and ADCC is induced, including CEA-high (e.g., MKN-45) and low expressing cell lines (e.g., LS-174T). Killing activity was CEA-dependent as no phagocytosis of CD47-positive but CEA-negative cells, including red blood cells, was observed. Likewise, no platelet activation occurred. In the mixed killing assay, NILK-2301 plus NILK-2401 combination showed an additive effect, both increasing maximum activity (Emax) and necessitating lower doses of the T-cell bsAb to reach Emax. E.g., Emax of 30% killing (NILK-2301 alone) was increased in combination with NILK-2401 at 0.1/1/10 µg/mL to 40%, 80%, and 80%, respectively. *In vivo*, NILK-2401 delayed tumor growth vs. mean of control in 100% (15/15) of mice and prevented establishment of detectable tumors (i.e., >50mm^3, d23 post co-engraftment) in 53% (8/15). In cynomolgus and Tg32 mice, doses of 0.5 and 20 mg/kg NILK-2401 (single IV dose) were well tolerated.

Conclusions NILK-2401 bsAb is active as single agent with limited potential side effects due to the tumor-targeted blockade of CD47. NILK-2401 plus NILK-2301 combination treatment significantly increases activity, without overlapping safety profiles. GMP drug substance has been produced for both molecules.

Ethics Approval Animal experiments were approved by the animal research committee of Geneva canton and experiments performed in accordance with the Swiss Federal Veterinary Office guidelines. This included submission and approval of the project by the Commission Cantonale d'Expérimentation Animale (CCEA; GE83 and GE134).

854 **HPK1 INHIBITION RELIEVES SUPPRESSION DOWNSTREAM OF TCR ACTIVATION TO DRIVE ENHANCED CYTOKINE PRODUCTION AND ANTIGEN-SPECIFIC KILLING, AN EFFECT THAT IS FURTHER ENHANCED BY IMMUNE CHECKPOINT BLOCKADE**

Rajesh Singh*, Bindi Patel, Rameshwari Rayaji, Sachie Marubayashi, Sean Cho, Stefan Garrido-Shaqfeh, Joseph Kulusich, Cesar Meleza, Nidhi Tibrewal, Joice Thomas, Pradeep Nareddy, Ehesan Sharif, Sharon Zhao, Dave Green, Manmohan Leleti, Jay Powers, Matt Walters, Daniel DiRenzo. *Arcus Biosciences, Hayward, CA, United States*

Background T cell activation is critical in the initiation and potentiation of anti-tumor immune responses. Hematopoietic Progenitor Kinase 1 (HPK1) is a member of the MAP4K family whose activity restrains T cell activation through phosphorylation of SLP-76 (pSLP-76) at Serine 376, leading to disassembly of the TCR complex. Mouse genetic deletion and kinase dead mutants of HPK1 have been shown to enhance T cell activity and combine with immune checkpoint inhibition. Therefore, we sought to demonstrate that inhibitors of HPK1 activity can increase T cell activation, drive antigen-specific cancer cell killing, and combine with immune checkpoint blockade to amplify anti-tumor T cell responses. Herein, we describe the characterization of novel inhibitors of HPK1 and assess their effects on T cell activation in combination with PD-1 blockade.

Methods Measurement of pSLP-76 using a flow cytometry-based assay was employed to assess HPK1 activity in human and mouse whole blood. Jurkat cells, human $CD8^+$ T cells and PBMCs were activated using anti-CD3/CD28 stimulation, CEF peptide pools, or Staphylococcal enterotoxin A (superantigen), in the presence of HPK1 inhibitors; levels of IL-2, IFN-γ and TNF-α were assayed in supernatants by cytokine bead array. Mouse OT-1 splenocytes were stimulated with SIINFEKL peptide and co-cultured with E.G7-OVA cells to assess cytokine production and target cell killing.

Results HPK1 inhibitors exhibited a potent, concentration-dependent reduction in pSLP-76, with a concurrent increase in IL-2 secretion in both Jurkat and human $CD8^+$ T cells. Human T cells also demonstrated increased IFN-γ and TNF-α secretion as well as a greater percentage of activated $CD69^+$ cells with HPK1 inhibition. These increases in T cell activation were mirrored in antigen-specific OT-1 T cell assays, in which HPK1 inhibition enhanced IFN-γ production in response to OVA peptide and greater killing of E.G7-OVA cancer cells. Similarly, antigen-recall assays demonstrated that inhibition of HPK1 increased IFN-γ production from human PBMC stimulated with CEF peptide and combined with PD-1 blockade to further enhance cytokine production. Consistent with these results, HPK1 inhibition and PD-1 blockade increased cytokine secretion in superantigen-stimulated human PBMC individually and further enhanced cytokine production in combination. Taken together, these data demonstrate that the combined activity of HPK1 inhibition with checkpoint therapy may yield greater anti-tumor T cell activity.

Conclusions These data demonstrate that pharmacological inhibition of HPK1 amplifies antigen-specific T cell activation alone or in combination with immune checkpoint blockade and provide a strong mechanistic rationale for targeting HPK1 to amplify anti-tumor immune responses.

855 DIACYLGLYCEROL KINASE ALPHA AND ZETA DUAL INHIBITORS ENHANCE T CELL RESPONSES AND PROMOTE ROBUST AND DURABLE ANTI-TUMOR T CELL IMMUNITY

Marcos Steinberg*, Darina Spasova, Danelle Eto, AnneMarie Pferdekamper, Phuong Nguyen, Brian Le, Zachary Naiman, Susan Murphy, Maricel Gozo, James Skipper, Taylor Ismaili, Xikui Liu, Sunil Sahdeo, Xiao Hu, Isharat Yusuf, Kristen Taylor Meadows, Laura Carter. *Gossamer Bio, Inc., San Diego, CA, United States*

Background Diacylglycerol kinases (DGK) convert diacylglycerol (DAG) into phosphatidic acid which limits DAG-induced propagation of T cell activation.[1] T cells predominantly express DGK alpha and DGK zeta isoforms (DGKalpha/zeta),[2] and deletion of either enhances T cell activation and function.[3,4] DGKalpha/zeta are overexpressed in tumor infiltrating T cells and may limit the anti-tumor activity of these cells.[5] Thus, inhibition of DGKalpha/zeta is a potential therapeutic avenue to enhance T cell anti-tumor responses. We demonstrate that inhibition of DGKalpha/zeta with novel dual DGKalpha/zeta inhibitors (DGKi) enhances anti-tumor T cell activity.

Methods The role of DGKalpha/zeta in T cell activation was studied using wildtype and CRISPR-knockout T cells. *In vitro* studies assessing the effect of DGKi were conducted using various mouse and human T cell functional assays. T cell exhaustion studies were performed in T cells from lymphocytic choriomeningitis virus (LCMV) clone 13-infected mice. *In vivo* activity of DGKi was assessed by measuring T cell activation in OT-I mice challenged with OVA-peptides. Efficacy studies and memory rechallenge experiments were performed in the MC38 syngeneic tumor model.

Results CRISPR knockout studies characterizing the role of DGKalpha/zeta on T cells demonstrated that both isoforms regulate T cell activation and function. DGKi enhanced IFN gamma production by human melanoma-specific T cells stimulated with the weak affinity MART1 antigen. Similarly, treatment of mouse OT-I cells with DGKi enhanced responses to low-affinity OVA-peptides and OT-I-mediated cytotoxicity of MC38-OVA tumor cells. Treatment of exhausted CD8 T cells with DGKi reverted exhaustion caused by chronic LCMV infection, and enhanced T cell function with PDL1 blockade. DGKi rescued cytokine release from T cells suppressed by adenosine, TGF beta or PGE_2 treatment. Oral administration of DGKi resulted in dose-dependent increase in T cell activation in mice. Furthermore, DGKi in combination with anti-PD-1 therapy was efficacious in the MC38 model with complete tumor regressions in treated animals. These mice eradicated tumors upon rechallenge with MC38 cells two months later, demonstrating durable anti-tumor memory responses.

Conclusions We demonstrate that DGKalpha/zeta negatively regulates T cell activity. Dual DGKalpha/zeta inhibition restores T cell responses to weak tumor antigens, overcomes cell exhaustion, and enhances CD8 T cell cytotoxic activity. *In vivo* efficacy data demonstrates that DGKi in combination with anti-PD-1 antibody therapy promotes robust anti-tumor responses and generates durable T cell memory. These data support dual DGKalpha/zeta inhibition in combination with anti-PD-1 antibodies as a therapeutic approach for cancer treatment.

856 SNS-101, A HIGHLY PH-SELECTIVE VISTA:PSGL-1 INHIBITORY ANTIBODY, POTENTIATES ANTI-PD-1 SENSITIVITY, EXPANDS MEMORY T-CELLS AND ENHANCES TUMOR INFILTRATION OF CD8 T-CELLS

Thomas Thisted, Tim Eitas, Kanam Malhotra, Yuliya Kleschenko, Faith Finley, Zhi-Gang Jiang, Arnab Mukherjee, Zuzana Biesova, Anokhi Cifuentes, Robert Pierce, Edward van der Horst*. *Sensei Biotherapeutics, Boston, MA, United States*

Background VISTA (V-domain Ig suppressor of T-cell activation) is a negative checkpoint regulator (NCR), highly expressed on myeloid cells.[1] PSGL-1 on T-cells has been identified as a novel NCR that limits survival and promotes T-cell exhaustion.[2] Recently, VISTA was reported to bind PSGL-1 and suppress T-cell activity exclusively under acidic conditions (~pH 6 in lymph nodes or the tumor microenvironment).[3, 4] Although VISTA inhibition demonstrated excellent therapeutic combinability with other modalities targeting NCRs (e.g. CTLA-4, PD-1/PD-L1),[5] clinical development of anti-VISTA antibodies has been challenging due to: 1) high clearance via target-mediated drug disposition (TMDD) by VISTA$^+$ neutrophils and monocytes at physiologic pH; and 2) cellular activation and cytokine release syndrome (CRS) at sub-therapeutic doses by engagement of VISTA in the blood.[6]

We developed SNS-101, a human monoclonal IgG1 antibody specific for the protonated, active form of VISTA, which is designed to disrupt the immunosuppressive VISTA:PSGL-1 interaction, avoid TMDD and mitigate potential CRS.

Methods The binding potential of SNS-101 to VISTA$^+$ cells was determined in human and non-human primate (NHP) whole-blood by flow cytometry. The effect of SNS-101 on human monocytes and T-cells was evaluated *in vivo* in human CD34$^+$ cord blood cell reconstituted BRGSF mice, which develop both human lymphoid and myeloid compartments. The pharmacokinetic (PK) profile was assessed in NHPs. Anti-tumor efficacy was assessed in VISTA-KI mice implanted with the syngeneic tumor model, MC38, and tumor-infiltrating T-cells were analyzed by flow cytometry.

Results SNS-101 did not bind to human or NHP VISTA$^+$ monocytes, neutrophils and natural killer cells. In humanized BRGSF mice, SNS-101 induced significant expansion of CD4 and CD8 central memory (CCR7$^+$CD45RA$^-$), and naïve (CCR7$^+$CD45RA$^+$) CD8 T-cells, respectively, but had no significant impact on monocyte activation. PK studies in NHPs showed linear elimination kinetics. Conversely, a non-pH-sensitive antibody bound VISTA$^+$ immune cells, induced monocyte activation followed by a decrease in cell numbers and was rapidly cleared in NHPs. Anti-tumor efficacy studies in MC-38 demonstrate that SNS-101 enhanced anti-PD-1 response and dose-dependently increased tumor-infiltrating CD8 T-cells.

Conclusions Our results demonstrate that SNS-101 exhibits linear elimination kinetics in NHPs, overcoming TMDD-induced PK limitations observed with other anti-VISTA antibodies. Importantly, SNS-101 induced expansion of naïve and memory T-cell phenotypes *in vivo* without activation or depletion of monocytes, differentiating it from non-pH-selective VISTA antibodies. In the MC-38 syngeneic tumor model, SNS-101 demonstrated significant enhancement of anti-tumor effects in combination with anti-PD-1 antibodies through an increase in CD8$^+$ T-cells.

857 IDENTIFYING NOVEL IMMUNOTHERAPY TARGETS UNDER THE PRESSURE OF INHIBITORY CYTOKINE TGF-β 1

[1]Liangzhe Wu*, [1]Nicholas Gascoigne, [1]Ling Wu, [1]Vivian Tan, [2]Manoj Krishnan, [2]Unnikrishnan Unniyampurath, [1]Benson Chua. *[1]National University of Singapore, Singapore, Singapore; [2]Duke-NUS, Singapore, Singapore*

Background T cell function is under regulation by some suppressive signals such as anti-inflammatory cytokines and immune checkpoint molecules in order to maintain self-tolerance and immune cells homeostasis. Transforming growth factor β1 (TGF-β1) is a pleiotropic cytokine which participates to orchestrate the negative regulation of T cell activity and is produced in large quantities within tumor microenvironment that ultimately promotes neoplastic progression, notably by suppressing the host's T-cell immunosurveillance.[1,2] Cancer immunotherapy with aims to re-activate tumour-induced exhaustive T cells to fight against cancer cells is a hot and promising field of cancer therapy in recent years. However, despite some positive results in the past years, success of immune checkpoint blockade therapies in clinic is still limited. These have suggested that albeit several key immune checkpoint genes have been identified, there is still an urgent and unmet medical need to discover new inhibitory genes.

Methods mRNA sequencing of human CD8+ T cells, either with or without TGF-β treatment, was performed and compared for novel immunosuppresive genes discovery.

CRISPR-Cas9 validation system was followed and applied in both Jurkat T cell line and primary T cells to investigate the knockout effect of the gene candidates in terms of T cell effector function, proliferation, cytotoxicity and in vivo anti-cancer ability.

Results Among the mRNA sequencing list, two genes – show the significant inhibitory effect to T cells. After being knocked out, T cell function would be impressively rescued in terms of cytokine secretion, proliferation, and target cell killing. In vivo study also demonstrated that adoptive transferred T cells with these genes knock out enhance the anti-cancer effect in terms of controlling tumor size and improving survival rate. On the other hand, these two genes also showed the ability to affect Treg polarization. With these genes knock out, CD4+ T cells tended to less likely to polarize to Treg population under polarizing conditions.

Conclusions Two genes, a regulator of G protein and a F actin-binding protein, are discovered to be novel T cell inhibitory genes and showed their potential to become the immunotherapy gene targets.

858 HBM7008 (B7H4X4-1BB HBICE®) SYNERGIZES HBM7004 (B7H4XCD3 HBICE®) FOR SOLID TUMOR THERAPY

Xiaodong Wu*, Yongqiang Wang, Gezi Jia, Bing Huang, Yunxing Yang, Yun He, Yiping Rong. *Harbour BioMed Co., Ltd., Shanghai, China*

Background B7H4 is a member of B7-family and its expression is not detected or barely detected in healthy tissues but highly expressed in multiple solid tumors. Thus, B7H4 is a good tumor associated antigen (TAA) for tumor therapy, especially used for construction of T cell engagers. CD3 T cell engager has shown promising efficacy in hematologic malignancies. However, the outcomes for solid tumors are still disappointing. One possible impediment to the efficacy could be that CD3 signal alone may cause rapid T cell exhaustion and apoptosis. 4-1BB(CD137) costimulation along with CD3 signal can significantly enhance T cell proliferation, cytotoxicity, as well as counteract T cell exhaustion and cell death. Combination B7H4xCD3 with B7H4x4-1BB T cell engagers may be a promising strategy for solid tumor therapy.

Methods Both B7H4xCD3 and B7H4x4-1BB bispecific antibodies were developed from Harbour BioMed heavy chain only antibodies (HCAb) based bispecific immune cell engager (HBICE®) platform. HBM7004 (B7H4xCD3 HBICE®) is composed of a bivalent B7H4 VH domain (2+1 format) to increase avidity driven cytotoxicity, and monovalent CD3 Fab domain with reduced activity to decrease systemic toxicity. *In vitro* cytotoxicity of HBM7004 was tested on multiple B7H4 positive tumor cell lines. HBM7008 (B7H4x4-1BB HBICE®) is composed of anti-B7H4 IgG1 and anti-4-1BB HCAb variable domains appended at C-terminus of Fc fragment (2+2 format). The synergistic effect of combination of HBM7004 and HBM7008 was studied in a series of assays.

Results HBM7004 (B7H4xCD3) showed potent *in vitro* efficacy to multiple tumor cell lines at high effector T cell: target cell (E: T) ratio. 2+1 HBICE® format showed much higher efficacy than monovalent B7H4 HBICE®. When the cytotoxicity assay was conducted in the co-culture with low E:T ratio, which mimicked the status in tumor microenvironment as measured by immunohistochemistry staining of T cell infiltration, HBM7004 could not kill the tumor cells. Combination with HBM7008 (B7H4x4-1BB) could restore HBM7004 cytotoxicity at low E:T ratio. It significantly reduced T cell apoptosis and increased T cell division, thus maintained T cell numbers after long-term co-culture with tumor cells. In addition to HBM7008 (B7H4x4-1BB), combination of HBM7004 with HER2x4-1BB HBICE® also had synergistic effect on killing SKBR3 cells which is B7H4 and HER2 double positive, indicating flexible combination approaches.

Conclusions Combination with HBM7008 (B7H4x4-1BB) could provide a secondary signal for T cell activation and significantly increase the efficacy of HBM7004 by reducing T cell apoptosis and increasing T cell division, providing a promising therapy solution for solid tumor therapy.

Ethics Approval The cancer tissue microarray was purchased from Fanpu Biotech, Inc. The company ensured ethical approval from the patients, and patient consent for publication.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0858

859 COMBINATION OF HER2 ADC AND LEMZOPARLIMAB ELICITS ENHANCED EFFICACY IN BOTH HER2 HIGH-AND LOW-EXPRESSING BREAST AND GASTRIC CANCERS

Yanni Zhang*, Yu Pang, Ao Li, Ke Xu, Ming Yang, Zhengyi Wang, Andrew Zhu. *I-Mab biopharma, Shanghai, China*

Background Lemzoparlimab (also known as TJC4) is a differentiated anti-CD47 antibody with novel epitope and RBC sparing properties. Previous data has shown that CD47 is upregulated preferentially in HER2-expressing cells and dual blockade of CD47 and HER2 increased tumor attack. The combination of lemzoparlimab with HER2 ADC maybe a promising therapy for treating HER2 positive patients. Here, we report the enhanced anti-tumor efficacy of the combination of lemzoparlimab with HER2 ADC in cell derived xenograft (CDX) and patient derived xenograft (PDX) breast and gastric cancer models.

Methods Breast and gastric cancer cell lines with different expression levels of HER2 and CD47 quantified by flow cytometry were selected for this study. *In vitro* cytotoxicity of RC48 (Disitamab Vedotin), alone or in combination with lemzoparlimab was evaluated in co-culture of human PBMC with tumor cell lines. *In vivo* activity of RC48 or in-house produced DS8201 analogue in combination with lemzoparlimab were investigated in CDX (HER2 0/1+/3+ by IHC) and PDX (HER2 2+ by IHC) models. Tumor infiltrating leukocytes (TILs) were analyzed by flow cytometry. The expressions of CD47 and CD68 in tumor were measured by immunohistochemistry.

Results In combination with lemzoparlimab *in vitro*, RC48-mediated cytotoxicity against both BT-474 and MCF-7 cells was enhanced, while the increase in cytotoxicity was more prominent in HER2-low MCF-7 cells than HER2-high BT474 cells. *In vivo* combination treatment of DS8201 analogue or RC48 with lemzoparlimab exhibited stronger anti-tumor efficacy compared with monotherapy in both CDX and PDX models with different levels of HER2 expression. The synergistic efficacy by combination treatment was more pronounced in tumor with HER2-low expression than that with HER2-high expression. Treatment effect in tumor microenvironment by RC48 and lemzoparlimab was further investigated. Compared to RC48 monotherapy, RC48 combined with lemzoparlimab significantly up-regulated the percentage of activated and total NK cells, $CD68^+$ macrophages and the ratio of M1/M2 macrophage in TILs ($p<0.05$ in all comparisons). In addition, the CD47 expression in tumor cells was also increased by the combination treatment.

Conclusions This study demonstrated the synergistic effect of combining CD47 blocker and HER2 ADC in tumors with different levels of HER2 expression. Lemzoparlimab potentiated HER2 ADC mediated tumor killing by modulating NK cells and macrophage activity to increase cytotoxicity and phagocytosis. These data support future clinical investigation of lemzoparlimab and HER2 ADC combination in HER2 positive patients, especially those with HER2-low expressing tumors.

860 ***IN VIVO* EFFECTIVENESS OF TUMOR TREATING FIELDS (TTFIELDS) CONCOMITANT WITH IMMUNE CHECKPOINT INHIBITORS IN NON-SMALL CELL LUNG CANCER (NSCLC)**

Yiftah Barsheshet*, Tali Voloshin, Boris Brant, Gadi Cohen, Lilach Avigdor, Roni Blatt, Shay Cahal, Tharwat Haj Khalil, Efrat Zemer-Tov, Rom Paz, Anat Klein-Goldberg, Catherine Tempel-Brami, Sara Jacobovitch, Alexandra Volodin, Tal Kan, Bella Koltun, Cfir David, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti. *Novocure Ltd, Haifa, Israel*

Background Tumor Treating Fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell division and tumor progression. Recently, cancer cell death following delivery of TTFields has been shown to stimulate anti-tumor immunity and promote maturation of dendritic cells. The efficacy of TTFields concomitant with anti-PD-1 was previously shown *in vivo*, and is currently under clinical investigation. Here, we investigated whether concomitant treatment with TTFields and the anti-PD-1 and anti-CTLA-4 combination can improve therapeutic efficacy.

Methods Lung tumor-bearing mice were treated with TTFields (150 kHz, continuously for 10 days), with the anti-PD-1 and anti-CTLA-4 combination (3 i.p. injections, one every 72 h), or with the two modalities together. At the end of treatment, tumor volume was measured, tumor single-cell suspensions were generated, and tumor-infiltrating lymphocytes (TILs) were characterized by flow cytometry using fluorochrome-conjugated anti-mouse antibodies for lineage defining factors. Furthermore, TILs were isolated using mouse pan T magnetic beads, and IFN-γ levels were examined. Blood and spleen were examined for changes in effector memory cells.

Results The combined treatment of TTFields and anti-PD-1/anti-CTLA-4 led to a significant decrease in tumor volume as compared to untreated control mice, as well as relative to mice treated with only one of the modalities. In addition, a significant increase in the number of tumor infiltrating immune cells, specifically cytotoxic T-cells, was observed in the TTFields plus anti-PD-1/anti-CTLA-4 group. Correspondingly, cytotoxic T-cells isolated from these tumors have shown higher levels of IFN-γ production relative to untreated mice. The levels of splenic and blood effector memory cytotoxic T-cells were elevated following TTFields with anti-PD-1/anti-CTLA-4 relative to control and TTFields alone, and were similar to those induced by anti-PD-1/anti-CTLA-4 alone.

Conclusions Our results suggest that combining TTFields with the immune checkpoint inhibitors combination anti-PD-1/anti-CTLA-4 may enhance antitumor immunity relative to each modality alone.

861 COMBINED IRREVERSIBLE ELECTROPORATION AND LOCAL CD40 AGONISM STIMULATE NEOANTIGEN SPECIFIC SYSTEMIC IMMUNE RESPONSES THAT INHIBIT LIVER METASTASIS IN AN ORTHOTOPIC PANCREATIC CANCER MODEL

[1]Jayanth Shankara Narayanan*, [1]Rebekah White, [1]Tomoko Hayashi, [1]Dennis Carson, [2]Stephen Schoenberger. *[1]University of California San Diego, La Jolla, CA, United States; [2]La Jolla Institute of Immunology, La Jolla, CA, United States*

Background Pancreatic ductal adenocarcinoma (PDAC) has a poor prognosis, and most patients present with either locally advanced or metastatic disease. Irreversible Electroporation (IRE) is a non-thermal method of ablation, used clinically in locally advanced PDAC, but most patients eventually develop distant recurrence. We have previously shown that IRE alone is capable of generating protective, neoantigen-specific immunity. Here we aim to generate meaningful therapeutic immune effects by combining IRE with local (intratumoral) delivery of CD40 agonistic antibody (CD40Ab)

Methods KPC46 organoids were generated from a tumor-bearing male *Kras$^{LSL-G12D}$-p53$^{LSL-R172H}$-Pdx-1-Cre (KPC)*mouse. Orthotopic tumors were established in the pancreatic tail of B6/129 F1J mice via laparotomy (KPC46O). Candidate neoantigens were identified by mutanome profiling of tumor. Tumors were monitored by ultrasound, and when they reached 4-5 mm, mice were randomized to either sham laparotomy, IRE alone, CD40Ab alone, or IRE followed immediately by CD40Ab injection. Metastatic disease and immune infiltration in the liver were analyzed 14 days post-procedure using flow cytometry and multiplex immunofluorescence assay with spatial analysis.

Results Sham-treated KPC46O mice showed a median survival of 14 days post-procedure due to rapid development of metastasis and increasing tumor burden. IRE or CD40Ab alone improved the median survival to 21 and 24 days, respectively, but significantly ($p<0.01$) lower than the median survival of >35 days achieved by the combination of IRE+CD40Ab. CD40Ab had a significant effect on metastatic disease with average liver weights significantly lower in the IRE+CD40Ab group than the Sham group ($p<0.01$) or IRE alone ($p<0.05$). Immunohistochemistry of metastatic nodules in the liver revealed a significantly ($p<0.01$) higher infiltration of CD8+ T-cells in the IRE+CD40Ab group than the other groups. Multiplex immunofluorescence imaging also revealed a 4-6-fold increase in the density of CD80+CD11c+ activated dendritic cells ($p<0.05$), which were spatially distributed throughout the tumor unlike the sham group, where they were restricted to the periphery.In contrast, CD4+FoxP3+ T-regulatory cells ($p<0.05$) and Ly6G+ MDSCs ($P<0.01$) were reduced and restricted to the tumor periphery in the IRE +CD40Ab group. T-cells from the IRE+CD40Ab group recognized more peptides (65 ± 9.3%) representing candidate neoantigens than did T-cells from IRE or Sham groups suggesting the dendritic cell activation and improved antigen presentation caused by IRE+CD40Ab treatment leads to wider tumor neoantigen recognition.

Conclusions IRE can induce local tumor regression and generate neoantigen-specific immune responses. Addition of CD40Ab to IRE improved neoantigen recognition, thereby generating a strong systemic anti-tumor T-cell response that inhibited metastatic disease progression.

862 ADMINISTRATION OF INTRATUMORAL HU14.18-IL2 IMMUNOCYTOKINE AND LOCAL RADIATION THERAPY TO ACTIVATE IMMUNE REJECTION OF SPONTANEOUS CANINE MELANOMA

[1]Mark Albertini*, [1]Cindy Zuleger, [1]Erik Ranheim, [2]Oyewale Shiyanbola, [1]Andrew Kosharek, [1]Paul Sondel, [1]Zachary Morris, [1]Jens Eickhoff, [1]Michael Newton, [1]Irene Ong, [1]Rene Welch Schwartz, [1]Rubi Hayim, [1]Sarah Adrianowycz, [1]Rachel Uyehara, [1]Ilene Kurzman, [1]Michelle Turek, [1]David Vail. *[1]University of Wisconsin, Madison, WI, United States; [3]Stanford University School of Medicine, Stanford, CA, United States*

Background Canine malignant melanoma provides a clinically relevant, large animal model to study the GD2-reactive hu14.18-IL2 immunocytokine (IC) as it is similar to human melanoma and expresses GD2. Murine preclinical studies have shown that intratumoral (IT) injection of IC (IT-IC) in combination with local radiation therapy (RT) can convert the injected tumor into an effective *in situ* tumor vaccine. We previously reported that IT-IC at 12 mg/m^2 on 3 consecutive days is well tolerated in tumor-bearing dogs.

Methods Twelve dogs (6 dogs/arm) with locally advanced or metastatic melanoma were randomized to receive a single 8 Gy fraction (Arm A) or three 8 Gy fractions delivered over 1 week (Arm B) to the primary site and regional lymph nodes (when clinically involved) with the single or last fraction 5 days prior to IT-IC at 12 mg/m^2 on 3 consecutive days. Tumor biopsies and peripheral blood mononuclear cells (PBMC) were obtained for immune monitoring at pre-treatment and various times post-treatment.

Results All 12 dogs completed protocol treatment and none experienced significant or unexpected adverse events. Antitumor activity includes 3 dogs with partial response at day (D) 30 and 4 dogs with mixed responses. Eleven dogs ultimately experienced progressive disease and 1 is currently alive in immune partial response 5 months post treatment initiation. Hematoxylin and eosin (H&E) stains of 5 serial biopsies (pre-treatment, D1, D10, D17, D24) show a variably timed increase in intratumoral lymphocytic inflammation post-therapy in 6/6 dogs in Arm A while 4/6 also show at least focal tumor necrosis post-treatment. In 2/6 dogs in Arm B, a clear increase in intratumoral lymphoid infiltrate occurred post-treatment. However, 5/6 of Arm B dogs also showed tumor necrosis with 2/6 with no viable tumor by D24. Immunohistochemistry (IHC) staining for CD3, CD8, and FOXP3 (pre-treatment, D1, D10, D17) show the large majority of intratumoral lymphoid cells to be CD3+ T cells, with only a minority staining for CD8 or FOXP3. A 9-marker multi-color immunophenotyping panel for flow cytometry (CD3, CD5, CD4, CD8, CD14, CD21, CD25, FoxP3, and PD-1) was optimized using cryopreserved healthy canine PBMC and will be used to assay PBMC from pre and post-treatment timepoints for the protocol treatment dogs.

Conclusions IT-IC in combination with local RT in canine melanoma is safe and has antitumor activity with potential to inform clinical development of IT-IC in melanoma patients.

866 POTENTIATING RADIOTHERAPY-INDUCED ABSCOPAL IMMUNITY BY ATR ABROGATION AND CTLA-4 BLOCKADE IN COLORECTAL CANCER

[1]Rodney Cheng-En Hsieh*, [2]Ricardo Alexandre De Azevedo, [2]Pham Hong Anh Cao,[2]Arthur Liu, [2]Akash Boda, [2]Michelle Winkler, [2]Broderick Turner, [2]Michael Curran. *[1]Chang Gung Memorial Hospital, Taoyuan City, Taiwan*; *[2]MD Anderson Cancer Center, Houston, TX, United States*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0866

Background Although radiotherapy has been widely adopted in localized colorectal cancer (CRC) treatment, its therapeutic efficacy for distal, non-irradiated tumors remains limited. Ataxia telangiectasia and Rad3- related (ATR) kinase has recently been identified as a key mediator in post-irradiation cancer immune evasion.[1] Here, we aimed to explore the systemic antitumor efficacy of ATR abrogation in combination with radiotherapy and immune checkpoint inhibition.

Methods We assessed the antitumor immune responses of focal radiotherapy, ATR abrogation, and CTLA-4 blockade by using microsatellite instability-high (MSI-H) MC38 and microsatellite stable (MSS) CT26 murine syngeneic CRC models. Flow cytometry, immunoblot, and gene knockdown were adopted to investigate the post-irradiation immune responses.

Results Ionizing radiation triggered the elevation of anti-phagocytic checkpoints, CD47 and PD-L1, in both MC38 and CT26 cells. ATR inhibition or short hairpin RNA knockdown (shATR) prevented RT-induced CD47 and PD-L1 upregulation and sensitized tumor cells to phagocytic clearance by bone marrow-derived antigen-presenting cells (APCs). We observed significantly improved complete response (CR) rates in both irradiated and abscopal tumors and prolonged survival in C57BL/6J mice bearing bilateral MC38-OVA tumors treated with unilateral radiotherapy, an ATR inhibitor, and anti-CTLA-4 antibodies, in comparison to untreated controls or mice undergoing mono- or dual therapies. In the irradiated tumor microenvironment, radiotherapy followed by ATR inhibition and CTLA-4 blockade significantly improved tumor antigen cross-presentation in APCs, increased NK and tumor-specific CD8 T cell infiltration, and decreased regulatory T lymphocyte accumulation. Concordantly, BALB/c mice bearing bilateral shATR-CT26 tumors treated with unilateral fractionated radiotherapy and anti-CTLA-4 antibodies had significantly higher CR rates in both irradiated and abscopal tumors and improved survival, compared with those bearing wild type CT26 tumors. Furthermore, a cecal orthotopic MC38 tumor model consistently demonstrated superior systemic antitumor efficacy of radiotherapy, ATR inhibition, and CTLA-4 blockade combinatorial therapy. Re-implantation of MC38 cells was performed in mice with complete remission of both irradiated and abscopal tumors, and the rechallenged tumors were rejected in all mice in the triple therapy group.

Conclusions Abrogation of ATR potentiates the systemic antitumor immune responses of radiotherapy and CTLA-4 blockade in both MSI-H and MSS murine CRC models.

DECIPHERING OF RADIOTHERAPY-INDUCED IMMUNOMODULATION EFFECT SYNERGIZED WITH IMMUNOTHERAPY IN HEPATOCELLULAR CARCINOMA BY SPATIAL MULTI-OMICS PROFILING

[1]Mai Chan Lau*, [2]Lisda Suteja, [3]Lawrence Cheung, [1]Jeffrey Lim, [1]Chun Jye Lim, [1]Xinru Lim, [4]Neslihan Kaya, [1]Jiang Feng Ye, [1]Felicia Wee, [5]Han Chong Toh, [5]Su Pin Choo, [5]Suat Ying Lee, [5]Joycelyn Jie Xin Lee, [2]Jin Liu, [6]Tony Kiat Hon Lim, [7]Weiwei Zhai, [5]David Tai, [1]Joe Poh Sheng Yeong. *[1]Institute of Molecular and Cell Biology, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]Singapore General Hospital, Singapore, Singapore; [4]Genome Institute of Singapore, Singapore, Singapore; [5]National Cancer Centre Singapore, Singapore, Singapore; [6]Singapore General Hospital, Singapore, Singapore; [7]Chinese Academy of Sciences, Beijing, China*

Background Multiple clinical trials have shown an overall improved response rate in hepatocellular carcinoma (HCC) by combining radiotherapy (RT) with immunotherapy (IO), however, treatment rates remain low and unpredictable.[1] The suboptimal outcomes are largely due to the lack of knowledge of the underlying immunomodulation effect and an effective treatment-response biomarker. Previous studies using tissue-based assays like multiplexed immunofluorescence (mIF) have demonstrated that cellular spatial organization within the tumor microenvironment represents a critical factor influencing anti-tumor immunity.[2, 3] Hence, we sought to characterize the in-situ molecular immune response of RT-treated HCC tissues, to advance our understanding of RT-induced immunomodulation effect and its synergistic benefits with IO.

Methods Using an HCC cohort treated with Yttrium-90 (Y90)-radioembolization (locoregional RT) and anti-PD-1 combination therapy,[1] we profiled the FFPE tissues collected at baseline and post-Y90 from 4 responders and 8 non-responders using NanoString's Digital Spatial Profiler (DSP), 10× Genomics Visium technology, and mIF. In DSP profiling, two types of regions of interest (ROIs) were selected by a pathologist: (1) geometric ROIs far from Y90 beads, and (2) contiguously micro-dissected ROIs contouring the Y90 beads; Visium data contains spatially barcoded spots (figure 1).

Results Tumor Immune Dysfunction and Exclusion (TIDE)[4] analysis using DSP geometric ROIs showed a counter-intuitively decrease of IO-responsiveness (i.e., higher TIDE scores) in responders post-RT. Immune analysis using DSP micro-dissected ROIs revealed that RT might have induced a systemic increase in T-cell exclusion and decrease in T-cell dysfunction in the non-responders, but opposite trends in the responders (figure 2). A possibly RT-induced systemic increase in CD274 (ligand of PD-1) expression was seen in the responders ($P_{treatment} < 0.001$, $P_{distance\text{-}to\text{-}Y90\text{-}beads} = 0.04$). Analysis using the higher-spatial-resolution Visium data showed a systemic increase in cytotoxic T-cell abundance in the non-responders post-RT where the cells were spread over the tissues (figure 3). mIF analysis showed a specific subset of T-cells, $CD38^{+}CD8^{+}$, in the responders preferentially interacted with the tumor cells ($P_{cell\text{-}to\text{-}tumor\ distance} = 0.08$), an effect possibly induced by RT ($P_{cell\text{-}to\text{-}Y90\text{-}bead\ distance} < 0.001$) (figure 4).

Conclusions TIDE, a transcriptomic-based IO-biomarker mainly tested in melanoma, is not directly applicable to HCC. Spatial multi-omics analysis enables identification of RT-specific immunomodulation effects that synergized with IO in HCC, including the systemic increase in T-cell dysfunction and CD274 expression. To explain for the systemic increase of cytotoxic T-cells in non-responders, further investigation on the tumor-specificity by cell-to-cell proximity analysis is needed.

868 CD122-DIRECTED IL-2/ANTI-IL-2 COMPLEXES MASSIVELY EXPAND STEM-LIKE TUMOR-SPECIFIC T CELLS AND ENHANCE ABSCOPAL RESPONSES TO RADIATION AND ANTI-PD-1

Kateryna Onyshchenko*, Ren Luo, Liqun Wang, Gabriele Niedermann. *University Hospital Freiburg, Freiburg im Breisgau, Germany*

Background Early clinical trials have provided evidence for RT-induced systemic effects in conjunction with aPD-1 or IL-2 in metastatic patients, but strong abscopal responses are clinically rare. Dual combinations of aPD-1 with more effective and less toxic IL-2 derivatives, e.g., CD122-directed pegylated IL-2, are also currently under investigation. Whether a combination of RT, aPD-1, and CD122-directed IL-2/anti-IL-2 complexes (IL-2c) can increase abscopal effects against established non-irradiated tumors is unknown. Also, in-depth analyses of the differentiation of tumor-specific $CD8^+$ T cells have not yet been reported for aPD-1/IL-2c. We investigated how adding IL-2c to hRT/aPD1 affects tumor-specific $CD8^+$ T cell differentiation and the potential of this triple combination to enhance the abscopal effect compared to the respective dual treatments.

Methods Mice bearing bilateral tumors were treated with two fractions of 8 Gy (C51 colon carcinoma model) or 12 Gy (B16 melanoma model); aPD1 was given weekly; IL-2c was given for five consecutive days. CD8 T cell-depleting and CXCR3-blocking antibodies were used to determine if the therapeutic effects depend on $CD8^+$ and $CXCR3^+$ T cells. Differentiation stages of tumor-specific $CD8^+$ T cells in tumor-draining lymph nodes, spleen, blood, and tumors were determined flow cytometrically using MHC-I tetramers and various antibodies.

Results The abscopal effect was significantly stronger in triple-treated mice compared to mice treated with RT/aPD1 (C51 model: $p < 0.01$; B16 model: $p < 0.05$), RT/IL-2c (C51 model: $p < 0.01$; B16 model: $p < 0.001$) or aPD1/IL-2c (C51 model: $p < 0.0001$, B16 model: $p < 0.01$). Moreover, triple therapy improved survival and resulted in complete cures of 3/12 mice in the C51 model and 2/12 mice in the B16 model. These anti-tumor effects were associated with dramatic expansion of tumor-specific $CD8^+$ T cells. Undifferentiated stem-like and effector-like but not terminally differentiated exhausted cells particularly strongly increased. Moreover, IL-2c induced CXCR3 mainly on non-terminally differentiated $CD8^+$ T cells. Both $CD8^+$ (C51 model: $p < 0.0001$; B16 model: $p < 0.01$) and $CXCR3^+$ (C51 model: $p < 0.0001$) T cells were crucial for the RT-induced abscopal effect upon RT/aPD-1/IL-2c treatment.

Conclusions RT/aPD-1/IL-2c triple treatment resulted in superior local and systemic expansion of tumor-specific $CD8^+$ T cells with stem- and effector-like phenotypes. Also, IL-2c strongly increased $CXCR3^+$ CD8+ T cells that were associated with pronounced abscopal responses in models with an established metastasis resistant to aPD-1/IL-2c and only transiently responding to RT/aPD-1 or RT/IL-2c. Therefore, such triple combinations appear promising for clinical evaluation in metastatic patients.

869 **NBTXR3-ENHANCED PROTON BEAM IMMUNORADIOTHERAPY RESHAPES TUMOR IMMUNE MICROENVIRONMENT AND IMPROVES ABSCOPAL EFFECT IN AN ANTI-PD1-RESISTANT LUNG CANCER**

[1]Yun Hu*, [2]Sebastien Paris, [1]Narayan Sahoo, [1]Genevieve Bertolet, [1]Qi Wang, [1]Qianxia Wang, [1]Hampartsoum Barsoumian, [2]Jordan SILVA, [1]Ailing Huang, [1]Claudia Kettlun Leyton, [1]Tiffany Voss, [1]Ethan Hsu, [1]Fatemeh Masrorpour, [1]Carola Leuschner, [1]Nahum Puebla Osorio, [1]Quynh Nguyen, [1]Saumil Gandhi, [1]Jing Wang, [1]Maria Cortez, [1]James Welsh. *[1]MD Anderson Cancer Center, Houston, TX, United States*; *[2]Nanobiotix, Paris, France*

Background Proton beam therapy (PBT) has frequently yielded superior results to conventional X-ray therapy. However, combination of PBT with checkpoint inhibitors is rarely reported for treating metastatic cancers. NBTXR3 is a radioenhancer with immunomodulatory capacities able to restore efficacy of anti-PD1 (aPD1) in a model resistant to this treatment with conventional X-ray therapy. Therefore, we hypothesized that addition of NBTXR3 to localized PBT combined with aPD1 could enhance the systemic antitumor immune response in aPD1-resistant lung cancer in mice.

Methods Five groups of 8 mice each were inoculated with $5x10^4$ aPD1-resistant 344SQR murine lung cancer cells in each hind leg, 4 days apart, to establish 'primary' (right, to-be-irradiated) and 'secondary' (left, not-to-be-irradiated) tumors. aPD1 (200 μg) was intraperitoneally administered on days 7, 10, 14, 21, 28, 35, and 42. Primary tumors were intratumorally injected with NBTXR3 on day 7, followed by 12 Gy PBT on days of 8 and 9 (24 Gy total). The immune microenvironment of both irradiated and unirradiated tumors was analyzed through NanoString and single cell sequencing. On day 76, the right flank of the survivor mice treated with NBTXR3+PBT+aPD1 was rechallenged with $5x10^4$ 344SQR cells.

Results The therapies of PBT, PBT+aPD1, NBTXR3+PBT, and NBTXR3+PBT+aPD1 each resulted in significantly delayed growth in both primary and secondary tumors relative to control. In addition, adding NBTXR3 to both PBT and PBT+aPD1 significantly retarded the progress of the two tumors. Remarkably, the combination therapy of NBTXR3 +PBT+aPD1 achieved 37.5% survival rate and the lowest number of lung metastases. Moreover, the survivor mice maintained potent antitumor immunological memory, effectively rejecting tumor re-challenge. NanoString analysis of immune-related genes revealed that the triple therapy (NBTXR3+PBT +aPD1) significantly upregulated the activities of a wide range of antitumor immune pathways in the two tumors. Single cell analysis demonstrated that both PBT+aPD1 and NBTXR3 +PBT+aPD1 increased tumor infiltration by NKT cells, innate lymphoid cells, and $CD8^+$ T cells, $CD4^+$ T cells, and gamma delta T cells, as well as promoted cytotoxic lymphocyte activation. Lastly, PBT-mediated immunoradiotherapy enriched specific TCR repertories that may target tumor antigens.

Conclusions PBT combined with aPD1 was able to potently activate systemic antitumor immunity and effectively control both irradiated and unirradiated tumors. In this context, the addition of NBTXR3 to PBT+aPD1 significantly improved treatment efficacy through modulating the tumor immune microenvironment.

Ethics Approval All mouse studies were approved by the Institutional Animal Care and Use Committee of MD Anderson Cancer Center.

870 HIGH-DOSE RADIATION IS REQUIRED FOR EFFECTIVE COMBINATION WITH TUMOR-SPECIFIC VACCINATION IN A PROSTATE CANCER MODEL

Hemanth Potluri*, Carolina Ferreira, Joseph Grudzinski, Christopher Massey, Reinier Hernandez, Jamey Weichert, Douglas McNeel. *UW-Madison, Madison, WI, United States*

Background The approval of Sipuleucel-T demonstrates the value of antigen-specific vaccination approaches for prostate cancer. We have studied a DNA vaccine specific for the ligand-binding domain of the androgen receptor (pTVG-AR) as a more scalable vaccination approach, though its efficacy is limited by the immunosuppressive prostate microenvironment. Radiation has been shown to sensitize poorly responsive tumors to immunotherapy. Our group has developed a compound, NM600, that is selectively retained by tumors following intravascular delivery, and is therefore capable of delivering radiation systemically to metastases (targeted radionuclide therapy, TRT). In this study, we evaluated whether TRT or external beam radiation therapy (EBRT) in combination with pTVG-AR could improve anti-tumor efficacy by increasing antigen-specific CD8+ T cell tumor infiltration in a murine prostate cancer model.

Methods 6-week old male C57Bl/6 mice were implanted subcutaneously with TRAMP-C1 cells. pTVG-AR or empty vector were administered weekly from the day after tumor implantation. Mice were then given an intravenous injection of 50 ("low-dose") or 250 μCi ("high dose") ^{90}Y-NM600, estimated to deliver a dose of 1-2 Gy or 5-6 Gy to 300 mm^3 tumors, respectively. EBRT was delivered to flank tumors in a single fraction of 6-12 Gy. Groups of mice (n=5) were euthanized at several timepoints for flow cytometry analysis of the tumors. Separate cohorts (n=7) were followed for tumor growth.

Results Single-dose TRT did not have greater anti-tumor efficacy when used in combination with vaccine, regardless of TRT dose or the schedule of the vaccine. Combination treatment did not increase CD8+ T cell infiltration. However, TRT administered twice three weeks apart, in combination with pTVG-AR, significantly slowed tumor growth, unlike fractionated TRT alone (p=0.01). Combination-treated mice did not have greater infiltration of memory CD8+ T cells or T cells more responsive to antigen-specific stimulation. However, PD-1 expression was lower on infiltrating CD8+T cells (p=0.047) and PD-L1 expression was lower on dendritic cells (p=0.004). We then used EBRT to evaluate whether these differences might be dose-dependent. We found that vaccination combined with 12 Gy of EBRT, but not 6 Gy or 8 Gy, elicited a significantly improved anti-tumor response compared with EBRT alone (p<0.001).

Conclusions These data suggest that doses of RT in excess of 8 Gy, higher than what can be delivered by single treatment with ^{90}Y-NM600, may be necessary to optimally combine with antigen-specific vaccines in this model. Further work will explore the mechanism of this potential dose threshold.

871 **IRRADIATION POTENTIATES NK CELLS FOR SURVEILLANCE AGAINST PARENTAL AND CANCER STEM CELLS OF HEPATOCELLULAR CARCINOMA THROUGH LFA-1/ICAM-1 AXIS**

[1]Tung Uong Nguyen Thanh*, [1]Huy Nguyen Phuoc Quang, [2]Mee Sun Yoon. *[1]Chonnam National University, Hwasun, Republic of Korea,; [2]Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea*

Background Radiation therapy (RT) is considered an effective local treatment for downstage or definitive therapy of inoperable localized hepatocellular carcinoma (HCC). However, the potential synergistic effect of RT in combination with local tumor irradiation, immune cytokines, and allogeneic NK cells has not been explored in metastatic liver cancer. In this study, we evaluated the efficacy of combination therapy in both localized and metastatic human liver cancer models.

Methods *Ex vivo* expansion of NK cells from human peripheral blood mononuclear cells was performed by co-culture with irradiated K562 cells. HepG2/HepG2-Luciferase and Hep3B cells were injected into the right lobe of the liver or intraperitoneally injected into NOD-SCID IL2 receptor gamma chain knockout (NSG) mice. A 2 Gy RT was delivered to the peritoneum or liver tumor of NSG mice. A 12 Gy local RT was applied to the HCC subcutaneous tumor. HCC tumor spheres were generated to evaluate the function of combination treatment against liver cancer stem cells (CSCs). Finally, HepG2 and Hep3B ICAM-1 knockout (KO) cells were generated using CRISPR/CAS9 to clarify the role of the LFA-1/ICAM-1 axis in combination therapy.

Results Allogeneic NK cells enhanced recognition and conjugation of irradiated liver cancer cells through the LFA-1(lymphocyte function-associated antigen 1)/ICAM-1(intercellular adhesion molecule-1) axis. In addition, combination with RT and IL-15 also increased allogeneic NK cells' degranulation ability against ICAM-1 positive HCC cell lines. Knock-out ICAM-1 in HepG2 cells significantly reduced the lysis and cytokine release ability of NK cells. The combination therapy significantly improved therapeutic efficacy over the monotherapies against localized liver tumors in subcutaneous (HepG2) and orthotropic (HepG2 and Hep3B) mice models. Interestingly, expanded NK cells pretreated with LFA-1 inhibitor before infusion failed to enhance the therapeutic efficacy against Hep3B tumors compared to RT treatment alone. Knockout ICAM-1 in HepG2 also prevented the combination therapy in controlling tumor growth in the xenografted model. In the metastasis model, the combination therapy enhanced the recognition and lysis of EPCAM+CD133+CD24 + CSCs by NK cells, which led to the improving survival of the mice. Moreover, the deficiency of ICAM-1 in the HepG2 and Hep3B tumor spheres also reduced the cytolysis ability of expanded NK cells. The LFA-1/ICAM-1 axis also correlated with better prognosis in patients with metastasis from the PANCAN database.

Conclusions Our data suggested that combination therapy enhances the ability of allogeneic NK cells to recognize and eliminate both parental and liver CSCs through LFA-1/ICAM-1.

Ethics Approval All animal procedures and experiments were approved by the Institutional Animal Care and Use Committee of Chonnam National University (CNU IACUC-H-2019-7).

872 LIPOSOMAL DOXORUBICIN ENHANCES THE RADIATION-INDUCED ABSCOPAL EFFECT BY PROMOTING THE RELEASE OF TUMOR CELL MITOCHONDRIAL DNA

Liqun Wang*, Ren Luo, Kateryna Onyshchenko, Gabriele Niedermann. *University of Freiburg, Freiburg, Germany*

Background Localized radiotherapy (RT) can cause a T cell-mediated abscopal effect on non-irradiated tumor lesions, particularly in combination with immune checkpoint blockade (ICB). By using syngeneic tumor models, we studied whether adding low-dose doxorubicin to RT and αPD-1 can enhance the RT-induced abscopal effect.

Methods In mice bearing bilateral subcutaneous tumors, the primary tumor was irradiated with 2 × 12 Gy (B16-CD133 melanoma model) or 3 × 8 Gy (MC38 colon carcinoma model). Liposomal doxorubicin (4 mg/kg) was given i.v. once together with RT; αPD1 was given weekly. Tumor growth and survival of mice were determined (5–9 mice per group). Depleting antibodies were used to elucidate whether the abscopal effect depended on $CD8^+$ T cells. Tumor-specific $CD8^+$ T cells were determined flow cytometrically using MHC tetramers and various antibodies. Mitochondrial DNA (mtDNA) was depleted in tumor cells with Zalcitabine. *In vitro*, extracellular (e)ATP release by tumor cells was determined by CellTiter-Glo® 2.0. Tumor cell production of type I Interferon (IFNb1) was measured by ELISA with/without incubation with cGAS-STING pathway inhibitors. CXCL10, cytosolic genomic DNA (gDNA), and cytosolic mtDNA were measured by qPCR.

Results Abscopal tumor control was as follows: RT/αPD-1/doxorubicin > doxorubicin/αPD-1 ($p < 0.01$) ≈ RT/doxorubicin ($p < 0.01$) ≈ RT/αPD-1 ($p < 0.05$) (B16 melanoma model); RT/αPD-1/doxorubicin > RT/αPD-1 ($p < 0.01$) ≈ RT/doxorubicin ($p < 0.001$) ≈ doxorubicin/αPD-1 ($p < 0.01$) (MC38 colon carcinoma model). Experiments with various inhibitors of the cGAS/STING pathway showed that liposomal doxorubicin induced type I IFN through the cGAS/STING pathway ($p < 0.05$ with vs. without inhibitors). In mtDNA-depleted tumor cells, doxorubicin induced less cytosolic mtDNA ($p < 0.001$) (but not less cytosolic genomic DNA), less IFNb1 secretion ($p < 0.05$), less eATP release ($p < 0.0001$), and less CXCL10 ($p < 0.0001$) than in non-mtDNA-depleted tumor cells. Triple therapy with RT, αPD-1, and liposomal doxorubicin induced more mature dendritic cells ($p < 0.05$) and more tumor-specific $CD8^+$ T cells ($p < 0.01$) compared to RT/αPD-1 and doxorubicin/αPD-1 therapy. When $CD8^+$ T cells were depleted or mtDNA-depleted tumor cells were implanted, the doxorubicin-induced enhancement of the abscopal effect was abolished ($p < 0.05$).

Conclusions Single low-dose liposomal doxorubicin can substantially enhance the RT-induced abscopal effect in conjunction with αPD-1. mtDNA leakage induced by doxorubicin appears crucial for the doxorubicin-enhanced RT-induced abscopal effect. These findings may be helpful for the planning of clinical radiochemoimmunotherapy trials in (oligo) metastatic patients.

Ethics Approval All animal experiments were approved by the animal care committee of the Regierungspräsidium Freiburg (registration number: G18-066).

873 **RADIATION-INDUCED DYNAMIC ALTERATIONS IN PD-1/PD-L1 ACTIVITY AND RELEVANT IMMUNE CELL PROFILES DEPENDING ON TREATMENT RESPONSE STATUS IN MOUSE TUMOR MODELS**

[1]Yi Na Yoon*, [2]Yu Jin Lim, [1]Jae-Sung Kim. *[1]Korea Institute of Radiological & Medical Sciences, Seoul, Republic of Korea; [2]Kyung Hee University College of Medicine, Seoul, Republic of Korea*

Background In order to assess the immunologic effects of anti-cancer treatment and their therapeutic implications, we investigated the dynamic changes in programmed death-1 (PD-1)/programmed death ligand-1 (PD-L1) expression patterns caused by radiotherapy (RT).

Methods In the CT26 mouse model, local RT with 2 Gy × 5 or 7.5 Gy × 1 was treated on the tumors. Tumors were excised and analyzed at certain time points depending on radiation response status: baseline, early (immediately after RT), middle (beginning of tumor reduction), late (stable state with RT impact), and progression (tumor regrowth). The activity of PD-1/PD-L1 and associated immune cell profiles were quantitatively measured.

Results RT potentiated PD-L1 expression levels in tumor cells from the middle to the late phase, which thereafter dropped to the equivalent PD-L1 levels to baseline in the progression phase. The fractionated RT treatment resulted in a lower degree of tumor regression than the 7.5 Gy regimen, although the frequency of PD-L1$^+$ myeloid-derived suppressor cells remained greater. In the progression phase, the frequency of PD-1+ and interferon (IFN)-γ$^+$ CD8 T cells was increased, meanwhile the mean fluorescence intensity (MFI) values of IFN-γ started to drop. The proportion of PD-1$^+$CD8$^+$ T cells in the spleen was dramatically increased and maintained longer with 2 Gy × 5. Further, we confirmed that RT promoted the overall transcription levels of immune-related genes in the transcriptome data, supporting previously confirmed sequential patterns.

Conclusions According to time-course radiation responses, the dynamic changes in PD-1/PD-L1 activity were analyzed. The sequential patterns and dose-fractionation effects should be considered to determine relevant radioimmunotherapy regimens.

874 OPTIMIZING A COMBINATION RADIO-IMMUNOTHERAPY REGIMEN IN A PRECLINICAL MODEL OF TREATMENT-RESISTANT, HIGH-RISK NEUROBLASTOMA

Lauren Zebertavage*, Amy Erbe, Taylor Aiken, Allison Schopf, Megan Nielsen, Sydney Katz, Zachary Morris, Alexander Rakhmilevich, Paul Sondel. *University of Wisconsin, Madison, WI, United States*

Background Neuroblastoma (NBL), a cancer derived from neural crest precursor cells, is the most common extra-cranial solid tumor in children, with a median age of diagnosis of 22 months. Patients diagnosed with NBL are segmented into prognostic categories with ~50% categorized as high-risk (HR). Of these patients, ~40% are refractory to, or relapse following, initial treatment; there are currently no effective treatment options for these patients once they have failed salvage therapy of chemotherapy combined with αGD2 therapy (dinutuximab). Our group has previously published work developing a **c**ombination **a**daptive and **i**nnate immunotherapy **r**egimen, "CAIR", to treat a murine model of treatment-resistant, HR-NBL.[1,2] CAIR utilizes αGD2 immunocytokine (hu14.18-IL2), radiotherapy (RT), αCD40, CpG, and αCTLA4 but questions remain about the relative contribution of each component. In this study, we tested if our model of HR-NBL is resistant to salvage therapy of temozolomide and irinotecan (TEM+IRI) and αGD2-based therapy and if components of our effective CAIR therapy can be removed, in order to determine their necessity.

Methods To establish 9464D-GD2 as a model for treatment-resistant, HR-NBL, tumor-bearing mice were treated with TEM+IRI and/or hu14.18-IL2. To establish the necessity of each component of CAIR, mice bearing 9464D-GD2 tumors were treated with CAIR (12Gy RT, αCD40, αCTLA4, CpG, and hu14.18-IL2) or variations of CAIR subtracting one component.

Results Salvage therapy of TEM+IRI and/or hu14.18-IL2 extended the survival of mice ($p<0.03$) but did not result in 9464D-GD2 tumor cures. Adding RT (12Gy, SARRP) improved survival ($p<0.0001$), but not more than RT alone ($p=0.29$), and still did not cure tumors.

Removing RT or hu14.18-IL2 from CAIR dramatically shortened survival ($p<0.0001$) and yielded few tumor cures (1/16, 0/16 versus 13/30). Conversely, removing αCD40, αCTLA4, or CpG did not alter survival ($p=0.81$, $p=0.85$, $p=0.70$) relative to CAIR, and resulted in similar rates of tumor cures (8/16, 9/21, 7/16 versus 13/30). Removing two of the "expendable" components (αCD40, αCTLA4, CpG) generally reduced efficacy, with only CAIR subtracting CpG and αCTLA4 (RT, hu14.18-IL2, and αCD40) curing a similar number of mice as CAIR (3/16 versus 13/30, survival $p=0.12$).

Conclusions Here we demonstrate that 9464D-GD2 tumors behave similarly to human HR-NBLs that fail to be cured by salvage therapy. In contrast, these tumors can be cured by both CAIR therapy and by several versions of a reduced CAIR therapy (CAIR subtracting αCD40, αCTLA4, or CpG). We are now exploring the role of each component of CAIR in anti-tumor immune responses in this immunologically cold model.

875 TARGETING CCR8-EXPRESSING TUMOR INFILTRATING TREGS IN COMBINATION WITH RADIOTHERAPY ENHANCES ANTI-TUMOR IMMUNITY

Yurun Zhang*, Vikash Bhagwandin, Sandra Hatcher, Ziyun Ding, Liang Tang, Ricky Sharma, Sophia Pfister. *Varian, a Siemens Healthineers Company, Los Altos, CA, United States*

Background Tumor infiltrating Tregs (TITRs) negatively regulates anti-tumor immunity and promotes tumor progression. Increased level of TITRs has also been associated with poor prognosis in multiple cancer types which led to identification of several TITR specific therapeutic targets. Chemokine receptor CCR8 is highly enriched in the TITR population. Depletion of TITR via anti-CCR8 antibody resulted in potent anti-tumor efficacy as single agent in checkpoint inhibitor responsive syngeneic models.[1] At Varian, immune profiling of *ex vivo* irradiated human head and neck tumors showed decreased viability in $CD4^+$ and $CD8^+$ T cells but not in the TITR population, which suggest depleting TITR as a therapeutic strategy to improve efficacy of radiotherapy (RT). Here, we hypothesized that combining anti-CCR8 with RT improves anti-tumor response via TITR depletion.

Methods To investigate the therapeutic potential of combining anti-CCR8 with RT, female Balb/c mice were orthotopically implanted with 4T1-Luc2-1A4 cells in mammary fat pad followed by focal radiation. Implanted mice were irradiated at 0 or 10 Gy on day 7 post-implantation. Anti-mouse CCR8 depleting antibody (BioLegend) or isotype control was administered intraperitoneally at 10 mg/kg on day 7, 10, and 14 post-implantation. Tumor measurements were taken three times per week for 47 days for efficacy evaluation. On day 15 post-implantation, treated and non-treated tumors were harvested for flow cytometric and bulk-RNA sequencing analyses.

Results Combining anti-CCR8 treatment with 10 Gy radiation significantly improved anti-tumor efficacy compared with anti-CCR8 treatment alone or radiation treatment alone. One day following completion of anti-CCR8 treatment, we observed increased percentage of $CD8^+$ T cells ($p < 0.01$) and decreased percentage of TITRs ($p < 0.05$) in anti-CCR8-treated and irradiated tumors versus anti-CCR8 treatment alone. Tumor $CD8^+$ T cells also demonstrated increased expression of activation marker CD39 ($p < 0.01$) in anti-CCR8 plus RT treated tumors. At the transcriptional level, combination of anti-CCR8 with radiation upregulated pathways associated with TNF-α and IFN-γ response in comparison to single-agent treatment, suggesting activation of anti-tumor immunity via enhanced T cell activation. Furthermore, anti-CCR8 plus RT significantly prolonged survival of tumor-bearing mice (78% alive) compared with anti-CCR8 treatment alone (11% alive).

Conclusions Our preclinical data demonstrate high therapeutic potential of combining anti-CCR8 depleting antibody with radiotherapy to trigger synergistic enhancement of immune response in tumors that are refractory to immune checkpoint blockade. In conclusion, targeting CCR8-expressing TITRs in combination with radiotherapy displayed superior anti-tumor activity and prolonged survival than single-agent treatment alone.

876 VOLUMETRIC MUSCLE LOSS INJURY IMPACTS MURINE TUMOR GROWTH AND RESPONSE TO IMMUNE CHECKPOINT BLOCKADE THERAPY

Anna Ruta*, Jordan Garcia, Locke Davenport Huyer, Joscelyn Mejias, Kavita Krishnan, Helen Nguyen, Elise Gray-Gaillard, Jin Han, Andrew Pardoll, Jennifer Elisseeff. *Johns Hopkins University, Baltimore, MD, United States*

Background Tumor resection and subsequent surgical reconstruction is a prevalent, often effective, treatment approach for many operable solid cancers. Unfortunately, post-operative surgical trauma and tissue injury induce major physiological stressors (i.e. acute inflammation and subsequent wound-healing) that can contribute to cancer progression, recurrence and metastatic spread. In this study, we investigate whether effectively treating distal tissue injuries with biologically-derived wound-healing therapeutics can help mitigate injury-induced accelerated tumor progression. Given the numerous clinical trials underway that couple surgical intervention with (neo)adjuvant immune checkpoint blockade (ICB) treatment, we further explore whether physiological stress due to tissue injury can impact tumor responsiveness to ICB therapy.

Methods A concurrent biological insult murine model was established in which a bilateral volumetric muscle loss (VML) injury, consisting of a 3x4mm excisional defect performed in the quadricep muscles, is followed by subcutaneous inoculation of syngeneic cancer cells on the flank (CT26 colon carcinoma and B16F10 melanoma, 100,000 cells/mouse). Wound-healing was promoted by directly implanting a porcine-derived decellularized extracellular matrix (ECM) scaffold into the muscle injury site. The ICB treatment regimen consisted of either aPD1 (5mg/kg, RMP1-14) monotherapy or aPD1/aCTLA4 (5mg/kg, 9H10) combination therapy delivered via intraperitoneal injection for 4 total doses. Tumor size was measured every 2-3 days with predetermined survival criteria of tumor volume >1500mm^3. The immunological landscape of tumors and draining lymph nodes was assessed via high-parameter flow cytometry, transcriptional analysis (RT-qPCR, bulk RNA sequencing) and immunofluorescence staining of paraffin-embedded tissue sections.

Results VML injury accelerated CT26 and B16F10 tumor growth in comparison to the non-injured control group. However, treatment of the VML injury site with pro-regenerative ECM scaffold slowed tumor progression to match the non-injured baseline. Tumors harvested from mice with ECM-treated muscle injuries displayed an elevated type 2 immune signature, marked by CD206+ M2 macrophages and interleukin (IL)-4 production by CD4+ T cells and myeloid cells. Lastly, mice with concurrent VML injury exhibited impaired response to ICB treatment measured by faster tumor growth and shortened overall survival.

Conclusions Physiological stress induced by tissue injury can impact tumor growth kinetics, immunological phenotype of tumor microenvironment, and responsiveness to ICB therapy. Treatment of injury site with wound-healing biomaterials may offer a novel approach to reducing exacerbated tumor outcomes. Further studies will help discern the immunological mechanisms that connect concurrent tissue injury and tumor insults.

Ethics Approval All animal studies were performed in accordance with approved Johns Hopkins University Animal Care and Use Committee protocol (Elisseeff, MO21M80).

877 BLOCKING SOLUBLE TNFα SENSITIZES HER2-POSITIVE BREAST CANCER TO TRASTUZUMAB THROUGH MUC4 DOWNREGULATION AND SUBVERTS IMMUNOSUPPRESSION

[1]Sofia Bruni*, [2]Mara De Martino, [1]Florencia Mauro, [1]Maria Mercogliano, [1]Cecilia Proietti, [1]Rosalia Cordo-Russo, [1]Patricia Elizalde, [1]Roxana Schillaci. *[1]Instituto de Biologia y Medicina Experimental (IBYME-CONICET), Buenos Aires, Argentina; [2]Department of Radiation Oncology, Weill Cornell Medical College, New York, NY, United States*

Background Trastuzumab resistance is an important clinical issue. Although a plethora of resistance mechanisms have been characterized, few have been shown to be actionable. We have demonstrated that soluble TNFα isoform (sTNFα) upregulates mucin 4 (MUC4) expression, which shields the trastuzumab epitope on HER2, hindering its therapeutic effect *in vitro* and *in vivo*.[1,2] Since the success of trastuzumab treatment relies on immune response, we addressed the role of MUC4 on modulating the tumor immune infiltrate to foster immune evasion in sTNFα-induced trastuzumab-resistant HER2-positive (HER2 +) breast cancer.

Methods *De novo* trastuzumab-resistant JIMT-1 and KPL-4 cell lines were engineered to express a doxycycline-inducible MUC4 shRNA (JIMT-1-shMUC4 and KPL-4-shMUC4, respectively). Female nude mice bearing these s.c. tumors (~100 mm^3), were treated i.p with IgG or trastuzumab (5mg/kg), a dominant negative (DN) sTNFα inhibitor (10 mg/kg) or trastuzumab+DN (n=4-6 per group). After 3 weeks of treatment, tumor-infiltrating immune cells were studied by immunofluorescence and flow cytometry. For macrophage and NK cell depletion, clodronate or anti-asialo GM1 was used, respectively. ADCP was studied using parental JIMT-1 cells pre-cultured for 48h with DN (10 μg/ml) or vehicle and then co-cultured with human macrophages for 1.5 h. A cohort of 91 HER2+ breast cancer patients treated with trastuzumab was used to correlate tumor MUC4 expression with tumor-infiltrating lymphocytes (TILs).

Results Upon MUC4 silencing through doxycycline induction, trastuzumab antitumor effect was reinstated (80% or 85% tumor growth inhibition, JIMT-1-shMUC4 or KPL-4-shMUC4, respectively; $p<0.0001$). The addition of DN did not further decrease tumor burden. In the absence of doxycycline, trastuzumab+DN inhibited tumor growth and modified the immunosuppressive tumor milieu, increasing M1-like macrophage polarization ($p<0.01$) and NK cell degranulation ($p<0.01$). In MUC4-silenced tumors, trastuzumab treatment alone mimics this tumor infiltrate. Depletion experiments revealed a cross-talk between macrophages and NK cells necessary for trastuzumab+DN antitumor effect. When MUC4 was silenced, trastuzumab antitumor effect was lost upon macrophage depletion, but it was preserved when NK cells were absent. Furthermore, JIMT-1 cells pre-treated with DN were more susceptible to trastuzumab-dependent cellular phagocytosis ($p<0.05$). Finally, MUC4 expression in HER2+ breast cancer negatively correlated with TILs ($p=0.004$), reflecting "immune desert" tumors.

Conclusions In all, we conclude that sTNFα isoform blockade is able to tackle MUC4 expression and, together with trastuzumab, triggers an effective antitumor immune response that relies on M1-macrophage-NK cell collaboration. These findings provide rationale to pursue sTNFα blockade combined with trastuzumab or trastuzumab drug-conjugates for MUC4+ and HER2+ breast cancer patients to overcome trastuzumab resistance.

878 **BET INHIBITION SENSITIZES IMMUNOLOGICALLY-COLD RB-DEFICIENT PROSTATE CANCER TO IMMUNE CHECKPOINT BLOCKADE VIA DNA DAMAGE-INDUCED STING/NF-κB/TYPE I IFN SIGNALING**

[1]Kiranj Chaudagar, [2]Marguerite Li*, [2]Christina Hong, [1]Srikrishnan Rameshbabu, [1]Raymond Chen, [2]Alison Thomas, [2]Brian Olson, [1]Akash Patnaik. *[1]University of Chicago, Chicago, IL, United States; [2]Emory University, Atlanta, GA, United States*

Background Non-T cell-inflamed immunologically "cold" tumor microenvironments (TME) are associated with poor responsiveness to immune checkpoint blockade (ICB), and can be sculpted by tumor cell genomics. We have previously described how Retinoblastoma (Rb) tumor suppressor loss of function, one of the most frequent alterations in human cancer and associated with lineage plasticity, poor prognosis and therapeutic outcomes, promotes an immunosuppressive TME *in vitro* and *in vivo*. Here, we evaluated how inhibition of the bromodomain and extraterminal (BET) domain family can reverse the consequences of Rb loss to enhance the efficacy of ICB.

Methods Wild-type or Rb-deficient murine MycCaP tumor cells were evaluated *in vitro* and *ex vivo* for how BET inhibition (BETi) alters DNA damage and type I IFN signaling pathways by qRT-PCR, Western blot, ELISA, and ImageStream analysis. Tumor-bearing animals were treated with BETi (alone or with STING or NF-κB inhibition), and immune infiltration into the TME was evaluated by flow cytometry. Anti-tumor responses to BETi was evaluated in the presence or absence of T cell and/or macrophage depletion. Finally, BETi was combined with PDL1 blockade, with or without androgen deprivation therapy (ADT), and anti-tumor responses were evaluated in the presence or absence of STING/NF-κB blockade.

Results BETi was found to increase tumor cell-intrinsic DNA damage, which induced STING/NF-κB signaling and type I IFN expression and T cell migration in Rb-deficient tumor cells, in part due to increased baseline STING expression following Rb loss. *In vivo* BETi treatment increased T cell infiltration into the TME and suppressed Rb-deficient tumor growth that were T cell- and macrophage-dependent as well as STING/NF-κB-dependent. BETi alone increased PD-1 expression on tumor-infiltrating T cells and PD-L1 expression on suppressive M2 and MDSC populations *in vivo*, resulting in increased susceptibility to combined BETi and PDL1 blockade in Rb-deficient tumors *in vivo*. Finally, ADT further enhanced the efficacy of BETi and ICB in a STING/NF-κB-dependent fashion.

Conclusions These data demonstrate that BETi increases immune infiltration into the immunologically-cold Rb-deficient TME via activation of tumor cell-intrinsic STING/NF-κB activation and type I IFN signaling within tumor cells. This results in differential macrophage and T cell-mediated inhibition of Rb-deficient prostate tumor growth and sensitization of Rb-deficient prostate cancer to ICB. This provides the mechanistic rationale to test combinations of ADT, BETi and ICB in clinical trials of Rb-deficient hormone-sensitive metastatic prostate cancer.

879 REVERSAL OF LACTATE AND PD-1-MEDIATED MACROPHAGE IMMUNOSUPPRESSION CONTROLS GROWTH OF PTEN/P53-DEFICIENT PROSTATE CANCER

[1]Akash Patnaik*, [1]Kiranj Chaudagar, [1]Hanna Hieromnimon, [2]Taghreed Hirz, [2]Shenglin Mei, [2]David Sykes. *[1]University of Chicago, Chicago, IL, United States; [2] Massachusetts General Hospital, Boston, MA, United States*

Background There has been renewed interest in immunotherapy for the treatment of advanced prostate cancer (PC), partly based on the anti-tumor immune activation that occurs with ADT, and partly based on the clinical responses to immune checkpoint inhibitors (ICI) targeting CTLA-4 and PD-1/PD-L1 in other cancers.[1-3] However, only 10-25% of metastatic castrate-resistant prostate cancer (mCRPC) patients respond to ICI, with a lack of durable benefit in the majority of patients.[4-5] PTEN LOF alterations, which occur in approximately 50-75% of mCRPC patients, are associated with poor prognosis, development of metastases,[6-8] and immunosuppressive tumor microenvironment.[9-11] Given the aggressive natural history and poor therapeutic outcomes of PTEN-mutant advanced PC to standard-of-care hormonal therapies,[6] chemotherapies[12] and ICI,[10] a deeper understanding of immune evasion mechanisms is critical for the discovery of new therapeutic strategies to effectively treat this molecular subset of AVPC.

Methods Prostate-specific PTEN/p53-deficient genetically engineered mice (GEM) (40) were screened for autochthonous prostate tumor development and monitored for response to therapy by ultrasound and MRI, respectively. Following the development of 150-200 mm^3 solid tumors, the mice were treated with either androgen deprivation therapy (degarelix), PI3K inhibitor (copanlisib), or PD-1 antibody, as single agents or their combinations. Harvested tumors following *in vivo* treatment underwent flow cytometry, or utilized for *ex vivo* studies on single cell suspensions or sorted TAM. Single cell RNAseq on human metastatic bone and lymph node samples were performed using established methods.[13]

Results We performed co-clinical trials in prostate-specific PTEN/p53-deficient genetically engineered mice, and discovered that recruitment of PD-1-expressing tumor-associated macrophages (TAM) thwarts androgen deprivation therapy (ADT)/PI3K inhibitor (PI3Ki) combination-induced tumor control. Strikingly, we observed TAM-dependent ~3-fold increased anti-cancer response with ADT/PI3Ki/PD-1 antibody (aPD-1) combination. Mechanistically, decreased lactate production from PI3Ki-treated tumor cells suppressed histone lactylation within TAM, resulting in their phagocytic activation, which was augmented by ADT/aPD-1 treatment and attenuated by feedback activation of Wnt/β-catenin-pathway. Furthermore, single-cell RNA-sequencing analysis in mCRPC patient biopsy samples revealed a direct correlation between high glycolytic activity and TAM phagocytosis suppression.

Conclusions Our findings demonstrate that immunometabolic strategies to reverse lactate and PD-1-mediated TAM immunosuppression by PI3Ki and aPD-1, respectively, in combination with ADT, controls tumor growth and warrants further clinical investigation in PTEN/p53-deficient mCRPC.

880 **ACTIVATION OF STAT3 SIGNALING IS ASSOCIATED WITH RESISTANCE TO IMMUNE CHECKPOINT INHIBITORS IN PATIENTS (PTS) WITH METASTATIC RENAL CELL CARCINOMA (MRCC)**

[1]Alexander Chehrazi-Raffle*, [1]Marice Alcantara, [2]Nazli Dizman, [1]Wilson Tang, [1]Luis Meza, [1]Zeynep Zengin, [1]Dongfang Wang, [1]Dayson Moreira, [1]Daniela Castro, [1]Ameish Govindarajan, [3]Alan Horsager, [1]JoAnn Hsu, [1]Sumanta Pal, [1]Marcin Kortylewski. *[1]City of Hope Comprehensive Cancer Center, Duarte, CA, United States; [2]Yale University School of Medicine, New Haven, CT, United States; [3]Duet Biotherapeutics, Pasadena, CA, United States*

Background Frontline nivolumab plus ipilimumab (N+I) has dramatically improved outcomes in mRCC pts. Nevertheless, only a minority of pts achieve an objective response to therapy. We investigated whether serum cytokine dynamics in pts receiving N+I can elucidate immunotherapy resistance mechanisms. We also evaluated targeted STAT3 inhibition combined with anti-PD-1 in a preclinical model.

Methods Pts who received N+I as first-line treatment of mRCC with baseline and week 12 (+/- 4 weeks) blood samples were identified using an institutional database. Spectral cytometry was used to investigate alterations in immune populations, and the Human Cytokine 30-plex protein assay (Invitrogen) was used to measure circulating cytokines. viSNE projection of peripheral blood analyzed using spectral cytometry was investigated for expression of PD-L1 and STAT3 activation. For studies utilizing syngeneic mouse models of RCC, 6-8 week female Balb/C mice were injected subcutaneously with 500,000 RENCA cells resuspended in a 1:1 ratio of 1x PBS and Matrigel. Mice were treated with either PBS, IgG, CpG-STAT3ASO (a novel oligonucleotide-based TLR9 activator and STAT3 inhibitor), anti-PD-1, or CpG-STAT3ASO plus anti-PD-1. Immune alterations in tumor were assessed via flow cytometric analysis of tumor and in tumor draining lymph nodes. Statistical significance was determined using two-way ANOVA or Wilcoxon signed ranked test with SEM.

Results We evaluated 37 mRCC pts (30:7 M:F) who received N+I, most of whom had clear cell histology (89%) and were IMDC intermediate-risk (76%). Sixteen pts (43%) achieved an objective response, all of which were partial responses. A significant increase in plasma concentrations of cytokines IL-6 ($p=0.0046$), IL-8 ($p=0.0174$), IP-10 ($p=0.0067$), IL-2R ($p=0.0174$), and IL-1RA ($p=0.0079$) as well as high pSTAT3 levels were observed in pts who did not respond to N+I. In our syngeneic mouse models, the anti-PD-1 plus CpG-STAT3ASO cohort demonstrated significant tumor growth inhibition vs PBS ($p=0.0006$), anti-PD-1 ($p=0.0285$), and CpG-STAT3ASO ($p=0.0353$) cohorts along with a 4-fold decrease in mean tumor growth when compared to the PBS cohort.

Conclusions Pts unresponsive to N+I exhibited significant increases in cytokines stimulating STAT3 signaling (IL-6, IL-8, and IL-2R) as well as higher levels of active pSTAT3. In addition, our preclinical models indicate that administering anti-PD-1 plus CpG-STAT3ASO leads to significant tumor growth restriction compared to either agent alone. Taken together, these findings suggest that STAT3 activation may be a key mediator of tumor immune evasion and support further exploration of targeting STAT3 in tumor-associated myeloid cells in combination with anti-PD-1 therapy in mRCC.

Ethics Approval The protocol was approved by the institutional scientific review committee, data safety monitoring board, and the institutional review board at the City of Hope Comprehensive Cancer Center. The study conformed with the amended Declaration of Helsinki and the International Conference on Harmonization Guidelines.

881 SIGNIFICANT THERAPEUTIC EFFECTS OF ANTI-ROR1 CAR NK AGAINST NEUROBLASTOMA BY ONCOLYTIC VIRUS ARMORED WITH IL-21 *IN-VITRO* AND *IN-VIVO*

[1]Yaya Chu*, [1]Meijuan Tian, [2]Uksha Saini, [2]Dean Lee, [2]Timothy Cripe, [2]Elaine Mardis, [3]Gregory Behbehani, [4]Stanley Riddell, [2]Kevin Cassady, [1]Mitchell Cairo. [1]*New York Medical College, Valhalla, NY, United States*; [2]*Nationwide Children's Hospital, Columbus, OH, United States*; [3]*The Ohio State University, Columbus, OH, United States*; [4]*Fred Hutchinson Cancer Research Center, Seattle, WA, United States*

Background Metastatic and relapsed/refractory neuroblastoma (NB) has very poor diagnosis.[1] Novel therapies are desperately needed.[2] ROR1 is overexpressed in a variety of human cancers including NB.[3-5] Our group has successfully expanded peripheral blood NK cells (exPBNKs) and modified exPBNK cells to express chimeric antigen receptor (CAR).[6]. Oncolytic herpes simplex viruses (oHSVs) have been safely used in clinical trials for a wide range of cancers.[7]. IL-21 sustained the survival and increased the cytotoxicity of NK cells.[8] We sought to determine the anti-tumor effect of anti-ROR1 CAR engineered exPBNK cells (CAR-exPBNKs) against ROR1$^+$ NB and if the anti-tumor efficacy can be improved by oHSV engineered to express human IL21.

Methods NK cells were expanded and electroporated with anti-ROR1-CAR mRNA. oHSV C134 was modified to express hIL-21 gene (C021). In-vitro cytotoxicity and cytokines levels of CAR-exPBNKs against NB cell lines were examined as we previously described (2). In-vivo hIL21 secretion and anti-tumor effect of CAR-exPBNKs with or without the C021 was examined utilizing human NB xenografted NSG mice.

Results NK cells were significantly expanded by co-culture with irradiated K562-mbIL21 cells at 14 days (>2000 folds), and expanded NK cells were isolated with more than 95% purity. Anti-ROR1-CAR was expressed on >90% of exPBNK cells after CAR mRNA electroporation. CAR-exPBNK cells had significantly enhanced in-vitro cytotoxicity compared to Mock-exPBNK against ROR1+ SKNBE(2)N, CHLA-255, and SKNFI NB cells at different E:T ratios ($p<0.001$) regardless of MYCN amplification status. Expression of CD107a and IFN-g were significantly increased in CAR-exPBNK cells compared to Mock-exPBNK ($p<0.05$). CyTOF analysis showed that phosphorylation of STAT5 was enhanced in CAR-exPBNK when targeting NB as compared to exPBNK cells. In-vivo study showed that CAR-exPBNK significantly extended mice survival in human NB xenografted NSG mice ($p<0.01$) (figure 1). Furthermore, the combination of C021 and CAR-exPBNK significantly enhanced the killing of NB with significantly enhanced secretion of IFN-g, granzyme B and perforin and significantly enhanced expression of NK activating marker CD25 (all $p<0.05$) compared to controls. Our in-vivo animal study showed that NB infected with C021 secreted hIL21 and the combination of C021 and CAR-exPBNK cells reduced tumor burden in human NB xenografted NSG mice compared to the untreated group ($p<0.05$) and the CAR exPBNKs-treated group ($P=0.056$) (figure 2).

Conclusions Our data demonstrate the significant anti-tumor efficacy of combining C021 with anti-ROR1 CAR-exPBNKs to therapeutically target NB in-vitro and in-vivo. (Funded by U54 CA232561).

882 USING ONCOGENIC PATHWAY AGONISM TO SENSITIZE RAS MUTANT CANCERS TO IMMUNOTHERAPY

[1]Alvaro De Mingo Pulido, [2]Charles Adelmann, [1]Kim Nguyen, [1]Cynthia Dixey, [1]Francisca Beato, [1]Karol Prieto, [1]Marco Napoli, [1]Elsa Flores, [1]Karen Mann, [1]Jason Fleming, [1]Kenneth Tsai*. *[1]H. Lee Moffitt Cancer Center, Tampa, FL, United States*; *[2]MD Anderson, Houston, TX, United States*

Background Overall, 30% of human cancers are driven by mutant *RAS* proteins. While immunotherapy is effective for *NRAS*-mutant melanoma, no options exist for resistant disease, and mutant KRAS-driven lung and pancreatic carcinomas are much less responsive. Oncogenic pathways are key targets for inhibition. However, pathway agonism has not been explored as a therapeutic approach. BRAF-mutant melanomas respond to BRAF inhibitors (BRAFi) due to decreased ERK signaling. They can recover signaling by acquiring activating RAS/MEK mutations, but exhibit decreased proliferation in the absence of inhibitor, suggesting that supraphysiologic ERK signaling also compromises fitness. Therefore, we observed that increasing ERK hyperactivation in RAS-mutant cancers might elevate ERK signaling, inducing senescence, and creating an inflammatory tumor microenvironment (TME)

Methods BRAFi have been used to study senescence by different assays. *In vivo* assays were performed in C57/Bl6 treated with BRAFi with/without anti-PD1 therapy to study tumor progression. Tumors single cell suspension was used for immunophenotyping by Flow Cyometry and scRNASeq data

Results We have shown that 15/21 RAS-mutant cancer cell lines undergo senescence following exposure to all FDA-approved BRAF inhibitors. Simultaneous MEK or ERK inhibition allows the cells to recover proliferation, and a BRAFi which does not induce ERK activation fails to have any effect, showing that ERK hyperactivation is the key driver of this response. Furthermore, our extensive preliminary data in two novel genomically-characterized, high TMB immunocompetent models of *NRAS*-mutant melanoma and *KRAS*-mutant pancreatic adenocarcinoma support our in vitro findings. Both murine models have shown that anti-PD1 therapy is more efficacious when mice are additionally treated with BRAFi. Molecular profiling of the TME reveals the expression of cytokines related to senescence and marked infiltration of activated CD8+ T-cells. To implement effective immunotherapies, we have analyzed the expression of different immune-checkpoint molecules and we have observed a high expression of LAG3 and TIM3 in the melanoma *NRAS*-mutant model treated with BRAFi. We will further analyze the effect of those checkpoints in combination with BRAFi to potentiate the anti-tumoral responses and tumor regression

Conclusions Oncogenic pathway agonism is a novel, effective, and untested strategy to induce proliferation arrest and sensitization to immunotherapy. The impact of this data is in the ability to broadly sensitize *RAS*-mutant cancers to immunotherapy in the settings of de-novo and acquired resistance. The direct connection between a tumor cell signaling vulnerability to immunotherapy response is a major point of novelty and provides a clear rationale for pursuing combined targeted and immunotherapy

883 **MCLA-145, AN ANTI CD137×PD-L1 BISPECIFIC ANTIBODY, INDUCES T CELL ACTIVATION AND PROLIFERATION IN EX VIVO MODELS OF HEPATOCELLULAR CARCINOMA**

[1]Jyaysi Desai*, [1]Lissane Noordam, [1]Patrick Boor, [2]Rachid Bouzid, [2]Diana Mittag, [2]Paul Tacken, [2]Jeroen Lammerts van Bueren, [2]Cecile Guijen, [1]Jaap Kwekkeboom, [1]Dave Sprengers, [1]Sonja Buschow. [1]*Erasmus Medical Center, Rotterdam, Netherlands*; [2]*Merus N.V., Utrecht, Netherlands*

Background Costimulatory molecules, such as CD137 (4-1BB), have emerged as promising targets for cancer immunotherapy. Despite promising results in animal tumor models, clinical trials with CD137 agonists have had limited success due to both dependency on FcgR-mediated clustering and dose limiting hepatotoxicity. Merus has developed an Fc-silenced Biclonics® CD137×PD-L1 antibody, MCLA-145, whose stimulatory activity is correlated with PD-L1-mediated CD137 clustering which is designed to be preferentially confined to the PD-L1 expressing tumor microenvironment. The aim of this study was to characterize the mechanism of action of MCLA-145 in resected hepatocellular carcinoma (HCC), a heterogenous solid tumor with limited therapeutic options. We studied target expression and *ex vivo* responses in human HCC tumor-infiltrating lymphocytes (TIL).

Methods Lymphocytes and myeloid cells isolated from resected HCC (n=10) tumors (TIL), paired tissues adjacent to tumor (TFL) and peripheral blood were characterized for CD137, PD-1 and PD-L1 expression by flow cytometry. Additionally, TIL proliferation upon either anti-CD3/CD28 stimulation or autologous B cell blasts electroporated with tumor-associated antigens (TAA) glypican-3 (GPC3) and/or melanoma-associated antigen (MAGE)-C2 stimulation was assessed *ex vivo* in presence of MCLA-145, its bivalent monospecific parental mAbs, the bivalent mAbs urelumab (anti-CD137) or atezolizumab (anti-PD-L1) or isotype control.

Results Compared to lymphocytes derived from adjacent tissues and blood, CD137 and PD-1 expression was found to be highest in TIL, and specifically on activated regulatory T cells. CD137 was also found to be expressed on myeloid cells such as tissue resident Kupffer cells and granulocytes. PD-L1 was mainly found to be expressed on $CD3^-$ cells. Treatment with MCLA-145 led to increased proliferation, as measured by Ki67 staining, of HCC-derived CD8+ TILs, compared to isotype control treatment. Expression of CD137 was significantly increased on these proliferating CD8 T cells upon the treatment with MCLA-145. Additionally, MCLA-145 enhanced CD8+ TIL proliferation more potently compared to its bivalent monospecific parent mAbs or Urelumab.

Conclusions Biclonics® antibody MCLA-145 has the capacity to enhance activation and proliferation of tumor-derived CD8 + T cells in the PD-L1 expressing tumor microenvironment of HCC *ex vivo*, warranting further evaluation in HCC.

Ethics Approval Ethical approval (METC) for this study has been obtained.

884 PERK INHIBITOR HC-5404 DEMONSTRATES IMMUNE-ACTIVATION AND ANTI-TUMOR EFFICACY IN COMBINATION WITH ANTI-PD1 IMMUNE CHECKPOINT INHIBITOR ANTIBODY

Anissa SH Chan*, Jeremy Drees, Yunfang Li, Takashi Kangas, Weiyu Zhang, Maria Fumagalli, Iman Dewji, Xiaohong Qiu, Nick Collette, Ben Harrison, Ashley LaCayo, Veronica Calvo Vidal, Crissy Dudgeon, Michael Stokes, Eric Lightcap, David Surguladze, Nandita Bose. *Hibercell, Inc., Roseville, MN, United States*

Background Protein kinase R-like endoplasmic reticulum kinase (PERK) is part of the unfolded protein response that facilitates cellular adaptation to ER stress. PERK is activated in cancer cells by accumulation of misfolded proteins in the ER, enabling adaptation and survival. PERK signaling has also recently been implicated in maintaining immunosuppressive functions of myeloid-derived suppressor cells (MDSCs) through inhibition of a type 1 interferon response[1] and macrophages through metabolic and epigenetic modification.[2] We are developing HC-5404, a highly selective and potent first-in-class, first-in-human PERK inhibitor that is currently in a phase 1 trial for solid tumors (NCT04834778). HC-5404 has demonstrated single agent and combinatorial efficacy in multiple solid tumor xenograft models. In this study, we sought to investigate the immunomodulatory effects of HC-5404 by evaluating efficacy and correlative immune effects of HC-5404 combined with an anti-murine-PD-1 immune checkpoint inhibitor (ICI) antibody.

Methods C57BL/6 mice were subcutaneously inoculated with syngeneic MB49 bladder cancer cells, and treatment started on day 8 post cell inoculation. A group of animals (n=10/group) received either vehicle, HC-5404 (PO, BID), anti-PD-1 antibody RMP1-14 (IP, every 3 days), or the combination of both. At various timepoints, flow cytometry was performed on blood or single cell suspensions from tumors or lymph nodes (n=6) of treated mice. MDSCs derived from human cord blood or mouse bone marrow were co-cultured with purified T-cells in the presence of HC-5404 *in vitro*, and proliferation was evaluated.

Results HC-5404 treatment alone showed only a modest anti-tumor effect (32% TGI), the addition of HC-5404 to aPD-1 provided combination antitumor benefits (75% TGI) and significantly improved the effects of aPD-1 alone (53% TGI). HC-5404 + aPD-1 efficacy was correlated with increased expression of type 1 interferon receptor (IFNAR1) and increased surface calreticulin on tumor cells. Additionally, IFNAR1 was also significantly increased on PMN-MDSCs and tumor-associated macrophages (TAM). TAMs also showed increased PD-L1 with combination treatment. Additionally, combination treatment increased the frequency of CD8 T-cells in the tumor along with increased expression of activation marker CD69 on T-cells in the tumor draining lymph node. Notably, the effect of HC-5404 on IFNAR1 was also detected on monocytes in peripheral blood, demonstrating surface expression of IFNAR1 as a potential biomarker for HC-5404 activity. MDSCs also showed a reduced inhibition of T-cells in the presence of HC-5404 in vitro.

Conclusions Collectively, these data demonstrate the efficacious and immuno-stimulatory effects of HC-5404 coadministered with anti-PD1 mAb and outline its potential application in ICI-treated cancers.

885 ENHANCING IMMUNE CHECKPOINT INHIBITOR EFFICACY WITH ANTI-ANGIOGENICS IN OVARIAN CANCER

Sarah Gitto*, Sergey Medvedev, Veethika Pandey, Dalia Omran, Matthew Anderson, Lauren Schwartz, Fiona Simpkins, Daniel Powell. *University of Pennsylvania, Philadelphia, PA, United States*

Background Clinical data from our group supports that ovarian cancer (OC) patients respond better to immune checkpoint blockade (ICB) when targeting both PD-1 and CTLA4 compared to anti-PD-1 alone (33% v. 10%, respectively),[1] yet there is still room to improve dual-ICB response. Bevacizumab is approved as a front-line therapy for OC and targets vascular endothelial growth factor A (VEGF-A). VEGF has been shown to have both anti-tumor and immunomodulatory effects as it induces macrophage infiltration and M2 polarization[2] and directly suppresses T-cell activation, proliferation, and cytotoxic activity.[3,4] Here we aim to determine if priming the immunosuppressive tumor microenvironment (TME) with anti-VEGF enhances the response of T-cell stimulating ICB.

Methods We developed a patient avatar model by administering *ex vivo* expanded tumor infiltrating lymphocytes (TILs) into immunodeficient mice harboring a patient-matched, patient-derived xenograft (PDX).[5,6] Autologous TIL reactivity was validated by flow cytometry and ELISA. Preclinical *in vivo* studies were performed to evaluate if the efficacy of dual-ICBs (nivolumab and ipilimumab) could be enhanced through priming with anti-VEGF (bevacizumab). *Ex vivo* culture systems using donor ascites specimens and viable tumor slices were evaluated to further evaluate this combination in OC.

Results Six distinct PDX/TIL models were developed. Co-culture of TILs with autologous tumor cells resulted in HLA-dependent IFNγ production by TILs with a parallel impact on TIL activation phenotype. In response to IFNγ, PD-L1 expression was increased on tumor cells, suggesting antitumor activity might be improved via PD-1 blockade.[5] As proof-of-concept, anti-PD-1 efficacy was tested in PDX/TIL models (n=3).[5] Anti-PD-1 reduced tumor burden and increased survival in two models compared to TIL treatment alone. Next, we tested the hypothesis that the efficacy of dual-ICBs could be enhanced through TME priming with anti-VEGF (n=3). Results revealed increased efficacy of dual-ICB with anti-VEGF priming in 2 models. Immunohistochemistry and flow cytometry analysis support that the TILs in the combination ICB +/- anti-VEGF have increased anti-tumor activity.

To better delineate the activity of dual-ICB and anti-VEGF in an intact TME, *ex vivo* cultures were used. OC ascites significantly increased the secretion of T-cell effector and myeloid cell associated immunosuppressive molecules in response to ICB treatment, and CD11b+ tumor associated macrophages (TAMs) significantly reduced T-cell activation. In tumor slice cultures, combination treatment with dual-ICB and anti-VEGF reduced overall tumor burden.

Conclusions This data supports the notion that, in addition to the effect of anti-VEGF priming, modulation of the immunosuppressive myeloid population may further enhance ICB efficacy.

886 **COMBINED ALLOGENEIC NK CELL AND HERZUMA® IS EFFECTIVE IN HER2-LOW BREAST CANCER PRECLINICAL MODEL BY ENHANCING ANTIBODY-DEPENDENT CELLULAR CYTOTOXICITY**

[1]Yong Moon*, [2]Mithun Gosh, [1]Hee-Jung An, [1]Tae Hoen Kim, [2]Sa Deok Hong, [2]Nar Bahadur Katuwal, [1]Minsil Kang. *[1]CHA Bundang Medical Center, Seongnam, Republic of Korea; [2]The Graduate School, CHA University, Seongnam, Republic of Korea*

Background Trastzumab has shown significant improvements in the overall survival in patients with HER2-positive breast cancer. But HER2 is expressed at varying levels in breast cancer patients, therefore, only a fraction with robust HER2 overexpression is beneficial from trastzumab therapy. However, the efficacy of trastzumab in HER2-low expressing breast cancer, which is defined as immunohistochemistry 1+ or 2+ and lack of HER2 amplification by in situ hybridization, is not reported yet. Therefore, to enhance the effects of trastzumab in HER2-low expressing breast cancers, we investigated a novel combination of Herzuma® (a trastzumab biosimilar), paclitaxel and allogeneic Natural Killer (NK) cells in the HER2-low breast cancer preclinical models.

Methods Two breast cancer cell lines, BT-474 (HER2-low, by western blot) and SKBR3 (HER2-high, by western blot) were used for in-vitro study. Cytotoxicity was analyzed by flow cytometry (CFSE, 7AAD) after co-culture, where cancer cells were used as target (T) cell and allogeneic NK cells as effector (E) cell at various E:T ratio in the presence or absence of Herzuma®. Antibody-dependent cellular cytotoxicity (ADCC) activity was analyzed by evaluating interaction of Herzuma® and FC□III (CD16) of NK cells. Lastly, HER2-low breast cancer patients-derived tumor xenograft (PDTX) model was used for in vivo efficacy test. When tumor size reached to 100mm^3, mice were randomly divided in 4 groups (control, Herzuma® + paclitaxel, NK, Herzuma® + paclitaxel + NK) and treated.

Results Cytotoxicity assay demonstrated that dead target cells were only increased in the combined Herzuma® and NK therapy as compared to NK monotherapy in both cell lines (BT474, SKBR3) at various E:T ratio. To confirm the above-mentioned cytotoxic effect of the combination therapy is an ADCC effect, we conducted co-culture using HER2-low BT474 cells after blocking the CD16 of NK cells. Dead target cells were not increased in the combined Herzuma® and NK therapy group after CD16 blocking, whereas similar cytotoxic effects were observed in NK monotherapy and combination therapy respectively, suggesting the above-mentioned cytotoxic effect resulted from ADCC. Finally, the in-vivo study using HER2-low breast cancer PDTX model showed that the NK therapy in combination with Herzuma® and paclitaxel group significantly inhibited the tumor growth as compared to combined Herzuma® and paclitaxel group or control (p=0.003, vs control; p=0.01, vs Herzuma® + paclitaxel).

Conclusions The combination of allogeneic NK therapy, Herzuma® and paclitaxel showed synergistic anticancer activity in HER2-low breast cancer preclinical model. This combination merits further clinical investigation in HER2-low breast cancer patients.

887 MULTIMODAL GLIOMA IMMUNOTHERAPY COMBINING TLR9-TARGETED STAT3 ANTISENSE OLIGODEOXYNUCLEOTIDES WITH PD1-SPECIFIC IMMUNE CHECKPOINT BLOCKADE

Marcin Kortylewski*, Chia-Yang Hung*. *Beckman Research Institute, City of Hope, Duarte, CA, United States*

Background Malignant gliomas (MG) are rapidly fatal despite multimodal treatments including radiation therapy, used to treat nearly all MG patients, or even the emerging cellular immunotherapies. Therapeutic resistance in glioma is related to tolerogenic STAT3 activity in both glioma cancer stem cells (GCSs) and in the tumor-associated myeloid immune cells, such as macrophages and microglia, which dominate MG microenvironment.[1,2] We previously demonstrated that STAT3 activity in GSCs and tumor-associated myeloid cells can be targeted using Toll-like Receptor-9 (TLR9)-targeted oligonucleotide therapeutics such as siRNA or antisense oligonucleotides (ASO).[2,3]

Methods Here, we describe development of a new TLR9-targeted and double-stranded STAT3 antisense oligonucleotide (CpG-STAT3dsASO) with optimized efficacy and safety for glioma immunotherapy.

Results Compared to our benchmark ASO oligonucleotides, the LNA-modified CpG-STAT3dsASO showed enhanced target gene knockdown in human and in mouse glioma cells and also in TLR9^{+} immune cells, such as macrophages and microglia. When tested against orthotopic model of human U251 glioma, intracranial injections of CpG-STAT3dsASO (1 mg/kg/q2w) inhibited tumor growth and significantly extended survival of immunodeficient NSG mice compared to benchmark oligonucleotide. Next, we tested CpG-STAT3dsASO against syngeneic GL261 model in immunocompetent mice. Our results demonstrated that CpG-STAT3dsASO was more effective but also significantly better tolerated than single-stranded CpG-STAT3ASO when injected intracranially, without evidence of severe acute neural toxicities within tested dosing. All tested CpG-STAT3ASO variants induced maturation/activation of intratumoral DCs, macrophages and microglia, while reducing numbers of tumor-associated M2 macrophages and resting microglia as assessed using flow cytometry. Importantly, CpG-STAT3ASO treatments improved the ratio of intratumoral CD8 T cells to Tregs. To elucidate changes in the glioma microenvironment related to STAT3-inhibition/TLR9-activation, we performed an initial single-cell RNAseq analysis of transcriptomic profiles in immune cell subsets isolated from tumors after treatment using CpG-STAT3dsASO^{LNA}. Our analysis indicated the reprogramming of tumor-associated myeloid cell populations within treated glioma with an increased ratio of CD8:regulatory T cells. Our results also suggested the elevation of several immune checkpoint molecules on tumor-infiltrating T cells likely as a result of IFN signaling. Importantly, our preliminary experiments demonstrated a synergy between systemic PD1 inhibition with low-dose (0.25 mg/kg) CpG-STAT3dsASO local therapy. While, neither of treatments alone was curative, the combination anti-PD1/CpG-STAT3dsASO therapy resulted in complete rejection of orthotopic GL261 tumors in the majority of treated mice (figure 1).

Conclusions We believe that further development of CpG-STAT3dsASO will pave way to clinical translation of this strategy to immunotherapy of malignant glioma.

888 SYNERGISTIC EFFICACY OF THE BRM/BRG1 ATPASE INHIBITOR, FHD-286, AND ANTI-PD-1 ANTIBODY IN MOUSE SYNGENEIC TUMOR MODELS

[1]Kana Ichikawa*, [1]Ammar Adam, [2]Hsin-Jung Wu, [1]David Lahr, [3]Lan Xu, [1]Brandon Antonakos, [1]Liv Johannessen, [1]Steven Bellon, [1]Ryan Kruger, [1]Richard Centore, [1]Martin Hentemann. *[1]Foghorn Therapeutics, Cambridge, MA, United States; [2]Blueprint Medicines, Cambridge, MA, United States; [3]Ikena Oncology, Boston, MA, United States*

Background The BAF family of chromatin remodeling complexes are critical regulators of chromatin accessibility and gene expression, and BRM and BRG1 (also known as SMARCA2 and SMARCA4), the catalytic subunits of BAF, provide the enzymatic activity required for chromatin remodeling activity. We have previously identified and characterized a series of novel dual inhibitors of the BRM/BRG1 ATPases, and FHD-286, a potent and selective BRM/BRG1 inhibitor, is currently under clinical investigation for the treatment of metastatic uveal melanoma and advanced hematological malignancies (NCT04879017 and NCT04891757). BAF chromatin remodeling complex activities are implicated in many immunologic responses, and previous studies have shown the involvement of PBAF in the regulation of antitumor immunity.[1]

Methods Given the recent reports correlating SMARCA4 deficiency and ICI response,[2] we explored the combination of BRM/BRG1 ATPase inhibition and anti-PD-1 antibody in syngeneic mouse models from various lineages and with different sensitivities to checkpoint inhibition.

Results The combination of FHD-286 and anti-PD-1 antibody provided synergistic efficacy and survival benefit compared to anti-PD-1 alone in A20, CT26, and the immunologically barren B16F10 melanoma model. FHD-286 increased MHCI expression on B16F10 cells, and increases in IFNγ and Th1-type chemokine CXCL10 levels were observed in immunocompetent mice following treatment, suggesting that combinatorial activity may result from effects on both the tumor and the immune system.

Conclusions FHD-286 has the potential to sensitize tumor to immune-checkpoint inhibition and represents a novel combination approach for cancer immunotherapy.

889 IOA-244 IS A NON-ATP-COMPETITIVE, HIGHLY SELECTIVE, TOLERABLE PHOSPHOINOSITIDE 3-KINASE DELTA INHIBITOR THAT DIRECTLY TARGETS SOLID TUMOURS AND BREAKS IMMUNE TOLERANCE

[1]Giusy Di Conza*, [1]Lars Van der Veen, [2]Chiara Tarantelli, [2]Francesco Bertoni, [3]Amy Fraser, [3]Pritom Shah, [4]Simon Tiede, [4]Laura Tesmer, [4]Gerhard Hummer, [5]Oscar Vadas, [1]Michael Lahn, [6]Nomanbhoy Tyzoonn, [1]Zoe Johnson. *[1]iOnctura SA, Geneva, Switzerland; [2]Institute of Oncology Research, Faculty of Biomedical Sciences, USI, Bellinzona, Switzerland; [3]Cancer Research Horizon, London, UK; [4]Max Planck Institute of Biophysics, Frankfurt, Germany; [5]University of Geneva, Geneva, Switzerland; [6]Activix, La Jolla, CA, United States*

Background Phosphoinositide 3-kinase delta (PI3Kd) inhibitors are used to treat lymphomas but safety concerns and limited target selectivity complicate their wider application. More recently, the potential for PI3Kd inhibition in solid tumours has become appreciated, through both the modulation of T cell responses and direct anti-tumor activity. Here we report the exploration of IOA-244/MSC2360844, a non-ATP-competitive PI3Kd inhibitor, for the treatment of solid tumors.

Methods To harness the differentiation of IOA-244 from other PI3Kd inhibitors, we have performed molecular dynamic and protein dynamic studies, as well as in-cell kinase assay where we compared structural and selectivity features of IOA-244 with other inhibitors. Then, to investigate the tumor intrinsic and extrinsic properties of IOA-244, we performed patient-derived xenograft models, in vitro proliferation assay and in vivo syngenic tumor models. Here, we tested IOA-244 in monotherapy or in combination with checkpoint blockade inhibitors.

Results Molecular dynamics and protein dynamics studies highlighted that, opposite to other inhibitors, IOA-244 binding to PI3Kd causes a bending of the C-terminal kα12 helix inwards towards the ATP binding pocket, overall resulting in the stabilisation of the inactive form of PI3Kd. Based on this unique binding mode, IOA-244 showed very selectivity when tested against a large set of other kinases, enzymes and receptors. IOA-244 inhibited the *in vitro* growth of cancer cells expressing high levels of PI3Kd, as well as of patient-derived xenografts of melanoma and mesothelioma, suggesting that there are cancer cell-intrinsic effects of IOA-244. Importantly, IOA-244 inhibits T_{reg} proliferation while having limited anti-proliferative effects on conventional $CD4^+$ T cells and no effect on $CD8^+$ T cells, highlighting immune-modulatory properties that can be exploited in solid tumors. Indeed, in CT26 colorectal and LL2 lung cancer model IOA-244 sensitised the tumours to anti-PD(L)-1 treatment, with similar activity in the Pan-02 and A20 syngeneic mouse models. In these models IOA-244 also reshaped the tumour-infiltrating cells, favouring infiltration of CD8 and NK cells, while decreasing suppressive cells. IOA-244 presented no significant safety concerns in animal and *in vitro* toxicology studies and is currently in clinical Phase I evaluation for lymphoma and solid tumors. In this study, IOA-244 treatment in cancer patients showed unprecedented tolerability and clinical benefit, particularly in patients with metastatic uveal melanoma.

Conclusions In conclusion, thanks to its unique structural and selectivity features, IOA-244 represent a first in class PI3Kd inhibitor, with an exceptional safety profile.

890 USING INTRATUMOR MICRODEVICES TO IDENTIFY HIGHLY SYNERGISTIC COMBINATIONS BETWEEN TARGETED AGENTS AND IMMUNOTHERAPIES IN BREAST CANCER

Oliver Jonas*. *Brigham and Women's Hospital, Boston, MA, United States*

Background Targeted therapies in cancer aim to block specific molecular pathways that are constitutively activated and are crucial for tumor cell growth and survival, but they also elicit immune responses. This raises the possibility that these treatments may be combined with immunotherapy to induce synergistic anti-tumor effects that improve treatment outcomes. How to rationally prioritize combinations of targeted agents with immunotherapies among the many possible options, represents a major unmet need in clinical oncology.

Methods We have developed a novel *in situ* approach that provides a phenotypic measurement of single and combinatorial drug effect directly within the tumors of patients or animal models. The approach uses implantable microdevices (IMD), which are loaded with nano-doses of up to 20 approved and experimental agents, and releases these treatments into confined and non-overlapping regions of the tumor where each treatment interacts with the native tumor microenvironment (TME) for multiple days. Upon retrieval of the IMD with surrounding tissue, a spatial analysis tissue phenotyping pipeline is employed to define the effect of each treatment on tumor and TME cells.[1,2] For each treatment, a specific response and resistance phenotype is described which leads to the identification of an immune-modulating agent which combines synergistically with the targeted therapy.

Results We have employed this combined IMD – spatial analysis platform to identify three novel and highly synergistic combinations in breast cancer models, including inhibitors of CDK4/6, HDAC and BCL-2, as well as anti-PD1, anti-CSF1R and anti-CD40 treatments.

Conclusions The approach is currently being used in multiple clinical studies, which provides a platform for validating the biomarkers and resistance signatures in patients.

891 IMMUNE RELATED VULNERABILITIES OF NON-NEUROENDOCRINE SMALL CELL LUNG CANCER

Ryan Kowash*, Mingrui Zhu, Benjamin Drapkin, John Minna, Luc Girard, Esra Akbay. *UT Southwestern Medical Center, Dallas, TX, United States*

Background Small Cell Lung Cancer (SCLC) is primarily a neuroendocrine (NE) cancer, however there is a subtype of SCLC that displays non-neuroendocrine (non-NE) phenotype. This subtype displays a unique immune and metabolic signature. Specifically, immune related vulnerabilities of this subtype are increases in expression of MHC-I and natural killer (NK) cell activating ligands. We discovered that there are additional immune modulators differentially produced in this subtype such as *NT5E*. *NT5E* encodes for CD73. CD73 acts as an ectoenzyme and is involved in adenosine production within the tumor microenvironment. Accumulation of adenosine limits the function of T and NK cells. Our recent studies suggest targeting CD73 in combination with immune checkpoint blockade results in an additive effect through decreased adenosine production in Non Small Cell Lung Cancer. However, the role of CD73 is yet to be explored in SCLC.

Methods We analyzed expression of *NT5E* for both SCLC cell lines and patient derived xenograft (PDX) models. Expression of CD73 at the protein level was validated in mouse and human cell line models. Mouse and human SCLC cell lines were used in co-culture experiments. Syngeneic mouse models were utilized for *in vivo* experiments. Flow cytometry was used to analyze changes in the tumor microenvironment.

Results Non-NE SCLC cell lines and PDX's express significantly higher levels of CD73 compared to NE models. Co-cultures of tumor cells with NK cells demonstrated that SCLC's with increased NK cell activating ligands display increased response to NK cell killing. Blockade of CD73 further enhanced activation of cytotoxic T cells in peripheral blood mononuclear cell (PBMC) co-cultures. When combined with immune checkpoint blockade treatment, syngeneic tumor growth was inhibited in mice. Combination treatment resulted in significantly increased activated T cells and NK cells within the tumor microenvironment as well as changes in myeloid cell populations.

Conclusions Our results argue that increased NK cell activating ligands and CD73 inhibition is a potential therapeutic target for non-NE SCLC. Increased NK cell activating ligands makes non-NE SCLC more susceptible to NK cell killing compared to NE SCLC. CD73 inhibition in combination with immune checkpoint blockade resulted in decreased tumor growth. This response was attributed to increased T cell and NK cell populations within the tumor microenvironment.

892 **THE NOVEL TELOMERASE-DIRECTED TELOMERE-TARGETED ANTICANCER AGENT 6-THIO-DG (THIO) DEMONSTRATES POTENT ACTIVITY AND INDUCES ANTITUMOR IMMUNITY IN HEPATOCELLULAR CARCINOMA (HCC) MODELS**

[1]Ilgen Mender, [1]Silvia Siteni, [2]Mihail Obrocea, [2]Vlad Vitoc, [2]Sergei Gryaznov*, [1]Jerry Shay. *[1]UT Southwestern, Dallas, TX, United States; [2]Maia Biotechnology, Inc., Chicago, IL, United States*

Background HCC is one of the leading causes of cancer-related deaths worldwide. Low response rates with current treatments for HCC demonstrate an urgent unmet need for more effective systemic therapies. However, development of novel treatments for HCC has been challenging due to a lack of functionally druggable targets. The nucleoside prodrug analogue THIO is a first-in-class telomerase-directed, telomere-targeted, anticancer agent that has shown potent activity in other tumor types, including colorectal, lung, melanoma, and brain cancer models. In cancer cells, THIO is converted into the corresponding 5'-triphosphate, which is efficiently incorporated into telomeres by telomerase, activating DNA damage responses and pro-apoptotic pathways. We hypothesized that telomerase-targeting agents may be effective in HCC given the high rate of mutations in the telomerase reverse transcriptase (hTERT) promotor. Moreover, since >90% of HCCs reactivate telomerase to drive escape from senescence-induced growth arrest, treatment with THIO or second-generation telomere-targeted analogues is likely highly selective for telomerase-positive cancer cells relative to nonmalignant hepatocytes.

Methods Activity of THIO and second-generation analogues was evaluated in vitro using telomerase-positive HCC cells and in vivo using syngeneic mouse models of aggressive HCC. HCC cells treated with or without THIO were analyzed for cell proliferation and stained with markers of replicative stress or cell cycle arrest, followed by confocal microscopy and/or flow cytometry. Immunophenotyping of tumor-infiltrating T cells in mice treated with THIO was performed by measuring the frequencies of MDSCs (Ly6C+Ly6G-), NK cells (NK1+), CD4 T cells (Ki67+/CD4+), and CD8 T cells (Ki67+/CD8+). Antitumor activity was assessed by serial measurements of tumor volume in mice sequentially treated with therapeutically relevant doses of THIO ± checkpoint inhibitors compared to control mice and mice treated with checkpoint inhibitors alone.

Results THIO treatment induced replicative stress, followed by cell cycle arrest and apoptosis in telomerase-reactivated HCC cells. In syngeneic mouse models of aggressive HCC, treatment with THIO activated pathways associated with innate and adaptive immunity (eg, cGAS-STING pathway and infiltration of CD8+ T cells into the tumor microenvironment) and altered the immune-suppressive tumor microenvironment. THIO treatment enhanced the response to checkpoint inhibitors, yielding complete responses in some HCC model systems with no dose-limiting toxicities. Similar results were observed with second-generation THIO analogues.

Conclusions Results of this study indicate that THIO, a first-in-class telomerase-directed, telomere-targeted agent, and its analogues may enhance the overall therapeutic efficacy of current immune checkpoint inhibitor-based treatments for HCC.

893 MYELOID DERIVED SUPPRESSIVE CELLS ATTENUATE THE ANTI-TUMOR EFFICACY OF ANDROGEN DEPRIVATION THERAPY AND TARGETED RADIONUCLIDE THERAPY IN A MURINE PROSTATE CANCER MODEL

Anusha Muralidhar*, Carolina Ferreria, Reinier Hernandez, Jamey Weichert, Douglas McNeel. *University of Wisconsin-Madison, Madison, WI, United States*

Background Androgen deprivation therapy (ADT) is the cornerstone treatment for recurrent prostate cancer. ADT is also routinely used in combination with external beam radiation therapy (EBRT) for localized prostate cancer, and the combination results in a high rate of cure for low-risk disease. However, for metastatic castration-resistant prostate cancer (mCRPC), EBRT is typically only used in the palliative setting, because of the inability to radiate all sites of disease. We have developed an alkyl phosphocholine compound, NM600, that is selectively retained by multiple tumor types following systemic delivery. ^{90}Y-NM600 is being explored as a means of targeted radionuclide therapy (TRT) to irradiate all sites of metastases specifically and simultaneously in different tumor models, and a treatment that might modulate the tumor immune microenvironment. We hypothesized that ADT with TRT should be effective in the treatment of metastatic prostate cancer and tested this approach in a relevant murine tumor model.

Methods 6-week-old male FVB mice were implanted subcutaneously with MycCaP tumor cells. Mice were given a single intravenous injection 250 μCi of ^{90}Y-NM600, estimated to deliver 16 Gy to 0.2 cm^3 tumors, in combination with ADT (degarelix). The sequence of administration was evaluated for effect on tumor growth, and groups of mice were euthanized at different time points to characterize the tumor-infiltrating immune populations by flow cytometry.

Results ADT delivered prior to TRT resulted in a significantly greater anti- tumor response and overall survival than if delivered after TRT. Similar studies performed in immunodeficient NRG mice demonstrated no difference with respect to the treatment sequence, suggesting this difference was immunologically mediated. Flow cytometry analysis revealed that CD4+ and CD8+ T cells persisted in the ADT prior to TRT group while they were significantly reduced in the other sequence. CD11b+Gr-1+ myeloid derived suppressor cells (MDSCs) were significantly increased in tumors following TRT prior to ADT treatment and retained immune suppressive function. Depletion of MDSC led to greater anti-tumor response following either treatment sequence.

Conclusions The combination of ADT and TRT significantly delayed tumor growth and improved anti-tumor responses in a murine model of prostate cancer, however this was dependent on the order of administration. This was found to be due to one treatment sequence leading to an increase in infiltrating MDSC. Current studies are investigating the mechanism of these findings.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0893

894 **A NOVEL ONCOLYTIC IMMUNOTHERAPY, VET3-TGI, OVERCOMES TGFB1 MEDIATED IMMUNOSUPPRESSION, AUGMENTS TYPE-1 IMMUNE RESPONSE, AND DISPLAYS POTENT THERAPEUTIC ACTIVITY IN MULTIPLE MOUSE TUMOR MODELS**

Ravikumar Muthuswamy*, Steve Thorne, Carly Carter, Ming Zhang, Dan Byrd. *Kalivir Immunotherapeutics, Pittsburgh, PA, United States*

Background TGFB1 mediated immune resistance is one of the major mechanisms of immune suppression utilized across multiple tumor types. Immune resistance imparted by TGFB1 is mediated through its pleiotropic effects on vasculature, fibrogenesis and regulatory/effector immune cells within the tumor microenvironment. Blockade of TGFB1 (TGFBi) will likely improve response to immunotherapy. IL-12 is a cytokine that through IFNg induction, promotes type 1 inflammatory response, M1 macrophages and effector CD8 T cell response. Combining TGFB1 blockade with IL-12 may maximize therapeutic benefits through simultaneously reducing immunosuppression and enhancing anti-tumor immune response. Current studies have developed a vaccinia-based immunotherapy, combining enhanced systemic virus delivery to CXCR3 ligand rich tumors and locally expressed IL-12 and TGFBi within the tumor microenvironment, for efficient control of multiple tumor models.

Methods An oncolytic vaccinia virus expressing CXCR3, IL-12 and a TGFB1 antagonizing mini-monomer was constructed (VET3-TGI) and the expression and function of the transgenes were confirmed. Using *in vivo* mouse RENCA, EMT-6 and MC38 tumor models, the functionality and therapeutic efficacy of VET-TGI were tested with comparison to control virus. Post mortem analysis was used to analyze the impact of VET3-TGI on immune/stromal/endothelial milieu of the tumors and to determine toxicity profile.

Results VET3-TGI infected cells expressed CXCR3 and showed enhanced migration to CXCR3 ligands *in vitro* and improved systemic delivery to tumors expressing CXCR3 ligands *in vivo*, even in the face of pre-existing anti-viral immunity. IL-12 expression and TGFBi blockade of TGFB1 mediated suppression of CD8 T cell proliferation were confirmed *in vitro*. *In vivo* mouse studies using EMT6, RENCA and MC38 tumor models demonstrated potent therapeutic activity, including 100% CRs, even at doses several logs below equivalent clinical doses and in multiple models. Mechanism of activity studies suggested that the therapeutic efficacy of VET3-TGI is associated with considerable modification of the tumor microenvironment. In addition, preliminary toxicity studies demonstrated the safety of VET3-TGI in mouse models.

Conclusions VET3-TGI demonstrated an ability to reduce immunosuppression and dramatically enhance antitumor immune response leading to safe and potent therapeutic activity in multiple mouse tumor models. This data led to the selection of VET3-TGI as our lead clinical candidate. A human version of the virus is currently undergoing clinical manufacture and toxicology testing.

Ethics Approval Animal studies were approved by IACUC, Hilltop animal center

895 ENHANCED ANTI-TUMOR EFFICACY BY COMBINATION OF CHECKPOINT IMMUNOTHERAPY AND ANTIBODY-DRUG CONJUGATES UTILIZING THE TOPOISOMERASE I INHIBITOR LINKER-PAYLOAD AZ'0133

Bilal Omar*, Steve Arbitman, Kalyani Daita, Ana Paucarmayta, Huiyanangel Chow, Judith Anderton, Raymond Rothstein, Allison Gerber, Kathy Mulgrew, Leslie Wetzel, Edward Rosfjord, Nadia Luheshi, Krista Kinneer, Scott Hammond. *AstraZeneca, Gaithersburg, MD, United States*

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0895

Background Recent clinical trials highlight the potential therapeutic benefit from combining checkpoint immunotherapies (IO) with antibody drug conjugates (ADC) incorporating different cytotoxic warheads. We hypothesize that diverse ADC warheads modulate different aspects of tumor immune biology.
Methods Antibodies specific for tumor antigens B7-H4 and other model antigens were conjugated to either topoisomerase inhibitor linker-payload AZ141470133 (AZ'0133) or microtubule inhibitor warhead monomethyl auristatin E (MMAE), and their biologic effects on immune-related endpoints in vitro and anti-tumor activity in vivo in mouse models were determined.
Results In vitro studies demonstrated that AZ'0133-ADCs increases the immunogenicity of tumor cells and enhances the activation and maturation of dendritic cells (DC) to an equal to or greater extent compared to MMAE-ADCs. Treatment of human tumor cell lines with B7-H4-AZ'0133 or another model antigen targeting-AZ'0133 ADC increased cell surface expression of MHC class I to a greater extent than the same ADCs conjugated to MMAE. Surface expression of TIGIT ligand PVR/CD155 was exclusively increased by the model antigen targeting-AZ'0133 ADC but not with the same antibody conjugated to MMAE. PD-L1, Nectin-2, MHC class II, and immunogenic cell death markers calreticulin and phosphatidylserine were increased by both AZ'0133- and MMAE-ADCs. Co-culture of immature DCs with tumor cell lines in the presence of model antigen targeting AZ'0133-ADCs induced expression of DC maturation markers and CTLA-4 ligands CD80 and CD86 as well as Nectin-2. The same ADC conjugated to MMAE upregulated only CD80 and decreased TIM-3 expression on DC.

In immunocompetent mouse models, the combination of anti-PDL1 with either AZ'0133- or MMAE-ADCs drove enhanced anti-tumor activity versus monotherapy controls. In a CT26 syngeneic model expressing mouse B7-H4, the combination of anti-PD-L1 with either a mouse cross-reactive anti-B7-H4 MMAE or anti-B7-H4-AZ'0133 ADC reduced tumor growth rates and increased overall survival versus monotherapy controls. In a CT26 model overexpressing a different human model tumor antigen, the combination of anti-PD-L1 with either an AZ'0133 conjugated-ADC or the same antibody conjugated to MMAE, reduced the rate of tumor growth and improved survival as compared to monotherapy controls. In both models, growth rate inhibition and survival benefit were comparable for the combination of anti-PD-L1 with either AZ'0133- or MMAE-ADCs.
Conclusions AZ'0133 and MMAE ADCs both combine with anti-PD-L1 to enhance anti-tumor activity in vivo. In vitro, whilst both classes of ADC induce immunogenicity and immune activation, they have differing impacts on T cell checkpoint ligand expression.
Ethics Approval All studies involving animals were approved by the Institutional Animal Care and Use Committee at AstraZeneca under protocol number AUP-21-05.

896 ONCOLYTIC HERPES SIMPLEX VIRUS IMMUNOVIROTHERAPY IN COMBINATION WITH TIGIT IMMUNE CHECKPOINT BLOCKADE TO TREAT GLIOBLASTOMA

[1]Eleni Panagioti, [1]J Kelley*, [2]William F Goins, [3]Keith Ligon, [1]Karen Dixon, [1]Ana Anderson, [1]Vijay Kuchroo, [1]Antonio Chiocca. *[1]Brigham and Women's Hospital, Boston, MA, United States; [2]University of Pittsburgh, Pittsburgh, PA, United States; [3]Dana Farber Cancer Institute, Boston, MA, United States*

Background Glioblastoma Multiforme (GBM) is an aggressive primary brain tumor and represents the most fatal type of malignant cancer. Despite rigorous clinical research efforts there is minimal improvement in GBM patient outcomes. Oncolytic herpes simplex virus 1 (oHSV-1) is emerging as a promising approach to promote anti-tumor responses in GBM patients. In this study, we hypothesized that intratumoral administration of a novel HSV-1 based oncolytic virus (HSV-1 rQNestin34.5v2) will result in synergy when combined with anti-TIGIT checkpoint blockade therapy. We investigated the antitumor efficacy of this combination in immunocompetent syngeneic murine glioma models that exhibit different genetic alterations and tumor mutations.

Methods HSV-1 based oncolytic virus (HSV-1 rQNestin34.5v2), currently investigated in a phase I clinical trial for recurrent glioblastoma (ClinicalTrials.gov: NCT03152318) was employed, that maintains a copy of the HSV-1- ICR34.5 gene, which is responsible for HSV-1 neurovirulence under transcriptional control of the tumor-specific promoter nestin to drive robust tumor-selective replication. Syngeneic GL261, CT-2A, IDH1 mutant and IDH1 wild type orthotropic glioma mouse models were used to evaluate immunotherapeutic and antitumor responses. Immune cell signatures at the tumor microenvironment and in the peripheral blood involved at the treatment response were assessed by multiparameter flow cytometry analysis.

Results HSV-1 rQNestin34.5v2 exhibited robust ability to infect murine glioma cells *in vitro* triggering cytotoxicity. Infection stimulated immunogenic cell death in glioma cells as evidenced by extracellular release of damage-associated molecular patterns (DAMPs) and proinflammatory cytokines. In vitro screens for upregulation of immune checkpoint molecules following infection with HSV-1 rQNestin34.5v2 identified CD155/CD112/TIGIT and PD-L1/PD1 axes as promising targets for combination therapies. TIGIT was found to be overexpressed in tumor infiltrating NK, CD4 and CD8 T cells suggesting systemic therapy with TIGIT blockade antibodies could have therapeutic utility in combination with HSV-1 rQNestin34.5v2 in GBM. Intratumoral administration HSV-1 rQNestin34.5v2 resulted in the development of a proinflammatory environment as shown by decreased CX3CR1 expression on tumor infiltrating NK cells. Benefit in overall survival was not observed by systemic anti-TIGIT monotherapy. Combination treatment with intratumoral HSV-1 rQNestin34.5v2 administration exhibited modest therapeutic effect with a cure rate 12% in mice bearing intracranial CT-2A tumors. Long term CT-2A tumor survivor mice were effectively protected by rechallenge with autologous CT-2A cells indicating the development of long lasting tumor specific immunity.

Conclusions Our findings show that the combination of HSV-1 rQNestin34.5v2 virotherapy with anti-TIGIT checkpoint blockade immunotherapy represents a promising strategy to overcome primary resistance to immune checkpoint inhibitors in GBM.

Ethics Approval All animal experiments and procedures described in this study were approved by Brigham and Women's Institutional Animal Care and Use Committee.

897 PARTNERS FOR BISPECIFICS: COMBINATORIAL APPROACHES TO AUGMENT T-CELL FUNCTION AND MITIGATE EXHAUSTION

Nora Philipp*, Marion Subklewe, Amelie Muth, Michael Von Bergwelt-Baildon, Veit Bücklein. *University Hospital, LMU Munich, Munich, Germany*

Background T-cell engaging bispecific antibody molecules (BsAb) redirect T cells towards antigen-expressing cells and have shown efficacy in various B-cell malignancies.[1-3] The CD19xCD3 BsAb blinatumomab was the first in class to be approved in the setting of R/R BCP-ALL with a response rate of 43%.[4] Evaluating mechanisms of resistance to bispecifics has been hampered by a lack of an appropriate model to mimic the clinical application of continuous BsAb exposure over several weeks to months. We developed an *in vitro* model system to simulate the clinical administration of blinatumomab as continuous infusion over 28 days and demonstrated that continuous exposure to a BsAb induces T-cell exhaustion.[5] To identify partners for bispecifics to mitigate exhaustion, a diverse toolbox of off-the-shelf immunomodulating agents was evaluated. Using our *in vitro* model system, we explored the potential of BsAb treatment in combination with i) the tyrosine kinase inhibitor dasatinib, ii) the immunomodulator lenalidomide and iii) aPD-1/aPD-L1 checkpoint blockade to enhance T-cell function (figure 1).

Methods Healthy donor T cells were cocultured with $CD19^+$ OCI-Ly1 cells and continuously stimulated with a CD19xCD3 BsAb alone or in combination with dasatinib (12.5 nM), lenalidomide (10 µg/ml), nivolumab (10 µg/ml) or atezolizumab (10 µg/ml) for 28 days. Every 7 days, T cells were isolated and characterized in functional assays: (1) Expression of inhibitory receptors (IRs; PD-1, Tim-3, LAG-3), (2) BsAb-mediated cytotoxicity against hCD19-Ba/F3 cells after 72h, (3) T-cell expansion as fold change of $CD2^+$ counts, (4) BsAb-mediated cytokine secretion measured via intracellular staining or in supernatants.

Results Dasatinib reduced IR co-expression and led to an increased proliferative and cytotoxic potential of T cells after 14 days of BsAb stimulation. Furthermore, it strongly increased granzyme B expression and secretion of IL-2 and IFN-g. Lenalidomide did not affect IR co-expression, but increased cytotoxicity of T cells after 14 and 21 days of BsAb stimulation. Additionally, it increased IL-2 and IFN-g secretion. Interestingly, both nivolumab and atezolizumab did not enhance T-cell function, suggesting a minor role of the PD-1/PD-L1 axis in the induction of exhaustion in our model system.

Conclusions Together, our findings highlight that T-cell function during BsAb stimulation *in vitro* strongly improves by combinatorial treatment with dasatinib or lenalidomide. Albeit checkpoint inhibitors can boost T-cell responses, they could not ameliorate BsAb-induced T-cell exhaustion. Our data supports combinatorial approaches of BsAbs and small molecules to achieve durable T-cell responses in patients.

898 TRIPLE THERAPY (BINIMETINIB, BEVACIZUMAB, PEMBROLIZUMAB) MODULATES THE TUMOR IMMUNE MICROENVIRONMENT IN MICROSATELLITE STABLE COLORECTAL CANCER PDXS IN A HUMANIZED MICE MODEL

Julie Lang*, Adrian Dominquez, Matthew Lewis, Sarah Hartmann, Jordi Lanis, Hannah Strassburger, Wells Messersmith, S Lindsey Davis, Alexis Leal, Sunnie Kim, Tyler Friedrich Kimberly,, Christopher Lieu, Todd Pitts. *University of Colorado Denver AMC, Aurora, CO, United States*

Background Single-agent checkpoint blockade inhibitors have shown great promise in recent years but has unfortunately been limited to a subset of tumor types. The tumor mutation burden as well as the tumor microenvironment are two key important features that distinguish immunogenic, from non-immunogenic tumors. There is currently a massive effort, including a wide range of strategies, turning tumors from cold to hot including combining with small molecule inhibitors.

For colorectal (CRC) cancers, anti-PD1 therapies have proven to be successful in the clinic for microsatellite instable (MSI-high) tumors but have no efficacy in the majority of patients with CRC that have microsatellite stable (MSS) cancers. Our primary goal is to determine if the addition of binimetinib (small molecule MEK inhibitor) and bevacizumab (anti-VEGF therapeutic antibody) increases the response rate of metastatic microsatellite stable colorectal cancer to pembrolizumab in humanized patient-derived xenografts (hPDXs) of CRC. We will also identify immune and pathway modulation in MSS CRC hPDXs treated with the combination of MEK, VEGF, and immune checkpoint inhibitors.

Methods In six independent experiments, we implanted distinct MSS CRC PDXs, that were recently isolated from patients on a matching clinical trial, into the flanks of humanized BRGS (BALB/c, $Rag2^{-/-}$, $IL2RgC^{-/-}$, NOD^{SIRPa}) mice that had been engrafted with human hematopoietic stem cells at birth. For each PDX we generated humanized mice cohorts treated with vehicle, binimetinib, binimetinib/pembrolizumab combination, or binimetinib/pembroliumab/bevacizumab/DC101. The human immune system in the immune organs and tumors were interrogated by flow cytometry to assess changes in the cellular composition and the activation state of the immune system as a result of treatments, and the expression of immune-related molecules were assessed on the tumor cells.

Results There were no significant differences in primary tumor growth in all treated models. However, immune modulation was observed in TILs in which we measured increased activated T cells (DR+, effector memory, TIM-3+), GrB+CD8+ and IFNg+CD8+ T cells. We also observed increased TNFa and IFNg and decreased T regulatory (FoxP3+CD25+) CD4+ T cells in the pembrolizumab/binimetinib and triple combination groups. Immune infiltrates were unique for the various PDXs.

Conclusions In this preclinical examination of combination MEK, VEGF, and PD-1 inhibition in CRC hPDXs no significant differences in tumor growth were noted, but immune modulation in TILs and tumor were observed suggesting potential immune modulation of the tumor microenvironment that may lead to greater susceptibility to immune checkpoint inhibition in patients with MSS mCRC.

Ethics Approval The human cord blood samples were generously provided as de-identified donors from Clinimmune Cord Blood Bank (Aurora, CO). All procedures and mouse husbandry were performed in accordance with IACUC protocols approved by the University of Colorado Denver Institutional Animal Care and Use Committee in the Office of Laboratory of Animal Resources (OLAR), a facility approved by the American Association for Laboratory Animal Care.

899 BET INHIBITORS SYNERGIZE WITH ANTI-PD1 BY ENHANCING TCF7 ACCESSIBILITY IN LEUKEMIA-DERIVED TERMINALLY EXHAUSTED CD8$^+$ T CELLS

Kyle Romine, Hyun-jun Cho, Yoko Kosaka, Patrick Flynn, Kaelan Byrd, Jesse Coy, Matthew Newman, Jamie Scott, Andrew Adey, Evan Lind*. *OHSU, Portland, OR, United States*

Background Our lab and others have shown that a proportion of blood and bone marrow specimens from AML patients have an immunosuppressive microenvironment and have hallmarks of immune exhaustion: increased frequencies of regulatory T cells (Tregs)[1] and myeloid-derived suppressor cells (MDSCs),[2] decreased T-cell proliferation,[3] elevated expression of immune checkpoint molecules[4] and increased TEx vs. TPEx[5-7] populations. Importantly, a subset of these patient samples containing dysfunctional T cells can be rescued by ICB[3]. We have identified the same immune-related features, in a mouse model of AML. BET inhibitors (BETi) havbeen shown to positively affect CD8$^+$ T cells, indirectly via reduction of PD-L1 expression on myeloid cells[8,9] and directly by inhibition of chronic TCR activation genes, increasing stem-cell like memory CD8$^+$ T cells.[10,11] We hypothesized that BETi may synergize with anti-PD1 therapy in AML through promoting T cell stemness.

Methods Our AML mouse model bears FLT3-ITD and deletion of TET2 restricted to the myeloid lineage (LysM-CRE). For *in vitro* studies, splenocytes were stimulated with anti-CD3 and either JQ1, anti-PD1 or both and proliferation and differentiation status were assessed by flow cytometry. For *in vivo* studies, treatment consisted of 2 weeks. s3-ATAC-seq; Cells were prepared as described.[12] Libraries were sequenced on a NextSeq 2000. Data was then analyzed and visualized using the ArchR. GSE Accession: GSE205386.

Results We show that inhibitors which target bromodomain and extra-terminal domain (BET) proteins rescue T cell exhaustion. *Ex vivo* treatment of cells from AML mice and AML patients with BET inhibitors (BETi) reversed CD8$^+$ T cell exhaustion by restoring proliferative capacity and expansion of the more functional TPEx (figure 1). This reversal is enhanced by combined BETi and anti-PD1 treatment. BETi synergized with anti-PD1 *in vivo*, resulting in the reduction of circulating leukemia cells, enrichment of CD8$^+$ T cells in the bone marrow, and increased expression of *Tcf7*, *Slamf6*, and *Cxcr5* in CD8$^+$ T cells (figure 2). Finally, we profiled the epigenomes of *in vivo* JQ1 treated AML-derived CD8$^+$ T cells by single-cell ATAC seq and find that JQ1 increases *Tcf7* accessibility specifically in Tex cells, suggesting that BETi likely mechanistically acts by relieving repression of progenitor programs in Tex CD8+ T cells and maintaining a pool of anti-PD1 responsive CD8 T cells (figure 3).

Conclusions Using an AML mouse model that exhibits leukemia-induced immune exhaustion, we demonstrate the pre-clinical efficacy of combining BETi and anti-PD1 therapy in the treatment of AML.

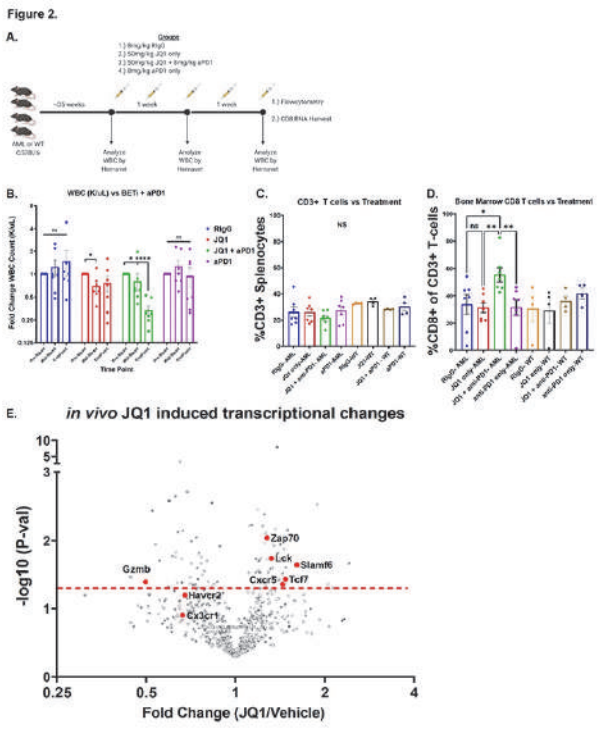
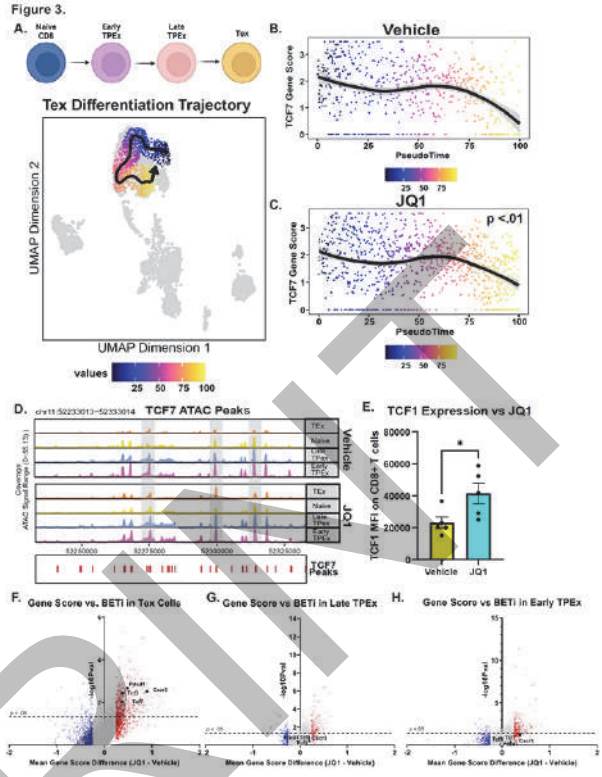
Abstract 899 Figure 1 BETi partially rescues T cell function in vitro Splenocytes were isolated from 7 AML (a) or 6 WT mice (b), stained with CFSE, and cultured for 72 hours without TCR stimulation (HIgG), anti-CD3 alone, anti-CD3 with anti-PD1 or titrations of anti-CD3 with JQ1 or anti-CD3 with both JQ1 and anti-PD1. Cells were stained and analyzed by flow cytometry. Plots represent the fold-change in proliferation in CD8+ T cells, as measured by percent CFSE diluted relative to anti-CD3 stimulated alone. Significance determined by Kruskal-Wallis multiple comparisons T-tests. Effect of BETi, anti-PD1, or BETi + anti-PD1 treatment on the percent of TPEx CD8+ T cells (c) and TEx CD8+ T cells (d) after culturing for 72 hours as previously in a-b. Significance determined by Kruskal-Wallis multiple comparisons T-tests. Splenocytes from 4 AML mice were stained with CFSE and plated for 72 hours without TCR stimulation (HIgG), anti-CD3 alone, anti-CD3 with anti-PD1 and titrations of anti-CD3 with JQ1 or anti-CD3 with both JQ1 and anti-PD1. Proliferation of TPEx (black) and TEx (red) CD8+ T cells from AML mice was assessed by flow cytometry (e). Significance determined by Kruskal-Wallis multiple comparisons t-tests.



Abstract 899 Figure 2 In vivo treatment with BETi and anti-PD1
a.) Schematic detailing in vivo BETi + anti-PD1 treatment strategy and functional readouts of efficacy. b.) Mice treated with RIgG, JQ1, JQ1 with anti-PD1, or anti-PD1 alone were bled periodically over a two-week period and assessed for WBC. Data displays fold-change WBC (k/μL) normalized per mouse in comparison to pre-treatment bleed WBC. Significance determined by one-way ANOVA. Timepoints are Pre-Bleed, Mid-bleed (day 7), Endpoint (day 14). c, d.) Bone marrow cells were isolated from treated AML and WT mice and assessed by flow cytometry. Graph denotes %CD3+ T cells in the bone marrow (c) and %CD8+ T cells in the bone marrow as a percent of all T cells (d). Significance derived from combining two experimental replicates and determined by one-way ANOVA. e.) CD8+ T cells were isolated from JQ1-treated and RIgG-treated AML mice and RNA harvested and analyzed by Nanostring. Volcano plot shows the fold-change in normalized transcript levels of JQ1-treated mice vs RIgG treated AML mice vs. –log10 P-value as determined by multiple t-tests. Hits of interest are highlighted in red. Dashed red line denotes significance threshold (0.05).



Abstract 899 Figure 3 ATAC-seq of CD8 T cells from animals treated with BETi

900 DECREASING TOXICITY OF IMMUNOCYTOKINES BY TRANSIENT AND SELECTIVE INHIBITION OF THEIR INTRACELLULAR SIGNALING ACTIVATION

[1]Sheila Dakhel Plaza*, [1]Giulia Rotta, [1]Samuele Cazzamalli, [1]Ettore Gilardoni, [1]Riccardo Stucchi, [2]Christian Pellegrino, [1]Jacqueline Mock, [1]Roberto De Luca, [3]Emanuele Puca, [3]Dario Neri. *[1]Philochem AG, Otelfingen, Switzerland; [2]University Hospital Zurich, Zurich, Switzerland; [3]Philogen S.p.A, Otelfingen, Switzerland*

Background The use of cytokine-based therapeutics has traditionally been limited by systemic toxicity, but it is now becoming evident that it may be possible to circumvent this problem in a number of ways. Tumor-targeting antibody-cytokine fusions proteins (also called "immunocytokines") typically allow to administer lower dosages of the payload as a result of the selective localization at the site of disease, thus, improving the therapeutic index. A second aspect relates to the non-linearity of cytokine-mediated toxicity and to the possibility of progressively increasing payload concentration in the tumor. At the clinical level, undesired side effects are often seen when the concentration of cytokines in blood exceeds a certain threshold. In most cases, adverse events disappear when cytokines are cleared from circulation.

Methods Here, we describe an innovative approach to transiently inhibit off-target toxicity of targeted-cytokines, while maintaining their antitumor activity. L19-TNF and L19-IL12 are two clinical-stage tumor-targeted antibody-cytokine fusion proteins that display potent activity by triggering the receptor-interacting serine/threonine-protein kinase 1 (RIPK1) and Janus Kinase 2 (JAK2) intracellular signaling pathways, respectively. Interestingly, small molecule inhibitors and immunocytokines based on antibody fragments have similar half-lives in blood, but only the immunocytokine accumulates at the tumor site for longer periods.

Results In a first study, GSK'963, a potent small molecule inhibitor of RIPK1, was tested in tumor-bearing mice with the aim to reduce acute systemic toxicity associated with TNF signaling. Transient inhibition of RIPK1 allowed the administration of TNF doses, which would otherwise be lethal. The protective effect of GSK'963 did not affect the selective localization of the immunocytokine to tumors. Moreover, L19-murTNF, when given in combination with GSK'963, was still able to induce tumor necrosis and to exert its potent anti-cancer effects. In a second study, tumor-bearing mice receiving L19-murIL12 were pretreated with Ruxolitinib (Jakafi®), a commercially available JAK2 inhibitor. The addition of Ruxolitinib could significantly improve the tolerability profile without affecting the anti-cancer properties of the immunocytokine. The safety profile was monitored following the body-weights of the animals and by measuring the interferon-γ (IFNγ) levels in blood at early time points after the intravenous injection of L19-murIL12.

Conclusions Our results are of clinical relevance, as patients treated with targeted cytokines L19-TNF and L19-IL12 could potentially benefit from judicious combinations treatments using GSK'963 or Ruxolitinib respectively.

901 INHIBITION OF GAS6/MERTK SIGNALING BY NOVEL MERTK ANTIBODY, 20A77, EXERTS SIGNIFICANT ANTI-TUMOR EFFICACY WITH LITTLE RETINAL DEGENERATION IN MICE

Atsushi Sawada*, Masayoshi Toyoura, Aki Takaiwa, Toshikazu Inoue, Koji Nakamura. *Chiome Bioscience Inc., Tokyo, Japan*

Background Mer Receptor Kinase (MerTK) is a member of TAM (**T**yro-3, **A**XL, **M**erTK) family of receptor tyrosine kinase and known as a macrophage receptor that mediates the efferocytosis. MerTK interacts with apoptotic cells through its ligands, Gas6 or protein S, and promotes the polarity of tumor-associated macrophages toward M2 phenotype.[1] Recent studies have revealed that MerTK signaling is involved in the immune suppression in the tumor microenvironment and specific inhibition of MerTK signaling suppressed tumor progression.[2-4] On the other hand, MerTK also plays an essential role in homeostasis of the retina through its ligands, Tubby and Tulp1 and the mutations in these genes cause retinal degeneration.[5-9] Thus, blockage of MerTK signaling have a potential risk for the retinal toxicity.

Methods Anti-MerTK monoclonal antibodies which recognized both with mouse and human antigen were established by immunization of recombinant human MerTK proteins in MerTK deficient mice. Isolated antibodies were analyzed their blocking activity against Gas-6 induced MerTK auto-phosphorylation by using MerTK-expressing cell-based assay. These antibodies were also analyzed their Inhibition activity of Tulp1-MerTK binding. The anti-tumor activity of isolated antibodies, 20A77 and 24A1, was evaluated in mouse colorectal CT26 bearing syngeneic mice model as monotherapy and in combination with anti-PD-1 antibody. In addition, retinal deficiency of 20A77 treated mice was analyzed histologically.

Results The isolated antibodies, 20A77 and 24A1, specifically recognized with both mouse and human MerTK and inhibited Gas6-dependent MerTK auto phosphorylation. In contrast, these antibodies didn't inhibit the Tulp1-MerTK binding. The treatment of either 20A77 or 24A1 antibody into CT26 bearing mice resulted in the reduction of the tumor growth. Tumor Infiltrated Lymphocyte (TIL) analysis revealed that the ratio of M1 polarized macrophage was increased in 20A77 treated mice. Moreover, the combination of anti-MerTK and anti-PD-1 antibody treatment indicated enhanced anti-tumor responses than any of single-agents of antibody treatment. Lastly, we analyzed the histological defect in the eyes of 20A77 treated mice. No deficiency of retina was detected in medical effective dose of 20A77 treated mice. However, increased amount of 20A77 treatment caused retinal degeneration.

Conclusions Novel anti-MerTK antibody, 20A77, which selectively inhibited GAS6-mediated MerTK signaling showed significant anti-tumor activity without retinal degeneration in a mouse model. Our results suggest that the strategy for ligand-selective inhibition of MerTK signaling by the specific antibody could become a novel treatment option with lower retinal toxicity for solid tumors.

902 NKX019, AN OFF-THE-SHELF CD19 CAR-NK CELL, MEDIATES IMPROVED ANTI-TUMOR ACTIVITY AND PERSISTENCE IN COMBINATION WITH CD20-DIRECTED THERAPEUTIC MABS

Mira Tohmé*, Tina Davis, Max Zhang, Hadia Lemar, Bao Duong, Joanne Tan, James Trager.
Nkarta Therapeutics, South San Francisco, CA, United States

Background NKX019 is an investigational CD19-targeting chimeric antigen receptor (CAR) natural killer (NK) cell therapy with engineered persistence for treating B cell malignancies. NKX019 exhibits more rapid cytotoxic kinetics than CD19-directed CAR T cells, and lower production of cytokines associated with cytokine release syndrome (CRS).[1] The safety and clinical activity of NKX019 are currently being evaluated in a phase I [GM1] clinical study [NCT05020678]. Recent studies[2,3] have shown that combining NK cell therapies with monoclonal antibodies (mAbs) may improve targeted NK cell activation and overcome some of the disadvantages associated with the stand-alone use of therapeutic mAbs. CD20-targeted mAbs such as rituximab (RTX) and obinutuzumab (OBI), can mediate antibody-dependent cellular cytotoxicity (ADCC), a key effector mechanism of NK cells. RTX also activates some levels of caspase-dependent direct cell death (DCD). OBI is engineered to induce improved DCD and ADCC mechanisms.[4] Antigen escape is reported in 30–95% of relapses after CD19-directed CAR T cell therapy in B cell –acute lymphoblastic leukemia (B-ALL).[5] Here, we describe the potential advantage of using NKX019 in combination with [GM2] RTX or OBI to reduce relapse following monotherapy with either agent alone by targeting both $CD19^+$and $CD20^+$ malignant B cells.

Methods NK cells, isolated from healthy PBMCs, were expanded and engineered to express a CD19-targeted CAR and membrane-bound interleukin 15 to generate NKX019. NKX019 cells were cryopreserved and freshly thawed for experimental use.NKX019 mediated-cytotoxicity was assessed in both 4-Hour (4H) and extended assays in the presence or absence of anti-CD20 mAbs, RTX or OBI, using $CD19^+$ and $CD20^+$ expressing tumor B cell lines: Raji (lymphoblast-like), DOHH-2 (follicular lymphoma) and EHEB (B-Lymphoblastoid) cells. A non-glycosylated version of RTX (RTX mutant) with compromised ADCC function was used to evaluate ADCC-mediated vs ADCC-independent activity of NKX019.

Results NKX019 in combination with RTX or OBI demonstrated increased activity and persistence against tumor B cell lines in a 4H kill assay and in tumor rechallenge experiments. NKX019 in combination with RTX demonstrated an enhanced cytotoxicity against EHEB lymphoblastoid cell line in a manner consistent with ADCC. OBI demonstrated increased activity in comparison to RTX, as a single agent and in combination with NKX019 cells.

Conclusions This study demonstrates increased activity and persistence of NKX019 when used in combination with approved CD20-targeted mAbs, RTX and OBI, against B cell malignancies. A first-in -human Phase I clinical trial of NKX019 in combination with RTX is planned.

903 APR-246 INDUCES AN INCREASE IN TUMOR IMMUNOGENICITY IN A P53 INDEPENDENT MANNER

[1]Divya Venkatesh*, [1]Judith Michels, [1]Cailin Lu, [1]Sadna Budhu, [1]Mariam George, [1]Ouathek Ouerfelli, [2]Lars Abrahmsen, [3]Roberta Zappasodi, [3]Jedd Wolchok, [3]Taha Merghoub. *[1]Memorial Sloan Kettering Cancer Center (MSKCC), New York, NY, United States; [2]Aprea Therapeutics, Solna, Sweden; [3]MSKCC and Weil Cornell Medicine (WCM), New York, NY, United States*

Background Immunotherapy has made a significant impact in treating cancer, yet more than 40% of the patients remain unresponsive or have a short-lived response to therapy. Rationally designed combinations of targeted therapies with immune modulators have the potential to enhance therapeutic efficacy[1, 2]. As p53 is also well known to differentially modulate the immune system[3], it is an attractive target to be used in combination with immunotherapy. Thus, we evaluated the immunogenic potential of APR-246, a targeted therapy that activates p53[4]. In addition, APR-246 can also elicit p53-independent effects mainly through the induction of endoplasmic reticulum stress and oxidative stress in several preclinical tumor models[5]. As these cellular stressors as well as p53 are capable of enhancing the immunogenicity of tumor cells[6, 7], we hypothesized that agents that stabilize p53 such as APR-246 may also increase the tumor antigenicity.

Methods We designed a set of *in vitro* and *in vivo* assays to evaluate the ability of targeted therapies to elicit an immunogenic response in tumor cells. Here, we use the preclinical melanoma cell line B16-F10 as a model since it is highly metastatic and responds poorly to immunotherapy alone[8, 9].

Results When we treated B16-F10 cells with APR-246 either in culture *in vitro* or implanted as a tumor in C57BL/6J mice *in vivo*, we observed an increase in MHC expression. Further, when mice were immunized with APR-246-treated B16-F10 cells and then implanted with healthy untreated melanoma cells, they had prolonged tumor free survival. Additionally, in our *in vitro* co-culture assays, APR-246 treatment enabled tumor cells to activate antigen-specific cytotoxic T cells when mediated by antigen presenting cells. Therefore, we hypothesized that APR-246 has the potential to mechanistically combine with immune modulation owing to its immunogenic potential. Thus, we rationally designed a treatment regimen to further enhance the tumor immunogenic effects elicited by APR-246. When APR-246 treatment was combined with the TLR4 agonist, Monophosphoryl lipid A (MPL) and a CD40 agonist antibody, we observed significant delay in the growth of B16 tumor in mice. Importantly, using CRISPR generated B16 p53 KO cells, we have identified that these immunogenic effects of APR-246 are observed independently of p53, albeit slightly reduced.

Conclusions Based on our findings, we propose that the combination of APR-246 with immunomodulatory agents may be effective in treating cancers irrespective of their p53 mutation status.

904 LDH INHIBITION IMPROVES RESPONSE TO CTLA-4 BLOCKADE BY ENHANCING EFFECTOR T CELL ACTIVITY AND IMPAIRING REGULATORY T CELL SUPPRESSION

[1]Svena Verma*, [1]Inna Serganova, [2]Sadna Budhu, [1]Lauren Dong, [2]Levi Mangarin, [2]Myat Ko, [2]Ronald Blasberg, [1]Roberta Zappasodi, [2]Jedd Wolchok, [2]Taha Merghoub,. [1]*Weill Cornell Medicine, New York, NY, United States*; [2]*Memorial Sloan Kettering, New York, NY, United States*

Background Tumor reliance on glycolysis is not only a hallmark of cancer, but also a mechanism of resistance to immunotherapy due to lactate-mediated immune suppression and competition for glucose between T cells and glycolytic tumor cells within the tumor microenvironment.[1,2] We have shown that CTLA-4 blockade is more effective in glycolysis-low tumors, or tumors lacking functional lactate dehydrogenase A (LDH-A), primarily due to functional destabilization of regulatory T cell suppression.[3] LDH inhibitors (LDHi) have been reported to inhibit tumor glucose uptake and slow tumor cell proliferation in pre-clinical models of cancer.[4] However, the optimal conditions for pharmacologic inhibition of LDH in combination with immunotherapy to maximize anti-tumor immune and therapeutic responses require further study.

Methods B16F10-bearing C57BL/6 mice were treated daily with LDHi GNE-140 (oral gavage) and/or biweekly with anti-CTLA-4 (intraperitoneal injection) and tumor volume was measured twice per week. Bioactivity of LDHi was confirmed by quantification of lactate and LDH enzymatic activity in sera and tumors, as well as immunoblotting for LDHA protein levels. In separate experiments, tumors were harvested after 3 administrations of anti-CTLA-4 and processed for flow cytometric analysis of tumor-infiltrating lymphocytes to assess infiltration, activation, and function. Glucose uptake was assessed in tumor and T cells by fluorescent glucose analog GlucoseCy3.

Results At baseline, tumor cells express higher levels of LDHA and consume more glucose than tumor-infiltrating T cells, creating a therapeutic window for tumor-specific targeting of glycolysis. Serum LDH and lactate levels correlate with primary tumor burden, as well as tumor LDH levels. LDHi relies on the adaptive immune system and the overexpression of tumor LDH to delay melanoma growth. Inhibiting LDH in combination with CTLA-4 blockade is more effective in controlling tumor progression compared to CTLA-4 blockade alone, and this combination promotes effector T cell infiltration and activation while functionally destabilizing regulatory T cells. Treatment with LDHi reduces tumor cell glucose uptake while facilitating increased glucose uptake by tumor-infiltrating T cells.

Conclusions CTLA-4 blockade with LDHi enhances effector T cell function while impairing regulatory T cell suppression. LDH inhibition is an effective strategy to reduce tumor cell glucose uptake, therefore increasing tumor glucose availability and facilitating an increase in tumor-infiltrating T cell glucose uptake. Serum LDH may serve as a biomarker for clinical response to LDHi. This study provides a rationale for combining immune checkpoint blockade with inhibitors of glycolysis for patients with highly glycolytic cancers.

905 BROAD ANTI-TUMOR ACTIVITY OF A POTENT AND SELECTIVE SMALL MOLECULE ANTAGONIST OF PD-L1 ABSK043 IN COMBINATION WITH OTHER AGENTS IN PRECLINICAL MODELS

Haiyan Ying*, Yongxian Zhang, Fei Yang, Wenqun Xin, Jie Wang, Jie Zhang, Zhui Chen. *Abbisko Therapeutics, Shanghai, China*

Background Immunotherapy has revolutionized cancer treatment in the last decade. Several monoclonal PD-1 and PD-L1 antibodies have been approved for various cancers. Unlike antibodies, small molecules may offer potential advantages in oral dosing, adjustable control of drug exposure, improved tumor penetration and many other aspects. Therefore, small molecule antagonist which can efficiently abolish interaction of PD-1 and PD-L1 may render a novel and alternative treatment approach with potentially improved clinical benefits. ABSK043, an oral small molecule antagonist of PD-L1 discovered by us, has entered into clinical Phase I in 2021. Preclinically, ABSK043 has shown significant tumor growth inhibition as a single agent in multiple models. To explore potential synergy of ABSK043 with other therapeutic agents, *in vivo* combination experiments were conducted.

Methods For *in vivo* studies, the tumor (MC38-human PDL1 knock in)-bearing syngeneic mice were treated with ABSK043 and other agents. In addition, we also developed a humanized bladder cancer model using the RT112/84 cell line. Mice were injected intravenously with human PBMC from healthy volunteer, and injected subcutaneously into flank with cancer cells.

Results ABSK043 demonstrated strong *in vivo* synergy with several therapeutic agents such as carboplatin, a key component of the widely used CRC standard-of care chemotherapy treatment regimen, as well as other target therapy or immune-oncology agents.

Conclusions Taken together, these data for the first time demonstrated broad combination synergy of a small molecule PD-L1 antagonist with other agents and provided basis for potential clinical evaluation of these combination treatment for cancer patients.

906 TELOMERE DYSFUNCTION MEDIATES ANTI-TUMOR IMMUNITY IN SMALL CELL LUNG CANCER

Mingrui Zhu*, Buse Eglenen-Polat, Matthew Bender, Ilgen Mender, Silvia Siteni, Benjamin Drapkin, Jerry Shay, Esra Akbay. *UT Southwestern Medical Center, Dallas, TX, United States*

Background Small cell lung cancer (SCLC) is a pulmonary neuroendocrine cancer with very poor prognosis and limited effective therapeutic options. Chemotherapy is used as first-line treatment for this highly proliferative cancer. High telomerase activity was observed in SCLC which may contribute to active proliferation. 6-thio-2-deoxyguanine(6T-dG) is a novel telomere-specific nucleoside precursor recognized by telomerase. It is incorporated into *de novo* synthesized telomeres and lead to telomere dysfunction. It specifically affects cells with high telomerase activity such as cancer cells. Here we induced telomere dysfunction in SCLC by 6T-dG to investigate the effects on tumor growth and the tumor microenvironment.

Methods We first evaluated the anti-tumor effect of 6T-dG on SCLC by cell viability assay and colony formation *in vitro*. Then the effect was examined *in vivo* by mouse allografts or xenografts. Post-treatment tumor microenvironment was characterized by flow cytometry and *in vitro* co-culture assay was performed to set up mechanistic study on drug-evoked immunity. For therapeutic studies 6T-dG was combined with other current treatments for SCLC to assess its therapeutic potential.

Results 6T-dG induces DNA damage in SCLC and inhibited tumor progression both *in vitro* and *in vivo*. Cancer cells with higher telomerase activity were more vulnerable to the inhibition. Flow cytometry analysis of 6T-dG treated mouse tumors revealed changes in the tumor microenvironment such as infiltration and activation of cytotoxic lymphocytes while reducing infiltration of immune-suppressive myeloid cells and T regulatory cells. 6T-dG also works synergistically with common clinical treatment of SCLC such as immune checkpoint blockade (ICB) in mouse allograft model.

Conclusions Inducing telomere dysfunction impairs tumor progression by eliminating cancer cells with high telomerase activity and triggers anti-tumor immunity in SCLC. Inhibiting telomerase activity is a promising therapeutic strategy as single agent or synergistically with immunotherapy in SCLC.

907 BLOCKADE OF VEGF, ANGIOPOIETIN-2, AND PD1 REPROGRAMS DYSFUNCTIONAL ENDOTHELIAL CELLS IN GLIOBLASTOMA TO QUASI-ANTIGEN-PRESENTING CELLS

[1]Zohreh Amoozgar*, [2]Jun Ren, [2]Nancy Wang, [2]Patrik Andersson, [2]Gino Ferraro, [2]Shanmugarajan Krishnan, [2]Pin-Ji Lei, [2]Sonu Subudhi, [1]Kosuke Kawaguchi, [3]Rong En Tay, [1]Igor Gomes-Santos, [1]Peigen Huang, [4]Hye-Jung Kim, [1]Dai Fukumura, [1]Rakesh Jain. *[1]MGH, Harvard Medical School, Boston, MA, United States; [2]MGH, Boston, MA, United States; [3]Singapore Immunology Network, Singapore, Singapore; [4]DFCI, Harvard Medical School, Boston, MA, United States*

Background Glioblastoma (GBM) is the most aggressive and deadly primary tumor. Endothelial cells (ECs) in GBM vessels form a barrier between circulating immune cells and parenchymal tissue. ECs in GBM are dysfunctional,[1, 2] conferring resistance to immunotherapy. Anti-VEGF-induced vascular normalization is insufficient to fully restore the EC function. Our studies and others have shown that antiangiogenic agents inhibiting VEGF signaling can transiently restore normal vascular function[1, 2] and thus significantly increase infiltration of cytotoxic T cells (CTLs)[3, 4] However, CTL accumulation in the tumor bed is necessary but not sufficient for the therapeutic response. Sustained activation of CTLs by antigen-presenting cells is a key step for effective antitumor responses.

Methods Using three orthotopic preclinical GBMs, ex vivo and in vitro studies, we investigated whether reprogramming the dysfunctional GBM ECs upregulates receptors on ECs that promote CTL trafficking, reprogrammed ECs present tumor antigens to CTLs, and this antigen presentation results in generation of an active tumor-immune niche in GBM.

Results Concomitant blockade of Ang2, VEGF using a bispecific antibody (A2V), and aPD1 reprograms dysfunctional endothelial cells to quasi-antigen presenting cells and upregulates receptors required for cytotoxic T lymphocyte entry into the tumor. Blocking VEGF, Ang2, and PD1 induces durable anti-tumor T cell response in preclinical GBM models. Upregulation of the transcription factor T-bet is both necessary and sufficient for generating resident memory T cells elicited by this therapeutic regimen (figure 1).

Conclusions Collectively, our data (i) provide heretofore unknown insights into targeting Ang2 as a shared resistance pathway for both aVEGF and aPD1 in experimental GBM models, (ii) demonstrate a strategy to reprogram ECs to activate and promote CTL recruitment into GBMs followed by retaining intratumoral T cells, (iii) offer a possible solution to overcome GBM resistance to aVEGF and aPD1, and (iv) provide mechanistic insights into how T cell memory forms after aPD1+A2V therapy. Multiple strategies to combine aPD1 and aVEGF are currently being evaluated in clinical trials for non-CNS tumors, and our study provides a foundation for testing the combination of a more effective vascular normalizer A2V in combination with αPD1/PD-L1 in GBM patients where aPD1 monotherapy and in combination with aVEGF+aPD1 have failed in all randomized clinical trials.

908 TUMOR-INTRINSIC P38 SIGNALING AS A THERAPEUTIC TARGET TO OVERCOME NON-T CELL-INFLAMED TUMORS AND IMMUNOTHERAPY RESISTANCE

[1]Rebekah Dadey*, [2]Shannon Winski, [2]Patrice Lee, [2]Sarah Brodeur, [1]Tullia Bruno, [1]Heath Skinner, [1]Robert Ferris, [1]Jason Luke, [1]Riyue Bao. [1]*University of Pittsbugh, Pittsburgh, PA, United States*; [2]*Pfizer, Boulder, CO, United States*

Background We previously identified WNT/β-catenin (*CTNNB1*) and an atlas of molecular alterations that drive the non-T cell-inflamed phenotype and immune-checkpoint inhibitor (ICI) resistance across cancers. To refine our analysis, we have subsequently separated tumor types by clinically relevant stratifications, such as human papilloma virus (HPV) in head and neck squamous cell carcinoma (HNSCC), to identify immune-exclusion mechanisms associated with specific patient populations. P38 MAPK is a known regulator of dendritic cells (DCs) and myeloid cells however a tumor-intrinsic immunomodulatory role has not been previously described.

Methods Using the T cell-inflamed gene expression signature we previously defined, we integrated tissue RNAseq from 395 HPV- HNSCCs in The Cancer Genome Atlas (TCGA) with single-cell RNAseq from two independent HNSCC studies. We detected differentially expressed genes in non-T cell-inflamed *versus* inflamed tumors by limma voom (v3.36) in concert with causal network prediction, followed by validation in two independent HNSCC cohorts. scRNAseq data was processed by Cellranger (v6) and Seurat (v3.99). We quantified pathway expression levels in tumor cells, DCs, macrophages, and other main cell types in the tumor microenvironment. Single-cell pathway comparisons were further conducted using generalized linear mixed-effects models (GLMM) and protein-protein interaction networks constructed by STRING. Pharmacologic inhibition of p38 MAPK was explored in combination with ICI in two syngeneic murine models. Patients with ICI refractory tumors were treated with p38 inhibitor plus ICI.

Results We identified 67 pathways as activated in non-T cell-inflamed tumors from the HPV- cohort of HNSCC, 59 of which were independently validated. This included CTNNB1 from our prior work and p38 MAPK, the therapeutic target in our ongoing clinical trial (NCT04074967). CTNNB1 and p38 pathway molecules both showed inverse correlation with CD8A protein abundance from the Clinical Proteomic Tumor Analysis Consortium. We observed a significant enrichment of pathway expression only in tumor cells ($p<0.05$) from both HNSCC scRNAseq studies and dominantly in non-T cell-inflamed tumors. Using an accumulative scoring system integrating bulk tissue and single cell sequencing data, we prioritized seven pathways as strongly connected in non-inflamed tumors, with the top regulators as CTNNB1 and p38, among others. EMT6 and CT26 syngeneic murine models demonstrated improved survival with the addition of p38 inhibitor to ICI relative to ICI monotherapy. Major and durable clinical responses have been observed in patients with anti-PD1 refractory tumors.

Conclusions p38 is a novel tumor-intrinsic mechanism that drives immune exclusion. P38 inhibition enhances ICI and can overcome anti-PD1 resistance in patients.

Ethics Approval Our study gained approval from IRB, HCC#19-097. Any/all participants in human studies gave informed consent before participating.

909 OVERCOMING RESISTANCE TO NK-MEDIATED LYSIS IN ENZALUTAMIDE-RESISTANT PROSTATE CANCER CELLS

Madeline Dahut*, Kristen Fousek, Lucas Horn, Haiyan Qin, Jeffrey Schlom, Claudia Palena.
National Cancer Institute, Bethesda, MD, United States

Background Enzalutamide, a next-generation hormonal agent, is approved for the treatment of metastatic castration-resistant prostate cancer (CRPC). Although treatment with enzalutamide results in initial clinical benefit in men with CRPC, resistance to therapy and disease progression are ultimately observed in the majority of patients. Several mechanisms of resistance have been described in this context, including reactivation of androgen receptor (AR) signaling via gene amplification, splice variants or mutations, activation of the glucocorticoid receptor (GR), and tumor cell plasticity. Our laboratory and others have shown that tumor cell plasticity, a phenomenon characterized by the acquisition of mesenchymal markers and the loss of epithelial features by carcinoma cells, can drive tumor resistance to immune effector cell lysis; however, the link between enzalutamide resistance, tumor cell plasticity, and resistance to immune-mediated lysis has not been yet investigated. In this study, we interrogated enzalutamide-resistant prostate cancer models for their susceptibility to NK-mediated cell lysis, and evaluated approaches to enhance immune-mediated lysis of prostate cancer cells that are resistant to enzalutamide.

Methods Models of enzalutamide-resistant prostate cancer were developed by long-term exposure of LNCAP and MDA-PCa 2b human prostate cancer cells to enzalutamide in culture. Resistant and parental cells were comparatively evaluated for phenotypic features via RT-PCR, ELISA, western blot, immunofluorescence, and RNAseq analysis. Sensitivity to NK-cell mediated cytotoxicity was evaluated with NK cells isolated from peripheral blood from healthy donors. Xenografts established in NSG MHCI/II-deficient mice were characterized for phenotypic markers and potential therapeutic targets.

Results Our findings demonstrated that LNCAP and MDA-PCa 2b cells resistant to enzalutamide had acquired a phenotype consistent with the occurrence of an epithelial-mesenchymal switch. In addition, enzalutamide-resistant cells had significantly decreased sensitivity to NK cell-mediated lysis. RNAseq and PCR analyses demonstrated a significant upregulation of estrogen receptor alpha (ESR1) in enzalutamide-resistant cells. Treatment with fulvestrant, a selective estrogen receptor degrader (SERD) was able to increase sensitivity to NK killing while decreasing mesenchymal tumor features and increasing expression of epithelial E-cadherin. In vivo data confirmed the ability of fulvestrant to increase epithelial tumor features in LNCAP enzalutamide-resistant xenografts.

Conclusions Our data indicates that blockade of estrogen receptor signaling in enzalutamide-resistant prostate cancer cells can revert mesenchymal tumor features resulting in increased sensitivity to immune attack. Future studies will evaluate combination of fulvestrant or other estrogen antagonists with NK-based immunotherapy in models of enzalutamide-resistant prostate cancer.

910 STING AGONISM OVERCOMES STAT3-MEDIATED IMMUNOSUPPRESSION AND ADAPTIVE RESISTANCE TO PARP INHIBITION IN OVARIAN CANCER

[1]Liya Ding*, [1]Qiwei Wang, [2]Antons Martincuks, [1]Michael Kearns, [1]Tao Jiang, [1]Ziying Lin, [1]Xin Cheng, [1]Changli Qian, [1]Hye-Jung Kim, [3]Inga-Maria Launonen, [3]Anniina Färkkilä, [1]Thomas Roberts, [1]Joyce Liu, [1]Panagiotis Konstantinopoulos, [1]Ursula Matulonis, [2]Hua Yu, [1]Jean Zhao. *[1]Dana-Farber Cancer Institute, Boston, MA, United States; [2]City of Hope National Medical Center, Duarte, CA, United States; [3]University of Helsinki, Helsinki, Finland*

Background PARP inhibition (PARPi) has demonstrated potent therapeutic efficacy in patients with BRCA-mutant ovarian cancer.[1] However, acquired resistance to PARPi remains a major challenge in the clinic.[2,3]

Methods PARPi-resistant ovarian cancer mouse models were generated by long-term treatment of olaparib in syngeneic Brca1-deficient ovarian tumors. STAT3-mediated immunosuppression was investigated *in vitro* by co-culture experiments and *in vivo* by analysis of immune cells in the TME of human and mouse PARPi-resistant tumors. Whole genome transcriptome analysis was performed to assess the anti-tumor immunomodulatory effect of STING (stimulator of interferon genes) agonists on myeloid cells in the TME of PARPi-resistant ovarian tumors. A STING agonist was used to overcome STAT3-mediated immunosuppression and acquired PARPi resistance in syngeneic and PDX models of ovarian cancer.

Results In this study, we uncover an adaptive resistance mechanism to PARP inhibition mediated by tumor associated macrophages (TAMs) in the tumor microenvironment (TME). Markedly increased populations of pro-tumor macrophages are found in BRCA-deficient ovarian tumors that rendered resistance to PARPi in both murine models and patients. Mechanistically, PARP inhibition elevates the STAT3 signaling pathway in tumor cells, which in turn promotes pro-tumor polarization of TAMs. STAT3 ablation in tumor cells mitigates polarization of pro-tumor macrophages and increases tumor infiltrating T-cells upon PARP inhibition. These findings are corroborated in patient-derived, PARPi-resistant BRCA1-mutant ovarian tumors. Importantly, STING agonists reshape the immunosuppressive TME by reprograming myeloid cells and overcome the TME-dependent adaptive resistance to PARPi in ovarian cancer. This effect is further enhanced by addition of PD-1 blockade.

Conclusions We elucidate an adaptive immunosuppression mechanism rendering resistance to PARPi in BRCA1-mutant ovarian tumors. This is mediated by enrichment of pro-tumor TAMs propelled by PARPi-induced STAT3 activation in tumor cells. We also provide a new strategy to reshape the immunosuppressive TME with STING agonist and overcome acquired PARPi resistance in ovarian cancer (figure 1).

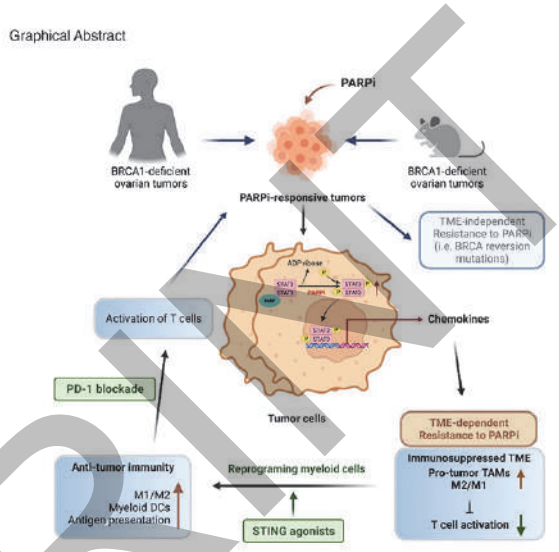
Ethics Approval Immunofluorescent staining and analysis of ovarian tumor sections from female ovarian cancer patients were conducted according to a City of Hope Institutional Review Board approved protocol. All the animal experiments described in this study were performed according to animal protocols approved by the DFCI Institutional Animal Care and Use Committee (IACUC).



Abstract 910 Figure 1 Graphical Abstract Overcoming TME-dependent adaptive resistance to PARPi in BRCA1-deficient ovarian cancer with STING agonist treatment. Over a course of PARPi treatment, BRCA1-deficient ovarian tumors develop TME-dependent or -independent adaptive resistance to PARPi therapy. PARPi induces STAT3 signaling in the tumor cells, which in turn polarizes macrophages towards pro-tumor M2-like TAMs and contributes to TME-dependent PARPi resistance in ovarian cancer. Treatment with a STING agonist can reshape the immunosuppressive TME to an anti-tumor status by reprograming myeloid cells, re-sensitizing the resistant tumors to PARPi therapy in BRCA1-deficient ovarian cancer

911 ANTI-VEGF THERAPY IMPROVES EGFR-VIII-CAR-T CELL DELIVERY AND EFFICACY IN SYNGENEIC GLIOBLASTOMA MODELS IN MICE

Xinyue Dong, Jun Ren, Zohreh Amoozgar*, Meenal Datta, Somin Lee, Sylvie Roberge, Mark Duquette, Dai Fukumura, Rakesh Jain. *MGH, Harvard Medical School, Boston, MA, United States*

Background Chimeric antigen receptor (CAR)-T cells have revolutionized treatment of multiple types of hematological malignancies, but have shown limited efficacy in patients with glioblastoma (GBM) or other solid tumors. This may be largely due to the immunosuppressive tumor microenvironment (TME) that compromises the delivery and anti-tumor activity of CAR-T cells. We previously showed that blocking VEGF (vascular endothelial growth factor) signaling can normalize tumor vessels in murine and human tumors, including GBM, breast, liver, and rectal carcinomas. Moreover, we demonstrated that vascular normalization can improve the delivery of CD8+ T cells and efficacy of immunotherapy in breast cancer models in mice. In fact, the US FDA has approved 7 different combinations of anti-VEGF drugs and immune-checkpoint blockers for liver, kidney, lung and endometrial cancers in the past 3 years.[1-25] Here we tested the hypothesis that anti-VEGF therapy can improve the delivery and efficacy of CAR-T cells in immunocompetent mice bearing orthotopic GBM tumors

Methods We engineered two syngeneic mouse GBM cell lines (CT2A and GSC005) to express EGFRvIII – one of the most common neoantigens in human GBM – and CAR T cells to recognize EGFRvIII. We tested our CAR T cells in orthotopic GBMs for their efficacy in recognizing, and killing tumor cells, and the survival advantage when tumor vessels are normalized.

Results We found that treatment with the anti-mouse VEGF antibody (B20) improved CAR-T cell infiltration and distribution throughout the GBM TME, delayed tumor growth, and prolonged survival of GBM-bearing mice compared to EGFRvIII-CAR-T cell therapy alone (figure 1).

Conclusions Our study provides a strategy to overcome major challenges in CAR-T cell therapy in GBM by: (i) increasing the CAR-T cell infiltration, intratumoral distribution, and activation in murine GBM models, and (ii) reprograming TME by increasing the number and activation of endogenous effector T cells, resulting in improved anti-tumor efficacy of CAR-T therapy in two GBM mouse models. Given that anti-VEGF therapies have been approved for a number of solid tumors, including GBM, our study provides mechanistic insights and compelling preclinical data in support of testing the combination of vascular normalizing agents and CAR-T therapies in GBM patients. Furthermore, this approach may also improve CAR-T therapy of other solid tumors that share similar TME features as well as for other cell-based therapies using autologous or allogenic immune cells (e.g., NK cells, macrophages).

912 EPIGENETIC REMODELING ENHANCES THERAPEUTIC RESPONSES TO STING AGONISM *IN VIVO*

[1]Rana Falahat*, [1]Anders Berglund, [1]Patricio Perez-Villarroel, [1]Shari Pilon-Thomas, [2]Glen Barber, [1]James Mule. *[1]Moffitt Cancer Center, Tampa, FL, United States; [2]University of Miami, Miami, FL, United States*

Background Despite evidence of therapeutic activity in preclinical models, STING activating agents have shown limited efficacy in early phase clinical trials. This discrepancy in outcomes suggests that in addition to antigen presenting cells, targeting STING pathway could be also functionally relevant in tumor cells with well documented epigenetically driven STING suppression.[1, 2] In this study, we determined if reversal of tumor cell-intrinsic STING silencing using a DNA methyltransferase inhibitor can improve the efficacy of a STING agonist in mouse models of melanoma.

Methods Using genome-wide methylation profiling, we assessed methylation levels of STING in B16-F10 and Yumm1.7 mouse melanoma cell lines before and after treatment with 5-aza-2'-deoxycytidine (5AZADC). We also evaluated their activation of STING following stimulation with the STING agonist ADU-S100. Using B16-F10 and Yumm1.7 models in STING-deficient and STING-sufficient hosts, we next assessed the effect of 5AZADC treatment on the efficacy of ADU-S100. Additionally, we performed mechanistic studies using T-cell depletion experiments as well as phenotypic and gene expression profiling.

Results While we observed hypermethylation of STING in both B16-F10 and Yumm1.7 cell lines, their treatment with 5AZADC resulted in a decrease in STING methylation levels. We also found reconstitution of STING protein expression in 5AZADC-pretreated cell lines as well as up to a 46-fold increase in induction of IFN-β ($p < 0.001$) and a 4.5-fold increase in MHC class I surface expression ($p < 0.01$) compared to untreated controls following stimulation with ADU-S100. In tumor-bearing mice, while treatment with a combination of 5AZADC and ADU-S100 resulted in a marked increase in Ifnb1 transcripts within tumors ($p < 0.001$), it significantly delayed tumor growth ($p < 0.05$). Antibody-mediated depletion studies in mice receiving the combination therapy further indicated that this antitumor activity depends on the generation of functional tumor antigen-specific $CD8^+$ T cells ($p < 0.001$); however, tumor growth remained unaltered by the depletion of $CD4^+$ T cells.

Conclusions We have shown that although epigenetic silencing of STING in melanoma cells can confer resistance to STING agonist therapy, a rational combination of a clinically available DNA methylation inhibitor with a STING agonist can reverse this silencing and lead to robust antitumor responses in the setting of two $STING^{low}$ murine models of melanoma. Therefore, identification and pharmacologic restoration of tumor cell-intrinsic STING defects through epigenetic reprograming might be critical for the successful use of STING agonists in the clinic.

913 TRANSLATIONAL ANALYSIS OF ADVANCED METASTATIC BLADDER CANCER PATIENTS TREATED WITH IO COMBINATION MAVEROPEPIMUT-S, CYCLOPHOSPHAMIDE, AND PEMBROLIZUMAB

Heather Torrey*, Walead Ebrahimizadeh, Valarmathy Kaliaperumal, Aurelio Lobo, Barry Kennedy, Tran Ngo, Lisa MacDonald, Stephan Fiset, Jeremy Graff, Heather Hirsch. *IMV inc., Dartmouth, Canada*

Background Maveropepimut-S (MVP-S, formerly DPX-Survivac) is comprised of immunogenic T cell peptides from the cancer antigen, survivin, as well as a universal T helper peptide, A16L, and the innate immune activator, poly-dIdC, packed within the proprietary DPX® lipid-in-oil delivery platform. When combined with intermittent low-dose cyclophosphamide (CPA), and the immune checkpoint inhibitor, pembrolizumab, the proprietary DPX lipid-in-oil delivery platform elicits a sustained immune response that has been associated with clinical benefit in multiple tumor types. Here, we present translational analyses of immune cell infiltration and peripheral, cell-mediated immunity in advanced metastatic bladder cancer subjects (n=19) from this Phase 2 trial, NCT03836352.

Methods Survivin specific immune response was measured in PBMCs by IFN-? ELISPOT (n=14) and MHC-Tetramer assay (n=13). Multiplex immunofluorescence (mIF) (n=5) was performed by Precision for Medicine. PD-L1 status (n=13) was analyzed using the 22C3 IHC assay at Covance. Gene expression analysis was performed using the NanoString IO360 panel (n=11).

Results Analysis of PBMCs by IFN-? ELISPOT or MHC-tetramer assay demonstrates antigen-specific cell response in 71.4% (10/14) of evaluable patients, and in all five patients with measurable tumor responses. Baseline profiling of RNA signatures suggests that levels of B, T, and NK cells are higher in tumors of responding patients similar to previous MVP-S trials (DeCidE[1]; NCT02785250). Preliminary mIF also shows that one complete responder (RECISTv1.1) has a higher density of infiltrate, including CD8+ cells, at baseline. Grouped analysis of five on-treatment samples suggests higher immune resistance pathways such as TGF and $CD71^+$ early erythroid cells, in non-responding patients, which has been linked to immune tolerance and suppression of T cells.[1] mIF of five paired pre- and on-treatment biopsies reveals higher levels of $FoxP3^+$ (T_{regs}) in post-treatment tumour of non-responders whereas the reverse is observed in tissue of responders. PD-L1 staining of pre-treatment tumor tissue by IHC, shows (4/4) of evaluable responding patients had a CPS score of $\geq$1%.

Conclusions The combination of MVP-S, CPA, and anti-PD-1 therapy provides a renewed approach directly targeting the TAA survivin and imposing a limit on immune suppression with CPA along with checkpoint inhibition. The data herein show that the treatment of advanced metastatic bladder cancer with MVP-S plus CPA in combination with pembrolizumab elicits a strong survivin-specific immune cell response in addition to the clinical response as reported previously (AACR 2022). Taken together, the translational data demonstrate that this novel immune oncology approach leads to immune education that is correlated with improved disease control.

914 REGULATING NEGATIVE IMMUNE REGULATORS TO ENHANCE IMMUNE CHECKPOINT BLOCKADE ANTITUMOR POTENTIAL

Yared Hailemichael*, Glenn Winn, Michael Davies. *The University of Texas MD Anderson Cancer Center, Houston, TX, United States*

Background Understanding the exact immunobiology of immune checkpoint blockade (ICB)-related relapse would be essential to augmenting ICB-induced antitumor immunity and overcoming resistance. In response to ICB, a specific and effective immune response is induced. However, the levels of distinct immune cell subsets and the specific signals that draw them into a tumor microenvironment (TME) following broad application of cancer immunotherapies such as immune checkpoint blockade (ICB) remain poorly characterized. We previously showed that lymphocyte function associated antigen-1 (LFA-1) activation is critical for converting CD8 T cell exclusionary tumor microenvironment (TME) and allowing enhanced ICB-induced tumor control.[1,2] Whereas very late antigen-4 (VLA-4) activation did not contribute to anti-CTLA-4 therapy antitumor response. Here, we evaluated the effect of integrin a4b7 blocker as a strategy to overcome immune resistance in the setting of combination immunotherapy (anti-CTLA-4, anti-PD-1 and/or anti-Lag-3).

Methods To evaluate synergy between ICB (anti-CTLA-4 and anti-PD-1 or anti-PD-1 and anti-Lag-3) and VLA-4 integrin blocker, once mice with B16 melanoma, Lewis lung carcinoma (LLC) or pancreatic adenocarcinoma (PAN-02) had developed tumors of approximately 20mm^2, they were treated with either IgG control, VLA-4 blocker, ICB, or combination of both therapies together.

Results We observed no difference in therapeutic benefit between a4b7 blocker and IgG control ($p<0.05$) in all tumor models. Interestingly, we observed that a4b7 integrin blocker demonstrated therapeutic synergy with anti-CTLA-4 and anti-PD-1 but not anti-PD-1 and anti-Lag-3. Likewise, a4b7 integrin blocker in combination with anti-CTLA-4 and anti-PD-1 significantly enhanced antitumor response in PAN-02 ($p<0.001$) and LLC tumor ($p<0.001$) models. Initial immune infiltrates analysis shows improved antitumor response corresponded with increase in CD8+ Teff/Treg, CD4+ Teff/Treg ratios at the TME.

Conclusions Our preliminary results from treatment of mice implanted with tumor and receiving combination checkpoint blockade therapies suggest that a4b7 could potentially enhance intratumoral CD8+ effector T cell/Treg ratios to establish antitumor immunity.

915 TARGETING LSD1 RESCUES MHC-I ANTIGEN PRESENTATION AND OVERCOMES RESISTANCE TO PD-L1 BLOCKADE THERAPY IN SMALL CELL LUNG CANCER

Evelyn Nguyen*, Andrew Chow, Charles Rudin, Triparna Sen, Hirokazu Taniguchi. *Memorial Sloan Kettering Cancer Center, New York, NY, United States*

Background Small cell lung cancer (SCLC) is an immunosuppressive tumor with modest clinical response to immune checkpoint blockade (ICB). Repression of major histocompatibility class I (MHC-I) molecules represents a potential mechanism driving ICB resistance in SCLC. Lysinespecific demethylase 1 (LSD1) has been regarded as a promising therapeutic target in SCLC. Our study investigated immunomodulatory functions of LSD1 in regulating MHC-I antigen presentation pathway (APP) in SCLC.

Methods We employed the inhibitor ORY-1001 and RNA interference to assess changes in MHCI expression in SCLC cell lines by flow cytometry. We then performed RNA-seq to characterize whole transcriptomic changes in SCLC cells following LSD1 inhibition. To explore effects of targeting LSD1 on T cell cytolysis, we co-cultured SCLC presenting endogenous peptides with pre-activated cognate CD8+ T cells. Finally, we treated immunocompetent mice bearing syngeneic SCLC tumors with ORY-1001 and/or anti-PD-L1 to evaluate tumor growth and characterize intratumor immune activities.

Results We found that targeted inhibition of LSD1 in SCLC restores MHC-I cell surface expression and transcriptionally activates genes encoding the antigen presentation pathway. LSD1 inhibition further activates interferon signaling, induces tumor-intrinsic immunogenicity, and sensitizes SCLC cells to MHC-I-restricted T cell cytolysis. Combination of LSD1 inhibitor with ICB augments the antitumor immune response in refractory SCLC models. Together, these data define a role for LSD1 as a potent regulator of MHC-I antigen presentation and provide rationale for combinatory use of LSD1 inhibitors with ICB to improve therapeutic response in SCLC.

Conclusions Epigenetic silencing of MHC-I in SCLC contributes to its poor response to ICB. Our study identifies a previously uncharacterized role for LSD1 as a regulator of MHC-I antigen presentation in SCLC. LSD1 inhibition enables MHC-I-restricted T cell cytolysis, induces immune activation, and augments the antitumor immune response to ICB in SCLC.

Ethics Approval All animal experiments were approved by and used in accordance with animal care guidelines from the Memorial Sloan Kettering Cancer Center (MSKCC) Animal Care and Use Committee.

916 ACQUIRED RESISTANCE TO IMMUNE CHECKPOINT BLOCKADE BY PHENOTYPIC PLASTICITY OF MELANOMA

[1]Emily Robitschek*, [2]Arnav Mehta, [3]Jia-Ren Lin, [4]Dennie Frederick, [5]Alvin Shi, [6]Ana Larque, [2]Benchun Miao, [7]Rumya Raghavan, [2]Tatyana Sharova, [2]John Shin, [5]Manolis Kellis, [4]Nir Hacohen, [2]Keith Flaherty, [2]Genevieve Boland, [2]Ivan Chebib, [1]David Liu, [2]Ryan Sullivan.
[1]Dana Farber Cancer Institute, Boston, MA, United States; [2]Massachusetts General Hospital, Boston, MA, United States; [3]Harvard Medical School, Boston, MA, United States; [4]Broad Institute of MIT and Harvard, Cambridge, MA, United States; [5]Massachusetts Institute of Technology, Boston, MA, United States; [6]Hospital Clínic Barcelona, Barcelona, Spain; [7]Broad Institute of Harvard and MIT, Cambridge, MA, United States

Background The vast majority of immunotherapy resistant tumors do not harbor obvious resistance mutations and little remains known about alternative mechanisms of adaptive resistance.

Methods We present a patient with Stage III melanoma treated with adjuvant Pembrolizumab (Pembro) who developed progressive disease three months after starting therapy. The patient was started on a trial of Pembrolizumab (Pembro) and Entinostat, a histone deacetylase inhibitor (HDACi), and had a mixed response. Progressive lesions were palliatively resected and found to have distinct histologies of either melanoma or pleomorphic rhabdomyosarcoma. Six tumors were analyzed with whole exome sequencing, bulk RNA-seq, and CyCIF (cyclic immunofluorescence). Quality-control, calling of somatic mutations and copy number alterations, and inference of phylogenetic relationships were performed.

Results Sequenced tumors shared 1007 SNV (single nucleotide variant) mutations and clonal loss of heterozygosity (LOH) of 1p, 4, 6q, 9, 18, 21q, and 22q confirming a common ancestor clone with homozygous deletion of CDKN2A and driver mutations in NRAS, NF1 (bi-allelic), CDK12, and SMARCA4. Genomic features unique to the melanoma phenotype included a clonal LOH of chromosome 11, while the rhabdomyosarcomas shared clonal LOH of chromosome 19. Phylogenetic analysis revealed an early split between histologic melanomas and rhabdomyosarcoma subtypes. We further uncovered enriched expression signatures for myogenesis, epithelial mesenchymal transition (EMT) and several immune signatures enriched in rhabdomyosarcoma samples relative to melanoma samples. CyCIF imaging confirmed the mutual exclusivity of the melanoma and rhabdomyosarcoma phenotypes, elevated levels of M2 macrophages in rhabdomyosarcoma samples, and high NGFR signaling in post combination treatment tumors.

Conclusions Our data suggest phenotypic switching as a form of immune evasion. The majority of lesions biopsied to be rhabdomyosarcomas initially emerged (radiographically) as progressive lesions on adjuvant Pembro. These lesions were resistant (stable/progressive disease) to Pembro/Entinostat, while other disease lesions responded, suggesting that the phenotype switch to rhabdomyosarcoma from an initial melanoma ancestral clone was associated with ICB resistance. Other resistant lesions had a melanoma phenotype, and our analysis revealed that the genomic divergence between the melanoma and rhabdomyosarcoma phenotypes occurred prior to Pembro/Entinostat treatment, suggesting alternative mechanisms of treatment resistance. While unlikely that a HDACi led to the phenotypic conversion of pre-existing tumor lesions, its role in selection or enrichment of phenotypically switched cells is undetermined. The higher NGFR signal post Pembro/Entinostat treatment could represent a concurrent therapeutic resistance mechanism. More broadly, detailed integrated clinical/genomic longitudinal studies within individual patients can shed light on the evolution and underlying mechanisms of clinical therapeutic resistance.

Ethics Approval The work described herein was approved by the Dana Farber Harvard Cancer Center IRB, protocol #11-181, to which the patient signed informed consent.

Consent The work described herein was approved by the Dana Farber Harvard Cancer Center IRB, protocol #11-181, to which the patient signed informed consent.

917 REVERSING THE IMMUNE-EXCLUDED ("COLD") TUMOR IMMUNE MICROENVIRONMENT IN ORAL SQUAMOUS CELL CARCINOMA

Yewen Shi, Alanis Rodriguez-Rosario, Tongxin Xie, Frederico Gleber-Netto, Curtis Pickering, Abdullah Osman, Andrew Sikora, Jeffrey Myers, Roberto Rangel*. *MD Anderson Cancer Center, Houston, TX, United States*

Background The tumor immune microenvironment (TIME), plays a major role in oral squamous cell carcinoma (OSCC) resistance to therapy, including immunotherapy. Many OSCC are considered poorly immunogenic tumors or "immune deserts" which lack immune infiltration, evade immune recognition and suppress immune system activation, all of which have been associated with early disease relapse and poor prognosis in OSCC patients. Somatic *TP53* mutations, the most common genetic alterations in 75% to 85% of OSCCs. The loss or mutation of *TP53* in a cancer can affect the recruitment and activity of myeloid and T cells, thereby enabling immune evasion and tumor progression. Here we generated a set of syngeneic mouse oral cancer cell lines (ROCs) from mice exposed to 4-nitroquinoline-1 oxide, a carcinogen that acts as a tobacco mimetic and causes DNA damage. The syngeneic murine ROC cell lines were tumorigenic, with different immune landscapes and response to immunotherapy.

Methods Orthotopic tongue injections were performed to (i) characterize tumor growth rate (ii) the TIME landscape by immunohistochemistry (IHC); and (iii) immunotherapy drug studies. We inactivated mutant p53 expression by shRNA, profile gene expression changes by RNAseq, and validated these findings by quantitative PCR, ELISA, co-culture and flow cytometry studies. Tumor response was achieved by combined therapy and TIME changes were evaluated by opal multiplex IHC.

Results We used the ROC1 cell line to investigate the effect of mutant p53 in the modulation of cell-intrinsic factors that shape the tumor immune landscape and affect sensitivity to immunotherapy. We observed that a carcinogen-induced *p53* mutation promoted a cold TIME enriched with immunosuppressive M2 macrophages highly resistant to ICI therapy. *p53*-mutated cold tumors failed to respond to combination ICI treatment; however, the combination of a programmed cell death protein 1 (PD-1) inhibitor and stimulator of interferon genes (STING) agonist restored responsiveness.

Conclusions Our syngeneic OSCC models provide an experimental system, which can be used to understand the interplay between cell-intrinsic genetic changes and immunosuppressive mechanisms that promote tumor progression, and serve as a translationally-relevant platform for evaluating immunotherapy combinations to improve treatment strategies for OSCC

918 TREATMENT-RELATED ADVERSE EVENT (TRAE)-RELATED DISCONTINUATION RATE OF IMMUNOTHERAPY ALONE (IO-ONLY) COMPARED TO IMMUNOTHERAPY COMBINED WITH CHEMOTHERAPY (CHEMO-IO): A META-ANALYSIS

[1]Seunghwan Shin, [2]Sumin Lee, [1]Huijeong Kim, [1]Chiyoon Oum, [1]Soolck Cho, [1]Yoojoo Lim, [1]Ken Nesmith*, [1]Chan-Young Ock. *[1]Lunit Inc., Seoul, Korea; [2]Korea University, College of Pharmacy, Sejong, Korea*

Background Chemo-IO is generally known to have better efficacy than IO-only, despite a higher incidence of TRAEs. The incidence of treatment discontinuation related to TRAE is generally related to uncontrollable TRAE. However, differences in TRAE-related treatment discontinuation rates between the two treatments has not been well studied. In this study, we compared the discontinuation rates of the two treatments for first-line treatment of NSCLC and other cancer types.

Methods We searched PubMed, Embase, and the Web of Science databases for eligible articles that include prospective phase III randomized controlled trial data of first-line treatments using IO-only or chemo-IO. IO-only was defined as a single immunotherapy drug or a combination of immunotherapy drugs, and chemo-IO was defined as a combination of immunotherapy and other chemotherapy drugs. The analysis was performed separately for NSCLC and other cancer types because most of the first-line trials with immunotherapy were published in NSCLC. We found 19 and 22 trials encompassing 6,114 and 7,492 patients in NSCLC and other cancer types, respectively. The data for discontinuation rate due to TRAEs and their 95% confidence intervals (CIs) were extracted.

Results Although there was heterogeneity of specific drugs in both the IO-only and chemo-IO groups, overall, IO-only showed a significantly lower TRAE-related discontinuation rate than chemo-IO. For NSCLC, we found that IO-only had a lower TRAE-related discontinuation rate (8.13%, 95% CI 5.90-10.36) than chemo-IO (17.54%, 95% CI 13.75-21.34) (figure 1). IO-only also showed a lower TRAE-related discontinuation rate (9.32%, 95% CI 5.94-12.69) compared to chemo-IO (21.78%, 95% CI 16.56-26.98) in other cancer types (figure 2). Clinical trials of NSCLC patients showed that there were differences in TRAE-related discontinuation rates associated with specific drugs in both IO-only ($p=0.02$) and chemo-IO ($p<0.001$), as well as in other cancer types trials (IO-only : $p=0.01$, chemo-IO: $p<0.001$).

Conclusions Compared to IO-only, chemo-IO showed a higher treatment discontinuation rate due to TRAEs. Since TRAE-related discontinuation may lead to suboptimal treatment outcomes, further study to discover the novel biomarker that dictates who could achieve durable response from IO-only, without early treatment discontinuation should be warranted.

COVID and Immunotherapy

919 ACUTE RESPIRATORY FAILURE AND THE RISK IMMUNOTHERAPY RELATED PNEUMONITIS DURING THE COVID PANDEMIC

Scott Amrhein*, Andrew Faucheux, Lara Khoury, John Kalada, Greg Russell, Thomas Lycan.
Wake Forest University School of Medicine, Winston-Salem, NC, United States

Background Immune checkpoint inhibitors are a newer modality of systemic cancer-directed therapy that is often more tolerable and has broader eligibility criteria than traditional cytotoxic chemotherapy. Unfortunately, pneumonitis is a feared complication of these drugs in around 5% of all patients, including a rare risk of death. Per professional guidelines, there are no pathognomonic features in radiology, clinical history, or laboratory testing to confirm pneumonitis. The global COVID-19 pandemic and the widespread utilization of these drugs have complicated this diagnostic challenge. We sought to develop a systematic method to measure the incidence of different etiologies of acute respiratory failure in the current landscape.

Methods We developed a novel patient registry from a retrospective cohort of patients treated with an immune checkpoint inhibitor for cancer and then presented to the hospital after the onset of the COVID19 pandemic in this region. We created a novel case report template in REDCap that collected all relevant data from clinical documentation, imaging reports, and laboratory values during the hospitalization and follow-up. The template prompted the physician reviewer to attribute the respiratory failure based on diagnostic criteria from professional guidelines.

Results Our retrospective cohort was made up of 110 patients who had 304 separate hospitalizations between March 2020 and June 2022. Nearly half of these encounters (n = 138, 45%) had a respiratory complaint noted on admission, and an additional 36 encounters (11%) had respiratory testing at any point during their hospitalization. Respiratory complaints were most commonly due to bacterial pneumonia (n = 52, 30.2%), COPD exacerbations (n = 20, 11.6%), pleural effusions (n = 18, 10.5%), malignant obstruction (n = 18, 10.5%), multiple etiologies (n = 16, 9.3%), other etiologies (n = 16, 9.3%), checkpoint inhibitor pneumonitis (n = 3, 2%) and COVID19 pneumonia (n = 2, 1%).

Conclusions Our analysis found that respiratory evaluations occurred in most hospitalizations among patients receiving an immune checkpoint inhibitor for cancer. Although the current widespread use of these drugs and the COVID19 pandemic have altered the diagnosis and management of respiratory failure patients with cancer, most cases were still due to bacterial infections or malignant progression. Our study also provides proof-of-concept for a novel case report template form that can systematically collect and categorize data from these complicated hospitalizations.

920 ALTERATION OF T CELL RESPONSES AGAINST SARS-COV-2 OMICRON VARIANT AFTER VACCINATION WITH MRNA BOOSTER IN LUNG CANCER PATIENTS

Karthik Chakravarthy*, No-Joon Song, Chelsea Bolyard, Kelsi Reynolds, Kevin Weller, Sarah Reisinger, Yi Wang, Anqi Li, Mark Rubinstein, Peter Shields, Zihai Li. *The Ohio State University, Columbus, OH, United States*

Background The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) Omicron variant has demonstrated high transmissibility and possesses several spike protein mutations that allow for evasion of previously established immunity.[1] mRNA vaccines against the spike protein of the ancestral strain of the virus have been reported to induce robust T cell immunity against the omicron variant when examined in healthy individuals.[2] However, the effectiveness of the booster vaccine doses in late-stage lung cancer patients undergoing active anti-PD-1/PD-L1 agent immunotherapy has yet to be investigated.[3]

Methods To address this question, we assessed both CD8+ and CD4+ T cell responses using a modified activation-induced marker (AIM) assay that was performed on peripheral blood mononuclear cells (PBMCs), which was coupled with high dimension spectral flow cytometry analyses. The PBMCs were obtained using cryopreserved blood samples collected from The COVID-19 Vaccine Study of Infections and Immune REspoNse (SIIREN) trial, and a total of 51 patient samples (20 non-cancer patients and 31 lung cancer patients) were assessed.

Results Our observations included that booster vaccines induced CD8+ T cell response in both non-cancer subjects and lung cancer patients against ancestral strain and omicron variant, while only marginal induction or trend was detected for CD4+ T cells in normal subjects. Pertinent results also consisted of identification of distinct subpopulation dynamics involving varying degrees of differentiation of antigen-specific CD8+ and CD4+ T cells in lung cancer patients compared to non-cancer subjects, thus demonstrating evidence of dysfunction. Another noteworthy finding included the observation of sex biased T cell responses with female lung cancer patients demonstrating more efficient antigen-specific T cell responses compared to males.

Conclusions We conclude that lung cancer patients in our study cohort have substantial qualitative deviation in their T cell response to mRNA vaccine from the normal individuals. This altered response may be a consequence of altered T cell differentiation states, resulting in the high degree of heterogeneity of AIM+ T cells identified in booster vaccinated individuals. Moreover, the dampened T cell response to omicron in cancer patients could implicate that less protection was established by vaccination for lung cancer patients, especially given that humoral response is also reduced in cancer patients.[4] This further highlights the need for heightened protective measures for cancer patients to minimize the risk of breakthrough infection with the omicron and other future variants of SARS-CoV-2.[5]

Acknowledgements We thank individuals who participated in sample collection, preparation, and preservation/storage, including Jamie Hamon, Donna Bucci, Mohamed Yusuf, Robert Davenport, and Taylor Chatlos from Pelotonia Institute for Immuno-Oncology and Immune Monitoring and Discovery Platform of the Pelotonia Institute for Immuno-Oncology. Additional gratitude is extended toward the Wherry lab, including Mathew Divij for providing detailed protocol for AIM assay and discussion.

922 EFFECT OF COVID-19 VACCINATION STATUS ON ADVERSE EVENTS AND OUTCOMES IN ADVANCED NON-SMALL CELL LUNG CANCER (ANSCLC) PATIENTS TREATED WITH IMMUNOTHERAPIES

Rohini George*, Babu Narayanan, Smita Agrawal. *ConcertAI LLC, Bengaluru, KS, India*

Background Immunotherapy is one of the most prominent therapies for NSCLC patients. While there is a lot of promise, adverse events (AEs) due to immunotherapies are a concern. Entering the era of COVID-19, the interaction of COVID-19 vaccination status with immunotherapy is not fully understood.[1-2] As most newly diagnosed NSCLC patients will be vaccinated, understanding this interaction is important for managing their treatment. This study aims at determining whether COVID-19 vaccination status has any significant effect on AEs and outcomes of aNSCLC patients treated with immunotherapies in 1st line.

Methods This retrospective study leverages ConcertAI's NSCLC Patient360™ dataset, a deeply curated real-world oncology dataset with patients from across the United States. aNSCLC patients who started 1st line treatment containing an immunotherapy at least 30 days after their last COVID-19 vaccine were included in the vaccine-primed cohort (N= 138). 1st line treatment in these patients started between January 2021 – April 2022. Similarly, a cohort of vaccine-naïve patients was created by including all patients in the dataset who received their 1st line immunotherapy treatment between January 2019 – April 2020 (N=1537) to ensure none of them received COVID-19 vaccine prior to immunotherapy treatment. Descriptive analysis on these cohorts showed no significant differences in terms of age, race, gender and treatment patterns. AEs for each patient during the course of 1st line immunotherapy treatment were identified. These AEs were categorised into 5 levels (table 1). To normalise the effect of length of treatment, AE/time on immunotherapy was calculated. Progression-Free Survival (PFS) and Overall Survival (OS) from start of L1 was also compared between the two cohorts.

Results 56% vaccine-naïve and 54% vaccine-primed patients had an AE while on immunotherapy. The distribution of severity of AEs between the two cohorts was also quite similar (table 2). Although the AE/time was higher in the vaccine-naïve cohort (p-value=0.03) (figure 1), this effect was mostly driven by 41 (2.6%) outlier patients who had many AEs in a very short span of time after starting immunotherapy. We believe such outliers were not seen in the vaccine-primed cohort primarily due to its smaller sample size. OS and PFS were similar between the two cohorts (figures 2 and 3).

Conclusions COVID-19 vaccination status does not affect frequency or severity of immunotherapy related AEs or have a significant impact on patients' outcomes. As more data becomes available on the vaccine-primed cohort the impact on rarer patient sub-populations can be evaluated

Acknowledgements The author would like to thank the following people from the Data Science Solutions team for help in generating accurate OS and PFS plots

923 DEEP SINGLE-CELL, PROTEOGENOMIC INSIGHTS FROM SARS-COV-2 INFECTED LUNG TISSUES

[1]Arutha Kulasinghe*, [2]Chin Wee Tan, [2]Ning Liu, [1]James Monkman, [3]Emily Killingbeck, [3]Youngmi Kim, [3]Liuliu Pan, [1]Tony Blick, [2]Dharmesh Bhuva, [2]Kristen Feher, [3]Michael Leon, [3]Mark Gregory, [1]Kirsty Short, [1]Fernando Guimaraes, [3]Michael Rhodes, [1]Gabrielle Belz, [2]Melissa Davis. *[1]The University of Queensland, Brisbane, Australia; [2]WEHI, Melbourne, Australia; [3]Nanostring Technologies, Seattle, WA, United States*

Background The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) that emerged in late 2019 has spread globally, causing a pandemic of respiratory illness designated coronavirus disease 2019 (COVID-19) and is likely to lead to complexities in treating thoracic malignancies. Patients with lung cancer are at an increased risk of becoming infected with the SARS-CoV-2 virus and experience higher morbidity and mortality than the general population. However, little is known about the host tissue and cellular responses associated with SARS-CoV-2 infection, symptoms, and disease severity.

Methods Here, we use the Nanostring GeoMX Digital Spatial Profiler (DSP) and CoxMX Spatial Molecular Imager (SMI) technology to determine tissue signatures, and spatially resolved quantitative single-cell proteogenomic changes driven by SARS-CoV-2 infection. This dual approach was used to generate an in-depth picture of the pumonary transcriptional and proteomic landscape of COVID-19, pandemic H1N1 and uninfected control patients.[1] Rapid autopsy COVID-19 lung samples were collected across two independent cohorts of patients, and tissue microarrays (TMAs) were prepared. For GeoMx, n=10 COVID-19, n=10 pH1N1 and n=5 normal control tissues were compared. For CosMx, n=19 COVID-19 cores in technical replicates, and n=20 normal control tissues were compared. Tissue-based gene signatures were subsequently tested in the peripheral samples from COVID-19 patients.

Results SARS-CoV-2 viral presence was confirmed by RNAscope and integrated to inform region of interest and cell types involved in infection. Analysis of the Nanostring GeoMx data revealed tissue signatures associated with SARS-CoV-2 infection, including Type 1 IFN, blood coagulation, hypoxia and angiogenesis. Analysis of the Nanostring CosMx data enabled single cell typing and mapping of tissue-specific signatures to cellular compartments of interest (e.g. macrophages, fibroblasts) and investigation of complex cell population heterogeneity and interactions. All these while preserving spatial context and highlighted differential cell type distribution in the lungs of COVID-19 patients compared to non-infected controls. Our tissue-based Type 1 IFN signatures, when tested in the blood, were found to be predictive of disease severity in COVID-19 patients when measured within the first few days of symptom onset.

Conclusions Here, we've used innovative, cutting-edge spatial transcriptomics approaches to delineate tissue signatures and cellular profiles unique to COVID-19 and common across acute respiratory distress syndrome. These data will aid in understanding the proteogenomic landscape of SARS-CoV-2 infected lung tissues and form new knowledge for the impact on thoracic malignancies, and treatments such as immunotherapy. Moreover, the study demonstrates how tissue-based findings can be rapidly developed into signatures tested in non-invasive samples.

924 **BARCODE ENABLED ANTIGEN MAPPING (BEAM) AND SINGLE-CELL SEQUENCING ENABLES NEXT-GENERATION SYSTEMS IMMUNOLOGY ANALYSIS OF THE POST-COVID-19 IMMUNE LANDSCAPE**

Peter Finnegan*, Bruce Adams, Daniel Reyes, Sean Marrache, Payam Shahi, FuNien Tsai, Thomas Vollbrecht, Micheal Stubbington. *10x Genomics, Walnut Creek, CA, United States*

Background The adaptive immune system identifies foreign antigens based on a series of highly specific interactions involving multiple immune cell types. Identifying the exact mechanisms of said interactions can be difficult to achieve using bulk sequencing methods due to poor resolution. Single cell sequencing offers the ability to match a specific antigen to an immune cell receptor sequence at the cellular level.

Methods We used Barcode Enabled Antigen Mapping (BEAM) and Single Cell Immune Profiling technology to profile hundreds of thousands of human peripheral blood mononuclear cells (PBMCs) from a donor following their recovery from COVID-19. These cells were screened for potential binding interactions with multiple antigens from SARS-CoV-2 and other viral pathogens. Sequencing data were also generated for gene expression and paired sequences for both BCRs and TCRs.

Results The combination of these two techniques allowed us to identify a number of antigen-specific clonotypes of T cells and B cells. The high throughput of the experiment allowed us to gain understanding on a global scale of the state of the immune system following recovery from a COVID-19 infection, as well as to identify potentially rare clonotypes that may not have been discerned from a smaller sample size.

Conclusions This experiment demonstrates the ability of BEAM to both profile the entire immune system at the cellular level at a given point in time as well as distinguish specific antigen-receptor interactions with the same resolution. Insights provided by similar experiments could be invaluable in the creation of precision cell therapies for use in cancer treatment, as well as the development of vaccines and analysis of allergic and autoimmune responses.

Data Sharing, Handling and Access

925 PHENOCOMB, A TOOL FOR EVALUATING COMPLEX PHENOTYPES IN HIGH-DIMENSION CYTOMETRY DATASETS

[1]Ann Strange*, [2]David Woods, [1]Brian Thompson, [1]Carol Amato, [1]Paulo Burke. *[1]CU Anschutz, Aurora, CO, United States; [2]University of Colorado School of Medicine, Aurora, CO, United States*

Background Modern cytometry can simultaneously measure dozens of markers, empowering investigation of complex phenotypes. However, manual gating relies on previous biological knowledge, and clustering/dimension-reduction tools fail to capture discrete phenotypes. Consequently, complex phenotypes with potential biological importance are often overlooked. To address this, we developed PhenoComb, an R package that allows agnostic exploration of complex phenotypes by assessing the frequencies of all marker combinations in cytometry datasets.

Methods PhenoComb uses signal intensity thresholds to assign markers to discrete states (e.g. negative, low, high). As PhenoComb works in a memory-safe manner, time and disk space are the only constraints to the number of markers and discrete states that can be evaluated. Next, the number of cells per sample from all possible marker combinations are counted and frequencies assessed. PhenoComb provides several approaches to perform statistical comparisons, evaluate the relevance of phenotypes, and assess the independence of identified phenotypes. PhenoComb also allows users to guide analysis by adjusting several function arguments such as identifying parent populations of interest, filtering low-frequency populations, and defining a maximum marker complexity. PhenoComb is compatible with local computer or server-based use.

Results In testing of PhenoComb's performance on synthetic datasets, computation on 16 markers was completed in the scale of minutes and up to 26 markers in hours. We applied PhenoComb to two publicly available datasets: an HIV flow cytometry dataset (12 markers and 421 samples) and the COVIDome CyTOF dataset (40 markers and 99 samples). In the HIV dataset, PhenoComb identified immune phenotypes associated with HIV seroconversion, including those highlighted in the original publication. In the COVID dataset, we identified several immune phenotypes with altered frequencies in infected individuals relative to healthy individuals.

Conclusions PhenoComb is a unique and powerful tool for agnostically assessing phenotypes. By more fully utilizing the high-dimension data in single cell datasets, PhenoComb empowering exploratory data analysis and discovery of phenotypes for further characterization. PhenoComb is publicly available at https://github.com/SciOmicsLab/PhenoComb.

926 EVALUATING DIVERSE DECONVOLUTION METHODS FOR TUMOR SPATIAL TRANSCRIPTOMIC DATASETS

Guangyuan (Frank) Li*, Amir Bayegan, Joon Sang Lee, Donald Jackson, Jack Pollard. *Sanofi US, Cincinnati, OH, United States*

Background Spatial transcriptomics technology may improve our ability to understand the organization of tumor microenvironment (TME) and uncover the recurrent interaction patterns across diverse cell types. While naturally complementing traditional scRNA-Seq, recent popular spatial platforms (such as 10x visium) fail to achieve single-cell resolution and require deconvolution methods to calculate the underlying cell type distributions. There are dozens of spatial deconvolution methods whereas systematic benchmarks comparing the methods are lacking.

Methods Here we present a comprehensive evaluation of 3 widely-used and top-performing deconvolution methods, DeconRNASeq, CARD, Cell2location, as well as 3 label transfer methods that assign a single cell type to one spot. We benchmarked these tools in four publicly available human breast cancer datasets by measuring the correspondence (spearmanr, pearsonr and F1-score) between inferred cell type proportions and normalized expressions of canonical marker genes at each spatial spot.

Results Cell2location consistently performs best. We further showed deconvolution methods that are particular designed for spatial context (CARD, Cell2location) achieved significantly better results compared to bulk deconvolution (DeconRNASeq) and label transfer methods (ingest, Seurat, Scanoroma), suggesting the explicit modeling of spatial correlations and consideration of technical artifacts between sequencing technologies are crucial. Furthermore, when pairing with clinically unmatched scRNA reference, the deconvolution performance is largely on par with the available matched reference for non-tumor cells, indicating that publicly available scRNA data can serve as reference for spatial deconvolution.

Conclusions Taken together, our study suggests that methods such as Cell2location with either matched or unmatched references will give actionable deconvolution in spatial studies in tumor tissues.

927 STREAMLINING CANCER IMMUNOTHERAPY RESEARCH WITH THE CRI IATLAS DATA RESOURCE AND WEB PORTAL

[1]Vésteinn Thorsson*, [1]Carolina Heimann, [2]Andrew Lamb, [1]David Gibbs, [3]Dante Bortone, [3]Sarah Dexheimer, [3]Steven Vensko, [2]Yooree Chae, [1]Ilya Shmulevich, [3]Benjamin Vincent, [2]James Eddy. [1]*Institute for Systems Biology, Seattle, WA, United States*; [2]*Sage Bionetworks, Seattle, WA, United States*; [3]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Background With the increased volume of genomics data from studies involving treatment with immune checkpoint inhibition (ICI) and other immunotherapies, researchers remain unable to to make full use of results due to lack of comprehensive access to data or th ability to compare outcomes across datasets.The Cancer Research Institute (CRI) iAtlas[1] (www.cri-iatlas.org) is a comprehensive web platform for interactive data exploration and discovery in immuno-oncology, originating in a study by The Cancer Genome Atlas (TCGA).[1–3] iAtlas provides topic-oriented analysis modules, each generating visualizations and statistics for studying interactions between tumors and the immune microenvironment (figure 1).

Methods Immunogenomic features from 15 ICI trials encompassing 1,142 samples were processed with a standardized bioinformatics workflow[4] and incorporated into iAtlas, augmenting the 11,535 patient samples from TCGA[1–3] and the Pan-Cancer Analysis of Whole Genomes[5] consortia. A compendium of in-development immunotherapy drug targets[6] and results of a study of germline genetic contribution to immune response in cancer[7] were included. For efficient access, all data were incorporated into a relational database, and programmatic access was made available through an application programming interface (API) (figure 2). The set of available iAtlas modules was vastly extended, and numerous improvements were made to the codebase. Users can now define sample cohorts and sample groups based on any available categorical or numerical variable.

Results iAtlas provides 17 interactive analysis modules (table 1) to explore immune-cancer interactions, immunotherapy treatment, and outcomes in 12,677 patient samples. Six modules are dedicated to ICI studies: dataset overview, immune readouts, immunomodulators, clinical outcome, regression analysis, and a machine learning module to enable identification of factors associated with response to therapy (figure 3). We added modules to explore how germline variation and copy number alterations relate to immune response, and how receptor-ligand interactions mediate interactions among tumor and immune cells (figure 4). Docker images using Common Workflow Language descriptors are provided so that researchers can run iAtlas workflows on their own data. Computational notebooks are provided to illustrate and explain iAtlas code, plots, and functionality and to facilitate integration of iAtlas data with data sourced from a researcher's own study.

Conclusions iAtlas serves as a repository and resource for harmonized data on immune response in cancer and response to immunotherapy. iAtlas enables researchers to readily test hypotheses and access data through multiple modalities: an interactive web portal, data download, tools,[8] and computational workflows and notebooks.

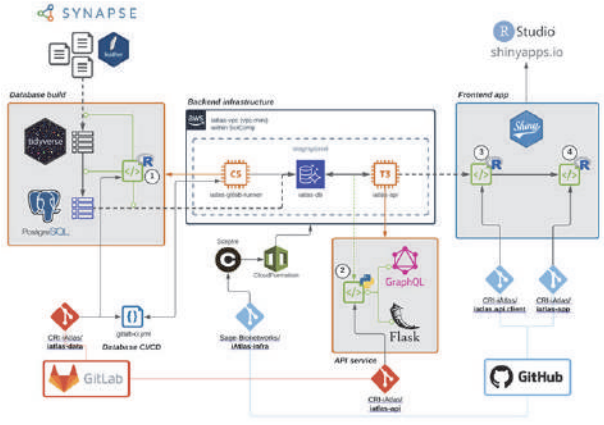
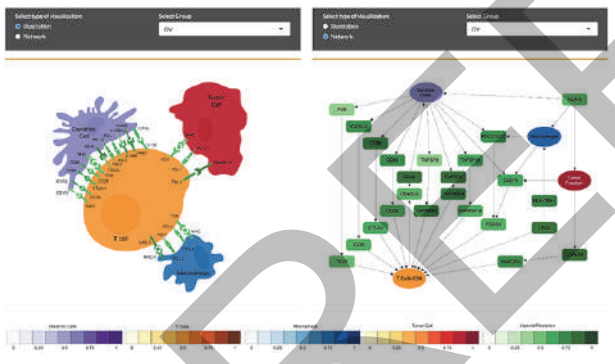
Abstract 927 Figure 1 CRI iAtlas Explorer
Entry into exploration of immune response in cancer with iAtlas. Researchers start by defining cohorts and sample groups, and can then explore and visualize results using any of 17 analysis modules (left navigation bar, and bottom right of image).



Abstract 927 Figure 2 iAtlas 2.0 infrastructureThe infrastructure underlying the iAtlas web application (top right) has four main components: 1. R scripts to (i) download data files from Synapse; (ii) extract tables from files and perform any transformations to fit database schema; and (iii) build PostgreSQL database tables, which are stored in Aurora DB. 2. Python package that implements a GraphQL API service using Flask; GraphQL query requests are resolved to SQL database queries using SQLAlchemy. 3. R package that implements a GraphQL API client to retrieve data (and transform JSON responses into tables) within the app, or as part of a regular R session. 4. Shiny/R app

code, including a set of reusable Shiny modules in the iatlas.modules R package; app is hosted using shinyapps.io and deployed manually using the rsconnect package

Abstract 927 Figure 3 iAtlas ICI Machine Learning ModuleTo identify factors that may be associated with response to Immune Checkpoint Inhibition (ICI), users choose test and training sets, factors of interest, and the response variable (top). After selection of the modeling method (here, Random Forest – other choices are Elastic Net, Logistic regression and Gradient Boosting) and parameters, the model can be trained (bottom left) and statistics are reported after running on the test set (bottom right)



Abstract 927 Figure 4 Interactions in the Tumor Immune Microenvironment
In this iAtlas analysis module, Cell-Interaction Diagram, the estimated levels of cells and associated ligands and receptors that bind are shown within a selected group of samples, in this case ovarian (OV) tumor samples in the TCGA. Users can elect to show interactions superimposed on an illustration (left) or on a node-edge network diagram (right). A related module, Extracellular Networks, infers from data the likely ligand-receptor-mediated cellular interactions in the microenvironment and displays those as a node-edge network diagram.

Abstract 927 Table 1 Interactive analysis modules available in iAtlas

Data Source	Module Name	Module Description
Immune Checkpoint Inhibition	Datasets Overview	Explore categories and groups of the available datasets.
	Clinical Outcomes	Plot survival curves based on immune characteristics and identify variables associated with outcome.
	Hazard Ratio	Create Cox Proportional Hazard Regression Models and visualize Hazard Ratio in a heatmap and a forest plot.
	Immune Features	See how immune readouts vary across your groups and ICI datasets.
	Immunomodulators	Explore the expression of genes that code for immunomodulating proteins, including checkpoint proteins.
	Machine Learning	Train and run multivariable models with cross-validation on ICI genomics and immunogenomics data.
Cancer Genomics	Cell-Interaction Diagram	Explore cell and protein abundance on an illustration.
	Clinical Outcomes	Quantify the relationship between immune response and disease outcome, in terms of either overall survival (OS) or progression free interval (PFI).
	CNV Associations	Explore associations of microenvironment with gene copy number.
	Driver Associations	Explore associations of microenvironment with cancer driver mutations.
	Extracellular Networks	Explore the extracellular networks modulating tumoral immune response.
	Germline Analysis	Explore the germline genetic contribution to the immune landscape of cancer.
	Immune Feature Trends	Visualize how immune readouts vary across sample groups.
	Immunomodulators	Explore the expression of genes that code for immunomodulating proteins, including checkpoint proteins.
	IO Targets	Explore the expression of genes that code for immuno-oncological (IO) targets.
	TIL Maps	Explore the characteristics of maps of tumor infiltrating lymphocytes obtained from analysis of H&E images.
	Tumor Microenvironment	Explore the immune cell proportions in sample groups.

928 STANDARDIZING THE ANALYSIS OF SPATIAL IMAGING FEATURES IN TUMOR SAMPLES

[1]Jason Weirather*, [1]Ian Dryg, [1]Madison Turner, [1]Ann-Elizabeth Le, [1]Anne Carlisle, [1]Kathleen Pfaff, [1]F Stephen Hodi, [2]Scott Rodig. *[1]Dana-Farber Cancer Institute, Boston, MA, United States; [2]Brigham and Women's Hospital, Boston, MA, United States*

Background The analysis of cellular imaging data produces annotations of image regions, derived features, and cellular annotations that are the basis for quantitative reports. This data can come from different instruments and annotations applied to regions of interest (ROI); annotations of this data require can arrive in many different formats, and these formats require standardization so they can be analyzed using a common syntax. Our software package, Pythologist (https://github.com/dfci/pythologist), provides the functionality for extracting spatial and cellular features from analyzed images.[1,2] Here we demonstrate how this software can be used to standardize the process of investigating and generating reports from annotated tumor samples.

Methods Multiplex-Immunofluorescence images from FFPE were analyzed by the DFCI Center for Immuno-Oncology as part of the Human Tumor Atlas Network (HTAN) to study the tumor immune microenvironment of cancers. We analyze samples stained by two panels: 1) a checkpoint specific panel measuring Tumor (SOX10 or Cytokeratin), CD8, PD-1, PD-L1, and FOXP3, and 2) a macrophage specific panel includes CD3, CD68, PD-L1, CD163, and Ki-67 in addition to the Tumor marker. Cellular features were annotated by InForm software, and region annotations were manually drawn, these include: cell segmentation, processed image regions, drawn tumor regions, and cellular annotations produced in InForm. A subset of cases were analyzed for cell density and percent cellularity measures in the context of the full-ROI but also within the tumor and invasive margin compartments. Furthermore, spatial features including cell-proximity, cell-cell-contacts, and nearest-neighbor distances are extracted and reported through the same tool.

Results As a vignette to demonstrate how this software package can be used to generate reports, two colorectal samples where the manually-annotated invasive margin annotations were available are analyzed. Within these two samples, treating all regions of interest as a single image, a greater density of CD8+ T cells (535 and 506 cells/mm2) are adjacent to the tumor region (within ~40um from the outside of the tumor region) compared to those CD8+ T cells within the tumor region (101 and 370 cells/mm2).

Conclusions Spatially informed annotations, enable us to examine cell populations in these different contexts. By standardizing imaging data annotation formats our tool provides a common platform for generating reports from the analyzed data. These capabilities provide a straight-forward approach to analyzing and visualizing tumor samples and provide insights into meaningful spatial contexts by performing hypothesis driven analyses of the tumor-immune microenvironment.

929 THE DATA MANAGEMENT AND RESOURCE SHARING CENTER FOR THE CANCER MOONSHOT IMMUNO-ONCOLOGY TRANSLATIONAL NETWORK

[1]Alan Hutson*, [1]Himangi Marathe, [1]Martin Morgan, [2]Kunle Odunsi, [1]Song Liu. *[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, United States; [2]University of Chicago, Chicago, IL, United States*

Background Background: Despite regulatory approval and advancements of immune-based interventions over the last decade, significant obstacles remain to be overcome before the full potential of immunotherapy can be realized to improve outcomes for cancer patients [1,3]. The NCI Cancer Moonshot Immuno-Oncology Translational Network (IOTN) was established in 2018 with the overarching goal of improving the efficacy, durability, and safety of immunotherapy across the spectrum of human cancers, as well as developing immunoprevention approaches that will prevent cancers before they occur.[1,2]

Methods The IOTN consortium, consisting of 29 research project awards spanning 33 institutions, conducts translational research focused on four thematic areas: Immunotherapy, Immuno-Engineering to improve immuno-therapy (i3), Mitigating immune related adverse events (irAE) and Immuno-Prevention.[2, 3] At each stage of the IOTN's translational studies, the Data Management Resource Sharing Center (DMRC) serves as an administrative and analytic hub, focusing on lowering barriers for access to analytic expertise, improving network productivity, maintaining a high standard for data collection and management, and fostering a collaborative and supportive research community.

Results The DMRC has developed centralized infrastructures to enhance the IOTN's research output, including a collection of publicly accessible and scalable resource sharing catalogs for Data, Model, Software and Clinical Trials.[4] In addition to supporting intra-network collaboration, the DMRC engaged cross-moonshot communication by hosting and coordinating a number of meetings and workshops, including the inaugural Cancer Moonshot Collaborative Meeting and monthly NCI Cancer Moonshot Seminar Series.[5, 6] The DMRC in collaboration with SITC has organized the highly popular SITC-NCI webinar series on "Computational Science in Immuno-Oncology", fostering collaboration, communication and outreach to the broader communities.[7]

Conclusions The IOTN's consortium structure, strengthened by the DMRC's centralized management, analytical, and data integration supports, has facilitated effective intra- and inter-moonshot communication and enabled collaborative translational studies.

930 PROVIDER INSIGHTS ON MANAGING PATIENTS ON IMMUNOTHERAPY, BARRIERS TO CLINICAL TRIALS, AND BIOMARKER TESTING PREFERENCES

[1]Tariqa Ackbarali*, [2]Joel Neal, [3]Yelena Janjigian, [4]Michael Overman. *[1]PlatformQ Health, Lake Worth, FL, United States; [2]Stanford Cancer Institute, Standford, CA, United States; [3]Memorial Sloan Kettering Cancer Center, New York, NY, United States; [4]MD Anderson Cancer Center, Houston, TX, United States*

Background With the advent of immunotherapies for a plethora of solid tumors, the standard of care has dramatically shifted. Approved and investigational options shaping the treatment paradigm for cancer include immune checkpoint inhibitors (ICIs), antibody-drug conjugates, CAR-T cell therapies, and treatments with tumor-infiltrating lymphocytes. As data from numerous clinical trials are reported, new indications are approved, and emerging combinations with checkpoint inhibitors show promise, the immunotherapy landscape continues to morph and evolve.

Methods A 2-part educational series was broadcast live-online in January 2022 and remains on-demand through January 2023 at OMedLive.com. The series was provided in collaboration with the Society for Immunotherapy in Cancer (SITC) and was divided into 2 sessions; the first of which focused on update and emerging approaches in small cell lung cancer and non-small cell lung cancer. The second session highlighted updated in gastroesophageal junction cancer (GEJ) and colorectal cancer (CRC). Knowledge and competence questions were administered pre-, immediate post-, and 2 mos. post-activity. Data from these questions were analyzed to determine engagement and clinical impact.

Results Interim outcomes of the series are reported as of July 2022 from 496 learners; 62% of whom were physicians, nurse practitioners, physician assistants, and pharmacists. The series has impacted care for 2,860 patients currently receiving immunotherapy for either lung cancer, GEJ, or CRC. Statistically significant improvements in knowledge and competence were observed across all nine assessment questions. Provider insights were captured related to biomarker practices and challenges/barriers experienced when managing patients on immunotherapy. The most commonly ordered immunotherapy-related biomarker was PD-L1 (50%) with the least commonly ordered being tumor mutational burden (21%). At baseline, only 56% of providers utilized biomarkers to drive treatment planning; however, following engagement in the educational series this % increased to 68%. The greatest challenges for providers managing patients on ICIs were 'patient ability to afford therapy' (28%), 'adherence to treatment schedules' (18%), and 'patient understanding of treatment options' (11%). Barriers to patient enrollment in immunotherapy clinical trials were noted by providers as 'lack of immunotherapy trials at my institution/in my geographic region' (35%), 'patient interest' (25%), and 'eligibility requirements' (14%).

Conclusions The educational series was successful in improving knowledge and competence immediate post-sessions. Provider practice patterns and perceptions of challenges were insightful for further educational opportunities for providers as well as patients.

Acknowledgements The educational series was supported by educational grants from Genentech, Merck & Co., Inc., and Regeneron.

931 TARGETING THE LYMPHOCYTE-ACTIVATION GENE-3 (LAG-3) IMMUNE CHECKPOINT IN PATIENTS WITH CANCER: AWARENESS AND CONFIDENCE AMONG ONCOLOGY HEALTHCARE PROFESSIONALS (HCP)

[1]Marie Becker*, [1]Timothy Quill, [2]Tian Zhang, [3]Evan Lipson. *[1]Clinical Care Options, LLC, Reston, VA, United States; [2]UT Southwestern Medical Center, Dallas, TX, United States; [3]Johns Hopkins University, Baltimore, MD, United States*

Background Over the last decade, immune checkpoint inhibitors targeting CTLA-4 and PD-(L)1 have revolutionized the care of patients with melanoma and many other tumor types. Recently, the immunoregulatory pathway comprised of LAG-3 and its ligands became the third immune checkpoint pathway for which blockade demonstrated benefit in a phase III clinical trial (RELATIVITY-047).[1] We explored oncology HCP familiarity with anti-LAG-3 mechanism of action, FDA-approved indications, and identification and management of associated adverse events.

Methods Between March and July 2022, we conducted an educational activity series for oncology HCPs. Each activity included 1) an interactive lecture led by a clinical investigator with expertise in the efficacy and safety of targeting LAG-3 in patients with melanoma and other cancers, and 2) polling questions designed to assess key aspects of HCP knowledge of LAG-3 and LAG-3-directed therapies.

Results 338 HCPs participated in 8 live and 1 online on-demand activities. Awareness of the role of LAG-3 and the rationale for combining a LAG-3 inhibitor with a PD-1 inhibitor was low at baseline with only 29% (37/126) of learners correctly identifying that the LAG-3 and PD-1 pathways are non-redundant, improving to 86% (115/134) after the lecture. A similarly low percentage of HCPs (21%, 28/132) could identify the FDA-approved indication for relatlimab (anti-LAG-3) plus nivolumab (anti-PD-1) (patients with advanced melanoma regardless of line of therapy or LAG-3 expression level) at baseline, improving to 85% (116/136) after the lecture. A majority of HCPs (83%, 99/119) reported low confidence to identify and appropriately manage adverse events associated with anti-LAG-3 combination therapy (baseline 2.42 on scale of 1-7, improving to 4.9 after the lecture). Participation in this educational activity improved HCP knowledge of the role of LAG-3 and of approved indications for anti-LAG-3 therapy. Self-reported confidence in managing adverse events associated with relatlimab plus nivolumab was also improved through education.

Conclusions HCP knowledge and confidence regarding the clinical utility of targeting LAG-3 with anti-LAG-3 therapies is low. Educational activities designed to address these deficiencies would be of clear benefit to HCPs treating patients with advanced melanoma and potentially other cancers. A detailed analysis of HCP trends will be presented.

932 IMMUNOTHERAPY EFFICACY AND TOLERABILITY IN ADVANCED HEPATOCELLULAR CARCINOMA (HCC) IN A DIVERSE AND UNDERSERVED POPULATION IN THE UNITED STATES – IMPORTANCE OF BASELINE LIVER FUNCTION AND SCREENING

[1]Fernand Bteich*, [2]Kush Desai, [2]Chenxin Zhang, [2]Charlotte Mcguckin, [3]John Yan, [2]Sharmin Sultana, [2]Lawrence Leung, [1]Andreas Kaubisch, [4]Milan Kinkhabwala, [4]Sarah Bellemare, [2]Adebola Adedimeji, [5]Clara Tow, [1]Yvonne Saenger. *[1]Montefiore Medical Center, Albert Einstein Cancer Center, Bronx, NY, United States; [2]Albert Einstein College of Medicine, Bronx, NY, United States; [3]Montefiore Medical Center, Bronx, NY, United States; [4]Montefiore Einstein Center for Transplantation, Bronx, NY, United States; [5]Montefiore Comprehensive Liver Program, Bronx, NY, United States*

Background Incidence of hepatocellular cancer (HCC) in the Bronx in 2019 was 61% higher than New York State as a whole.[1] The advent of immune checkpoint inhibitors (ICI) has changed HCC therapy. ICI efficacy has not been extensively studied in underserved populations often excluded from clinical trials.

Methods 183 patients treated with nivolumab (n = 118), pembrolizumab (n = 22), nivolumab with ipilimumab (n = 4), atezolizumab (n = 6) and atezolizumab with bevacizumab (n = 33) between 2017 and 2021 (data cut-off) at the Montefiore-Einstein Cancer Center were identified based on electronic medical record (EMR) review. Kaplan Meier and Chi-squared analysis were performed.

Results

Racial and ethnic composition was: 42.1% Hispanic, 21.3% Black, 13.1% White, 4.9% Asian and 18.6% unknown. Hepatitis C and alcoholism were more commonly the sole cause of liver disease relative to the SEER database (13.7% vs 4.7% and 39.3% vs 8.2% respectively).[2]64.33% of patients were diagnosed with HCC upon symptomatic presentation rather than by screening. Child-Pugh score at start of ICI was: A (51.4%), B (36.1%), and C (10.4%). (table 1). Median overall survival (mOS) after immunotherapy initiation was 9.0 (95% CI, 7.0-13.0) months. Child-Pugh A, B, and C patients had a mOS of 16.0, 5.0, and 1.0 months respectively (p=0.003). mOS was longer when pre-treatment AFP was <400 (13.0 vs 6.0 months; p=0.024) (figure 1). Patients diagnosed based on screening had prolonged mOS from diagnosis relative to those presenting with symptomatology (58.0 vs 16.0 months; p=0.004). 145 patients were evaluated on follow-up imaging. Disease control rate (DCR) was 39.3%. 8 patients (5.52%) had a complete response (CR). Patient achieving disease control were more likely to be diagnosed based on screening than were progressing patients (p=0.045), and all patients with Child-Pugh C cirrhosis progressed. There was no difference in survival when data were stratified by etiology of cirrhosis or race/ethnicity. 50 patients (27.3%) reported any immune related adverse event (irAE). 8 patients (4.4%) experienced grade ≥3 irAEs. One patient died of perforated immune colitis.

Conclusions In an underserved population of patients in the Bronx, enriched for alcoholism and hepatitis C, ICI to treat HCC yielded a DCR of 39.3%, mOS of 9 months, and toxicity in line with published reports.[3] Etiology of cirrhosis did not predict benefit of immunotherapy, but baseline liver function and diagnosis made based on screening correlated with mOS and disease control. These results highlight a need for earlier HCC diagnosis and immunotherapy administration.

933 REAL-WORLD TREATMENT PATTERNS AND CLINICAL OUTCOMES IN PATIENTS WITH METASTATIC NSCLC AFTER RECEIVING FIRST-LINE PEMBROLIZUMAB WITH PEMETREXED/PLATINUM CHEMOTHERAPY IN THE US ONCOLOGY NETWORK

[1]Jerome Goldschmidt, [2]Srinivas Annavarapu, [2]Divea Venkatasetty, [3]Melissa Santorelli, [3]Thomas Burke*, [4]Nathan Pennell. *[1]The US Oncology Network, Blacksburg, VA, United States; [2]Ontada, Irving, TX, United States; [3]Merck & Co., Inc., Rahway, NJ, United States; [4]Cleveland Clinic, Cleveland, OH, United States*

Background Pembrolizumab-pemetrexed-platinum is a standard of care in previously untreated metastatic non-squamous non-small cell lung cancer (NSCLC) based on significantly longer overall survival (OS) compared to pemetrexed-platinum in the Keynote 189 clinical trial.[1] In Keynote 189, 77% of patients received maintenance pemetrexed after induction while real-world studies in the United States (US) using the Flatiron Health database observed only 44-48% of patients received pemetrexed beyond cycle 4.[2-4] This study aimed to further describe treatment patterns and clinical outcomes in metastatic non-squamous NSCLC patients receiving first-line pembrolizumab-platinum-pemetrexed in the US community oncology setting.

Methods First-line metastatic non-squamous NSCLC patients without actionable alterations (ECOG 0-2, known PD-L1 expression) starting pembrolizumab-platinum-pemetrexed between May 10, 2017, and August 31, 2020, within The US Oncology Network, were retrospectively identified and described using structured data. Patients who completed the 4-6 induction cycles without disease progression and continued pembrolizumab, with or without maintenance pemetrexed, were further examined using chart review. Continuation pembrolizumab patients were followed until earliest of August 31, 2021, last visit, or date of death. Patient characteristics and treatment patterns were summarized using descriptive statistics. Real-world time on treatment and OS were evaluated using Kaplan-Meier (KM) methods.

Results In the induction cohort (figure 1, n=751), 532 patients completed induction (71%) and among them, 50% (266/532) received continuation pembrolizumab with maintenance pemetrexed based on review of the structured data. The median (95% confidence interval [CI]) times on pembrolizumab and pemetrexed treatments were 5.1 (4.6-5.7) months and 4.2 (3.5-4.6) months from start of induction, respectively. In the continuation pembrolizumab cohort (figure 1, n=241), the median (95% CI) OS was 20.3 (13.8-26.2) months from start of continuation pembrolizumab. In the continuation pembrolizumab cohort, 64% received maintenance pemetrexed and 36% received pembrolizumab alone. Patients receiving maintenance pemetrexed were more commonly <75 years of age, male, PD-L1 <1%, and had more metastatic sites than those receiving pembrolizumab alone (table 1). Reasons for pemetrexed discontinuation were most frequently noted as progressive disease (38%) and toxicity (29%) in patients who received maintenance pemetrexed and partial response (68%) and completion of planned therapy (53%) in patients who received pembrolizumab alone.

Conclusions Reasons for pemetrexed discontinuation and patient characteristics varied for patients receiving continuation pembrolizumab with maintenance pemetrexed relative to those receiving continuation pembrolizumab alone. More information is needed to understand clinical decision making around pemetrexed discontinuation in the real-world community oncology setting, extension to other clinical settings, and associated impact on clinical outcomes.

IMMUNOTHERAPY-BASED STRATEGIES FOR ADVANCED NON–SMALL CELL LUNG CANCER: IDENTIFYING AND REDUCING CLINICIAN KNOWLEDGE GAPS WITH ONLINE EDUCATION

[1]Elizabeth Heller*, [1]Keira Smith, [1]Eden Maack, [1]Lyn Brook, [1]Sarah Williams, [2]Beth Sandy. *[1]i3 Health, Rochelle Park, NJ, United States; [2]Abramson Cancer Center University of Pennsylvania, Philadelphia, PA, United States*

Background Research indicates that some of the continuing burden of advanced non–small cell lung cancer (NSCLC) may be attributed to the difficulty for the multidisciplinary team in maintaining a working knowledge of emerging data and recommendations that can inform clinical decision making, particularly surrounding the use of immunotherapy. This study was conducted to investigate whether an online, case-based continuing medical education (CME)/nursing continuing professional development (NCPD)–approved activity could address gaps in clinicians' knowledge regarding recent advances in immunotherapy and the need for personalized care of patients with advanced NSCLC without driver mutations.

Methods Ticiana Leal, MD, and Beth Sandy, MSN, CRNP, presented a video viewpoint strategy session titled *Harnessing Immunotherapy-Based Strategies for Advanced Non–Small Cell Lung Cancer.* This CME/NCPD-approved activity was made available online starting on April 6, 2022. Learners participated in a 1.25-hour session that explained the latest guidance on patient selection, efficacy, safety, and supportive care strategies for NSCLC immunotherapy. Learners completed a repeated-pairs pre- and post-activity assessment consisting of case-based questions that gauged their ability to apply emerging data to clinical decision making. Baseline knowledge gaps and subsequent learning gains were calculated based on percentages of learners obtaining correct responses on the pre- and post-activity assessments. Significance was assessed using a chi-squared test of independence. In addition, learners reported self-perceived gains in confidence and competence using 5-point Likert scale questions.

Results As of July 27, 2022, 189 clinicians had completed the activity for credit. Baseline assessment data revealed gaps in knowledge regarding patient selection criteria, emerging actionable targets, and management of treatment-related adverse events. Learners scored an average of 34% on pretest topics; after completing the activity, the posttest average rose to 86%. The activity resulted in significant gains in knowledge and competence related to these topics, with $P < 0.0001$ for all learning gains (table 1, figure 1–3). Upon completion of the activity, 88% of learners self-reported that knowledge acquired from this activity would be utilized to improve the outcomes of their patients, and 86% of learners self-reported that after the activity, they felt more confident in treating patients with advanced NSCLC.

Conclusions These data indicate that a substantial knowledge gap exists regarding the latest developments in the treatment of advanced NSCLC. They also demonstrate that online, case-based CME/NCPD-approved activities can result in statistically significant improvements in clinicians' knowledge of therapeutic advances and management of treatment-related adverse events for patients with advanced NSCLC receiving immunotherapy.

Acknowledgements This activity was supported by an independent educational grant from Merck.

Abstract 934 Table 1

Learner Competence

Case-based topic	Knowledge gap	Learning gain
Immunotherapy treatment selection for advanced NSCLC	58.73%	3.5% (p<.001)
Adverse event monitoring for immunotherapy combinations	64.55%	28.3% (p<.001)
Management of immune-related adverse events	73.54%	34.0% (p<.001)

NSCLC = non-small cell lung cancer.

935 A CASE REPORT OF PEDIATRIC ADENOVIRAL REACTIVATION AFTER CAR T-CELL THERAPY

Jimmy Maiarana*, Saara Kaviany, Jim Connelly, Carrie Kitko, Richard Ho. *Vanderbilt University, Nashville, TN, United States*

Background The patient is an 11-year-old male with pre-B acute lymphoblastic leukemia (ALL) in second relapse 15 months after a hematopoietic stem cell transplant (HSCT) who presented for anti-CD19 CAR T-cell therapy with tisagenlecleucel. Tumor burden prior to therapy revealed ~60% bone marrow involvement by leukemia without CNS disease. He received Fludarabine/Cyclophosphamide for lymphodepletion followed by CAR T-cell infusion on D0 (Image 1). He developed grade 1 CRS, grade 1 neurotoxicity for which he received Tocilizumab and 10 days of dexamethasone, and carHLH (grade 3 transaminitis, hyperferritinemia, coagulopathy) for which he received 5 days of Anakinra (figure 1). He developed abdominal pain and tenesmus that progressed to hematochezia on D+12. CT abdomen revealed bowel wall thickening and mucosal hyperenhancement suggestive of pancolitis. Stool viral panel and Clostridium difficile were negative. He was empirically treated for typhlitis with Zosyn and switched to Cefepime/Flagyl without improvement. Fecal Adenovirus resulted positive while CMV and enterovirus were negative. Blood Adenovirus was detected at <190 copies/mL. Endoscopy showed crypt epithelial apoptosis with scattered atrophy and loss. Colonic biopsy was positive for Adenovirus. The patient slowly improved and discharged on D+36.

Methods Adenovirus infection leads to significant morbidity and mortality among pediatric HSCT patients.[1–3] After infection, adenovirus persists in mucosal lymphocytes but competent host immunity prevents viral expansion in gut epithelial cells [4]. When host immunity is compromised, viral reactivation can lead to adenoviremia resulting in enteritis, hepatitis, and death.[2,5] Historically, supportive care has been used with cidofovir reserved for fulminant disease. Recently, viral specific T-cells (VSTs) have shown promise.[6]

A recent study noted that adenovirus was the most common identifiable pathogen in a cohort of pediatric patients receiving CAR T-cells.[7] However, previous studies have not identified it as a common cause of post-CAR infections.[8] Pre-infusion disease burden, lymphodepleting regimens, carHLH, neutropenia duration, hypogammaglobulinemia, high grade CRS, and previous HSCT have been identified as risk factors for infections.[7–9]

We propose three contributors to adenoviral reactivation in the gut during CAR T-cell treatment (Image 2):

1. Pre-infusion lymphodepletion destroys gut mucosal lymphocytes, spreading viral particles to host epithelial cells and reactivating infection.
2. CAR T-cell expansion leads to generalized immune dysregulation/contraction during CRS and HLH/MAS
3. Immune blockade blunts immune regulation.

Conclusions Adenovirus should be considered in patients who develop gastrointestinal symptoms (abdominal pain, diarrhea, tenesmus, hematochezia) after CAR infusion. Further research is needed to identify those at risk for severe disease who may warrant additional treatment.

936 ASSESSING EDUCATIONAL NEEDS FOR IMMUNE-RELATED ADVERSE EVENTS CURRICULUM IN CLINICAL PRACTICE

Gong He*, Austin Wesevich, Pankti Reid. *University of Chicago, Chicago, IL, United States*

Background Immune checkpoint inhibitors (ICIs) are increasingly used to treat cancer but can lead to immune-related adverse events (irAEs) such as hepatitis, pneumonitis, or thyroiditis. While ICIs and irAEs are typically managed in an outpatient setting by oncologists, 11% of patients receiving ICIs require hospital admission for irAEs.[1] While rheumatologists' irAE management knowledge and skills have been assessed in prior studies,[2] clinicians within oncology and hospital medicine have been understudied despite their relevance to the care of patients with irAEs.

Methods In June and July 2022, we administered a web-based survey to University of Chicago (UChicago)-affiliated oncology providers: oncology fellows and attendings, oncology nurse practitioners (NPs) and physician assistants (PAs). We also surveyed UChicago hospitalists and medicine residents and community oncologists practicing in Chicago. We assessed current knowledge, prior experience, provider confidence, and current educational resource utilization regarding irAE diagnosis and management. We also surveyed how receptive our participants would be to future educational resources dedicated to irAE evaluation and therapy. Linear regression and logistic regression were utilized to analyze relationships between different variables.

Results In total, we had a 37% response rate (171/467): highest for UChicago-affiliated oncology providers (55-59%) (table 1). Oncology attendings and fellows scored the highest on knowledge-based questions (67-68%). Higher levels of ICI and irAE experience over the past year were associated with higher levels of knowledge (OR 1.5, $p<0.002$). Confidence levels were also significantly associated with higher knowledge and more ICI and irAE experience ($p<0.001$). Almost all participants surveyed (93%) were receptive to using an online irAE resource with delineated guidelines, patient handouts, and frequently asked questions regarding irAEs. Oncology fellows and NPs/PAs were also more interested in online CME-accredited irAE sessions dedicated to irAEs than medicine residents and hospitalists (83% versus 65%).

Conclusions The knowledge gaps across various groups of providers caring for patients with irAEs reflect a significant need to develop an effective didactic program aimed at enhancing knowledge and confidence for irAE evaluation and treatment. Our results support the development of an online curriculum with interactive online modules to provide case-based and simulated experiential didactics that will lead to increased knowledge and confidence in caring for patients with irAEs.

Abstract 936 Table 1 Response rates by respondent type

	Medicine Resident	Oncology Fellow	Oncology NP/PA	Oncology Attending	Community Oncologist	Hospitalist	Total
Surveyed	119	18	51	74	144	61	467
Responded	51	10	30	41	11	28	171
Response Rate	43%	56%	59%	55%	8%	46%	37%

937 POST-IMMUNOTHERAPY SURVIVORSHIP IN ADVANCED MELANOMA (AMEL): ROUTINE VERSUS SYMPTOM-BASED IMAGING SURVEILLANCE, A RETROSPECTIVE REVIEW IN A LARGE INTEGRATED HEALTHCARE NETWORK, KAISER PERMANENTE NORTHERN CALIFORNIA (KPNC)

Juraj Kavecansky*, Richie Xu, Lue-Yen Tucker, Jahan Tavakoli, Alexander Menter, Thach-Giao Truong. *Kaiser Permanente, Oakland, CA, United States*

Background Best practice in surveillance imaging for survivors after immune checkpoint inhibitors (CPI) remain poorly defined for stage 3-4 aMEL; KPNC oversees care for 4 million patients and has 300 new diagnoses of aMEL per year. Follow-up after CPI is coordinated in KPNC via care pathways using national guidelines.

Methods We report a retrospective study of patients treated between 2014 and 2018 for aMEL with CPI. Data was obtained by chart review. Patients were included who received anti-PD1, anti-CTLA4, or combination; had ≥1 dose of any-line palliative (pTX) or adjuvant therapy (adjTX); and had ≥1 year of follow-up after treatment, and imaging response (SD/PR/CR) or >=6 months without recurrence if after adjTX. Symptomatic versus asymptomatic progression was defined by evidence of documentation of symptoms at time of imaging. Events from patients who had >1 line of CPI therapy were counted separately. Log-rank test was used to determine Kaplan-Meier survival estimates, and rates were calculated per 100 person-months.

Results 176 patients met inclusion criteria. These patients underwent 191 lines of therapy (69 adjTx and 122 pTX). Progression after therapy occurred in 29 lines of treatment (42%) after adjTX, of these 62% were symptomatic. 51 (41.8%) patients relapsed after pTX and 44% were symptomatic. Comparing asymptomatic and symptomatic progression, there were no differences in risk of relapse after adjTX (p=.14) or pTX (p=0.73). Within adjTX, patients with asymptomatic recurrences had lower all-cause mortality (ACM) than those with symptoms (Relative Risk (RR) 0.6 [0.0-1.3] vs 1.9 [0.8-3.0], p=.03) and lower melanoma-specific mortality (MSM) (RR 0.2 [0.0-0.6] vs 1.2 [0.3-2.1], p=0.03 for MSM). No differences were detected for ACM and MSM for patients receiving in pTX with asymptomatic versus symptomatic recurrence (ACM RR 1.9 (1.0-2.9) in asymptomatic recurrence vs 2.8 (1.4-4.2) in symptomatic, p=0.15 for ACM and; MSM RR 1.6 (0.7-2.4) vs 2.4 (1.2-3.7), p=0.12 for MSM). There were differences in ACM (p=0.02) and MSM survival (p=0.01) in adjTX but not in pTX (ACM p=0.90; MSM p=0.79).

Conclusions Our study finds identification of asymptomatic relapse has survival benefit in the curative setting but not for aMEL treated with palliative intent. This finding is likely because curative therapy can be offered if relapse is identified early for resectable disease. Our study findings suggests a symptom-based imaging surveillance strategy similar to that used in histologies with effective systemic therapy is effective (e.g. lymphoma, breast cancer) could potentially be used for melanoma. Prospective study is needed to further guide clinical practice.

Immune Cell Types and Biology

939 AUGMENTATION OF CD8 T CELL MEMORY VIA CDK4/6 INHIBITION CAN BE SEQUENTIALLY COMBINED WITH PD-1 BLOCKADE TO AVOID TOXICITIES

Lestat Ali, Ana Garrido-Castro, Sara Tolaney, Stephanie Dougan*. *Dana-Farber Cancer Institute, Boston, MA, United States*

Background CDK4/6 inhibitors are approved to treat breast cancer and are in trials for other malignancies. We examined CDK4/6 inhibition in mouse and human CD8 T cells during early stages of activation. Mice receiving tumor-specific CD8 T cells treated with CDK4/6 inhibitors displayed increased T cell persistence and immunologic memory. CDK4/6 inhibition upregulated Mxd4, a negative regulator of Myc, in both mouse and human CD8 T cells. Silencing of *Mxd4 or Myc* in mouse CD8 T cells demonstrated the importance of this axis for memory formation. We used single cell transcriptional profiling and TCR clonotype tracking to evaluate recently activated human CD8 T cells in breast cancer patients before and during treatment with either palbociclib or abemaciclib. CDK4/6 inhibitor therapy in humans increases the frequency of CD8 memory precursors and downregulates their expression of MYC target genes, suggesting that CDK4/6 inhibitors in cancer patients may augment long-term protective immunity (Heckler and Ali et al. Cancer Discovery 2021).

Methods We will present unpublished data on samples collected from a Phase I trial of combination ribociclib with PD-1 blockade (NCT03294694). Unfortunately, combination of CDK4/6i and PD-1 blockade leads to high rates of adverse events, as seen in several clinical trials. To better understand the mechanism of action of CDK4/6i versus PD-1 blockade on tumor-specific CD8 T cells, we performed single-cell RNA-sequencing and T-cell receptor clonotype tracking of breast and ovarian cancer patients treated with the CDK4/6 inhibitor ribociclib and PD-1 blockade.

Results We confirmed our observation of increased memory skewing of peripheral CD8 T cells, and we identified TCR clonotypes that matched tumor-infiltrating T cells. We highlight evidence of two orthogonal treatment-associated phenomena: expansion of T cell effector populations and promotion of T cell memory formation. Augmentation of the antitumor memory pool by ribociclib boosts the efficacy of subsequent PD-1 blockade in a mouse models of melanoma and breast cancer.

Conclusions We therefore demonstrate that PD-1 blockade and CDK4/6 inhibition augment nonoverlapping features of CD8 T cell activation in metastatic cancer, pointing toward sequential therapy as a potentially safe and synergistic strategy in patients.

Ethics Approval For breast and ovarian cancer patients, we obtained written informed consent from the patients, and the studies were conducted in accordance with the Declaration of Helsinki and the Belmont Report. Patient peripheral blood samples were obtained via Dana-Farber Cancer Institute Institutional Review Board protocols 18-258, 13-364, and/or 17-024. Animals were housed at the Dana-Farber Cancer Institute and were maintained according to protocols approved by the DFCI IACUC (#14-019 and #14-037).

940 **SIRNA SCREEN OF UPREGULATED GENES IDENTIFIES TARGETS FOR A MULTIANTIGEN POLYEPITOPE VACCINE TO PREVENT HNSCC**

[1]FNU Alka*, [2]James Annis, [1]Brady Bernard, [1]Sasha Stanton. *[1]Earl A. Chiles Research Institute, Portland, OR, United States; [2]Blackhat Limited, Seattle, WA, United States*

Background Oral Dysplasia (OD) is a precursor lesion for developing head and neck squamous cell carcinoma (HNSCC). The risk of developing HNSCC from OD is 12% in 2 years. In HNSCC, presence of tumor-specific type I T-cells predict improved progression free survival compared to the patients with tumor that do not have tumor-specific Th1 T-cells. We therfore sought to identify candidate antigens overexpressed in both OD and HNSCC as targets for a vaccine that can both treat and prevent HNSCC.

Methods Selected target genes were overexpressed in human OD and HNSCC and were selected from curated open access GEO data sets. Functionally relevant candidate genes were selected as targets that were necessary for survival using high-throughput siRNA screen. We evaluated the effect of 3 pooled siRNA per target in 3 human HPV negative HNSCC cell lines (FaDu, SSC15, SCC25) and 1 hyperplastic keratinocyte (NOK) as compared to the non-malignant human gingival fibroblast (HGF) cell line. We prioritized candidate antigens whose loss induced $\geq$50% decreased viability in HNSCC cell lines and OD but not in non-malignant gingival cell line.

Results We identified 46 targets that were overexpressed greater than 2-fold in both OD and HNSCC but not in normal tissue, from 2 OD and 5 HNSCC datasets including 206 normal samples, 66 OD samples, and 198 HNSCC samples. To increase the number of candidate antigens, a literature search of gene expression studies, not included in public data set was performed including four studies with 58 normal samples, 21 OD samples, 179 HNSCC. 80 genes that were highly overexpressed in OD and HNSCC and overexpressed in greater than 75% of datasets were selected for the siRNA screen. 17 candidate antigens that reduced viability >50% in 2 or more HNSCC cell lines were selected: COL1A1, COL1A2, COL4A1, LOXL2, JUP, WDR66, POSTN, TNC, HOXB7, WDR72, TENM3, FN1, PDPN, SERPINE1, INDO, IFI6, ACTN1. All these 17 genes have known roles in HNSCC tumor progression.

Conclusions We have identified 17 candidate antigens that are functionally relevant to survival in OD and HNSCC. Future studies will evaluate if these candidate antigens are immunogenic in OD and HNSCC by evaluation if autoantibodies to these targets are present in the serum of OD and HNSCC patients but not in normal controls. These antigens will be used to design an MHC class II multiantigen polyepitope vaccine.

941 **BOTENSILIMAB MODULATES INNATE AND ADAPTIVE GENE EXPRESSION PROGRAMS RESULTING IN SUPERIOR IMMUNE STIMULATION RELATIVE TO A FIRST-GENERATION ANTI-CTLA-4 ANTIBODY**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0941

[1]Shanmugarajan Krishnan*, [1]Jacky Chow*, [1]Kah Teong Soh, [1]Kayla Ostergard, [1]Christopher MacDermaid, [2]Marc Van Dijk, [1]Dennis Underwood, [1]Dhan Chand, [1]Cailin Joyce. *[1]Agenus Inc., Lexington, MA, United States; [2]Mink Therapeutics, Lexington, MA, United States*

Background Botensilimab is a next-generation fragment crystallizable (Fc)-enhanced anti–cytotoxic T-lymphocyte antigen 4 (CTLA-4) antibody that promotes optimized T cell priming, activation, memory formation, and intratumoral regulatory T cell depletion. In patients with advanced solid tumors, botensilimab alone and in combination with balstilimab (anti-programmed cell death protein 1 [PD-1] antibody) demonstrated durable clinical responses in nine different immunotherapy-resistant or poorly immunogenic tumor types. We hypothesize that botensilimab engages multiple immune cell types, including macrophages, dendritic cells (DCs) and natural killer (NK) cells through its enhanced Fc region, to drive deep and broad clinical responses. Here, we applied high-resolution single-cell profiling to demonstrate the differentiated molecular mechanisms of botensilimab relative to a first-generation IgG1 (non-Fc-enhanced) anti-CTLA-4 antibody (bot-IgG1).

Methods Human *ex vivo* peripheral blood mononuclear cells were stimulated with staphylococcus enterotoxin antigen followed by treatment with botensilimab, bot-IgG1 or an IgG1 Fc-enhanced isotype control. Secreted cytokines and single-cell measurements of RNA and protein were evaluated over multiple time points and across various immune cell populations. Treatment-specific changes were evaluated within and across donors.

Results Enhanced interleukin-2 (IL2) secretion in botensilimab-treated cultures relative to bot-IgG1 or isotype control was confirmed across donors. To identify the upstream mechanisms of botensilimab-induced immune activation, RNA and protein expression patterns were interrogated at different time points leading up to maximum IL2 secretion. Sub-clustering of myeloid cells revealed monocyte-, macrophage-, and DC-like populations. Within the myeloid fraction, botensilimab increased the frequency of DCs relative to monocytes and macrophages, and upregulated innate immune signaling pathways distinct from that of first-generation IgG1 anti-CTLA-4. Notably, botensilimab increased the frequency of leukocyte immunoglobulin like receptor B1 (LILRB1 or ILT2)-expressing myeloid cells. Sub-clustering of lymphocytes revealed CD4, CD8, Treg, NK, NKT, and B cell-like populations. Botensilimab increased activation and effector gene expression, including granzyme B and tumor necrosis factor receptor superfamily 9 (TNFRSF9; CD137) in lymphocyte subsets superior to that observed with an IgG1 anti-CTLA-4.

Conclusions The differentiated ability of botensilimab to reshape myeloid transcriptional programs is consistent with its clinical activity in poorly immunogenic tumors where improved antigen presentation or cross-priming could potentiate responses. Increased expression of LILRB1 and TNFRSF9 in botensilimab-treated immune subsets supports the combination strategies with AGEN1571 (anti-ILT2) and AGEN2373 (anti-CD137) currently under clinical investigation.

Ethics Approval This study was approved by WCG IRB Ethics Board; approval number 120160614.

942 FLOW CYTOMETRY IMMUNOPHENOTYPING OF NECK LYMPH NODES SAMPLED BY FINE NEEDLE ASPIRATION (FNA) IN PATIENTS SUFFERING FROM ADVANCED CUTANEOUS SQUAMOUS CELL CARCINOMA: A PILOT STUDY

Vilma Lagebro*, Krzysztof Piersiala, Gregori Margolin, Susanna Kumlien Georén, Lars-Olaf Cardell. *Karolinska Institutet, Stockholm, Sweden*

Background Cutaneous Squamous cell cancer (cSCC) is one of the most common forms of cancer and has the highest incidence increase in Sweden. cSCC has a good prognosis, however around 5% develops advanced cSCC which is difficult to treat. Check point inhibitor (CPI) treatment is promising, but many patients do not show long-lasting remission. Therefore, we need to understand how the CPI modulation works to increase its clinical benefit.

Methods We analysed the lymphocyte phenotypes in peripheral circulation (PBMC), unfixed tumour tissue and sentinel lymph node samples from advanced cSCC patients with flow cytometry. The sentinel nodes were of particular interest since they are rarely analysed in this context but are essential for a well-functioning anticancer immune response. The lymphocytes were phenotypically characterized and analysed with the focus on activation markers and CPI expression.

Results In this pilot, we analysed samples from six patients. Sentinel node samples had a higher percentage of CD4+ T cells compared to PBMC. Furthermore, the number of activated CD4+CD69+ T cells was higher in sentinel nodes (32.4%) compared to PBMC (1.1%). A smaller amount of CD4+ cells in sentinel node expressed PD-1 compared to CD4+ cells in the tumour samples. CTLA-4 was expressed on CD4+ cells in sentinel nodes at low levels compared to the tumour samples.

Conclusions Our results confirm that the sentinel node is rich in highly activated cells that express immune checkpoint molecules. Further experiments are needed to investigate how the systemic treatment with immune checkpoint inhibitors influence the phenotypes and function of lymphocytes in sentinel nodes. In this project, we are going to look into correlation between flow cytometry findings (activation level, expression of CPI molecules) and clinical outcome of our patients (locoregional control, survival, response to the treatment). In the future, this could also help us discover biomarkers predicting response to CPI treatment. Furthermore, the results might also strengthen the role of flow cytometry analysis in clinical assessment and staging of cSCC patients.

Ethics Approval All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the study. Regional Ethics Committee Approval: 2019-03518.

943 HARNESSING ANTI-TUMOR METABOLIC SENSING SWITCH GPR84 ON MACROPHAGES FOR CANCER IMMUNOTHERAPY

Gang Xin, Ruohan Zhang, Bao Zhao, Cankun Wang, Wantong Li, Qin Ma, Nuo Sun, Haitao Wen, William Carson, Zihai Li, Anjun Ma, Jianying Li*. *Ohio State University, Columbus, OH, United States*

Background Immune checkpoint blockade (ICB) has shown tremendous clinical success, but this clinical response is limited to a small proportion of patients, and one of the major resistance mechanisms is the macrophage enriched in the immunosuppressive tumor microenvironment (TME).[1-3] Majorities of tumor-associated macrophages (TAMs) are associated with enhanced pro-tumorigenesis activity, significantly impairing T cell function and facilitating tumor escape from immune checkpoint blockade therapy.[4-6] Due to the plasticity of macrophages, excitement has been growing for the possibility of reshaping these pro-tumorigenic TAMs toward the anti-tumorigenic phenotype to enhance immunity against cancer.[7, 8] Emerging evidence reveals that free fatty acids (FFAs) accumulated in TME are critical in determining macrophage function. Though a majority of studies highlight the impact of metabolic processes, fatty acids also serve as vital signaling molecules for regulating immune response, however the molecular mechanism remains elusive.

Methods By an unbiased analysis of single-cell transcriptome data from multiple tumor models, we discovered that anti-tumorigenic TAMs uniquely express elevated levels of a fatty acid receptor, G-protein-coupled receptor 84 (GPR84). To determine the role of GPR84 in TAM-mediated immunity against cancer, we have established new mice with myeloid-specific deletion of GPR84 ($Gpr84^{flox/flox}$ $LysM^{Cre}$) and evaluated the GPR84 agonist 6-OAU using the MC38 tumor model.

Results Herein, the bioinformatics analysis of the clinical patient sample finds that GPR84 enriched TAM is associated with enhanced anti-tumor function. Furthermore, genetic ablation of GPR84 will impair the pro-inflammatory phenotype and enhance the anti-inflammatory phenotype. In contrast, GPR84 activation by 6-OAU subverts TAM-mediated immunosuppression via enhanced NF-kB activity. Moreover, 6-OAU treatment significantly retards tumor growth and increases the anti-tumor efficacy of anti-PD-1 therapy.

Conclusions Overall, we identify a previously unappreciated fatty acid receptor, GPR84, as an important metabolic sensing switch for orchestrating anti-tumorigenic macrophage polarization. Pharmacological agonists of GPR84 hold great promise to reshape and reverse the immunosuppressive TME, and thereby restore responsiveness of cancer to overcome resistance to immune checkpoint blockade. Overall, GPR84, a not fully understood fatty acid receptor, can repolarize the TAM towards the antitumor phenotype and enhance the anti-PD1 response, which is a promising potential therapeutic target.

Acknowledgements Words cannot express my gratitude to my mentors: Dr. Gang Xin and Dr. Qin Ma for their invaluable patience and feedback. I also could not have undertaken the bioinformatics journey without Anjun Ma, Cankun Wang, Ruohan Zhang, and Yao Chen, who generously provided their knowledge and expertise. Additionally, this endeavor would not have been possible without the generous cooperation of Dr. Zihai Li's lab, Dr. Haitao Wen's lab, and Dr. William E. Carson's lab.

944 TARGETING OF NOTCH LIGAND JAGGED2 IN LUNG CANCER CELLS DRIVES ANTI-TUMOR IMMUNITY VIA NOTCH-INDUCED FUNCTIONAL REPROGRAMMING OF TUMOR-ASSOCIATED MACROPHAGES

[1]J Mandula, [1]Rosa Sierra-Mondragon, [1]Darwin Chang*, [1]Rachel Jimenez, [2]Eslam Mohamed, [1]Jimena Trillo, [1]Alyssa Obermayer, [1]Carlos Moran-Segura, [1]Das Satyajit, [1]Julio Vazquez-Martinez, [1]Timothy Shaw, [1]Jose Conejo-Garcia, [1]Paulo Rodriguez. *[1]H. Lee Moffitt Cancer Center, Tampa, FL, United States; [2]California Northstate University, Elk Grove, CA, United States*

Background Signaling through the Notch family of receptors after engagement with ligands, Jagged (JAG1-2) or Delta-like ligands (DLL1-4), promotes the development and progression of several tumors and modulates anti-tumor immunity. However, whether expression of Notch ligands in tumor cells impacts anti-tumor immunity remains practically unknown. Herein, we sought to determine the impact of the expression of Notch ligands, Jagged1 and Jagged2, on lung tumors in the modulation of anti-tumor immunity.

Methods We evaluated the correlation between *JAG*1-2 expression in lung tumors along with clinical outcome and intratumoral T-cell infiltration. Furthermore, we eliminated Jagged forms in murine lung tumors via Crispr-based approaches followed by studies identifying the tumor immune-landscape and functional changes in T-cells and macrophages.

Results Analyses of the TCGA lung adenocarcinoma datasets showed that augmented expression of *JAG2* in tumors, but not *JAG1*, correlated with reduced patient survival. Additionally, tumor tissue microarray-based studies showed a correlation between lower Jagged2 levels in lung cancer cells and increased intra-tumor T-cell frequency. Consistently, elimination of *Jag2*, but not *Jag1*, in murine lung cancer cells activated anti-tumor T-cell immunity and delayed tumor growth in mice. Elimination of T-cells restored growth of $Jag2^{KO}$ tumors *in vivo*. Moreover, analysis via single-cell RNA sequencing (scRNAseq) and flow cytometry indicated the expansion of effector T-cells and, perhaps more importantly, a subset of macrophages in $Jag2^{KO}$ tumors. The expanded subset of macrophages in $Jag2^{KO}$ tumors displayed a further differentiated phenotype, exhibited increased antigen presentation, and consequently promoted lymphocyte-driven anti-tumor immunity. Moreover, transfer of macrophages from $Jag2^{KO}$ tumors into wild-type tumors reduced growth in immunocompetent mice but not in $Rag1^{KO}$ mice. Prevention of macrophage expansion using anti-CSF1 receptor blockade, treatment with clodronate, or ablation of *Ccr2* rescued growth in $Jag2^{KO}$ tumors and blocked intra-tumoral accumulation of T-cells. Mechanistically, *Notch*1/2 signaling on macrophages promoted *Irf*4-dependent immunostimulatory reprogramming. Subsequent knockout of *Irf*4 in myeloid populations abrogated the development of this subset of macrophages and reinstated growth of $Jag2^{KO}$ tumors.

Conclusions Our findings demonstrate an underlying, pivotal role for Jagged2 in lung tumor cells in directing immune evasion. Our experiments provide mechanistic opportunities to reprogram immunosuppressive myelopoiesis *in vivo* for the benefit of cancer immunotherapy.

945 OVERLAPPING AND DISTINCT PATTERNS OF LILRB RECEPTORS SUPPORT COMPLEMENTARY TARGETING APPROACH IN CANCER

Jeffrey Smith, Amy Mueller, Vikki Spaulding, Michelle Priess, Krithi Bala, Andrew Dunn, Sarah Jaffe, Morgan Thompson, Jean-Christophe Pignon, Alexa Diiorio, Andre Cunha, Heather Condurso, Kristin O'Malley, Olivia Petrillo, Prashanna Balaji Venkatasubramanian, Geneva Young, Christina Meyer, Michael Meehl, Katalin Kis-Toth, Monica Gostissa, Dmitri Wiederschain, Ben Umiker, Yasmin Hashambhoy-Ramsay*. *Jounce Therapeutics, Cambridge, MA, United States*

Background Leukocyte immunoglobulin-like receptors (LILRBs) are cell surface immunoinhibitory proteins that have been recently recognized as therapeutic targets of interest in immuno-oncology. LILRB1, LILRB2 and LILRB4 among them are broadly expressed on myeloid cells; however, their individual expression patterns have been difficult to define due to high sequence homology. To devise rational treatment options, it is important to develop a better understanding of LILRB1, LILRB2 and LILRB4 specific expression patterns as well as functional overlap and differences, as suggested by their diverse ligand binding partners. Here we characterize expression of these receptors on human immune cells in tumor and blood samples across different cancer indications. In addition, we performed pharmacodynamic analysis and unbiased clustering after individual LILRBs (1,2 or 4) were blocked in primary human tumor ex vivo systems to understand the roles of these receptors in complex cellular environments.

Methods Cell-specific anchoring across multiple single cell RNAseq data sets was performed to characterize temporal and spatial LILRB gene expression on individual cells. Proteins were detected on human tumor specimens using ligand, cell type and LILRB-specific IHC antibodies. LILRB protein levels on immune cells from dissociated human tumors and peripheral blood mononuclear cells (PBMCs) were quantified using flow cytometry. Fresh treatment-naïve human tumor samples were treated with anti-LILRB1, anti-LILRB2, anti-LILRB4 or isotype control antibodies and gene expression analysis was performed on treated samples.

Results LILRBs (1,2,4) are expressed on myeloid cells but distinct expression patterns also emerge. LILRB1 is expressed by T, B and NK cells; LILRB4 is highly expressed on plasmacytoid dendritic cells (pDCs) and a subset of conventional DCs (cDC2); LILRB2 is prominently expressed on immunosuppressive macrophages as well as monocytes, and within that population, intermediate monocytes display higher levels of LILRB2 than classical monocytes. In complex ex vivo systems, treatment with blocking anti-LILRB molecules induced both overlapping and distinct patterns of gene expression changes.

Conclusions LILRB1, LILRB2 and LILRB4 each display unique cell-specific expression patterns and blocking their ligand binding activity in ex vivo systems suggests that they have non-redundant functions. Thus, context-dependent inhibition of one or more of these molecules can contribute to the optimal activation of anti-tumor immunity.

Ethics Approval Human blood and tumor samples were acquired from commercial providers and from the CHTN and NDRI networks respectively. Specimens were collected under each provider's human subject research institutional review board approved protocols and were fully anonymized or otherwise permanently de-identified to recipient investigators.

946 DISSECTING MYELOID CELL-MEDIATED MECHANISMS OF RESISTANCE TO IMMUNE CHECKPOINT BLOCKADE IN BLADDER CANCER

Michelle Tran*, Adam Farkas, Kristin Beaumont, Amir Horowitz, John Sfakianos, Matthew Galsky, Nina Bhardwaj. *Icahn School of Medicine at Mount Sinai, New York, NY, United States*

Background PD-(L)1 immune checkpoint blockade (ICB) therapy yields objective responses in 15-25% of patients with bladder cancer (BC), suggesting that tumor-associated resistance mechanisms undermine their efficacy.[1-6] We previously identified two gene signatures derived from pre-treatment tumor tissue independently associated with ICB outcomes in BC patients: 1) a signature enriched in adaptive immune response genes and associated with better ICB outcomes named the "adaptive immune response signature" and 2) a signature enriched in innate immune and inflammation genes and associated with worse ICB outcomes labelled the "pro-tumorigenic inflammation signature".[7] The adaptive immune response: pro-tumorigenic inflammation score ratio, named the 2IR score, was highly correlated with ICB response and validated in an independent cohort.

Methods Single-cell RNA sequencing (scRNAseq) was performed on BC tumors (n=26) and normal-adjacent tissue (n=3) to resolve the cellular composition underlying the 2IR score. Ingenuity Pathway Analysis was applied to predict upstream ligands skewing MΦ phenotypes and such ligands were tested for their effects on healthy donor peripheral blood monocytes differentiated with (G)M-CSF. Patient plasma was assessed for pro-inflammatory cytokines across disease stage using O-Link Proteomics and Enzyme-Linked Immuno-Sorbent Assay.

Results From our scRNAseq, we discovered the adaptive immune response and pro-tumorigenic inflammation signatures were enriched in distinct MΦ subsets we labelled immunostimulatory (is)MΦs and pro-tumorigenic (pt)MΦs, respectively. ptMΦs upregulated inflammatory markers: SPP1, TREM1, and CLEC5A; expressed pro-angiogenic and hypoxic programs; and downregulated antigen presentation machinery. ptMΦs were enriched in tumor versus normal-adjacent tissue, which was confirmed by flow cytometry on additional patients. From our screen of predicted upstream ligands, lipopolysaccharide (LPS) induced the highest amount of ptMΦs ($p<.05$), as defined by Clec5a and Trem1 surface expression, in GM-CSF-induced MΦs, while IL-1β induced the most for M-CSF-induced MΦs ($p<.005$). ptMΦs also upregulated SPP1 on a transcriptional level. Inflammatory cytokines (e.g. IL-1β, IL-6, IL-8) as well as macrophage-colony stimulating factor (CSF-1) were elevated in the plasma of advanced stage BC patients as compared to early stage and healthy donors.

Conclusions From our BC scRNAseq cohort, we discovered a pro-tumorigenic inflammatory MΦ subset underlying a gene signature previously linked to ICB resistance in bladder cancer. We recapitulated these MΦs using blood monocytes differentiated with G(M)-CSF and skewed with LPS/IL-1β. We also found inflammatory cytokines associated with these MΦs were elevated in the peripheral blood of advanced patients. Together, these findings identify a distinct MΦ transcriptional state that may underlie tumor-promoting inflammation and ICB resistance and be therapeutically modulated to overcome ICB resistance.

947 QUIESCENT CANCER CELLS RESIST T CELL ATTACK BY FORMING AN IMMUNOSUPPRESSIVE NICHE

Judith Agudo*, Pilar Baldominos. *Dana-Farber Cancer Institute, Boston, MA, United States*

Background Triple Negative Breast Cancer (TNBC) is the most aggressive form of breast cancer and lacks expression of hormone receptors and HER2, preventing its treatment with targeted therapies. Until recently, chemotherapy was the only systemic therapy for these patients, limiting their options. Recently, two phase III clinical trials showed that immune checkpoint blockade (ICB) in combination with chemotherapy resulted in improved progression-free survival in metastatic PD-L1-positive TNBC, which led to approval of these regimens as a first line treatment.[1,2] Thus, immunotherapy is currently a promising approach for TNBC, however, only a fraction of patients benefits from it. An outstanding question is what mechanisms lead to resistance to these therapies.

Methods We investigated resistance to T cell killing in breast cancer cells that unequivocally expressed the targeted antigen by using the Green Fluorescent Protein (GFP) as a visible tumor neo-antigen. This was possible by exploiting our GFP-specific CD8+ T cells called Jedi.[3]

To understand how T cell infiltration and function was decreased in specific regions of the tumor, we used single cell RNA-sequencing (scRNA-seq) with precise spatial resolution. We adapted a technique involving photo-labelling, FACS-sorting and scRNA-seq[4] to large breast tumors, which we named Photo-conversion of Areas to Dissect Micro-Environments (PADME-seq).

Results By isolating antigen (GFP) positive breast cancer cells that survived during attack by CD8+ Jedi T cells, we uncovered quiescence as their principal feature. Quiescent cancer cells (QCCs) were found forming clusters with reduced immune infiltration and demonstrated a higher tumorigenic potential. By employing PADME-seq, we profiled cells infiltrating clusters of QCCs and, in parallel, cells in other regions. This enabled, for the first time, a comparison of intra-tumor infiltrates from functionally distinct niches within the same tumor mass by scRNA-seq. We uncovered that QCCs form a niche that contains immune-suppressive fibroblasts, dysfunctional dendritic cells, and highly exhausted T cells. Such ecosystems were orchestrated by a distinct quiescent population of cancer cells through activation of a hypoxia-induced program.

Conclusions QCCs constitute immunotherapy-resistant reservoirs by orchestrating a local hypoxic immune-suppressive milieu that blocks T-cell function. Eliminating QCCs holds the promise to counteract resistance to immunotherapy and prevent disease recurrence in TNBC.

948 DEVELOPING ENGINEERED ANIMAL MODELS TO INVESTIGATE TUMOR-SPECIFIC T CELL RESPONSES AND IMMUNE-RELATED ADVERSE EVENTS AFTER IMMUNOTHERAPY

Martina Damo, Noah Hornick, Nikhil Joshi*. *Yale School of Medicine, New Haven, CT, United States*

Background The rise of immune checkpoint blocking therapies (ICBs) as treatments across multiple cancer types has revealed a previously underappreciated role for the immune response in the natural regulation of cancer development. ICBs potentiate the functions of anti-tumor CD8 T cells, leading to durable tumor regression, yet, ICB treatment (particularly combination ICB) is associated with frequent and poorly-understood immune related adverse events (irAEs), which has limited the broader use of combination ICB. Thus, it is important to better understand how ICBs impact T cell responses in both tumor and non-tumor contexts, and these differ.

Methods A major gap in the field remains the availablity of animal models that faithfully recapitulate the immune-tumor microenvironment associated with different types of human cancers, and models that recapitulate the disease biology of irAEs. Our laboratory previously developed the iNversion INducible Joined neoAntigen (NINJA) model, which allows for tight spatial and temporal regulation of the induction of an known neoantigen. Using NINJA, my lab has now developed autochthonous genetically engineered mouse cancer models for studying anti-tumor T cell responses and models for studying the mechanisms by which ICBs break peripheral T cell tolerance and result in irAEs. We use paired single cell-RNAseq (scRNAseq) and T cell receptor (TCR) seq to validate that our NINJA models faithfully recapitulate the responses of T cells participating in human irAEs and in human cancer. Moreover, because T cells recognize the same antigen across all our models, tumor-specific and disease-causing CD8 and CD4 T cells can be directly compared.

Results In a model of skin-antigen induction, we identified recruitment of CD11c+ CD11b+ CD14+ CD16+ PD-L1+ myeloid cells in response to effector CD8 T cell infiltration, but not disease—unless mice are also treated with anti-PD-1 antibodies—suggesting that skin myeloid cells prevent disease pathology via the PD-1 pathway. Analyses of the CD8 T cells showed a PD-1-blockade induced upregulation of CD103 and Granzyme A, but otherwise minimal transcriptional impact. By contrast, protein-level increases in effector cytokines and degranulation were associated with blockade, as was migration into the epidermis and tissue destruction. Similar clonal CD8 T cell expansion and increased effector gene expression was seen in skin irAE patients.

Conclusions These data highlight that NINJA serves as platform for understanding mechanisms that lead to irAEs in different tissues, which could be used to testing interventions to prevent ICB-induced disease. Ongoing work focuses on elucidating the role of PD-1/PD-L1 in skin-myeloid cell-mediated suppression of skin-specific CD8 T cells.

INOVATIVE *IN VIVO* (*IN OVO*) CAM MODEL TO PREDICT EFFICACY AND MODE OF ACTION OF A NEW ANTITUMOR VACCINE STC-1010 ON HUMAN COLORECTAL ADENOCARCINOMA

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0949

[1]Yan Wang, [2]Corinne Tortorelli, [1]Arnaud Peyronnier, [2]Benoit Pinteur, [2]Lionel Chalus, [2]Paul Bravetti, [1]Jean Viallet, [3]François Ghiringhelli. *[1]Inovotion, La Tronche, France*; *[2]Brenus Pharma, ISSOIRE, France*; *[3]Centre Georges François Leclerc, Dijon, France*

Background Colorectal cancer (CRC) is the second-most deadly cancer. Therapeutic resistance to immuno-oncology drives the need for new treatments. Stimulated tumor cell (STC) vaccine (Brenus Pharma) is composed of selected tumor cell lines, stimulated to overexpress tumor-associated or tumor-specific antigens and neoantigens including resistance factors. Haptenization of these proteins forms an immunogenic complex which stimulate the immune system to recognize and target the patient's tumor cells expressing same resistance factors. We report *in vivo* results of STC-1010 vaccine, on human CRC adenocarcinoma from HT29 cell using chorioallantoic membrane (CAM) assay developed by Inovotion in immune reactive model.

Methods This study was carried out in 2 steps: Firstly, three batches of naïve chicken embryos were stimulated by injections of STC1010 at Embryo Development Day (EDD) 11 and EDD13. At EDD18 of each batch, chicken peripheral blood mononuclear cells (PBMCs) were collected and used as anti-tumor reagent to treat respectively, at EDD 11, EDD 13 and EDD16 chicken embryos xenografted with HT29 cells. Activation of PBMCs was evaluated by IL2 and IL12 secretion quantified by ELISA. At EDD18, i.e., 9 days post-graft, *in ovo* anti-tumor efficacy was evaluated by tumor weight, metastatic invasion (qPCR analysis of human Alu sequence in lower CAM) and quantification of tumor-infiltrating by CD8, CD4, IFN-gamma, Perforin and TNF-alpha.[1,2]

Results Compared to negative control, STC-1010 vaccine induced: 1) significant increase of IL-12 and IL-2 secretion in peripheric blood during the generation of all three batches of PBMCs, confirming previous results (IL-12: +52%, p=0.0003 ; IL-2: +482%, p=0.0033); 2) a significant expression of IFN-gamma in tumor (+130,83%, p=0.0185); 3) a tendency to increase infiltrating cells: CD4+: +79,2%, CD8+: +29,4% , Perforin: +105,5%, TNFα : +78,63% confirmed by immunohistochemistry and translated into 4) a significant increase of tumor necrosis (p = 0.0267); and 5) a tendency of metastasis regression (-49%); with 6) no embryonic toxicity/mortality (daily evaluation of embryonic viability) induced by STC-1010.

Conclusions This *in ovo* study confirms efficacy of the STC-1010 observed in previous CRC syngeneic models and gives more insight about STC mechanism of action with the activation and maturation of dendritic cells, induction of CD8+ and LTh1 against tumor as the main driver of the response, all without toxicity.

Inovotion's CAM model could be used for indication screening and as a pre-proof-of-concept before syngeneic model study.

950 TNFR2 HUGEMM™ MURINE MODEL FOR EVALUATION OF HTNFα-HTNFR2 SIGNALING EFFECT ON INDUCED REGULATORY T CELL DIFFERENTIATION

Demi Liu, Xuefei Yan. *Crownbio, Beijing, China*

Background Peripheral induced regulatory T cells (iTreg) play an important role for immune homeostasis. Dysregulation of iTreg differentiation is frequently associated with autoimmune diseases or tumors. Tumor necrosis factor (TNF) α is a pleiotropic cytokine with multiple biological function. Some studies suggest that mouse TNFα inhibits the differentiation of iTregs via TNFR2, providing TNFα-TNFR2 as an attractive target for drug development, for potential control of various diseases including malignant tumors and autoimmune diseases. However, whether human TNFα-TNFR2 signaling pathway plays similar role on iTreg differentiation remains unknown. Moreover, no optimal animal model is currently available for candidate drug evaluation targeting human TNFα-TNFR2. In this study, a humanized TNFR2 mouse model (TNFR2 HuGEMM) was developed to evaluate the effect of human TNFR2 agonist or antagonist on iTreg differentiation, which may be useful in the development of immunotherapies to treat tumors or autoimmune diseases, respectively.

Methods A humanized TNFR2 mouse model (HuGEMM) in C57BL/6 background was generated by replacing the extracellular domain of mouse TNFR2 with its human counterpart. Naïve $CD4^+$ T cells were isolated from the splenocytes of homozygous TNFR2 HuGEMM. To validate the signal transduction function of this humanized chimeric TNFR2 upon human TNFα stimulation and its effect on iTreg differentiation, the isolated naïve mouse $CD4^+$ cells were cultured under iTreg differentiation condition with mouse cytokines in the presence or absence of human TNFα. To test the effect of human TNFα-TNFR2 signaling on iTreg function, standard Treg suppression was performed.

Results The expression of humanized chimeric TNFR2 in mouse $CD4^+$ T cells were determined by flow cytometry. Exogenous human TNFα significantly inhibited iTreg differentiation but had no effect on iTreg function in the suppression of naïve mouse $CD3^+$ T cell proliferation.

Conclusions This study provided a novel and useful murine model to evaluate the drug candidate targeting hTNFa-hTNFR2 signaling pathway. *In vitro* iTreg differentiation assay can be used to evaluate the drug candidate's effect on hTNFa-hTNFR2 signaling. These data also suggest that TNFa-TNFR2 signaling plays an important inhibitory role on iTreg differentiation, while it has no obvious effect on iTreg suppressive function on T cell proliferation.

951 SPATIAL ATLASES OF IMMUNOLOGICAL DEVELOPMENT WITHIN THE LYMPH NODE

Tyler Hether*, Stephanie Zimmerman, Zachary Lewis, Shanshan He, Liang Zhang, Kathy Ton, Liuliu Pan, Wei Yang, Stefan Phelan, Charles Glaser, Andy Nam, Emily Brown, Michael Patrick, Gary Geiss, Sarah Church, Michael Rhodes, Yan Liang, Jason Reeves, Joseph Beechem. *NanoString Technologies, Inc., Seattle, WA, United States*

Background Immunological mechanisms regulating detection and clearance of cancer, including CTLA-4 and PD-L1, were discovered by studying the natural physiological processes regulating immune cell maturation, attenuation, and dissemination throughout the body. Single-cell atlases mapping immune cells provide hints to these aspects of immunology but lack essential spatio-temporal relationships between cells. With the advent of spatial 'omics we can resolve thousands of RNA or more than 60 protein molecules simultaneously *in situ*, enabling direct insight into the dynamics occurring as immune cells mature and migrate through tissue.

Methods We profiled lymph node samples using complementary spatial 'omics platforms: the GeoMx® Digital Spatial Profiler and the CosMx™ Spatial Molecular Imager. With GeoMx, we profiled whole transcriptomes from 5 patients focusing on key structures within the lymph node including the germinal center, mantle zones, medulla, and paracortex. With CosMx, we examine one FFPE lymph node with clear germinal center zonation, analyzing 1000 genes and 55 proteins across serial sections covering >100mm^2 and >1.4 million cells/section. We used a novel, semi-supervised clustering algorithm to map cells to CosMx from lymph node scRNAseq.

Results Across structures profiled with GeoMx we observed 11,316 genes above background in >10% of tissue regions profiled. We identified 2,618 genes (FDR<0.05) associated with distinct functional regions, and 928 significant pathways (FDR<0.05). Profiling with CosMx identified 27 cell types, 6 of which were not captured in the dissociated reference. Integrating results from GeoMx and CosMx, we observed 643 pathways enriched (FDR<0.05) in dark (n=283) and light (n=206) zones of the germinal center or at their interface (n=154), as well as 139 key ligand-receptor interactions driving such pathways. For example, we found co-stimulation of CD28 was enriched within the light zone (FDR<7.5e-06, GeoMx). CosMx confirmed that CD86 ligands within light zone B cells were significantly colocalized with the CD28 receptors of the T_fH cells of the germinal center (FDR<1.5e-05). We also found IL18 signaling between macrophages and B cells within the germinal center (FDR<5.6e-09), which was confirmed with protein profiling with CosMx.

Conclusions The spatial ecosystem provided by the GeoMx and CosMx platforms captures an unprecedented view into architecture, hard-to-profile cells, and immunological processes happening within tissue. These findings shed light on novel interactions happening at key immunological interfaces, which can be compared to immune infiltrate into tumors to identify perturbed interactions active during tumor immune escape.

952 THE TEMPORAL CONTRIBUTION OF INTERFERON-γ IN DRIVING T-CELL EXHAUSTION AND RESPONSE TO IMMUNE CHECKPOINT BLOCKADE

[1]Vaishali Aggarwal*, [2]Chang Liu, [1]Lawrence Andrews, [1]Madhu Malinee, [1]Carly Cardello, [1]Creg Workman, [1]Dario Vignali. [1]*University of Pittsburgh, Pittsburgh, PA, United States*; [2]*Nanjing University, Pittsburgh, PA, United States*

Background Immune checkpoint blockade (ICB) therapies have revolutionized treatment for cancer patients, yet minority do not respond, highlighting the importance of understanding therapeutic resistance. Interferon-gamma (IFNγ) drives protective T cell responses and augments anti-tumor immunity yet also promotes T cell exhaustion during tumor progression. Such dichotomy exhibited by IFNγ impacts immunotherapeutic responses. However, whether IFNγ continues to modulate immune responses on exhausted T (T_{EX}) cells remains unanswered. Our lab has been extensively studying lineage plasticity of T_{EX} cells by lineage-tracing lymphocyte activation gene-3 (LAG3)-expressing cells in the context of anti-tumor responses. We hypothesize that understanding the temporal expression profile of IFNγ on T_{EX} cells will help address mechanistic insights into diverse responses to ICB.

Methods To evaluate the pleiotropic role of IFNγ, we established two unique murine models, one assessing temporal tamoxifen induced global transcriptional expression of *Ifnγ* on *Lag3*-expressing cells (*Lag3*^{iCreERT2} *Ifnγ*^{YFP} *Rosa26*$^{LSL\text{-}tdTomato}$). This allows the immune cell-specific contribution of IFNγ on progenitor T_{EX} and terminal T_{EX} cells to be assessed. The second model temporally induces genetic deletion of *Ifnγ* on *Lag3*-expressing cells (*Lag3*^{iCreERT2} *Ifnγ*$^{L/L}$ *Rosa26*$^{LSL\text{-}tdTomato}$). Melanoma (B16F10) and adenocarcinoma (MC38) models were used to evaluate tumor growth and survival kinetics, T_{EX} cell profile and response to ICB therapy.

Results Assessing the transcriptional profile of *Ifnγ* shows that IFNγ is expressed by LAG3-expressing cells as early as D7, a progenitor T_{EX} state, with NK and NKT cells as major contributors. Expression of IFNγ is maintained through a terminally exhausted state (D23), with $CD8^+$ T cells as the major IFNγ-producing cells. Our *Lag3*^{iCreERT2} *Ifnγ*$^{L/L}$ *Rosa26*$^{LSL\text{-}tdTomato}$ model system, allows to examine the pleiotropic effects of IFNγ in early immune responses as well as T cell exhaustion (early vs terminal). Early temporal deletion of IFNγ (D5∼D7) potentiates tumor growth in MC38 model with no survival advantage with anti-PD1. This suggests that during initial antigen exposure, IFNγ is necessary for reinvigoration of anti-tumor response and deletion of *Ifnγ* augments T cell exhaustion. However, with later time-point deletion (D11∼D13), we observed 50% survival advantage with anti-PD1 ICB, which suggests modulating tumor microenvironment in a time-dependent manner is the key to augmenting ICB response.

Conclusions This study highlights the distinct temporal response patterns and exhaustion profile with deletion of *Ifnγ* from pre-exhausted to terminally exhausted *Lag3*+ cells. IFNγ production at early time points (D5∼D7) is a key mediator of anti-tumor immunity while the deletion of *Ifnγ* at terminal points (D11∼D13) highlights better ICB response.

953 TREATMENT WITH SQ3370, A DOXORUBICIN-BASED THERAPEUTIC, CORRESPONDS WITH IMMUNOMODULATION OF THE TUMOR MICROENVIRONMENT

Masa Aleckovic*, Sangeetha Srinivasan, Jesse McFarland, Leslie Priddy, Matthew Tso, Jose Mejia Oneto. *Shasqi Inc, San Francisco, CA, United States*

Background The CAPAC platform uses click chemistry to activate potent anti-cancer drugs specifically at the tumor while minimizing systemic toxicity. SQ3370, the lead investigational asset, consists of 1) tetrazine-modified biopolymer injected into the tumor protodrug; 2) intravenously administered protodrug of doxorubicin (Dox). Active Dox is released in the tumor through an efficient chemical reaction between the biopolymer and protodrug. SQ3370 enables a 19-fold increase over the conventional Dox dose in mice with minimal systemic toxicity.[1] Moreover, SQ3370-treated tumor-bearing mice show improved survival, T-cell infiltration, and a robust anti-tumor response against both biopolymer-injected and non-injected lesions,[2] suggesting SQ3370 promotes anti-tumor immune activation.

SQ3370 is currently in a Phase I clinical trial in patients with advanced solid tumors (NCT04106492). The on-going dose escalation phase has shown no dose limiting toxicity thus far. No acute cardiotoxicity has been observed with Dox levels >12-times the molar equivalent dose of conventional Dox treatment.

We performed in-depth evaluation of tumor immune infiltration after SQ3370 treatment using syngeneic tumor models and correlated findings with data obtained from clinical samples from patients treated with SQ3370. Based on these data, we present a mechanism-of-action for SQ3370 and propose rationale for combination therapies of SQ3370 with immunotherapies.

Methods SQ3370 treatment is described in figure 1. Immunocompetent mice were inoculated with B16-F10 or MC38 tumor cells. SQL70 was given intratumorally; SQP33 was given intravenously as five daily doses. Tumors used for immune analysis were harvested 2 weeks after the last SQP33 dose and were assessed by flow cytometry and multiplex immunofluorescent analysis. Patient samples were assessed by multiplex immunohistochemistry (tumor biopsies) and CyTOF analyses (blood cells).

Results SQ3370 treatment induced immune activation in patient tumor biopsies despite assessment of a diverse, heavily pre-treated population. Similarly, SQ3370 promoted immune activation in preclinical models. The data are consistent with immunogenic cell death and characterized by activation of T-cell responses.

Conclusions SQ3370, CAPAC's lead candidate, improves safety and efficacy as compared to conventional Dox. It also activates an anti-tumor immune response through induction of immunogenic cell death and modulates adaptive and innate immune cell populations. Consistency between immune responses observed in clinical samples and mouse syngeneic tumor models underlines the translatability of the SQ3370 preclinical data and suggests a window of opportunity for combination strategies with immunotherapies.

954 **SQ2270, A NOVEL MMAE-BASED THERAPEUTIC, PROMOTES TUMOR GROWTH INHIBITION AND EXTENSIVE IMMUNE CELL INFILTRATION IN THE RENCA CANCER MODEL**

Masa Aleckovic*, Sangeetha Srinivasan, Jesse McFarland, Leslie Priddy, Matthew Tso, George Coricor, Jose Mejia Oneto. *Shasqi Inc, San Francisco, CA, United States*

Background The CAPAC™ platform aims to help patients beat cancer by activating powerful therapies at the tumor site while minimizing systemic exposure. The click chemistry-based technology is highly modular and can be applied to a broad range of cancer drugs whose use is limited by toxicity.

The platform consists of an intratumorally injected biopolymer and an intravenously administered protodrug. Efficient reaction between the biopolymer and prodrug releases the active drug in situ. SQ3370, the lead asset, uses a Doxorubicin protodrug and is being evaluated in a Phase 1 clinical trial in solid tumors (NCT04106492).

We've developed a new protodrug of monomethyl auristatin E (MMAE) and demonstrated its antitumor efficacy when combined with the biopolymer in two tumor models. Here, we performed analyses of immune infiltration into syngeneic tumors that were treated with this novel therapeutic, SQ2270.

Methods SQ2270 treatment is described in figure 1. Immunocompetent mice were inoculated with RENCA tumor cells. The biopolymer was given intratumorally and MMAE protodrug was given intravenously. Control groups— vehicle and MMAE (1 mg/kg), were treated intravenously. After 2 weeks, tumors were harvested, and immune infiltration was assessed by flow cytometry and immunofluorescent (IF) analyses. Tumor histology was evaluated by H&E staining.

Results SQ2270 and MMAE control significantly inhibited growth of RENCA tumors compared to vehicle ($p<0.0001$). Histological analysis indicated increased stromal cell infiltration, extracellular matrix deposition, and presence of large phagocytic cells in SQ2270- and MMAE-treated tumors. Flow cytometry indicated >110-fold increase in CD45+ cells fraction of SQ2270-treated tumors compared to vehicle (41% vs 0.4%, $p=0.01$). MMAE, on the other hand, expanded the CD45+ fraction in tumors by 27-fold (10% vs 0.4%, $p=0.0004$). SQ2270-treated tumors showed significant increases in several immune populations compared to vehicle, including CD3+, CD8+ (including activated and PD-1+) and CD4+ T-cells, NKT-cells, and activated NK cells. MMAE-treated tumors exhibited less pronounced increases. IF analysis supported these findings, showing increased frequencies of total and Granzyme B-positive CD8+ T-cells in SQ2270-treated tumors compared to controls.

Conclusions SQ2270, CAPAC's novel MMAE-based candidate, is a potent anticancer therapeutic. Here, we show that it also activates an anti-tumor immune response through an extensive immune cell infiltration. Several immune cell types infiltrate the SQ2270-treated tumors where they become activated, including cytotoxic CD8+ T-cells.

Ethics Approval These studies, project numbers SQONCO22-001 and SQONCO22-002, were approved by the Institutional Animal Care and Use Committee (IACUC) of the vendor, following the guidance of Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC), accreditation number 001738.

955 GINGIVO-BUCCAL ORAL CANCER: INFERRING PROGNOSIS FROM IMMUNE CONTEXTURES OF TUMOR AND SURROUNDING MARGIN

[1]Ankita Chatterjee*, [2]Partha Majumder, [2]Ankita Chatterjee, [2]Nidhan Biswas, [2]Arindam Maitra, [2]Arnab Ghosh. *[1]NIBMG, Kolkata, India*; *[2]National Institute of Biomedical Genomic, Kalyani, India*

Background Interactions between cancer and immune cells create a tumor-promoting or tumor-rejecting environment and correlate with prognosis for many cancers. The variability of immune contextures among oral squamous cell carcinoma of gingivobuccal region (OSCC-GB) patients and their relationship with prognosis are largely unknown.

Methods In this study we estimated the immune infiltration in the tumor, surrounding surgical negative margins and adjacent normal tissues of 43 treatment naïve OSCC-GB patients, using bulk RNA-sequencing and immunohistochemistry. Prognosis of each patient was followed-up for at least two years. Immune subtypes were inferred from gene expression data. Association of patient subtypes and disease prognosis was studied.

Results Using expressions of 544 immune related genes (IRGs) we identified a subgroup of patients with poor prognosis (high recurrences and deaths). High expression levels of three genes – CD73, ITGA3, and ITGA6 – were associated with poor overall survival and higher recurrence. Patients with good prognosis had (a) in their tumors, a high proportion of CD4+ and CD8+ T cells, B cells, NK cells, M1 macrophages, higher TCR and BCR repertoire diversity and cells positive for immune checkpoint markers, and (b) their surgical negative margins were enriched with resting memory-T and dendritic cells.

Conclusions Better prognosis in OSCC-GB is associated with appropriate immune contextures and a subgroup, with high expression of immune checkpoint genes, may further benefit from immunotherapy.

956 SPATIAL CLUSTERING REVEALS IMMUNE HUB INTERACTION WITH RESERVOIR OF STEM-LIKE CD8 T CELLS AND PREDICTS IMMUNOTHERAPY RESPONSE IN LUNG CANCER PATIENTS

[1]Jonathan Chen*, [1]Linda Nieman, [1]Maxwell Spurrell, [1]Mari Mino-Kenudson, [1]Justin Gainor, [2]Nir Hacohen, [1]Jonathan Chen,. [1]*Massachusetts General Hospital, Boston, United States*; [2]*Broad Institute, Cambridge, MA, United States*

Background Immunologic tumor control involves coordination of multiple cell types, but the organization of these interactions in human tumors is poorly understood. We recently reported that immunogenic tumors contain spatially-localized multicellular immunity hubs characterized by expression of interferon-stimulated genes, including *CXCL10*/*CXCL11* (T cell attracting chemokines), and the presence of *IFNG*+ T cells.[1] This suggested a positive feedback loop where T cell-derived IFNγ stimulates production of CXCR3 ligands, thereby attracting more T cells. However, we did not know (1) whether these hubs predict response to immunotherapy and (2) how hubs intersect with the various CD8 T cell states which play central roles in anti-tumor immunity.

Methods To understand the composition of this immunity hub and its potential association with immunotherapy response, we performed multiplex RNA FISH to visualize hub components in NSCLC tissue from 68 patients prior to PD1-blockade. Cells were segmented and phenotyped automatically. We additionally imaged serial sections with a second panel for markers of CD8 T cell state. We then computationally registered sequential images, integrating our panels. To identify hubs in an unbiased manner, we employed kmeans clustering.

Results We found that the presence of the immunity hub is predictive of subsequent response to PD1-blockade. Image registration revealed that hubs are enriched for CD8 T cells in multiple states, confirming their role as key sites of anti-tumor T cell activity. Furthermore, immunity hubs in responders contained more activated CD8 T cells and *IFNG*+ cells than those in nonresponders. To determine how hub heterogeneity may influence hub functions, we subclustered hubs by phenotypic composition. This analysis uncovered a 'hybrid hub' subclass that spatially overlaps with structures containing stem-like TCF7+ CD8 T cells, resembling the interfollicular zone of lymph nodes. The presence of a single hybrid hub was strongly associated with RECIST response ($p = 0.0005$), found in 85% of responders and only 24% of non-responders. Hybrid hubs also showed a striking association with patient PFS ($p = 0.0014$).

Conclusions Our study provides insight into the multicellular networks that underlie anti-tumor immunity. Immunity hubs are predictive of response to immunotherapy in human lung cancer and organize intratumoral CD8 T cell activity. Moreover, hybrid hubs may represent an active intra-tumoral niche for tumor-specific stem-like T cells that sustain anti-tumor immunity. These multicellular networks are excellent candidates for biomarker development and targets for immunotherapy.

957 **ASSESSMENT OF THE SPATIAL DISTRIBUTION AND CELL-TO-CELL INTERACTIONS INTO THE TUMOR MICRO-ENVIRONMENT, WITHIN AND BETWEEN SERIAL SLIDES STAINED WITH BRIGHTPLEX®, A SEQUENTIAL CHROMOGENIC MULTIPLEX ASSAY**

[1]Aurelie Collignon*, [1]Alboukadel Kassambara, [1]Alex Trinh, [1]Maité Chamourin, [1]Georgia Culley, [1]Marion Olive, [1]Clemence Jaume, [1]Assil Benchaaben, [2]Jerome Galon, [1]Jacques Fieschi. [1]*Veracyte, Marseille, France*; [2]*Inserm, Paris, France*

Background Tumor-infiltrating immune cells play an important role against cancer and are critical to control tumor growth and spread. Immunotherapy and immune checkpoint inhibitors, which aim to reinvigorate exhausted T cells have revolutionized cancer therapy. Despite inducing long-term response in many cancer types, these therapies remain ineffective for most patients.

A better understanding of tumor microenvironment and in particular the presence of immune cells and other stromal cells, along with their abundance, distribution and interactions with other immune/or tumor cells, may help to better stratify patients and understand mechanisms of resistance to immunotherapy. Indeed, the distribution of T cells in tumor could be associated to favorable prognosis in different cancers and the relationship between cells could be linked to patient outcome. For instance, the presence of macrophages close to tumor cells in non-small cell lung cancer or the proximity of regulatory T cells (Treg) cells to cytotoxic CD8+ T-cells in gastric cancer are associated with worse outcome.

Methods The analysis of the spatial distribution of immune and non-immune cells and of their proximity in the tumor microenvironment seems relevant to understand response to immunotherapy. Here, we propose a new tool allowing the assessment of 3 spatial parameters: 1) Evaluation of cell-to-cell proximity metrics between 2 different populations or within the same population (clustering), 2) Interaction of two cell populations using nearest neighbor distance measurement (G-function) and 3) Spatial cell distribution highlighting hot spots (Kernel's heatmap).

Brightplex® is a chromogenic multiplex immunohistochemistry technology allowing the detection of several biomarkers on a single FFPE slide to identify and quantify complex cell populations such as T-cells expressing immune checkpoints, M1 and M2 macrophages, Treg cells and myeloid-derived suppressor cells. Following staining and digitization, images are fused to create a virtual multi-channel image where cells of interest are detected by digital pathology (DP). With Brightplex and DP, we have developed a workflow to assess the spatial distribution and potentially cell-to-cell interactions within a slide or between two or three adjacent slides stained with different multiplex panels. Following cell detection, spatial analysis is performed using spatstat module on R-studio software.

Integrated to Immunogram, this new tool could help clinical researchers to understand tumor landscape, predict response to treatment and patient outcome.

959 PD-1 AND ICOS CO-EXPRESSION IDENTIFIES TUMOR-REACTIVE CD4 T CELLS IN HUMAN SOLID TUMORS

Rebekka Duhen, Olivier Fesneau, Kimberly Samson, Alexandra Frye, Michael Beymer, Venkatesh Rajamanickam, David Ross, Eric Tran, Brady Bernard, Andrew Weinberg, Thomas Duhen*. *EACRI | Providence Cancer Institute, Portland, OR, United States*

Background CD4 T helper (Th) cells play a key role in orchestrating immune responses, but the identity of the CD4 Th cells involved in the immune response against cancer remains to be defined.

Methods To better define the composition of the CD4 Th cells infiltrating human solid tumors, we analyzed the phenotype of CD4 T cells in 22 patients with head and neck squamous cell carcinoma and 16 patients with microsatellite stable colorectal cancer by high dimensional flow cytometry. In addition, we determined their spatial location and cellular interactions in the tumor microenvironment by multiplex IHC to understand their role in the anti-tumor immune response. We also assessed the capacity of the CD4 Th cell populations sorted and expanded based on the expression of PD-1 and ICOS to recognize tumor-associated antigens and tumor-specific neoantigens. Finally, we investigated whether the presence of PD-1+ICOS+ CD4 Th cells in the tumor was associated with disease-free survival in HNSCC patients.

Results Following t-SNE analysis, we identified a subset of CD4 Th cells distinct from FOXP3+ regulatory T cells that co-expressed PD-1 and ICOS. This cell population, which was present in the tumor but absent in the periphery, exhibited features of chronic stimulation and displayed characteristics of tissue resident memory T cells. PD-1+ICOS+ tumor-infiltrating (TIL) CD4 Th cells were located primarily in the tumor stroma in proximity to MHC class II+ cells and were proliferating, suggesting local antigen recognition. Interestingly, both PD-1+ICOS+ CD4 Th cells and CD39+CD103+ tumor-reactive CD8 T cells were enriched for cells secreting CXCL13, a chemokine involved in the recruitment of B cells. PD-1+ICOS+ CD4 Th TIL were shown to recognize both tumor-associated antigens and tumor-specific neoantigens, which were distinct from the epitopes recognized by the CD8 T cells from the same patients. Finally, higher frequencies of PD-1+ICOS+ CD4 Th TIL in patients with HNSCC was associated with better disease-free survival.

Conclusions Our findings provide an approach for isolating tumor-reactive CD4 Th TIL directly ex vivo that will help define their role in the anti-tumor immune response and potentially improve future adoptive T -cell therapy approaches.

Ethics Approval All surgical tumor samples and blood samples used in this study were taken from individuals treated at the Providence Cancer Center. All patients signed written informed consent approved by the Providence Portland Medical Center Institutional Review Board (IRB protocol n0. 06-108A) and the study was conducted in accordance with the ethical standards established by the Declaration of Helsinki.

960 **TT-816, A NOVEL SMALL MOLECULE IMMUNE CHECKPOINT INHIBITOR TARGETING CANNABINOID CB_2 RECEPTOR, STIMULATES INNATE AND ADAPTIVE IMMUNITY FOR CANCER THERAPY**

Peidong Fan*, Elfatih Elzein, Lina Yao. *Teon Therapeutics, Inc., Redwood City, CA, United States*

Background The endocannabinoid system is widely expressed in the human body, including the innate and adaptive immune system, where endocannabinoids, Δ9-tetrahydrocannabinol and synthetic ligands regulate immune response. The effects of endocannabinoids on immune regulation are primarily mediated by G-protein coupled cannabinoid CB_2 receptors (CB_2R) via several mechanisms, including development, migration, proliferation and effector functions. The upregulated expression of CB_2R and elevated levels of endocannabinoids have been observed in a variety of tumor microenvironments and are associated with the aggressiveness of cancer.

Methods Membranes prepared from CHO-K1 cells stably expressing human CB_2R were used for receptor binding assays in the presence of TT-816 and [3H]CP-55,940, and for GTPγS binding assay in the presence of TT-816, 10 μM GDP and 0.3 nM [35S]GTPγS. cAMP assay was performed by incubating the CHO-K-1 cells for 30 min with TT-816, 25 μM forskolin and 12 nM CP-55,940, or with TT-816 and 5 μM forskolin. NK cell function was determined by co-culturing TT-816 pretreated NK cells with K562 cancer cells for 24 hours. The mixed lymphocyte reaction assay was conducted by co-culturing human CD4+ T cells with monocyte-derived dendritic cells. Cell viability was measured by FACS and IFN-γ by MSD.

Results TT-816 is a competitive and selective CB_2R antagonist. It bound to human CB_2R with an IC50 26.2 nM, showing greater than 380-fold selectivity over cannabinoid CB_1 receptors. The ability of TT-816 to inhibit the constitutive activity of CB_2R was characterized in both GTPγS and cAMP assays. TT-816 concentration-dependently inhibited the basal GTPγS binding response, antagonized CB_2R agonist-mediated cAMP production and enhanced the forskolin response on basal cAMP level. Consistent with its inhibition of CB_2R function, TT-816 inhibited the growth of human breast, colorectal and lung cancer cells. In addition, TT-816 concentration-dependently enhanced the functions of NK cells, dendritic cells and T cells. It increased NK cell killing of the human cancer cells and IFN-γ production, significantly stimulated the expression of CD86, HLA-DR, IL-12 and TNF-a in monocyte-derived dendritic cells, and enhanced CD4+ T cell proliferation and IFN-γ production in a mixed lymphocyte reaction assay.

Conclusions TT-816 is a novel, oral small molecule immune checkpoint inhibitor that selectively blocks CB_2R on cancer cells and immune cells. Preclinical data have demonstrated that it stimulates antitumor innate and adaptive immune response and inhibits cancer cell proliferation. TT-816 is currently undergoing phase 1 clinical trials for the treatment of a broad range of solid tumors.

961 TUMOR-INFILTRATING MUCOSAL-ASSOCIATED INVARIANT T CELLS (MAIT) FROM PATIENTS WITH PANCREATIC CANCER RECOGNIZE SHARED TUMOR ANTIGENS IN AN MR1-RESTRICTED FASHION

[1]Jéssica Kamiki*, [1]Patrícia António, [1]Rodrigo Eduardo, [1]Sara Cascais, [1]Bernardo Marinheiro, [1]Andreia Maia, [1]Eric De Sousa, [1]Joana Lerias, [1]Carolina Gorgulho, [1]Mireia Castillo-Martin, [1]Markus Buechler, [1]Antonio Beltran, [1]Carlos Carvalho, [2]Ridong Chen, [2]Sam Jeong, [1]Markus Maeurer. *[1]Champalimaud Foundation, Lisbon, Portugal; [2]Human Cell Inc., Napperville, IL, United States*

Background Pancreatic adenocarcinoma (PDAC) is one of the most lethal cancers with a 5-year survival rate of 10%.[1] Standard chemotherapeutics have failed to produce relevant increased survival for patients with pancreatic cancer.[2] Cellular immunotherapies are a viable option to achieve anti-tumor directed clinically relevant treatment modalities.

Mucosal-associated invariant T-cells (MAIT) are defined by the restricted usage of the invariant Vα7.2 T-cell receptor (TCR) α-chain combined with different TCR β-chains that bridge innate and adaptive immune responses. MAIT produce pro-inflammatory cytokines[3,4] and are present in primary and metastatic cancer lesions.[4,5] MAIT may contribute to control malignant cells by either MR1-restricted recognition of cancer cells and/or by production of anti-cancer directed cytokines induced by tumoral-associated bacterial species. A set of bacterial species has been associated with improved survival in patients with PDAC.[6,7] We studied the role of MAIT in tumor-infiltrating lymphocytes (TIL) from patients with PDAC.

Methods MAIT were identified in PDAC specimens by immunohistology. Freshly harvested tumor specimen allowed to expand TILs from patients with PDAC and to selectively isolate MAIT by immunomagnetic sorting. MR1-restricted recognition and cancer specificity was tested in an autologous tumor cell recognition model- blocked by antibodies against MR1 and in a MR1+ allogeneic tumoral cell line via MR1-siRNA downregulation defined by IFN-γ production. Phenotypic and functional analysis of MAIT was carried out by flow cytometry and ELISAs. Deep TCR-sequencing of tumor tissue and TIL was performed to gauge TCR diversity and spatial transcriptomics to localize Vα7.2 cells associated with MR1 and immune effector gene expression.

Results PDAC lesions are positive for MR1 and Vα7.2+ cells defined by immunohistology and spatial transcriptomics. MAIT were isolated and found to be specifically reactive against autologous tumor determined by IFN-γ and IL-17A production. The majority of MAIT resided in the effector-memory pool (CD45-CCR7-) and tested positive for CD8, CD161 and CD26. Reactivity against a panel of candidate bacteria associated with patient survival was confirmed by cytotoxicity and a CD107a degranulation assay.

Conclusions MAIT infiltrate into PDAC lesions, they recognize the tumor in a MR1-restricted fashion defined by IFN-γ release and cytokine production could be augmented by a defined set of bacterial species. MAIT represent biologically relevant immune cells that may aid to kill cancer cells. Anti-tumor directed TCRs can be used as a molecular blueprint to construct anti-cancer directed transgenic immune cells restricted by commonly shared MR1.

962 IFI16 PROMOTES IMMUNE RESPONSES THROUGH IFN-γ PATHWAY ACTIVATION IN METASTATIC CUTANEOUS MELANOMAS

[1]Yuta Kobayashi*, [1]Matias Bustos, [2]Qiang Yu, [1]Dave Hoon. *[1]Saint John's Cancer Institute, Santa Monica, CA, United States; [2]Genome Institute of Singapore, Biopolis, Singapore*

Background IFN-γ–inducible protein 16 (IFI16) is known to initiate STING pathway cascade, which leads to the downstream activation of various cytokines and chemokines that play important roles in enhancing tumor microenvironment immune responses. IFI16 activates STING signaling through the cooperation with cyclic GMP-AMP synthase (cGAS) through the detection of cytoplasmic DNA. Recently, we have shown that IFI16-dependent STING signaling upregulates effective anti-HER2 cellular immune responses in HER2 (+) breast cancer.[1] The aim of this study was to assess the role of *IFI16* levels with immune responses in metastatic cutaneous melanomas.

Methods Cutaneous melanoma datasets for mRNA expression were obtained from TCGA SKCM, GTEx, GSE7553, GSE15605, and GSE46517. The fraction of tumor-infiltrated immune cells (TIIC) was estimated by CIBERSORT. Patients from TCGA were divided into high- and low-*IFI16* mRNA level groups, based on the highest and lowest quartiles. Extraction of Expression Module (EEM) analysis was performed. Correlations between variables were calculated with the Mann-Whitney U test with FDR corrections.

Results *IFI16* mRNA levels were significantly upregulated in metastatic cutaneous melanomas (AJCC III/IV, n = 193) compared to normal skin (figure 1A, $p < 0.0001$), but significantly downregulated in metastatic versus primary melanomas in GSE7553 dataset (figure 1B, $p = 0.016$). High levels of *IFI16* were significantly associated with poor prognosis in stage III/IV melanoma patients (figure 1C, $p < 0.0001$). The analysis of TIIC showed that M1 macrophage subset levels were significantly higher in the high-*IFI16* vs low-*IFI16* group (figure 1D, $p = 0.0028$). IFN-γ score was significantly higher in the high- vs low-*IFI16* group in TCGA (figure 1E, $p = 0.00051$), GSE46516 ($p = 0.00068$), and GSE15605 ($p = 0.026$). EEM analysis showed that the activity scores of IFN-γ response were significantly higher in high-*IFI16* vs low-*IFI16* groups ($p = 0.0048$). Furthermore, data integration from EEM and differential expressed genes analysis identified 34 immune-related genes, of which chemokines *CXCL10* and *CXCL11* were significantly upregulated by the IFN-γ response pathway. The elevated *CXCL10* and *CXCL11* are known to enhance tumor immune microenvironment activity. *CXCL10* and *CXCL11* were significantly higher in high-*IFI16* group in both the TCGA (figure 1F, $p < 0.0001$, $p < 0.0001$, respectively) and GSE46517 ($p = 0.00016$, $p = 0.00062$, respectively).

Conclusions High-*IFI16* mRNA levels may represent predictive biomarkers of good prognosis in metastatic melanomas, whereby *IFI16* mRNA levels were associated with significant immune responses through the upregulation of the IFN-γ pathway, M1 macrophage subset, and *CXCL10*/*CXCL11*.

SIGNIFICANTLY DIFFERENT IMMUNE MICROENVIRONMENT BETWEEN TRIPLE-NEGATIVE BREAST CANCER WITH AND WITHOUT NEOADJUVANT CHEMOTHERAPY THROUGH MULTIPLEX IMMUNOHISTOCHEMISTRY

[1]Miseon Lee*, [2]Hyun Lee, [3]Gyungyub Gong, [3]Hee Jin Lee. *[1]Seoul St. Mary's Hospital College of medicine, Seoul, Korea, Republic of; [2]NeogenTC corp., Gyeonggi-do, hanam-si, Korea, Republic of; [3]University of Ulsan College of Medicine, Seoul, Korea, Republic of*

Background Understanding the tumor immune microenvironment in triple-negative breast cancer (TNBC) is essential for the development of successful immunotherapy. Although neoadjuvant chemotherapy (NAC) for TNBC is increasing, studies about the difference in tumor immune microenvironment with or without NAC and the association with clinical data are lacking.

Methods We made tumor microarray for 181 TNBC surgical specimens [84 cases (46.4%) without NAC and 97 cases (53.6%) with NAC] and performed multiplex immunohistochemistry (pan-cytokeratin, CD4, CD8, CD45RO, FOXP3, PD-1, PD-L1, and CD103) (figure 1). In cases without NAC, 23 patients (27.4%) were in stage I and 61 (72.6%) in II or III. In the cases with NAC, the residual cancer burden (RCB) class was 20 (20.6%) in 0, 5 (5.2%) in I, 51 (52.6%) in II, and 21 (21.6%) in III.

Results Tumors without NAC had significantly higher amounts of CD4+, CD8+, CD103+, CD45RO+, FOXP3+, or PD-1 + with CK- cells per area compared to tumors with NAC (p-value range: <0.001 ~ 0.001). In the Kaplan-Meier survival analysis of patients without NAC, disease-free survival (DFS) was significantly better in the group with higher amount of CK-CD4+PD-1+CD45RO+CD103+ (p=0.023), CK-CD4 +PD-1-CD45RO+CD103+ (p=0.018), CK-CD8+PD-1 +CD45RO+CD103+ (p=0.023), CK-CD8+PD-1-CD45RO +CD103+ (p=0.023), CK-CD8+PD-1-CD45RO-CD103+ (p=0.023), CK-CD8+ (p= 0.024), CK-CD8+PD-1+CD45RO +CD103-(p=0.023), and CK-CD8+PD-1-CD45RO+CD103- (p=0.024) per area than the median value. In tumors with NAC, the DFS was significantly better in the group with a higher amount of CK-CD8+PD-1+CD45RO-CD103+ (p=0.020) and CK-CD8+PD-1+CD45RO-CD103- (p=0.042) per area than the median. In the multivariable analysis of tumors without NAC, the high histologic grade was a significant prognostic factor of unfavorable DFS [Hazard ratio (HR), 0.029; 95% confidence interval (CI), 0.004 to 0.217; p=0.001] and a higher amount of CK-CD8+ per area than median value was a significant prognostic factor of favorable DFS (HR, 0.094; 95% CI, 0.014 to 0.613; p=0.013). In tumors with NAC, a higher amount of CK-CD8+PD-1 +CD45RO-CD103+ per area than median value (HR, 0.398; 95% CI, 0.192 to 0.825; p=0.015) and low RCB class (class 0 vs. class III; HR, 0.097; 95% CI, 0.023 to 0.418; p=0.002, class II vs. III; HR, 0.192; 95% CI, 0.085 to 0.433; p=< 0.001) were significantly favorable prognostic factors of DFS.

Conclusions In TNBC, the tumor immune microenvironment between tumors without NAC and tumors with NAC was significantly different, and the immune phenotype with a clinically significant effect was distinct. A deeper understanding of the difference in the tumor immune microenvironment between TNBC with and without NAC will help develop successful immunotherapy.

964 DYNAMIC IMMUNE LANDSCAPES DURING MELANOMA PROGRESSION REVEAL A ROLE FOR ENDOGENOUS OPIOIDS IN DRIVING T CELL DYSFUNCTION

[1]Davide Mangani*, [2]Linglin Huang, [3]Meromit Singer, [2]Ruitong Li, [1]Rocky Barilla, [1]Giulia Escobar, [1]Katherine Tooley, [1]Hanning Cheng, [3]Conor Delaney, [3]Kathleen Newcomer, [4]Jackson Nyman, [4]Nemanja Marjanovic, [1]James Nevin, [5]Orit Rozenblatt-Rosen, [1]Vijay Kuchroo, [5]Aviv Regev, [1]Ana Anderson. *[1]Evergrande Center for Immunologic Diseases, Ann Romney Center for Neurologic Diseases, Harvard Medical School and Mass General Brigham, Boston, MA, 02115, USA, Boston, MA, United States; [2]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA, 02115, USA, Boston, MA, United States; [3]Dana-Farber Cancer Institute, Boston, MA 02215, USA, Boston, MA, United States; [4]Klarman Cell Observatory, Broad Institute of Harvard and MIT, Cambridge, MA, USA, Cambridge, MA, United States; [5]Klarman Cell Observatory, Broad Institute of Harvard and MIT, Cambridge, MA, USA ; Genentech, South San Francisco, CA, USA., Cambridge, MA, United States*

Background Immune checkpoint blockade (ICB) therapies aimed at invigorating the anti-tumor immune response have achieved unprecedented responses in several tumor types, including melanoma.[1,2] Despite this great success, approximately 50% of melanoma patients either fail to respond or develop resistance to ICB.[3] As the immune response becomes progressively disabled as tumors advance, achieving a better understanding of the immunosuppressive mechanisms that take hold during tumor progression is needed to identify novel therapeutic targets and extend the benefit of immunotherapy to more patients

Methods We performed an unsupervised examination of the immune infiltrate of B16F10 melanoma tumors over the course of tumor progression using single-cell RNAseq. At each time point we harvested tumors of different sizes to enable parsing of changes associated with tumor size and time from implant separately. We investigated dynamic changes in composition of the tumor infiltrate and in genes and pathways expressed in $CD8^+$ T cells over the course of tumor progression

Results We uncovered an unexpected role for endogenous opioid signaling in the development of $CD8^+$ T cell dysfunction during melanoma progression. The endogenous opioid-polypeptide hormone pro-enkephalin (*Penk*) was progressively up-regulated in $CD8^+$ T cells that transitioned from the effector to terminally exhausted T cell state with tumor progression. We applied gain- and loss-of-function approaches to test the role of *Penk* in tumor antigen-specific responses. Adoptive transfer of OT-I $CD8^+$ T cells transduced with a lentiviral vector to over-express *Penk* had reduced cytolytic capacity and secretion of effector cytokines (IFNg, TNFa) and failed to control the growth of B16F10-OVA compared to WT OT-I cells. Conversely, CRISPR-Cas9-mediated knock-out of *Penk* in OT-I cells led to enhanced tumor control. Further, *Penk* deficiency in $CD8^+$ Pmel T cells that recognize the mouse homologue of the human premelanosome protein, overcame the poor ability of Pmel T cells to exert tumor control. Notably, *Penk*-deficient $CD8^+$ T cells exhibited increased cytolytic potential and effector function, without acquiring features of terminal dysfunction as determined by TOX, Eomes, and TIM3 expression. Lastly, treatment of established B16F10 melanoma with an inhibitor of opioid signaling significantly improved tumor growth control

Conclusions Our data reveal an unexpected role for endogenous opioids in driving T cell dysfunction, thereby linking analgesic pathways and the dampening of T cell functionality in cancer. Finally, our findings have high clinical relevance as patients with advanced tumors are often treated with opioids, which may ultimately limit anti-tumor $CD8^+$ T cell responses and ICB efficacy

965 DEFICIENCY OF METABOLIC REGULATOR PKM2 ACTIVATES THE PENTOSE PHOSPHATE PATHWAY TO GENERATE TCF1+ PROGENITOR CD8 T CELLS TO IMPROVE EFFICACY OF PD-1 CHECKPOINT BLOCKADE

Geoffrey Markowitz*, Yi Ban, Diamile Tavarez, Michael Crowley, Liron Yoffe, Mitchell Martin, Tito Sandoval, Dingcheng Gao, Juan Cubillos-Ruiz, Timothy McGraw, Nasser Altorki, Vivek Mittal. *Weill Cornell Medicine, New York, NY, United States*

Background TCF1^{high} progenitor CD8+ T cells have been shown to mediate the efficacy of PD-1 checkpoint blockade.[1-3] However, the mechanisms that govern generation of TCF1^{high} cells are poorly understood.

Methods We sequenced bulk RNA from tumor-infiltrating lymphocytes to identify differentially expressed genes based on tumor progression. We utilized *in vitro* co-cultures of tumor-specific T cells tumor cells to examine differentiation, effector function, and metabolism of T cells with different genetic and pharmacologic manipulations by flow cytometry, metabolic flux analyses, and metabolomic profiling. We performed *in vivo* adoptive transfers of control and genetically manipulated tumor-specific T cells into tumor-bearing mice from both a non-small cell lung cancer and a melanoma model to examine effects of genetic manipulation on differentiation and effector function, as well as determine tumor burden and overall mouse survival both in the treatment-naïve and anti-PD-1 treated contexts.

Results RNA Sequencing demonstrated a metabolically active response in tumor-infiltrating CD8+ T cells isolated from large and late-stage tumors. Using a genetic screen targeting glycolytic enzymes up-regulated in tumor-infiltrating CD8+ T cells, we demonstrate that PKM2 deficiency (PKM2^{KO}) enriched for TCF1^{high} progenitor cells (figure 1). Antigen-specific PKM2^{KO} CD8+ T cells from draining lymph nodes and tumors exhibited a central memory-like phenotype (figure 2) with reduced effector cytokine production, increased CD44/CD62L expression, and increased TCF1 and Eomes in non-small cell lung cancer and melanoma. Adoptive transfer of PKM2^{KO} CD8+ T cells in combination with PD-1 blockade impaired tumor growth and improved survival (figure 3). PKM2^{KO} CD8+ T cells showed reduced glycolytic flux and accumulation of glycolytic intermediates with concomitant increases in pentose phosphate pathway (PPP) metabolites. Importantly, small molecule agonism of PPP was sufficient to skew activated CD8+ T cells towards the TCF1^{high} population (figure 4).

Conclusions Here we show that targeting glycolytic flux by deletion of pyruvate kinase muscle 2 (PKM2) results in elevated pentose phosphate pathway activity, leading to generation of an altered differentiation state responsive to PD-1 blockade. Our study demonstrates a novel metabolic reprogramming that contributes to a memory-like T cell state amenable to checkpoint blockade.

966 MULTISPECTRAL IMMUNOHISTOCHEMISTRY REVEALS AN IMMUNOSUPPRESSIVE TUMOUR MICROENVIRONMENT IN ESOPHAGEAL ADENOCARCINOMA

[1]Charles Rayner*, [1]Tyler Wooldridge, [1]Sunny Sunshine, [2]Izhar Bagwan*, [2]Shaun Preston, [1]Hardev Pandha, [2]Nima Abbassi-Ghadi, [1]Nicola Annels. [1]*University of Surrey, Guildford, UK*; [2]*Royal Surrey NHS Foundation Trust, Guildford, UK*

Background Esophageal cancer – of which adenocarcinoma (EAC) is the predominant type in the UK – is a highly aggressive malignancy, with 5-year survival rates of approximately 15%.[1] Surgically resectable disease is treated with neo-adjuvant chemo+/-radiotherapy. The recent publication of Checkmate-577 supports the use of anti-PD-1 immunotherapy in EAC post chemoradiotherapy and surgery.[2] Beyond $CD8^+$ T cells and PD-1/PD-L1 expression, the immune tumour microenvironment of EAC is poorly understood. Further research is required to understand the immune phenotype of the EAC microenvironment and how this could be modulated to improve outcomes.

Methods Treatment naïve patients who had undergone esophago-gastrectomy at the Royal Surrey County Hospital, Guildford, United Kingdom, for esophageal adenocarcinoma, between April 2009 and March 2020 were identified through analysis of a retrospectively collected database. Formalin fixed paraffin embedded (FFPE) tissue was retrieved for multispectral immunohistochemical analysis. Adjacent normal and tumour tissues were stained with primary antibodies for CD68, CD57, CD8, CD4, FoxP3, Granzyme B, PDL1 and pancytokeratin. Cell populations and spatial relationships were analysed using the Phenoimager HT (Akoya Biosciences) and QuPath.[3]

Results A total of 44 patients were identified. Significantly increased populations in tumours compared to normal tissue were seen for $CD68^+$($p<0.0001$), $FoxP3^+$($p=0.0001$) and $PDL1^+$($p<0.0001$) cells. Geographical distribution analysis of these cells showed that the increases seen were mainly in the stromal compartment of the invasive margin of the tumour rather than the tumour core. Spatial relationship analysis demonstrated a survival benefit for those that had an increased median distance from tumour cells ($PanCK^+$($p=0.002$)) $CD8^+$($p=0.0469$) or $CD4^+$ ($p<0.0001$) cells to $CD68^+$ cells.

Conclusions Our results demonstrate that the immune tumour microenvironment of EAC appears to be an immunosuppressive phenotype. Increases in cell types associated with a pro-tumour microenvironment but no significant alteration in cytotoxic cell phenotypes ($CD8^+$, $CD57^+$, Granzyme B^+) suggests that in order to improve response rates in EAC, immunotherapeutic strategies need to focus on decreasing immunosuppressive cells, as well as recruiting cytotoxic cells into the tumour microenvironment. Further works needs to be undertaken to fully understand the phenotype of macrophages seen in the TME of EAC.

967 UNFAVORABLE NEOANTIGEN ARCHITECTURES BLUNT ANTI-TUMOR T CELL RESPONSES IN A MOUSE MODEL OF LUNG ADENOCARCINOMA

Malte Roerden*, Kim Nguyen, Nory Klop-Packel, Christopher Copeland, Nishant Singh, Michael Birnbaum, Stefani Spranger. *Massachusetts Institute of Technology, Cambridge, MA, United States*

Background Intra-tumoral heterogeneity (ITH) can limit effective anti-tumor immune responses despite the presence of immunogenic neoantigens. Yet, there is little mechanistic insight into how ITH blunts anti-tumor T cell responses or how clonal and sub-clonal neoantigens define immunologically unfavorable neoantigen architectures, preventing the rational design of neoantigen-targeting immunotherapy approaches for heterogenous tumors.

Methods Using lentiviral transduction, we expressed single or multiple neoantigens with different levels of immunogenicity in a transplantable, syngeneic mouse model of lung adenocarcinoma (driven by an oncogenic $Kras^{G12D}$ mutation and a deletion of p53). Modeling ITH-associated clonal and sub-clonal neoantigen expression, we systematically analyzed the impact of neoantigen architectures on neoantigen-specific T cell responses and overall immune-mediated tumor control.

Results Clonal co-expression of multiple neoantigens by tumor cells had distinct, converse effects on neoantigen-specific T cell responses dependent on neoantigen immunogenicity. Clonal expression of a poorly immunogenic (weak) neoantigen together with a highly immunogenic (strong) neoantigen, resulted in stronger T cell responses toward both antigens. The synergistic effect extended to increased neoantigen-specific in-vivo killing capacity and improved tumor control. In contrast, clonal co-expression of multiple strong neoantigens had detrimental effects on neoantigen-specific T cell responses, with immunogenic competition weakening the response against each individual neoantigen. Analysis of cross-presenting dendritic cells (cDC1) in the tumor-draining lymph node implicated differential T cell priming as a pivotal mechanism for these converse effects. When modeling sub-clonal tumors, the observed synergistic effects on T cell responses were less profound. Expression of multiple strong neoantigens on the other hand continued to impair anti-tumor immunity. Unfavorable neoantigen architectures were able to hinder immune-mediated tumor control even in tumors with a highly immunogenic clonal neoantigen trunk.

Conclusions Neoantigen architecture and ITH can be beneficial or detrimental for T cell responses. In tumors with high ITH, synergistic effects are reduced while detrimental effects may persist, providing a rationale for the higher immunogenicity of clonal tumors compared to their sub-clonal counterparts. These findings have strong implications for the design of immunotherapy approaches, including but not limited to cancer vaccines.

968 IMPROVED ANTITUMORAL ACTIVITY OF ANTIGEN-SPECIFIC CD8+T CELLS IN COMPARISON TO UNSPECIFIC ACTIVATED CD8+T CELLS IN A 2D T CELL KILLING ASSAY TARGETING HER2+ BREAST CANCER

Ina Rohleff, Matthias Bleisch, Kanstantsin Lashuk, Julia Schueler*. *Charles River Laboratories, Freiburg, Germany*

Background Breast cancer is one of the leading causes of death in women worldwide. Hence, it is important to develop and improve (immuno)therapies for breast cancer patients. Adoptive T-cell therapy with autologous $CD8^+$T cells is a promising method that has already succeeded in melanoma patients. Unfortunately, there is almost no information about the use in breast cancer patients.

Methods We developed an in vitro protocol to generate antigen-specific $CD8^+$T cells by priming on the HER2+ breast cancer cell line JIMT-1. Subsequently, these primed $CD8^+$T cells were tested in a 2D immune cell killing assay in a life cell imaging device in combination with an endpoint viability assay. The activity was compared with unspecific $CD8^+$T cells activated by phytohemagglutinin (PHA) or αCD2/αCD3/α CD28 beads. All T cells were tested as monotherapy and in combination with pembrolizumab (anti-PD1 antibody).

Results The antigen specific CD8+T cells displayed a significantly improved killing potential of JIMT-1 cells compared to unspecifically activated or non-activated CD8+T cells. Along these lines, those cells showed the highest TNF-alpha secretion and expression of CD69 (determined by flow cytometry, FC) among all T cell lines. The use of complete peripheral blood monocytes (PBMC) instead of isolated CD8+T cells did not influence the activity against JIMT-1 significantly. Combination treatment with pembrolizumab did not increase the antitumoral activity, which was in line with the fact that PD-1 expression did not increase across the different settings. Testing of different donors revealed a donor dependent degree of killing, however in all donors the activity pattern was the same with antigen specific CD8+T cells being the most active. A direct comparison of fresh vs frozen immune cells from the same donors indicated no significant differences in the killing activity of unspecifically activated CD8+T cells. However, there were substantial differences in antigen-specific immune cells: the killing potential of the freshly isolated immune cells was significantly higher than of the frozen.

Conclusions In summary, we have developed a protocol to produce antigen-specific tumor-infiltrating $CD8^+$T cells primed to the heterologous JIMT-1 breast cancer cell line. The antigen-specific $CD8^+$T cells showed an increased killing potential over non-specific $CD8^+$T cells. The 2D immune cell killing assay proved to be robust and amendable for mid throughput screening. The impact of donor variability and fresh vs frozen immune cells must be further evaluated. In the future, this assay will be used to screen novel drugs in combination with antigen-specific $CD8^+$T cells to select the most promising candidates.

969 NEXT-GENERATION IMMUNOTHERAPY USING PATIENT-DERIVED APC

Zhen Bian*, Lei Shi, Harry Stylli, Yuan Liu, Jane Zen. *Karnelian X, Inc, Atlanta, GA, United States*

Background Immune cell-based therapies with monocytes-derived macrophages and/or dendritic cells (DC), both phagocytic antigen-presenting cells (APCs), have arisen to be a powerful branch of immunotherapy against cancer. The promises of phagocytic APCs are their abilities to not only initiate phagocytosis towards cancer cells (to "eat off" tumor) but also, more importantly, to mediate antigen presentation to activate tumor-specific adaptive immunity, including tumoricidal T cells and long-lasting anticancer antibodies. However, the absence of technology that robustly drives monocytes from cancer patients to differentiate into proinflammatory DC/macrophage-like, effective APCs hinder the clinical application of APC therapy.

Results We through a proprietary process created a unique cellular agent (termed Karnelian X) that robust differentiate monocytes from cancer patients (cancer monocytes, **cMo**) to be potent antigen presenting cells (termed kAPC) that have profoundly enhanced phagocytic capability and, most importantly, antigen presentation machinery, resulting in enhanced uptake and presentation of tumor neoantigens that activate tumor-specific CD4 and CD8 T cells derived from patients TIL (tumor-infiltrating lymphocytes) or the patients peripheral T cells. The expanded tumor-specific CD8 T cells are highly tumoricidal demonstrated in both murine and human tumors, whereas the CD4 T cells contribute memory and supports that create a favorable environment for CD8 T cell, NK cell and other anticancer activation and expansion.

Conclusions We believe κAPC and Neo-T are novel drug vectors with unique features.

Ethics Approval All experiments using animals and procedures of animal care and handling were carried out following protocols approved by the Institutional Animal Care and Use Committee (IACUC) of the T3 lab at the Georgia Institute of Technology. Patient and healthy donor's peripheral blood mononuclear (PBMC) were provided by the Cooperative Human Tissue Network or purchased from StemCell Technology. All of the samples were anonymized

970 EXHAUSTED T CELLS ARE CHARACTERIZED BY INAPPROPRIATE LIPID ACCUMULATION

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0970

[1]Kellie Spahr*, [2]Nicole Scharping, [1]Greg Delgoffe. [1]*University of Pittsburgh, Pittsburgh, PA, United States*; [2]*University of California – San Diego, San Diego, CA, United States*

Background The efficacy of immunotherapy depends on the presence and persistence of functional immune cells within the tumor. While tumor-specific T cells can be activated and infiltrate the tumor microenvironment, they are quickly rendered dysfunctional by the combination of chronic antigen stimulation, hypoxia, and nutrient stress that creates a uniquely immune-suppressive environment. Thus, T cell dysfunction remains a significant hurdle for immunotherapeutic success. We have shown T cell exhaustion and metabolic dysfunction are driven by mitochondrial stress.[1] These features evoke an image of weak, starving T cells that are unable to sufficiently fuel their effector function. However, we and others have observed that CD8+ T cells accumulate large lipid stores as they progress towards exhaustion.[2] What remains unclear is whether lipid accumulation in these cells contributes to their dysfunction or represents an untapped source of carbon that may be the key to their reinvigoration.

Methods Using an *in vitro* model of T cell exhaustion developed in our lab, we evaluated the effect of perturbing lipid metabolism by inhibiting synthesis or promoting catabolism.[3] We also used CRISPR-Cas9 deletion of the mitochondrial citrate transporter, SLC25A1, to assess the effect of perturbing lipid synthesis on tumor-infiltrating T cell exhaustion. Cogenically mismatched SLC25A1 deficient and control OT-I T cells were co-transferred into mice bearing ovalbumin-expressing B16F10 melanoma tumors. We immunophenotyped CD8+ T cells for markers of terminal exhaustion, cytokine production, and lipid accumulation.

Results Here we sought to define the role lipid metabolism plays in the progression of CD8+ T cell exhaustion. Inhibition of citrate transport from the mitochondria via SLC25A1 in CD8+ T cells resulted in reduced lipid accumulation and expression of inhibitory receptors, PD-1 and Tim-3, known to be upregulated on exhausted T cells. We also observed increased production of inflammatory cytokines IFNγ and TNF in response to TCR restimulation after chronic antigen exposure.

Conclusions Taken together, our results indicate a role for mitochondrial citrate flux in the accumulation of cytosolic lipids and progression of CD8+ T cell exhaustion. We propose that as exhausted T cells experience mitochondrial stress and perform less oxidative phosphorylation, they shuttle excess citrate to the cytosol where it fuels production of acetyl-CoA and de novo fatty acid synthesis. This pathway may be targeted to delay exhaustion or reinvigorate exhausted T cells within tumors. These data provide new insight into the mechanisms of T cell exhaustion and may inform future immunotherapeutic development.

971 **VISTA REGULATES THE DIFFERENTIATION AND FUNCTION OF MYELOID-DERIVED SUPPRESSOR CELLS**

[1]Keman Zhang*, [2]Amin Zekeri, [3]Juan Dong, [2]Sarah Stone, [2]Li Wang. *[1]Cleveland Clinic Foundation, Lerner Research Institute, Cleveland, OH, United States; [2]Lerner Research Institute, Cleveland, OH, United States; [3]Hong Kong-Shenzhen Hospital, Shenzhen, China*

Background Previous studies show that VISTA is a critical immune-checkpoint protein controlling the maturation of myeloid antigen-presenting cells in response to TLR signaling that in turn stimulates T cell activation. The role of VISTA in the differentiation and function of myeloid-derived suppressor cells (MDSCs) remains incompletely understood.

Methods Wild type and VISTA knockout mouse bone marrow monocytes were purified and myeloid-derived suppressor cells (MDSC) were cultured and purified. Total RNAs were isolated and cDNAs were made to examine the genes expression. Whole cell lysates were prepared and proteins level were determined by Western blot. MDSC cells were analysed in tumor models by flow cytometry.

Results Here, by studying BM-derived MDSCs and tumor-associated MDSCs, we have discovered that ablation of VISTA significantly reduces the expression of Arg1 and iNOS, as well as diminishing the inhibitory effects of MDSC on T cell activation. Mechanistically, VISTA directly controls the signaling of monocytes in response to inflammatory stimuli including GM-CSF and IL-6.

Conclusions Our studies uncover VISTA as an important regulator of MDSC differentiation and suggest that targeting VISTA may alleviate MDSC-mediated immunosuppression.

972 ENRICHMENT OF ATYPICAL MEMORY DOUBLE NEGATIVE (CD27⁻ IGD⁻) TUMOUR INFILTRATING B CELLS FOLLOWING NEOADJUVANT CHEMOTHERAPY FOR EARLY-STAGE BREAST CANCER

[1]Esme Carpenter*, [2]Thanussuyah Alaguthurai, [2]Farhana Hossain, [1]Rosalind Graham, [1]Helen Kakkassery, [1]Sean Keane, [1]Sheeba Irshad. [1]*King's College London, London, UK*; [2]*Guy's and St Thomas NHS Foundation Trust, London, UK*

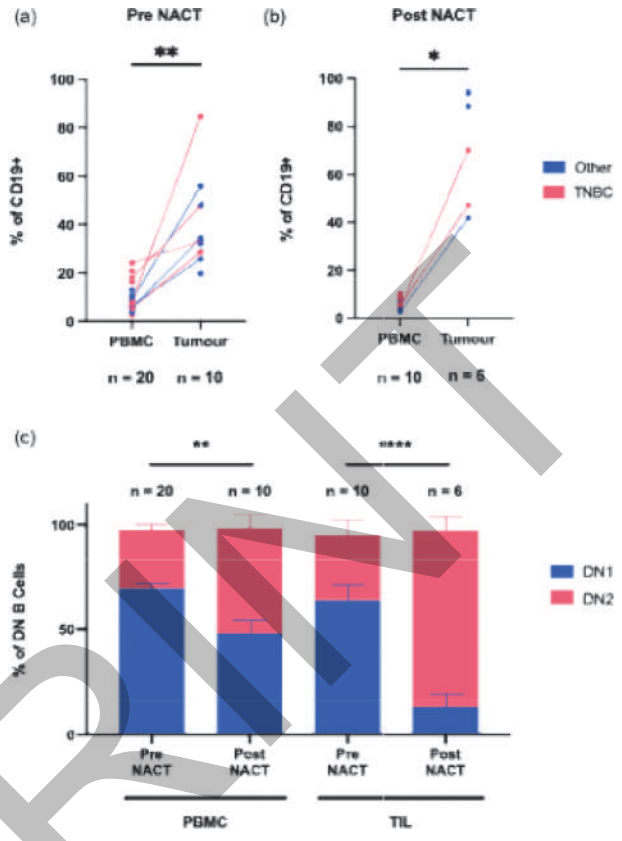
Background Humoral immune responses have previously been associated with improved outcomes, with B cell infiltrates able to independently predict pathologic complete response to neo-adjuvant chemotherapy (NACT). B cells represent a diverse population of cells and the complex interplay between specific B cell subsets in the context of chemotherapy treated breast cancers remains unclear. Here, we investigate the dynamic changes in the B cell immune landscape before and after NACT treatment across different breast cancer subtypes.

Methods Treatment naïve, mid-treatment and post-NACT breast tumour tissue samples were dissociated into single cells, stained with two panels of B cell-specific antibodies recognising a total of 24 target proteins, and analysed by flow cytometry. In addition, PMBC before and after NACT were also profiled. B cell subsets were classified as either naïve ($CD27^{-}IgD^{+}$), class-switched memory ($CD27^{+}IgD^{-}$), unswitched memory ($CD27^{+}IgD^{+}$) or double negative (DN) ($CD27^{-}IgD^{-}$). DN B cells were further characterised into DN1 ($CXCR5^{+}CD21^{+}$) and DN2 ($CXCR5^{-}CD21^{-}$) subsets. *In vitro* co-cultures of breast cancer cell line spheroid and PBMC were carried out.

Results In both treatment naïve and chemotherapy treated samples, we observed a significant expansion in the DN B cell population within the tumour microenvironment (TME) compared to the periphery. DN B cells represented on average 40.96% of B cells in treatment naïve tumours vs 9.48% in PBMC ($p<0.0001$), and 71.80% vs 6.34% of B cells in post-NACT tumour vs PBMC samples respectively ($p<0.05$) (figure 1). Interestingly, in treatment naïve PBMC and tumour tissue samples, the largest proportion of the DN subset consisted of DN1 cells, 69.35% and 64.11% respectively. In contrast, following NACT, DN2 cells constituted the majority of the DN population both within the TME (86.30%) and in the periphery (50.44%) (figure 1). Although the specific functions of these B cell subsets remain unclassified, deeper phenotyping suggests DN1 cells more closely resemble the phenotype of class-switched memory cells, whilst DN2 cells are thought to have antibody-secreting properties and more closely resemble the plasmablast phenotype. scRNA sequencing of B cells pre- and post NACT is currently underway.

Conclusions To our knowledge, this work is the first to identify an expanded population of DN B cells in breast tumour tissue and highlights the requirement for further investigation into these cells to decipher their role in the context of chemotherapy treatment and resistance in breast cancer.

Ethics Approval Written informed consent was obtained from all individuals in accordance with the Declaration of Helsinki under the following research ethics committee; London-Chelsea approved study (REC ID 13/LO/1248).



Abstract 972 Figure 1 Expansion of DN B cells in early breast cancers
The DN B cell population is elevated in the TME of breast cancer patients compared to the periphery, in both treatment naïve (a) and post-NACT (b) samples. Significance was assessed using paired t test with *p<0.05. (c) There is a phenotypic change in DN B cells in the TME upon chemotherapy treatment from predominantly DN1 cells pre-NACT to predominantly DN2 cells post-NACT. Significance was assessed using 2way ANOVA with *p<0.05

973 EXTRAFOLLICULAR EXPANSION AND DIFFERENTIATION OF B CELLS DRIVES ANTI-TUMOR RESPONSES IN METASTATIC CANCER

[1]Noor Nader*, [2]Dongyan Liu, [1]Hye Mi Kim, [1]Ayana Ruffin, [1]Sheryl Kunning, [1]Xiaron Zhang, [1]Daniel Dunlap, [1]Roy Semaan, [1]Rajeev Dhupar, [1]Adam Soloff, [1]Tullia Bruno. [1]*University of Pittsburgh, Pittsburgh, PA, United States*; [2]*Tsinghua University, Beijing, China*

Background Recent studies have demonstrated that B cell infiltration in patients with primary tumors is associated with increased survival and superior response to immune checkpoint blockade (ICB). Further, B cells play a significant role in the tumor microenvironment, such as the production of tumor-specific antibodies, antigen presentation, modulation of the cellular immune response by the production of specific cytokines, and formation of tertiary lymphoid structures (TLS). One knowledge gap in the field is determining how B cells function within microenvironments that don't have TLS, specifically in metastatic spaces that occur because of a primary tumor. Malignant pleural effusions (MPEs) are metastatic microenvironments that are marked by the accumulation of interstitial fluid and the infiltration of tumor and immune cells into the pleural space of the lung of patients with advanced disease. Currently, there is no treatment for patients with MPE; thus, there is a need to improve our understanding of the complete MPE microenvironment. B cells highly infiltrate MPE, and antibody accumulation is significant in this space. Thus, our studies have geared to functionally interrogate MPE B cells to better understand how to target B cells in metastatic disease.

Methods We aimed to assess B cell subsets in MPEs and correlated these subsets with the initial primary tumors of origin for patients with benign and MPE fluids. Specifically, we compared the infiltration of memory and naïve B cells within these patients, antibody isotype and production in the paired fluids, antigen specificity of the antibodies, and differentiation of B cells in the presence or absence of MPE fluid. When cellularly possible, we also interrogated antigen presentation by B cells subsets to CD4+ and CD8+ T cells.

Results We observed increased levels of naive B cells in MPE compared to benign fluids and a high level of double negative 3 (DN3) memory B cells, suggesting potential extrafollicular B cell differentiation in the MPE microenvironment. Furthermore, we quantified tumor antigen-specific IgG antibodies in MPE fluid and matched plasma reactive to extracellular antigens of breast and lung tumor cell lines. Moreover, we determined that MPE-associated B cells are often superior to professional antigen-presenting cells (APCs) at educating CD4 + T cells.

Conclusions Understating B cell composition and function in metastatic spaces is critical for engineering future immunotherapies. Here we highlight B cells in metastasis as a potential immunotherapeutic target given increased extrafollicular B cell expansion and differentiation into tumor antigen-specific plasmablast in MPE.

974 REGULATORY B CELLS PRODUCING IL-10 ARE INCREASED IN HUMAN TUMOUR DRAINING LYMPH NODES

[1]Krzysztof Piersiala*, [2]Pedro Farrajota Neves da Silva, [1]Vilma Lagebro, [1]Gregori Margolin, [1]Susanna Kumlien Georén, [1]Lars Olaf Cardell. [1]*Karolinska Institute, Stockholm, Sweden*; [2]*Karolinska University Hospital, Stockholm, Sweden*

Background The contribution of different immune cell subsets, especially T cells, in anti-tumour immune response is well established. In contrast to T cells, the anti-tumour contribution of B cells has been scarcely investigated. B-cells are often overlooked, even though they are important players in a fully-integrated immune response and constitute a substantial fraction of tumour draining lymph nodes (TDLNs) known also as Sentinel Nodes.

Methods Samples including TDLNs, non-TDLNs and metastatic lymph nodes (LNs) from 23 patients with oral squamous cell carcinoma (OSCC) were analyzed by multicolour flow cytometry with a focus on B cells populations.

Results TDLNs were characterized by a significantly higher proportion of B cells compared with nTDLNs (p= 0,0112). TDLNs associated B cells contained high percentages of naïve activated B cells, in contrary to nTDLNs which contained significantly higher percentages of memory B cells. Patients having metastases in TDLNs showed a significantly higher presence of B regulatory cells among TDLNs associated B cells (p=0,0008) compared with N0 patients. B cells derived from TDLNs were characterized by significantly higher expression of an immunosuppressive cytokine – IL-10 compared with non-TDLNs (p= 0,0077).

Conclusions Our data indicate that B cells in human TDLNs differ from B cells in nTDLNs and exhibit more naïve and immunosuppressive phenotypes. We identified a high accumulation of regulatory B cells within TDLNs which may be a potential obstacle in achieving response to novel cancer immunotherapies in HNSCC. Elevated levels of regulatory B cells in TDLNs are associated with the advancement of the disease. Detailed knowledge of pre-existing antitumor immune response in human TDLNs is needed in order to fully understand the mode of action of ICI agents and potentially solve tumour and host-dependent mechanisms leading to resistance towards ICIs.

Ethics Approval All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the study. Regional Ethics Committee Approval: 2019-03518.

975 CHARACTERIZATION OF SIGNALING AND METABOLIC DIFFERENCES BETWEEN γδ AND αβ CAR T CELLS

Xiomar Bustos*, Daniel Abate-Daga, Leticia Tordesillas. *H. Lee Moffitt Cancer Center & Research, Tampa, FL, United States*

Background γδ T cell-based immunotherapies have emerged as an alternative to the traditional αβ T cell-based products. For example, our group has shown that γδ CAR T cells can reduce tumor burden and mitigate tumor-induced bone deterioration in a preclinical model of bone metastatic prostate cancer. In the present study, we investigated the signaling events triggered by a second-generation CAR (originally designed for αβ T cells) in γδ T cells, to test the hypothesis that CAR-induced signaling varies depending on the T cell subset. The ultimate goal of our study is to gain mechanistic insight into the biology of γδ T cells and to inform future CAR design for improved γδ-based adoptive cell therapies.

Methods We designed our analysis as a side-by-side comparison of phosphorylation events, resulting from CAR activation, between γδ and αβ T cells. These were expanded in parallel from a healthy donor and transduced with a retroviral vector (MSGV1) to express a second-generation anti-PSCA CAR (PSCA-8t28z). CAR-T cells were then cocultured independently with metabolically labelled C4-2B-PSCA tumor cells, for 1 hour, and protein phosphorylation was quantified using **L**iquid **C**hromatography–**T**andem **M**ass **S**pectrometry (LC/MS-MS). Statistically significant differences in phosphorylation were defined using a Welch's *t*-test (fold-change $\geq$ 1.5 and *p*-value $<$ 0.05). Using Qiagen's Ingenuity Pathway Analysis software, we identified canonical pathways that were significantly over-represented in the population of proteins that displayed differential phosphorylation in γδ CAR T cells relative to αβ. We used the SeaHorse XF kits for Glycolytic Rate Assay and T Cell Metabolic Profiling for functional characterization of the metabolic properties of CAR-T cells. Finally, flow cytometry was used to analyze Glut-1 expression (anti-Glut1, clone 202915), glucose intake (2NBDG), mitochondrial mass (Mito-Tracker Green), and mitochondrial membrane polarization (TMRE).

Results We identified 323 phosphorylation events that were differentially abundant between T cell subsets. Within this group, glycolysis and gluconeogenesis were within the top overrepresented canonical pathways. Stimulated γδ T cells showed significantly lower glycolytic rate compared to αβ. CAR expression was accompanied by higher glycolytic rate and expression of Glut-1 receptor in both T-cell types. Finally, oxidative phosphorylation (OXPHOS) was lower in γδ CAR T cells, potentially related to their also lower mitochondrial mass.

Conclusions CAR-induced signaling varies among T cell subsets, and γδ T cells display lower glycolytic and OXPHOS rates upon activation. Ongoing efforts are focused on delineating molecular causes and functional consequences of the metabolic differences between αβ and γδ T cells.

976 T-CELL METABOLIC ACTIVITY IS IMPACTED BY THE NUTRIENT COMPOSITION WITHIN THE TUMOR MICROENVIRONMENT

Jesse Bucksot*, Dorys Lopez-Ramos, Tushar Pandey, Anuja Antony, Joseph Peterson, Daniel Cook. *SimBioSys, Inc., Chicago, IL, United States*

Background Immunotherapy use is increasing across cancer types, however, how the nutrient microenvironment affects immune cell activity is not fully understood.[1] We addressed this challenge using a novel framework combining nutrient distributions within a tumor, single cell RNA-seq data, and genome-scale metabolic modeling[2] to understand how immune cell cytotoxic potential varies within tumor microenvironments.

Methods We constructed 3D nutrient composition atlases of over 1200 breast cancer tumors using the SimBioSys TumorScope software. We then constructed a genome-scale metabolic model of tumor infiltrating T-cells based on single cell RNA-sequencing data from over 5000 single T-cells from breast cancer patients. We simulated this T-cell metabolic model across the range of nutrient compositions present in our tumor atlases to understand how nutrient availability affects the cytotoxic potential of T-cells.

Results Our results demonstrated that the local nutrient composition has a dramatic impact on T cell functionality, with fundamental cellular behaviors being significantly impaired by a reduction in key nutrients such as glucose and oxygen. Additionally, the degree of impairment varies between the various types of T cells. For example, proliferative T cells are relatively insensitive to hypoxia, but very sensitive to reduced glucose, which may be related to the increase in IO response that we observe in tumors with a greater degree of hypoxia.

Conclusions Overall, we found that the nutrient composition of the tumor microenvironment has a strong influence on T-cell activity, especially in hypoxic tumor regions.

977 HIGHLY CYTOTOXIC RESILIENT CD8+ T CELLS AVOID EXHAUSTION BY LOWERING ROS THROUGH ME1 UPREGULATION

[1]Joanina Gicobi*, [1]Haidong Dong, [2]Cindy Liu. [1]*Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN, United States*; [2]*Department of Urology, Mayo Clinic, Rochester, MN, United States*

Background Cytotoxic T cells are indispensable in protecting the organism from malignant disease. Even though they are prone to be exhausted in patients with large tumor burden, some of them can regain their antitumor activity upon immune checkpoint inhibitor (ICI) therapy and reject large tumors or metastatic malignances. Our knowledge to these "rebound" effector T cells is limited. Recently, resilient T cells have been perceived to explain the presence of highly cytotoxic T cells that are less exhausted and rebound in responses to ICI therapy, however the phenotypic and functional characters of resilient T cells have not been clearly defined.

Methods CD8+ T cells were isolated from PBMCs and stained with TMRM. They were then sorted into Low and High Δψm cells. Following activation with or without other experimentation, we conducted killing assays, metabolic assays, flow cytometry, Bulk RNA sequencing, western blot, qPCR etc.

Results We found ICI-therapy responsive CX3CR1$^+$ CD8$^+$ T cells are endowed with low mitochondrial potential (Δψm). The frequency of CX3CR1$^+$ CD8$^+$ T cells with low Δψm increased in patients with metastatic malignances who have better clinical outcomes in responses to ICI therapy and radiation therapy. Further characterization of CD8$^+$ T cells with low Δψm revealed that they are highly cytotoxic and produce less ROS (reactive oxygen species) but express more ME1 (malic enzyme 1). Interestingly, overexpression of ME1 reduced ROS in CD8$^+$ T cells and augmented tumoricidal activity of CD8$^+$ T cells. Importantly, enhanced expression of ME1 in T cells isolated from patients improved cytotoxic T cell responses to ICI treatment in vitro.

Conclusions Our study suggests that not all highly cytotoxic CD8$^+$ T cells are exhausted but some of them are functionally resilient in patients with advanced cancers. Modification of ME1 expression in T cells could be a new method to avoid T cell exhaustion and to improve the efficacy of cancer immunotherapy.

Ethics Approval Study approval. "Healthy Donor" human blood leukocytes were acquired from anonymous donors who had consented for blood donation at the Blood Transfusion Center at Mayo Clinic. All donors and patients provided signed informed written consent; the study was approved by the Mayo Clinic Rochester IRB and was conducted according to Declaration of Helsinki principles.

978 DENDRITIC CELL-INTRINSIC PTPN22 NEGATIVELY REGULATES ANTI-TUMOR IMMUNITY

Santiago Acero-Bedoya*, Thomas Gajewski, Emily Higgs. *University of Chicago, Chicago, IL, United States*

Background Checkpoint blockade immunotherapies have revolutionized cancer treatment, yet only a subset of patients benefit. Individuals with a loss-of-function single nucleotide polymorphism in the gene encoding PTPN22 are at increased risk for autoimmune disease and display a lower incidence of certain cancers. Studies in PTPN22 knockout (KO) mice have established it as a negative regulator of T cell responses in autoimmune and cancer models. However, these studies have not defined the cell lineage-intrinsic roles of PTPNN22 in distinct immune cell compartments, and the potential role of PTPN22 in dendritic cells remains undefined.

Methods We developed a novel dendritic cell (DC) PTPN22 conditional KO (cKO) mouse model that enables specific deletion in $CD11c^+$ cells. Using the B16.SIY melanoma model, tumor growth and immune profiles of tumors and tumor-draining lymph nodes (tdLNs) were analyzed. $CD8^+$ T cells were depleted to establish their necessity using an anti-CD8b monoclonal antibody. Antigen-specific T cell priming was tested by IFN-γ ELISpot analysis on the spleens of tumor-bearing mice. Lastly, the MC38.SIY cell line was used to establish the applicability in different cancer models.

Results Deletion of PTPN22 in DCs resulted in augmented tumor control. At endpoint, total $CD8^+$ T cells, but not $CD4^+$ T cells or Tregs, were increased in the tumors of $CD11c^+$ PTPN22 cKO mice. Moreover, $CD8^+$ T cells demonstrated increased activation and memory markers at day 10 in the tdLN and in day 27 tumor-infiltrating lymphocytes. Depleting $CD8^+$ T cells eliminated the tumor growth control in this model, suggesting a reliance on the DC-$CD8^+$ T cell axis. Accordingly, day 7 tumor-bearing mice revealed an increased frequency of IFN-γ-producing T cells in the presence of tumor antigen SIY, indicating improved $CD8^+$ T cell priming. Further, spectral analysis of tumor antigen-specific T cells in the tdLN also showed a significant increase of $CD8^+$ SIY^+ T cells displaying elevated activation and memory markers. Analysis of DCs in the tdLN similarly revealed an overall increase attributed to an increase of $CD103^+$, but not $CD11b^+$, DCs displaying increased activation and proliferation markers. Together, the number of tumor-infiltrating $CD8^+$ T cells and $CD103^+$ DCs correlated with decreased tumor volumes. Lastly, PTPN22 cKO mice similarly showed greater tumor control of the colon cancer line MC38.SIY.

Conclusions We show that deletion of PTPN22 in DCs is sufficient to drive a tumor antigen-specific T cell response resulting in enhanced tumor control. This work highlights the potential to modulate anti-tumor immunity through the manipulation of DC signaling.

Ethics Approval This study obtained ethics approval by the Institutional Animal Care and Use Committee (IACUC) at the University of Chicago as outlined in the animal protocol #71621.

979 COMPOUND SCREEN IDENTIFIES INHIBITOR OF APOPTOSIS PROTEINS (IAP) ANTAGONIST AS AN INDUCER OF T CELL PROLIFERATION AFTER CROSS-PRESENTATION BY DENDRITIC CELLS

Esmee Hoefsmit*, Paula van Royen, Disha Rao, Johanna Stunnenberg, Petros Dimitriadis, Cor Lieftink, Ben Morris, Elisa Rozeman, Irene Reijers, Ruben Lacroix, Huma Shehwana, Maarten Ligtenberg, Roderick Beijersbergen, Daniel Peeper, Christian Blank. *Netherlands Cancer Institute, Amsterdam, Netherlands*

Background Cross-presentation of tumor antigens by dendritic cells (DCs) is crucial to prime and (re-) stimulate $CD8^+$ T cells. This process is important in initiating and maintaining an anti-tumor response. Previously, we found that tumor presence of conventional type 1 DCs (cDC1), a subtype that excels at cross-presentation, correlates with response to neoadjuvant immune checkpoint blockade (ICB) in melanoma. This led us to hypothesize that patients failing to respond to ICB could benefit from enhanced cross-presentation of tumor antigens.

Methods A cross-presentation assay to screen over 5,500 compounds for improvement of $CD8^+$ T cell proliferation after cross-presentation of tumor antigens by DCs was established. For this purpose, bone marrow derived GM-CSF DCs were cultured in the presence of irradiated B16F10-$OVA^{B2m-/-}$ tumor cells, CpG ODN class B and naïve CTV-labelled $CD8^+$T cells that have a TCR specificity for $OVA_{257-264}$ (SIINFEKL) in the context of H2-k^b (OT-I TCR). In this setting, tumor antigens (OVA) that have been processed into SIINFEKL peptide and are presented in the context of H2-k^b by the DCs can induce $CD8^+$ t cell proliferation and activation.

Results A total 145 compounds were identified that significantly improved T cell proliferation after cross-presentation of tumor antigens by DCs. Subsequently, we selected compounds that also increased IFN-γ production. A total of 11 compounds were confirmed to significantly enhance $CD8^+$ T cell proliferation and IFN-γ production. A particular strong effect was observed for AZD5582, an antagonist of inhibitor of apoptosis proteins (IAPs) cIAP1, cIAP2 and XIAP. AZD5582 treatment led to DC activation of the non-canonical nuclear factor kappa B (NF-kB) pathway, enhanced antigen import from endolysosomes into the cytosol and increased expression of genes involved in cross-presentation. Furthermore, it upregulated expression of CD80, CD86, MHC class II, CD70 and secretion of TNF by DCs. This enhanced DC activation and maturation program was observed also in tumor-bearing mice upon AZD5582 treatment, culminating into an increased frequency of systemic tumor antigen-specific $CD8^+$ T cells.

Conclusions We identified several compounds that enhance T cell proliferation after cross-presentation. Addition of the identified AZD5582 to (combinations of) ICB might improve outcome in unfavorable patients.

Ethics Approval The protocol and amendements of the OpACIN-neo and PRADO trial were reviewed and approved by the appropriate review boards and ethics committees of each institute. All participating patients provided written informed consent before enrollment.

All animal procedures were approved by the Animal Welfare Committee of the Netherlands Cancer Institute, in accordance with institutional and national guidelines.

980 IN-DEPTH CHARACTERIZATION OF CDC1 EX VIVO AND IN VITRO MODELS: DEVELOPMENT AND COMPARISON OF CONVENTIONAL DENDRITIC CELL CULTURE SYSTEMS FOR INDUSTRY

Anna Licht*, Tamera Ashworth, Laura L Goodfield, Hannah Gardner, Johanna Lahdenranta, Philip Brandish, Kevin McDonnell, Nicholas Keen. *Bicycle Therapeutics, Lexington, MA, United States*

Background Conventional dendritic cells (cDC) are innate immune cells specialized in antigen sampling and subsequent cross-presentation to immune cells, and are critical for an effective anti-tumor immune response. The relatively rare subset cDC type I (cDC1) has been associated with human cancer patient survival, and strategies aimed at increasing their abundance and activation in the tumor microenvironment (TME) are of interest. It is a challenge to use these rare cells in screening assays as they constitute less than 0.05% of cells in the blood and are difficult to isolate with high viability and purity.

Methods We compared two systems that generate a mixed culture containing cDC1 cells from human CD34+ hematopoietic stem cells (HSC) isolated from cord blood. In the first system, we developed a scalable in vitro differentiation method that expands and differentiates the CD34+ HSC to generate cDC1s over the course of 3.5 weeks. The second system utilized a humanized mouse model. Mice engineered to express human GM-CSF and IL-3 to support the myeloid compartment were engrafted with human CD34+ HSC and boosted twice with Flt3L-IgG. Femurs were taken at day 10 for bone marrow extraction and subsequent cDC1 culture.

Results The human CD34+ HSC and cytokine treatments in these methods yield an increase in number of cDC1 cells in a mixed cellular population. The cDC1 cells are phenotypically and functionally similar to those in the blood; they express high levels of CD141 and Clec9a, and respond to activating stimuli such as poly(I:C). The ex vivo cDC1 system using bone marrow from humanized mice is highly reproducible across laboratory operators and with multiple cord blood donors, and it is less laborious than the in vitro differentiation assay. A single operator can process 4 to 5 mouse femur pairs at one time to collect on average enough cells for 15 test compounds at a 5-pt dose curve with controls. Multicolor flow cytometry was used to further phenotype and assess functionality of other cell types present in the ex vivo culture.

Conclusions Both systems demonstrate that HSC-derived cDC1 cultures can be reliably generated with cDC1 phenotype and functionality, and may be used for screening assays in industry settings. The ex vivo system allows for a faster and higher throughput but requires supply of humanized mice.

981 PERITUMORAL STROMAL REMODELING LICENSES CDC1 THROUGH CD40 TO ELICIT T-CELL INFLAMMATION

[1]Athanasios Papadas*, [1]Alexander Cicala, [1]Alejandro Rizo, [2]Chelsea Hope, [3]Katerina Politi, [2]Christian Capitini, [2]Kristina Matkowskyj, [4]Scott Abrams, [1]Fotis Asimakopoulos. *[1]UCSD, San Diego, CA, United States; [2]UW-Madison, Madison, WI, United States; [3]Yale, New Haven, CT, United States; [4]Roswell Park, Rochester, NY, United States*

Background T-cell-inflamed tumor microenvironments (TME) are pre-requisite for immunotherapy efficacy; however, the drivers for promoting T cell priming and infiltration within the TME remain incompletely understood. Conventional type I dendritic cells (cDC1) are indispensable for anti-tumor immunity. Several key studies have documented the paradoxical localization of cDC1 within tumor stroma. We hypothesized that conserved provisional matrix signals emanating from peritumoral stroma remodeling play an unrecognized role in this paradox and license cDC1 to promote T-cell repriming and tumor entry.

Methods We performed multiplex IHC in human lung cancer biopsies using antibodies against anti-VCAN proteolysis neoepitope DPEAAE, cDC1 ($XCR1^+$), $CD8^+$ and $CD4^+$ T cells. Multiparametric flow cytometry was used to characterize stroma-licensed cDC1. Therapeutic anti-PD1 antibodies were used in a preclinical model of lung cancer (LLC).

Results We found that in human T-cell inflamed cancers, even though T cells penetrated the tumor core, cDC1 remained confined within tumor-adjacent stroma recurrently demonstrating versican (VCAN) proteolysis, an extracellular matrix modification typically associated with provisional matrix remodeling in embryonic development and wound healing. VCAN proteolysis releases a bioactive N-terminal fragment, versikine. Using multi-parametric flow cytometry, we found that versikine-exposed cDC1, but not cDC2 or monocyte-derived (Mo)-DC, overexpressed CD40 whereas all three DC subtypes overexpressed PD-L1. Moreover, cDC1, but not other tumor DC subtypes, expanded in absolute numbers in versikine-replete tumors. Versikine sensitized refractory LLC tumors to anti-PD1 immunotherapy and produced a survival benefit in vivo, suggesting that versikine overcomes immune checkpoint inhibitor resistance. Human lung cancers demonstrated a predominant localization of CD4+ and CD8+ T cells within peritumoral stroma. Consistent with CD40-mediated cDC1 licensing models, we observed enhanced antigen-specific T cell responses using the model antigen OVA in versikine-replete TME.

Conclusions Peritumoral stroma has traditionally been viewed as an immune barrier. Our data provide an alternative view and demonstrate that peritumoral stroma mimicking embryonic or wound provisional matrix remodeling instead promotes cDC1 abundance and activation. “Stroma-licensed” cDC1 may represent a conserved homeostatic response against nascent tumors during immune surveillance (“elimination” and “equilibrium”). Progressive loss of stromal proteolytic remodeling (e.g., versikine loss) and transition into stromal fibrosis are associated with immunoediting "escape". Stroma-licensed cDC1 overexpress CD40 and localize near stromal CD4+ and CD8+ T cells, raising the possibility that CD4 T-cells may provide CD40L-CD40-mediated “help” in stromal locations. These data provide novel insights into the role of stroma in regulating the nature of the T-cell-inflamed TME and may permit optimized designs for T-cell penetration into solid tumors.

982 CDC1 CELLS ARE REQUIRED TO SUSTAIN CD8 T CELL STEMNESS IN CANCER AND FOR THE SUCCESS AT THE ONSET OF VARIOUS IMMUNOTHERAPIES.

Alvaro Teijeira*, Carlos Luri, Saray Garasa, Assunta Cirella, Ignacio Melero. *CIMA, Universidad de Navarra, Pamplona, Spain*

Background cDC1 cells are a subset of antigen presenting cells highly specialized in cell-associated antigen crosspresentation.[1] The presence of this DC population in human cancer correlates with good patient prognosis and response to immunotherapy.[2] Mice that are ontogenically deficient in cDC1 or crosspresenting mechanisms fail to effectively prime antitumor immune responses and therefore show poor response to immunotherapy.[3-6] The mechanisms by which cDC1 support immunity during immunotherapy mediated responses have not been well defined.

Methods Using XCR-1-DTR venus mice we were able to track and deplete at will cDC1 cells at different time points during immunotherapy. Tumor growth studies were performed with different types of immunotherapies (adoptive T cell transfer, anti-PD-1, anti-CD13 and anti-CTLA-4 mAbs). Flow cytometry and multiplex immunofluorescence were used to characterize CD8 T cell responses and intravital imaging was used to track the behavior of cDC1 and antitumor CD8 T cells.

Results The presence of cDC1 cells was an absolute requirement at the onset of immunotherapy for most of the therapies tested but once the first dose of immunotherapy their absence had lesser impact on the antitumor response. We observed that immunotherapy affected cDc1 migratory capacities and interaction with anti-tumor T cells and that cDC1 were important to maintain a pool of $TCF7^{+}$ CD8 cells in the TDLN and to some extent in the tumor preventing T cell exhaustion during immunotherapy.

Conclusions cDC1 presence is important during the onset of various immunotherapies to maintain CD8 T cell stemness and as a consequence to allow tumor rejection. However once immunotherapy has already been established cDC1 requirement is less pronounced.

983 BCL-2 INHIBITION MEDIATES TREG TO T_H17 PLASTICITY THROUGH INHIBITION OF FOXO1

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0983

Rosy Liao*, Anika Thomas-Toth, Joshua McKeever, Andrew Koh, James LaBelle. *University of Chicago, Chicago, IL, United States*

Background The specific BCL-2 small molecule inhibitor venetoclax has been shown to effectively induce apoptosis in a wide range of malignancies either alone and in combination with other drugs. Based upon these results, there has been considerable growth in its use in clinical studies used alone and in combination with chemotherapy and immune-based therapies. Lymphocytes, and T cells in particular, rely heavily on BCL-2 for survival and function. This has been determined largely by genetic deletion or overexpression of BCL-2 in murine models. However, the adaptive effects of short or long-term small molecule BCL-2 family blockade on surviving immune cell subsets and their function is not fully understood. In the current work, we aimed to better understand the effect of long-term systemic treatment with venetoclax on regulatory T (Treg) cells, which are relatively apoptotically resistant to specific BCL-2 drugging compared to other T cells. We found that venetoclax altered surviving global T cell signaling and induced Treg cells towards a T_H17-like Treg (Tr17) via PI3K pathway activation and FOXO1 inhibition.

Methods Normal and MC38-bearing C57BL/6 $FOXP3^{IRES\text{-}GFP}$ mice were treated systemically with venetoclax for 14 days followed by phenotypic, functional, apoptotic, and genetic (RNA sequencing, ATAC seq, etc.) evaluation of Tregs isolated from immune organs and tumor infiltrating lymphocytes from these animals.

Results We show that venetoclax treatment resulted in Treg cell plasticity resulting in the conversion of a subset of canonical Tregs to a Tr17-like cell in normal and tumor-bearing mice. Venetoclax induced Tr17-like cells which were found to express increased IL-17A and IFNγ. RNA expression profiling of treated Tregs indicated that the PI3K pathway is activated. PI3K pathway activation was consistently also found in $CD8^+$ and conventional $CD4^+$ T cells (Tcons), similar to our recently reported observations in homeostatically expanding naive T cells from stem cell transplanted animals treated with venetoclax.[1] PI3K activation in Tregs resulted in inhibition of FOXO1 through phosphorylation at Ser256, leading to exclusion of FOXO1 from the nucleus. This resulted in transcriptional activation of a Th17 -associated genetic program through RORγt upregulation in Tregs, but not Tcons, and as confirmed by altered genome wide accessibility patterns in treated Tregs.

Conclusions Our results indicate that long-term BCL-2 blockade by venetoclax results in Treg plasticity towards a Th17-like functional state through PI3K activation. We believe that this phenomenon may be beneficial for recently reported immune-mediated anti-tumor effects as a result of venetoclax therapy.

984 MEK1 WITHIN EXTRACELLULAR VESICLES INHIBITS TUMOR GROWTH BY PROMOTING ANTI-TUMOR IMMUNITY

[1]Jack Bui*, [1]Stephen Searles, [1]Jarrod Yee, [1]Preston Lee, [1]Christine Caron, [1]Calvin Lee, [2]Irina Matei, [2]David Lyden. [1]*University of California, San Diego, La Jolla, CA, United States*; [2]*Weill Cornell Medicine, New York, NY, United States*

Background All cells have the capability to produce and release extracellular vesicles (ECVs), small vesicles that have similar topology to the cell and can deliver diverse cargo to mediate cell-cell communication. ECVs derive from the late endosomal pathway and contain bioactive cargo that can include lipids, nucleic acids (both RNA and DNA), and proteins. Once released into the extracellular space, ECVs can bind to and enter other cells, resulting in the physical transfer of bioactive cargo between cells, leading to functional changes in the target cell. Cancer cells secrete more ECVs than non-transformed cells. Tumor-derived (TD) ECVs can affect numerous cell types, including other cancer cells in an autocrine/paracrine manner and non-cancer host cells exerting both pro- and anti-tumor effects on immunity.

Methods To identify ECV proteins that could modulate immune responses, we have used a model of regressor and progressor cell lines that undergo immune rejection or progressive growth, respectively. We isolated ECVs from these cultured cell lines and performed proteomic analysis of the ECVs to identify unique proteins in ECVs secreted by regressor versus progressor cell lines. Having identified MEK1 as a unique protein in regressor-derived ECVs, we developed a model system to test the effect of MEK1-containing ECVs on tumor immunity.

Results We found that the signaling molecule MAP2K1 (MEK1) was enriched in ECVs secreted by regressor versus to progressor cells. ECVs engineered to have levels of MEK1 similar to regressor ECVs could inhibit tumor growth. In labeling experiments, ECVs were found to be taken up by tumor macrophages, delivering MEK1 into the cytoplasm, resulting in upregulation of certain genes such as chemokines. In tumors expressing MEK1 in ECVs, the microenvironment was enriched in cytolytic lymphocytes, resulting in induction of genes in the interferon gamma (IFNg) pathway. Blocking IFNg, MEK1 inhibition, or lack of adaptive immunity prevented the effect of MEK1-containing ECVs. Our results support a mechanism by which MEK1 protein within certain ECVs is delivered to tumor macrophages to promote adaptive immune responses against the tumor via IFNg (figure 1).

Conclusions We conclude that MEK1 activity within exosomes and macrophages promote tumor immunity. These results suggest that the delivery of MEK1 to tumor-associated macrophages, either by ECVs, nanoparticles, or some other means, could be a useful strategy to treat cancer. On the other hand, the use of systemic MEK1 inhibitors in patients could reduce anti-tumor immunity. Therefore, targeting MEK1 inhibition to tumor cells could spare its putative immune suppressive effects.

985 **INHIBITION OF FIBROBLAST GROWTH FACTOR RECEPTOR 4 (FGFR4) SIGNALING ACTIVATES TUMOR INTERFERON (IFN) SIGNALING IN HEPATOCELLULAR CARCINOMA (HCC)**

Nannan Zhang*, Zhui Chen, Bin Shen, Zhixuan Zhu, Jueping Shi, Jiacheng Zhang, Pan Liang, Jie Wang. *Abbisko Therapeutics, Shanghai, China*

Background Hepatocellular carcinoma (HCC) is the most common primary liver cancer. Deregulation of FGF19-FGFR4 signaling has been found in HCC and several FGFR4 inhibitors have shown preliminary efficacy in patients with FGF19 overexpression. The combination of FGFR4 inhibitors with anti-PD-(L)1 antibodies is also under clinical investigation. However, the role of FGFR4 inhibition in tumor microenvironment (TME) remains to be elucidated. ABSK011 is a potent, selective FGFR4 inhibitor that has demonstrated strong antitumor activity in preclinical models and advanced into phase 1b clinical trials. In this study, we investigated the role of ABSK011 in TME of FGF19 overexpressed HCC models, and especially its crosstalk with interferon (IFN) pathway and antitumor immunity *in vitro* and *in vivo*.

Methods We evaluated the effects of ABSK011 in multiple FGF19 overexpressed HCC cell lines and *in vivo* models by RNA sequencing, quantitative PCR, flow cytometry and immunohistochemistry (IHC).

Results RNA sequencing revealed that IFN pathway was consistently enriched after treatment with ABSK011 across various HCC models. Quantitative PCR analysis showed that ABSK011 upregulated mRNA expression of several key genes related to IFN pathway, including *IRF1, IFIT1 and CXCL10*, both in cell lines and tumor models. Furthermore, expression of surface PD-L1 on HCC cells were significantly increased and reached the plateau with the treatment of ABSK011 at the concentration higher than 0.1μM. In addition, we found that ABSK011 increased $CD8^+$ T cell infiltration in humanized HCC mouse models.

Conclusions These preclinical data demonstrated that ABSK011 treatment increased IFN related response as well as $CD8^+$ T cell infiltration in FGF19 overexpressed HCC models, supporting the combination of FGFR4 inhibitor and immune checkpoint molecules such as anti-PD-(L)1 antibodies to achieve enhanced antitumor activity.

986 LOCAL AND LYMPHOID IMMUNE SURVEILLANCE MECHANISMS IN "EXCEPTIONAL SURVIVORS" OF STAGE IV BREAST CANCERS FOLLOWING STANDARD OF CARE CHEMO- AND TARGETED THERAPIES

[1]Helen Kakkassery*, [2]Thanussuyah Alaguthurai, [1]Rosalind Graham, [1]Esme Carpenter, [2]Farhana Hossain, [1]Sean Keane, [1]Sheeba Irshad. *[1]King's College London, Ilford, UK; [2]Guy's and St Thomas NHS Foundation Trust, London, UK*

Background Breast cancer patients with metastatic disease can exhibit rapid disease progression, disease stabilisation or partial responses of varying duration. However, for reasons that are not fully elucidated, a small fraction of patients will elicit an exceptional durable response to standard anti-cancer treatments or survive significantly longer than patients with clinically comparable tumours. Here, we investigate the drivers of immune surveillance mechanisms of long-term survivors of metastatic breast cancers.

Methods Peripheral blood mononuclear cells (PBMCs) from long-terms survivors of metastatic breast cancer patients alongside matched control cohorts of stage IV rapid progressors and typical responders, early breast cancer patients and healthy volunteers were isolated. High-dimensional flow cytometry and proteomic analysis of the PBMCs across these groups was performed. In vitro activation of candidate immune cell types isolated from PBMCs was conducted for downstream proteomics analysis of activated phenotypes.

Results Principle Components Analysis (PCA) showed distinct segregation of the exceptional survivors from the other control groups with an immune signature in exceptional survivors constituting of activated NK, CD8 T cells and gd T cells pointing towards higher innate immunogenicity in these individuals. Specifically, although these metastatic exceptional responder patients possessed comparable NK cell frequencies, the proportion of $NKG2D^{+}CD56^{dim}CD16^{+}$ NK cells were significantly enriched compared to the typical responders. Additionally, proportions of $CD8^{+}$ central memory ($CD45RA^{-}$ $CD27^{+}$) and effector memory ($CD45RA^{-}$ $CD27^{-}$) Vd1 and Vd2 gd T cells, were also seen to be significantly increased. Moreover, proteomics analysis on PBMCs of the responders revealed proteins involved in cell cycle progression and cell proliferation such as RBBP7, KCTD10 and PTH2 were elevated in the exceptional responders compared to the typical responders. Functional in vitro validation of these findings by analysing the proteome of activated immune effector cells along with scRNA sequencing of lymph node and tumour tissue is currently underway.

Conclusions To our knowledge, this work is the first to explore in depth the immune signatures in the peripheral blood of exceptional survivors with metastatic breast cancer. Elucidating the immunological reasons for favourable atypical responses alongside functional tumour microenvironment analysis offers unique insights for predictive biomarker identification and discovery of axes that could be exploited therapeutically to benefit those with less favourable responses.

Ethics Approval Written informed consent was obtained from all individuals in accordance with the Declaration of Helsinki under the following research ethics committee; London-Chelsea approved study (REC ID 13/LO/1248).

987 COMPREHENSIVE IMMUNOPHENOTYPING AND GENOMICS FROM SINGLE BLOOD TUBE FOR T-CELL DYNAMICS IN CLINICAL TRIALS

Manling Ma-Edmonds*, Gregg Masters, Omar Jabado, Lisa Grimm, Mahesh Bachu, Matthew Loya, Gabrielle Suppa, Jordan Blum, David Soong, Han Si, Brandon Higgs, Nicole Bottrel, Erin Henitz, Christopher Chiu, Kate Sasser, Mark Fereshteh. *Genmab, Princeton, NJ, United States*

Background Analysis of peripheral whole blood is a cornerstone of investigational therapeutic development. Phase I/II trials request multiple blood draws from patients to understand pharmacokinetics and pharmacodynamics; in cases where they are experiencing severe disease, reducing draw volumes is desirable. Long distances between collecting hospitals and bioanalytical labs risks sample degradation. To conserve patient whole blood samples, we coupled deep immunophenotyping and transcriptomic workflows using a single, cryopreserved tube as input (figure 1). This method allowed characterization of T-cell immune state by flow cytometry, TCR diversity and transcriptomics in a global clinical trial of Non-Hodgkin Lymphoma (NHL).

Methods Peripheral blood mononuclear cells (PBMC) were collected from NHL patients (n = 165; NCT03625037) and age matched normal healthy volunteer donors (n = 24). PBMC extraction was performed in three central labs located in Europe, Asia, and North America. A T-cell focused, 16-parameter flow cytometry panel was performed on PBMCs and then RNA was purified from the remaining cells in the tube. T-cell receptor β sequencing (TCRseq) using a multiplex PCR (Illumina) and transcriptomics using EdgeSeq (HTG Molecular) was performed. In parallel, patient whole blood samples were assessed by flow cytometry in the central labs. Data from all three platforms was integrated and analyzed with linear models in R.

Results We compared immunophenotyping from patient whole blood (overnight shipped) to cryopreserved PBMCs from the same blood draw; the viable cell percentage of PBMCs after thawing averaged 55%. T-cell populations in high viability PBMC samples (>70%) were correlated to whole blood estimates (average Spearman's ρ of 0.7). Samples with viability >30% retained correlation across the immune subsets of interest (T naïve, effector, central memory and regulatory). Our flow cytometry workflow consumed 1M cells, 70% of patients profiled had sufficient sample remaining for TCR and transcriptomic assays (500k+ cells; average RNA yield of 350ng).

Combining TCR and transcriptomics with flow cytometry enables a composite picture of T-cell activity. Statistical analysis revealed $CD4^+$ naïve proportions were the primary driver of TCR diversity. Top genes associated with diversity were *CD69*, a well-known activation marker, *DUSP10/MKP5*, an immune regulator[1] and *GPR183/EBI2* an oxysterol receptor with a role in lymphoid development.[2,3]

Conclusions This streamlined workflow is amenable to global clinical trials with long shipping distances and reduces blood draw requirements. Integration of flow cytometry, TCR diversity and the transcriptome allows a deeper understanding of T-cell activity that can support mechanism of action analyses.

988 B-CELL RECEPTOR (BCR) REPERTOIRE AND ANTIBODY RECOGNITION ANALYSIS OF MELANOMA PATIENTS TREATED WITH NEOADJUVANT IMMUNE CHECKPOINT BLOCKADE (ICB)

Monika Zelazowska*, Somnath Paul, Joshua Plummer, Manoj Chelvanambi, Beth Helmink, Russell Witt, Michael White, Shalaka Lotlikar, Melissa Simper, Sarah Johnson, Alexandra Hebertson, Bin Liu, Jennifer Wargo, Kevin McBride. *The University of Texas MD Anderson Cancer Center, Houston, TX, United States*

Background Enriched B cell signature is correlated with positive outcome of immune checkpoint blockade (ICB) therapy in melanoma[1] and other cancers.[2] B cells have the capability to engage and activate other immune effector cells by recognition and further presentation of tumor antigens. B cells can also secrete an array of cytokines that modulate tumor microenvironment (TME) driving anti-tumor response. Though the mechanism through which B cells contribute to the treatment outcome is still not completely understood, we hypothesize that the BCR and antibodies produced by tumor-residing B cells play an important role in immunotherapy response by recognizing tumor.

Methods Immunoglobulin sequences from intratumoral B cells were reconstructed from single-cell RNAseq data using VDJ Puzzle algorithm.[3] Additionally, single B cells were sorted from melanoma tumor tissue and/or adjacent lymph nodes. DNA sequences encoding antibody heavy and light chains were recovered by RT-PCR. Reconstructed immunoglobulin sequences were annotated and analyzed using NCBI IgBlast[4] or IMGT/HighV-QUEST.[5] The hallmarks of antigen recognition like somatic hypermutation (SHM), isotype switching, and clonal expansion were analyzed based on heavy chain sequences. Simultaneously, selected Ig transcripts were cloned into expression vectors enabling the production of tumor-derived human recombinant monoclonal antibodies (rmAbs) in mammalian expression system. Antibodies were subsequently purified and tested for tumor and or cell line binding. A subset of which are being subjected to antigen identification analysis.

Results We successfully utilized our workflow pipeline (figure 1) to generate human rmAbs from tumors of 10 melanoma patients; 6 responders, 2 partial responders and 2 nonresponders. In total, we have been cloning hundreds of antibodies, over 600 from complete and partial responders, and almost a hundred from nonresponders. We observed expansion of selected clones and acquisition of SHM in a manner consistent with an immune selection process. We find a large number of antibodies bind tumor tissue or related cell lines and antigen identification is ongoing.

Conclusions Ig sequence analysis indicates that the B cells in TME participate in antigen-driven selection process and a large percentage of the antibodies recognize antigens from the tumor or related cell lines. We conclude that the expanded B cell signature is recognizing and being selected for by tumor antigens. The utilization of single-cell RNAseq and single-cell Ig isolation in patients with response to ICB therapy can be used to identify and clone antibodies associated with tumor samples. This method has potential to identify unique tumor antigens and offer novel therapies.

989 A LUCIFERASE-BASED METHOD TO ASSESS ANTIGEN-SPECIFIC T CELL RESPONSES AND ANTIGEN PRESENTATION TO EVALUATE IMMUNOMODULATORY CHECKPOINTS AND THERAPEUTICS

Jimena Alvarez Freile*, Yuzhu Qi, Lisa Jacob, Maria Franceskin Lobo, Harm Jan Lourens, Gerwin Huls, Edwin Bremer. *Universitair Medical Centrum Groningen (UMCG), Groningen, Netherlands*

Background Targeted reactivation of the immune system, e.g. using immune checkpoint inhibitors (ICI), has shown great potential in the treatment of cancer. However, *in vitro* tools to rapidly investigate the impact of checkpoints in the context of specific T cell receptor (TCR) activation as well therapeutic effects of ICI treatment are lacking. Here, we have developed a simple method using the human papilloma virus 16 (HPV-16) E7-peptide (HLA-A2*02:01) and corresponding antigen-specific NFAT-luciferase model to assess antigen presentation and antigen-specific T cell responses and evaluate the impact of immunosuppressive factors and therapeutics that target such factors.

Methods HPV-16_$E7_{11-20}$ peptide was used as model antigen.[1] Jurkat NFAT-luciferase cell line or isolated primary T cells were modified with a previously reported TCR recognizing the $E7_{11-20}$ peptide.[2] HLA-A2+/- cancer cells were pulsed and incubated with Jurkat/T cells, with and without the $E7_{11-20}$-TCR. To study E7 presentation endogenously, CaSki cells were used. For the luciferase-based assay, T cell activation was correlated with the luminescence read out. For primary T cells, CD25/CD69 expression (Flow Cytometry), cytokine production (ELISA) and clustering (microscopy) were evaluated. As proof of concept for monitoring immunomodulatory events, cells were also treated with TGF-beta or modified to overexpress inhibitory immune checkpoints (e.g., HLA-G, VISTA).

Results Upon $E7_{11-20}$ pulsing of HLA-A2+ cells, an E:T ratio dependent increase in luminescence compared to non-pulsed cells (2-25 fold-increase) was observed upon coculture with Jurkat $E7_{11-20}$-TCR but not with parental Jurkat cells. Analogous experiments with CaSki yielded 30% increase in luminescence, demonstrating that the method is valid for measuring endogenous $E7_{11-20}$ processing and MHC presentation. Both HLA-A2+ pulsed cells and CaSki triggered specific T cell activation, illustrated by 5-20 fold-increase in MFI values for CD25 and CD69 expression and T cell clustering. For cytokine production, only the combination peptide: $E7_{11-20}$-TCR significantly triggered TNFa and IFNy production in HLA-A2 + pulsed cells, whereas for CaSki only higher IFNy production was observed. Overexpression of inhibitory molecules, such as HLA-G and VISTA, had a significant negative impact on TCR-induced luminescence compared to EV or non-treated cells. Moreover, treatment with immunosuppressive cytokines such as TGF-beta significantly impacted on luminescence.

Conclusions The MHC-I-specific Jurkat $E7_{11-20}$-TCR NFAT-luciferase system presented here can be used as an alternative method for the rapid evaluation of antigen-specific T cell responses *in vitro*. This method may be used as a rapid tool to study the impact of the TME or novel ICI in triggering effective T cell responses within the immune-oncology field.

990 HETEROGENEITY IN GLIOBLASTOMA TUMOR MICROENVIRONMENT: STRATEGIES FOR CANCER-ASSOCIATED FIBROBLAST TARGETING

Jonathan Stauber, Corinne Ramos*, Sandra Delebecq, Adele Ponzoni, Lisa Guzzi. *ImaBiotech, Loos, France*

Background Glioblastoma (GBM) is the most common and aggressive form of brain tumor, characterized by a poorly accessible microenvironment that render it notoriously hard to treat. The insufficient treatment success is, in large parts, due to its tremendous molecular heterogeneity, which affects the overall prognosis and response to therapies. The significant intra- and inter-tumor microenvironment (TME) composition heterogeneity plays a crucial role in GBM progression. Mostly due to this high, multifactorial immunosuppression occurring in the microenvironment, the efficacy of immunotherapy in GBM is low. Focusing on characterizing the components of different TMEs to evaluate their molecular and cellular component heterogeneity has a significant advantage to target group of cancer patients that would normally be resistant to immunotherapy.

Methods Deep spatial transcriptomics profiling was performed on non-treated glioblastoma human tissue microarrays (TMA) using NanoString's *GeoMx* Digital Spatial Profiler (*DSP*). 6 tumor tissues from 6 different patients were hybridized and analyzed with the Whole Transcriptomic Atlas (WTA) panel that includes 18,000 genes. Three regions of interest (ROIs) were selected per tissue sample. All the statistical analysis were performed with GeoMx® DSP Analysis Suite. Cell deconvolution using the SpatialDecon® algorithm (Nanostring®) was then performed to estimate mixed cell type abundance in the spatially-resolved gene expression defined segments.

Results Spatial transcriptomic analyses revealed that glioblastoma tumors varied dramatically in their global gene expression profiles and suggested the existence of differential gene expression among the tumors highlighting the inter-tumors heterogeneity of glioblastoma. Interestingly, different areas of the same tumor did not display distinct molecular profiles. Upregulation of stromal collagen genes was significantly detected in some patient specifically the fibrillar collagens type I, III and VI. Those findings indicated excessive collagen depositions in the surrounding of the tumor for some patient characteristic of tumor progression and involvement of cancer associated fibroblasts (CAFs) in the dysregulated collagen turnover leading to tumor fibrosis.

Conclusions As a cold tumor, malignant glioma has strong immunosuppression and immune escape characteristics. The TME provides the "soil" for the survival of malignant tumors, and recent studies have highlighted a major role for cancer-associated fibroblasts (CAFs) in promoting immunotherapy resistance by excluding T cells from tumors in the TME. Here the spatial transcriptomic analyses allowed a better phenotypical stratification of the cancer patient. In some, targeting CAFs would improve the TME and enhance the efficacy of immunotherapy.

991 **AB598, A THERAPEUTIC ANTI-HUMAN CD39 ANTIBODY, BINDS AND INHIBITS CD39 ENZYMATIC ACTIVITY *IN VIVO* TO PROMOTE ANTI-TUMOR IMMUNITY**

Kaustubh Parashar, Julie Clor, Amy Anderson, Urvi Vani, Jaskirat Singh, Enzo Stagnaro, Ferdie Soriano, Angelo Kaplan, Janine Kline, Lisa Seitz, Stephen Young, Nigel Walker, Matthew Walters, Ester Fernandez-Salas, Christine Bowman*. *Arcus Biosciences, Hayward, CA, United States*

Background AB598 is being developed as a novel cancer immunotherapy which potently binds and inhibits CD39 enzymatic activity. CD39 catalyzes the conversion of extracellular adenosine triphosphate (ATP) into adenosine monophosphate (AMP), resulting in decreased amounts of immunostimulatory ATP and increased levels of immunosuppressive adenosine in the tumor microenvironment (TME). By blocking CD39 in the TME, local levels of ATP increase, leading to myeloid cell activation and improved tumor control. AB598 is highly potent and specific, binding and inhibiting human CD39 with sub-nanomolar potency. AB598 binds and inhibits both human and cynomolgus monkey CD39 but not murine CD39, presenting a challenge for studying CD39 inhibition in an immune-competent syngeneic tumor model.

Methods Human CD39 knock-in (hCD39KI) mice were employed to examine the preclinical anti-tumor efficacy of AB598 in animals with a fully competent immune system. The use of a murine model with natural expression and distribution of human CD39, targetable by AB598, allowed for a more physiological assessment of CD39 inhibition in solid tumors compared to the alternative use of human cancer cells growing in immuno-deficient mice. Combination of CD39 inhibition with chemotherapy was explored. A murinized version of AB598, ch39_mIgG2a, which contains a murine Fc silent domain was used for *in vivo* studies.

Results Real-time measurement of ATP showed the ability of oxaliplatin to induce ATP release in MC38 tumor cells *in vitro*. In a hCD39KI mouse MC38 tumor model, ch39_mIgG2a in combination with oxaliplatin significantly inhibited tumor growth compared to treatment with either single agent. The combination was well tolerated and no decreases in body weight were observed. Analysis of cytokines in the periphery resulted in no significant increases after ch39_mIgG2a administration. Analysis of tumors from both MC38 and 4T1 models revealed substantial inhibition of intratumoral CD39 enzymatic activity in ch39_mIgG2a-treated mice. Tumor draining lymph nodes in the MC38 model showed a decrease in cell surface CD39 in ch39_mIgG2a mice, a finding supported by peripheral receptor occupancy studies. Relative percentages of the immune cells in the lymph nodes were unaffected, suggesting internalization or downregulation, not cellular depletion, as the mechanism for the decrease in cell-surface CD39.

Conclusions Our results indicate the superb ability of AB598 to inhibit enzymatic activity and tumor growth *in vivo* and provide a rationale for the combination of CD39 inhibition with ICD-inducing chemotherapy in the clinic.

992 INTRATUMORAL S100A8-TO-CD8 RATIO IN INFLAMED MERKEL CELL CARCINOMA TUMORS CORRELATES WITH RESPONSE TO PD-1 PATHWAY BLOCKADE

http://dx.doi.org/10.1136/jitc-2022-SITC2022.0992

[1]Shira Tabachnick-Cherny*, [1]Thomas Pulliam, [1]Haroldo Rodriguez Chevez, [2]Kimberly Smythe, [1]Rima Kulikauskas, [1]Kristina Lachance, [2]Daniel Hippe, [1]Paul Nghiem. *[1]University of Washington, Seattle, WA, United States*; *[2]Fred Hutchinson Cancer Center, Seattle, WA, United States*

Background PD-(L)1 blockade has changed the landscape for advanced Merkel cell carcinoma (MCC) as over 50% of patients initially respond to therapy. There are no clinically useful approaches to assess a patient's likelihood of response to PD-1 blockade. Understanding the underlying biology of anti-PD(L)1 responses and identifying predictive biomarkers can inform future combination therapies for patients that do not benefit from treatment. MCC is caused by the Merkel cell polyomavirus in ~80% of cases with the remaining cases being due to extensive UV exposure. Both of these processes are highly immunogenic due to viral oncoprotein expression or UV-neoantigens, respectively. Historically, studies have focused on adaptive immunity, and little is known about innate immunity in MCC which may play an important role in immune evasion. Myeloid cells are heterogenous and have been shown to play a suppressive role in many cancer types. We sought to investigate the link between tumor-infiltrating myeloid cells and outcomes to PD-(L)1 blockade.

Methods Identification of myeloid subtypes in MCC tumors was determined by single-cell RNA sequencing (scRNAseq) of dissociated tumor samples obtained from 9 patients. Following unsupervised clustering based on differential gene signatures, we selected major markers expressed in the myeloid subtypes in MCC (CD14, CD163, S100A8) and a cytotoxic T cell marker (CD8) for multiplex immunohistochemistry (m-IHC) analysis of 51 pre-treatment patients' tumors.

Results scRNAseq analysis discovered tumor associated macrophages in MCC tumors that express hallmarks of monocytic myeloid derived suppressor cells (M-MDSCs)[1]: the surface molecules $CD14^{+}CD11b^{+}HLA\text{-}DR^{lo/-}$ and upregulated S100A8 and S100A9 genes. Initial m-IHC analysis comparing pre-treatment tumors of 32 responders and 18 non-responders did not show differences between the response groups. However, after classifying tumors by CD8 infiltration status (intratumoral $CD8^{+}$ cells/1mm – Hot score: CD8 > 60, Cold score: CD8 < 60), we observed higher ratios of S100A8-to-CD8 in patients with hot tumors that did not respond to PD-(L)1 blockade treatment ($p=0.046$).

Conclusions S100A8 is associated with a tumor promoting effect and is a potential prognostic biomarker for advanced melanoma.[2] Our data suggests a correlation of S100A8-expressing cells in MCC tumors with response to treatment, as the ratio of S100A8-to-CD8 is higher in inflamed tumors that did not respond to immunotherapy. Future approaches to target M-MDSCs, or S100A8 directly might modify the ratio of S100A8-to-CD8 and potentially improve patient responses to PD-(L)1 blockade treatment.

993 INTERACTPRINT PREDICTS CLINICALLY MEANINGFUL INTERACTIONS BETWEEN CANCER EPITHELIAL CELLS AND IMMUNE CELLS: LESSONS FROM A SINGLE-CELL BREAST CANCER ATLAS

[1]Lily Xu, [1]Kaitlyn Saunders, [2]Hildur Knutsdottir, [1]Kenian Chen, [3]Julia Maués, [3]Christine Hodgdon, [4]Evanthia Roussos Torres, [1]Sangeetha Reddy, [1]Lin Xu, [1]Isaac Chan*. *[1]University of Texas Southwestern Medical Center, Dallas, TX, United States*; *[2]Johns Hopkins University Whitting School of Engineering, Baltimore, MD, United States*; *[3]GRASP Cancer, Baltimore, MD, United States*; *[4]Keck School of Medicine, University of Southern California, Los Angeles, CA, United States*

Background While immunotherapy has revolutionized the treatment of many solid tumors, the efficacy of immunotherapy regimens is comparatively lower in breast cancer. Immunotherapy efficacy is often negatively correlated with intratumor heterogeneity. Novel breast cancer immunotherapy approaches should leverage how intratumor heterogeneity affects immune cells in the tumor microenvironment. However, current definitions of heterogeneity in breast cancer have limited resolution. Single-cell RNA-seq (scRNA-seq) provides an unprecedented opportunity to further define cancer epithelial cell heterogeneity and identify how it influences immune interactions.

Methods We generated a novel dataset of 236,363 cells from 119 primary breast tumors biopsied from 88 patients taken from 8 publicly available datasets, currently the largest published scRNA-seq dataset in breast cancer. To define cancer epithelial cell heterogeneity, we performed unsupervised and supervised clustering based on molecular subtype and clinical target expression of all cancer epithelial cells. This identified 10 gene elements (GEs), which reflect molecular features that vary between cancer epithelial cells. Receptor-ligand pairing analysis determined how cells that highly express each GE interact with immune cells. We developed InteractPrint, a score which predicts the predominant tumor-interacting immune cells based on GE composition of a patient's tumor.

Results In our dataset, 20% of samples were HER2+, 46% HR+, and 32% TNBC. This dataset was statistically powered to characterize cancer epithelial cell heterogeneity. For the 10 GEs, we predicted interactions with immune cells. GEs with predicted NK cell interactions were resistant to NK cell cytotoxicity. In a spatial transcriptomics dataset, GEs with predicted T cell interactions demonstrated colocalization with CD8+ T cells. To infer GE-immune interactions at the patient level, we developed InteractPrint and assessed its accuracy in predicting response to anti-PD-1 therapy. Across two trials and clinical subtypes, T cell InteractPrint demonstrated significant improvement over PD-L1 in predicting response to anti-PD-1 therapy. In an scRNA-seq dataset of samples from patients treated with pembrolizumab, we observed AUC of 81% for T cell InteractPrint versus 54% for PD-L1. In patients treated with paclitaxel + pembrolizumab in the I-SPY2 trial, we observed AUC of 84% for T cell InteractPrint versus 73% for PD-L1.

Conclusions We defined intratumor heterogeneity and leveraged it to predict immune cell interactions within a patient's tumor. We developed T cell InteractPrint which captures heterogeneity in cancer epithelial and CD8+ T cell interactions and is predictive of anti-PD-1 therapy response at higher AUC than PD-L1. This provides a path forward for the interpretation of intratumor heterogeneity in a clinically meaningful way.

994 INVESTIGATING THE ABILITY OF TUMOR CELL-DERIVED TYPE I INTERFERON TO POTENTIATE ANTI-OVARIAN CANCER IMMUNE RESPONSES

Fiona Chatterjee*, Ellen Duong, Arjun Bhutkar, Stefani Spranger. *Massachusetts Institute of Technology, Cambridge, MA, United States*

Background Ovarian cancer is the fifth leading cause of cancer-related death in women in the United States.[1] The standard of care for ovarian cancer remains surgical debulking and chemotherapy. While this treatment is effective initially, most patients experience relapse within five years of initial diagnosis, and recurrent tumors are often chemotherapy-resistant.[2-4] Ovarian cancer generally induces extremely poor immune responses (characterized by poor effector immune cell infiltration and a lack of innate immune activation), and thus, efforts to induce robust anti-tumor immunity will require potent activation of the innate immune system.[5] The period between the end of chemotherapy and disease recurrence, often termed first remission, presents a unique opportunity to induce anti-tumor immune responses to delay or even prevent tumor regrowth. Recent work in our lab has demonstrated that inducing tumor cell-derived type I interferon (IFN-I) can rescue dysfunctional anti-tumor immune responses by activating a specific dendritic cell subset that subsequently activates $CD8^+$ T cells.[6] In this project, we aim to investigate how tumor cell-derived IFN-I induction impacts anti-ovarian cancer immunity.

Methods To model first remission and the subsequent tumor regrowth, we inoculated syngeneic ovarian cancer cells into the intraperitoneal spaces of mice, which resulted in the development of solid metastatic tumors and ascites. We utilized two cell lines: BPPNM, driven by $Brca1^{-/-}$ $p53^{-/-R172H}$ $Pten^{-/-}$ $Nf1^{-/-}$ and Myc^{OE}, to model homologous recombination-deficient (HR-deficient) tumors and CPAK, driven by $Ccne1^{OE}$ $p53^{-/-R172H}$ $Akt2^{OE}$ and $Kras^{G12V}$, to model homologous recombination-proficient (HR-proficient) tumors.[7] Interferon beta and interferon-stimulated gene transcript levels were assessed by qPCR. Dendritic cell and T cell infiltration were assessed by flow cytometric analysis of BPPNM and CPAK tumors 14 days after injection into wildtype mice.

Results BPPNM tumor cells, which are HR-deficient, expressed higher levels of interferon beta and downstream signaling target transcripts compared to CPAK tumor cells, which are HR-proficient. Flow cytometry immunophenotyping of BPPNM and CPAK tumors revealed that BPPNM tumors were more infiltrated by DC1, DC2, ISG^+ DC, $CD8^+$ T cells, and $CD4^+$ T cells. Finally, wildtype C57BL/6 mice implanted with BPPNM tumors displayed extended survival compared to mice implanted with CPAK tumors.

Conclusions Our data suggest that ovarian cancer cells with the ability to produce IFN-I induce more potent anti-tumor immune responses. Understanding how to induce IFN-I production in HR-proficient ovarian cancer could not only improve our knowledge of interactions between ovarian cancer cells and immune cells but also lead to novel therapeutic strategies for ovarian cancer.

995 **V DOMAIN IMMUNOGLOBULIN SUPPRESSOR OF T CELL ACTIVATION (VISTA) RE-PROGRAMS MACROPHAGE BIOLOGY AND PROMOTES PHAGOCYTOSIS AND M2C-DIFFERENTIATION**

[1]Yusheng Lin candidate*, [1]Ghizlane Choukrani, [2]Lena Dubbel, [2]Lena Rockstein, [1]Jimena Freile, [1]Yuzhu Qi, [1]Harm Jan Lourens, [1]Nienke Visser, [1]Valerie Wiersma, [3]Hao Zhang, [1]Emanuele Ammatuna, [1]Tom Meerten, [1]Gerwin Huls, [1]Edwin Bremer. *[1]University Medical Center Groningen, Groningen, Netherlands*; *[2]Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany*; *[3]Jinan University Medical College, Guangzhou, China*

Background VISTA is an established T cell immune checkpoint. However, its role in innate immunity is less established, with VISTA regulating cytokine production and chemotaxis by myeloid cells. The role of VISTA in macrophage biology and effector functions such as phagocytosis has not been delineated. Here, we investigated the impact of VISTA on phagocytosis and macrophage polarization.

Methods The frequency of $CD14^+$ monocytes expressing VISTA was determined in peripheral blood mononuclear cells (PBMC) from 37 healthy donors by flow cytometry. Macrophages, differentiated from VISTA overexpressed THP-1 cells and cord blood $CD34^+$ cell-derived monocytes, were used in phagocytosis assay using B-cell lymphoma target cells opsonized with rituximab. PBMC-derived macrophages were used to assess the correlation between phagocytosis and VISTA expression. qRT-PCR and flow cytometry were performed to analyze the impact of VISTA on other checkpoints and M1/M2-like macrophage biology. Enzyme-linked immunosorbent assay was performed to evaluate cytokine secretion of macrophages.

Results VISTA surface expression was identified on $CD14^+$ monocytes of 28 of the 37 healthy donors. On PBMC-derived macrophages, VISTA expression was higher in M2-like macrophages than in M0- or M1-like macrophages, and positively correlated with phagocytic activity in M2-like macrophages. Endogenous VISTA expression on monocytes coincided with the expression on $CD3^+$ T lymphocytes, whereas absence of VISTA on monocytes coincided with the absence on T lymphocytes. Ectopic expression of VISTA in THP-1 cells facilitated differentiation towards macrophage lineage upon PMA treatment. Additionally, VISTA elicited transcriptional and functional changes in THP-1 and $CD34^+$ cell-derived macrophages, increasing M2-like macrophage-related gene expression, while decreasing SIRPα, HLA-ABC, and M1-like macrophage-related gene expression. Further, ectopic VISTA augmented phagocytosis of cancer cells, with a marked decrease in IL-1beta secretion and a significant increase in IL-10 secretion.

Conclusions Collectively, our findings reveal that VISTA expression associates with M2-like activation of macrophages with a high phagocytic capacity, suggesting a role for VISTA in macrophage-mediated immune suppression.

996 FUNCTIONAL AND TRANSCRIPTOMIC PROFILING OF MYELOID CELLS IN PEDIATRIC SOLID TUMORS TO INFORM NEXT GENERATION IMMUNOTHERAPY

[1]Sabina Kaczanowska, [2]Francesca Buffa, [1]Rosandra Kaplan, [1]Cristina Contreras*. [1]*National Cancer Institute, Bethesda, MD, United States*; [2]*University of Oxford, Oxford, UK*

Background Monocytes are innate immune cells recognized for their ability to play both tumor permissive and surveillant roles in cancer. The heterogeneity of monocyte function can be guided by tumor-derived factors. Phenotypic and transcriptional alterations in circulating monocytes and other myeloid-derived cells in patients with solid tumors have been reported and associated with clinical outcomes. However, specific monocyte functions and their perturbations in the setting of solid malignancies have not been well explored.

Methods Primary monocytes isolated from healthy donors and pediatric patients with sarcoma were used to examine the production of reactive oxygen species (ROS) via staining with 2',7' –dichlorofluorescin diacetate (DCFDA). Monocyte-mediated phagocytosis of tumor cells was tested by co-culture with the HuO9-H3 human osteosarcoma cell line. Functional populations from healthy donor monocytes were sorted by FACS and bulk RNA-seq was performed on the sorted samples for transcriptomic profiling.

Results We found that monocytes are functionally heterogeneous and identified populations of low and high ROS production as well as phagocytic and non-phagocytic cells. Phagocytosis was dysregulated in patients when compared to healthy donors. In addition, phagocytosis significantly increased when tumor cells were pre-incubated with anti-CD47, a blocker of the "do not eat me" signal on tumor cells (53.16% vs 12.06%, p=0.0456). We successfully enriched for these functional populations from three healthy donors by FACS. Pathway enrichment analysis revealed key inflammatory processes increased in phagocytic cells such as GM-CSF, VEGF and PDGF signaling. Of note, phagocytic monocytes of tumor cells blocked with anti-CD47 had downregulated inflammatory signaling and increased anti-inflammatory PPAR signaling, compared to those from the isotype control. In addition, phagocytic cells had higher expression of MHC class II surface receptors than nonphagocytic cells suggesting an activation of antigen presentation.

Conclusions Myeloid ROS production and phagocytosis can provide circulating markers of tumor microenvironment activity. Phagocytosis of tumor cells triggers transcriptional changes in monocytes related to inflammatory and antigen presentation responses. Such changes are dampened when levels of phagocytosis were increased by the addition of anti-CD47, highlighting the importance of evaluating the delicate balance between pro- and anti-tumoral myeloid function. The incorporation of functional selection with -omic characterization provides insights into our understanding of monocyte-function in solid malignancies, which will in turn inform the design of myeloid-mediated therapies.

997 T CELL IMMUNOTHERAPIES TRIGGER NEUTROPHILS TO ELIMINATES HETEROGENOUS TUMORS

[1]Sadna Budhu, [2]David Redmond, [1]Jacob Ricca, [1]Billel Gasmi, [1]Mathieu Gigoux, [1]Cailian Liu, [1]Yanyun Li, [1]Czrina Cortez, [1]David Schroder, [1]Arshi Arora, [1]Travis Hollman, [1]Lukas Kraehenbuehl, [1]Hyejin Choi, [1]Sara Schad, [1]Isabell Schulze, [3]Rebekka Duhen, [3]Andrew Weinberg, [1]Andrew Chow, [4]Mikala Egeblad, [1]Katherine Panageas, [5]Gabrielle Rizzuto, [1]Olivier de Henau, [1]Aliya Holland, [4]Jean Albrengues, [1]Linda Hamadane, [4]David Ng, [4]Xue-Yan He, [1]Jedd Wolchok, [1]Taha Merghoub, [1]Daniel Hirschhorn*. *[1]MSKCC, New York, NY, United States; [2]Weill Cornell Medical School, New York, NY, United States; [3]Earle A. Chiles Research Institute, Portland, OR, United States; [4]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, United States; [5]UCSF, San Francisco, CA, United States*

Background Immune surveillance can eliminate developing cancers at the early stages of malignant transformation. The selective pressure that the immune system imposes on tumor cells, however, can "edit" tumors, yielding immune escape variants. Many tumors contain clones that cease to express antigenic proteins. Intra-tumoral antigenic heterogeneity is an important mechanism by which progressing tumors become refractory to standard immunotherapeutic interventions. This is particularly problematic for interventions that target a single antigen, such as adoptive T cell therapies and CAR T cells.

Current immunotherapies in the clinic consist of strategies that mobilize the adaptive compartment of the immune system. The most common approaches include immune checkpoint blockade with antibodies, infusion of ex vivo educated or genetically modified tumor-specific T cells, and therapeutic anti-tumor vaccination. Moreover, a wave of agents that target tumor necrosis factor receptor (TNFR) superfamily members expressed by activated T cells, such as glucocorticoid induced TNF receptor (GITR), 4-1BB and OX40 are being further investigated.

The role of neutrophils in tumor promotion versus tumor elimination is not well understood. The pro-tumorigenic role of neutrophils in chronic inflammation has been described. Higher neutrophil-to-lymphocyte ratios are associated with deleterious outcomes in patients receiving immune checkpoint blockade. Moreover, neutrophil effector mechanisms such as the formation of NETs can promote metastases and can shield tumors from effector T cell elimination. In other models, however, neutrophils and NETs can directly kill cancer. The role of neutrophils as potential effectors in the context of immunotherapies that target T cells remains incompletely defined.

Methods We applied a combination therapy consisting of cyclophosphamide (CTX), CD4+ T cells specific for the melanoma antigen Trp1 (Trp1 cells), and an anti-OX40 agonist or anti-CTLA-4 antagonist antibodies to mice bearing advanced antigenically heterogeneous melanomas.

Results Complete eradication of heterogenous melanomas was observed in mice treated with the combination therapy. Surprisingly, regressing tumors were heavily infiltrated with neutrophils with a distinct anti-tumorigenic phenotype and neutrophil depletion abrogated tumor eradication. Upon closer examination, we observed that inducible nitric oxide synthase expressed by neutrophils was necessary for heterogenous tumor elimination. In support of these findings, extensive neutrophil activation in biopsies of melanoma patients treated with immune checkpoint blockade. Moreover, our findings uncover a novel interplay between T cells mediating the initial anti-tumor immune response, and neutrophils mediating the destruction of tumor antigen loss variants.

998 NEUTROPHIL SUBSETS IN HEAD AND NECK CANCER

[1]Sandra Ekstedt*, [1]Krzysztof Piersiala, [2]Magnus Starkhammar, [2]Gregori Margolin, [1]Susanna Kumlien Georén, [1]Lars Olaf Cardell. *[1]Karolinska Institutet, Solletnuna, Sweden; [2]Karolinska University Hospital, Solna, Sweden*

Background The neutrophil is the first cell recruited to the site of inflammation in HNSCC.[1] Neutrophils have been perceived as a relatively homogenous cell type. However, our group has demonstrated that neutrophils can be divided into different subsets.[2-5] and we have identified a subset that can migrate into the tumour in HNSCC patients.[6] HNSCC may promote a shift towards more activated neutrophil subsets and the neutrophils may thereafter migrate to the lymph nodes.

Methods Thanks to our unique access to unfixed samples of lymph nodes and tumour biopsies of patients with oral HNSCC were we able to identify neutrophil subsets in each tissue and compare them to neutrophils found in the blood. The tissue, homogenized to a single cell suspension, and blood were analyzed with flow cytometry.

Results There are more $CD16^{High}CD62L^{High}$ Neutrophils in the blood compared to lymph nodes and the tumour tissue. The neutrophils subset $CD16^{High}CD62L^{dim}$ neutrophils are found mainly in the lymph node of the cancer patients and the subset $CD16^{dim}CD62^{dim}$ is almost only present in the tumour site. In healthy lymph nodes is the dominant subset $CD16^{High}CD62L^{High}$.

Conclusions Our study suggests that neutrophil subsets have different functions and play role in HNSCC.

999 INVESTIGATING THE IMMUNOMODULATORY ROLE OF INNATE LYMPHOID CELLS IN EPITHELIAL OVARIAN CARCINOMA

Douglas Chung*, Kathrin Warner, Jehan Vakharia, SeongJun Han, Maryam Ghaedi, Carlos Garcia-Batres, Nicolas Jacquelot, Azin Sayad, Sarah Ferguson, Pamela Ohashi. *Princess Margaret Cancer Center, Toronto, Canada*

Background Innate lymphoid cells (ILCs) are an emerging family of effector cells that mostly reside within non-lymphoid peripheral tissues and orchestrate innate and adaptive immunity in response to infections.[1] ILCs play an important role in cancer including its ability to directly kill cancer cells and promote anti-tumour immunity within the tumour microenvironment (TME).[2] In addition to these classical pro-inflammatory functions of ILCs, our group and others have identified a subset of immunoregulatory ILCs (ILCregs) in various diseases including cancer.[3] We previously found a $CD56^+$ ILCreg population that suppressed T cells in slow growing ex vivo tumour-infiltrating lymphocyte (TIL) cultures.[4] The objective of this study is to identify markers that distinguish immunoregulatory and non-immunoregulatory ILCs straight from primary tumours and uncover its role within the TME of epithelial ovarian carcinoma (EOC).

Methods Women with suspected EOC were recruited and consented pre-operatively at the Gynecology Cancer Clinic at Princess Margaret Hospital. Surgical resections were processed and analyzed by flow cytometry and single-cell RNA sequencing (scRNA-seq). In vitro stimulation of peripheral blood $CD56^+$ ILCs were performed over 7 days in IL-15 with 50% ascites supernatant.

Results We identified subsets of intratumoural ILCs including ILC1s, ILC2s, ILC3s, and $CD56^+$ ILCs within lineage negative populations. Interestingly, a population of $CD56^+$ $GZMB^-$ ILCs exhibited distinct tissue-resident-like properties including expression of tissue-retention marker CD69 and reduced expression of tissue-egress marker CD49e. Interestingly, transcriptomic profile of $CD56^+GZMB^-CD49e^-$ ILCs from our scRNA-seq dataset (n=3) had similar gene expression as intraepithelial ILC1s (ieILC1) from other studies.[5] These ieILC1-like cells were associated with poor recurrent free survival and reduced granzyme B expression in CD8+ TILs. Moreover, ieILC1-like phenotypes can be induced from peripheral blood CD56+ cells using ascites supernatant from patients with EOC. Finally, ieILC1-like cells from primary tumours expressed gene signatures that have been previously upregulated in ILCregs and regulatory T cells (Tregs), suggesting that these populations may have immunoregulatory properties. Ongoing work is being done to identify whether ieILC1-like cells directly suppress T cells in vitro, and uncover mechanisms of immunosuppression.

Conclusions Our findings suggest that ieILC1-like CD56+ cells are negatively associated with prognosis of EOC and may play a unique role in modulating the tumour microenvironment. Further investigation into the biology of ILCs in human tumours may provide novel therapeutic targets for ovarian carcinoma and beyond.

1000 MELANOMA LYMPH NODE METASTASES ARE ASSOCIATED WITH HYPOXIA AND IMMUNOLOGIC DYSFUNCTION

[1]Dustin McCurry*, [2]Chistopher Deitrick, [2]Yan Zang, [2]Arivarasan Karunamurthy, [2]Theresa Whiteside, [2]Diwakar Davar, [2]Hassane Zarour, [2]Jason Luke, [2]John Kirkwood, [2]Riyue Bao, [2]Yana Najjar. [1]*University of Texas MD Anderson Cancer Center, Houston, TX, United States*; [2]*UPMC Hillman Cancer Center, Pittsburgh, PA, United States*

Background Deranged cellular metabolism is a hallmark of cancer and the hypoxic tumor microenvironment (TME) is associated with T-cell dysfunction. We have shown that in melanoma patient samples, high tumor cell oxidative stress is associated with T-cell dysfunction, intratumoral hypoxia, and worse clinical outcomes. Less is known about the impact of tumor cells on the environment of sentinel lymph nodes (SLN), though recent studies have implicated SLN as critical sites in the efficacy of the anti-tumor immune response. Thus, we sought to assess the impact of melanoma SLN metastasis on intra-nodal immune cell composition and hypoxia.

Methods We identified 87 patients with primary melanoma who had undergone SLN biopsy. Tumor FFPE slides were stained and imaged using Vectra OPAL panels (immune: CD3, FOXP3, CD8, CD68; tumor: SOX10; checkpoint receptor/ligands: PD-1, PD-L1, IDO [indoleamine 2,3-dioxygenase]; hypoxia: HIF-1a [Hypoxia-inducible factor 1-alpha], CAIX [carbonic anhydrase IX]). 732 regions of interest (ROIs) were selected from 47 patients who had a positive SLN, and 426 ROIs from 40 patients with a negative SLN. 20X images were analyzed for cell segmentation by StarDist, and phenotyping by Random Forests machine learning models. Images from adjacent tumor sections were co-registered using SimpleITK to enable spatial evaluation of markers across panels. Cell density and distances in tumor, tumor/stroma boundary (+/-50um), and stroma were compared between groups using linear mixed-effects models (LMM). The study was approved by the University of Pittsburgh's Institutional Review Board.

Results Within tumor infiltrated sentinel lymph nodes, areas of SOX10+ metastatic melanoma were enriched for CAIX, a marker of hypoxia. IDO, an immunosuppressive enzyme which is upregulated in hypoxic conditions, was more frequently expressed within the surrounding stroma (CD3-SOX10-) of tumor infiltrated nodes compared to negative nodes ($p<0.0001$). The immune composition of CD68+ myeloid cells, FOXP3+ T-cells, and CD8+ T-cells was similar in infiltrated and non-infiltrated nodes. Consistent with other reports of immune dysfunction within tumor infiltrated nodes, the frequency of PD-1+CD8+ cells was significantly enriched compared to negative lymph nodes ($p<0.01$).

Conclusions Infiltration of tumor draining lymph nodes by metastatic melanoma is associated with markers of immunologic dysfunction and intranodal hypoxia. This constellation of features recapitulates the hypoxic primary tumor microenvironment. Studies are underway to evaluate the potential of oxidative balance within melanoma SLN as a prognostic biomarker.

Ethics Approval The study was approved by the University of Pittsburgh's Institutional Review Board.

1001 IMMUNOPHENOTYPING OF BRAIN TUMORS IDENTIFIES INTERFERON ENRICHED PHAGOCYTES IN HUMAN GLIOMAS

[1]Pravesh Gupta*, [1]Minghao Dang, [1]Dapeng Hao, [1]Krishna Bojja, [1]Tuan Tran, [1]Huma Shehwana, [1]Carlos Kamiya-Matsuoka, [1]Jianzhuo Li, [1]Alessandra Audia, [1]Cynthia Kassab, [1]Martina Ott, [1]Joy Gumin, [1]Sanaalarab Alenazy, [2]Alicia Goldman, [2]Sameer Seth, [2]Atul Maheshwari, [1]Veerakumar Balasubramaniyan, [3]Brian Vaillant, [1]John de Groot, [4]Antonio Lavarone, [1]Frederick Lang, [1]Nicholas Navin, [5]Amy Heimberger, [1]Linghua Wang, [1]Krishna Bhat. *[1]University of Texas MD Anderson Cancer Center, Houston, TX, United States; [2]Baylor College of Medicine, Houston, TX, United States; [3]The University of Austin, Austin, TX, United States; [4]Columbia University Medical Center, Herbert Irving Comprehensive Cancer Center, New York, NY, United States; [5]Feinberg School of Medicine, Northwestern University, Chicago, IL, United States*

Background Gliomas are recalcitrant brain tumors. Anti-glioma immunity and immunopathogenic responses are critical contributors for better survival of isocitrate dehydrogenase-mutant (IDH^{mut}) over wild-type (IDH^{wt}) gliomas. Despite this correlative pattern of immunity and survival, an unbiased understanding of cell-type specific transcriptomic and epigenomic states of glioma-derived myeloid cells beyond immunosuppressive paradigms remains elusive.

Methods To this end, we performed single-cell RNA-sequencing (scRNA-seq) on 140,000 tumor-associated immune cells from eighteen IDH mutation classified primary (N=8) and recurrent (N=10) human gliomas and three non-glioma brains (NGBs). We performed unsupervised clustering and cell annotation based on overlapping canonical lineage and signal dependent transcription factors. Gene ontology and gene set enrichment analyses were performed to define functional states of glioma associated myeloid cells.

Results Our analyses revealed twelve myeloid cell types across glioma subgroups. We noted abundant microglial cells in IDH^{mut} than IDH^{wt} gliomas. Concomitantly, continnum of microglia and macrophage phenotypes were observed in IDH^{wt} glioma, which exhibit more severe tumor pathologies. Strikingly, we identified a hybrid microglia/macrophage cell subset with enriched interferon module inferred from our gene ontology analyses. These hybrid phagocytes were significantly increased in recurrent IDH^{wt} gliomas. As tissue macrophages exhibit multifaceted polarization in response to microenvironmental cues, we clarify the existence of microglia/macrophage functional states beyond M1/M2 paradigms exemplified by the presence of palmitic-, oleic- acid, and glucocorticoid responsive polarized states. Specifically, certain microglia and monocyte-derived subpopulations were associated with antigen presentation gene modules, akin to cross-presenting dendritic cells. Furthermore, immune related gene ontology analysis identified enriched antigen presentation and phagocytosis gene modules in distinct microglia-like clusters. Importantly, the phagocytic immunomodulator; Triggering Receptor Expressed on Myeloid Cells 2 (TREM2) was upregulated in these microglia-like cells. Contrary to tumor promoting role of TREM2 myeloid cells in non-brain cancers, we identify TREM2 axis as a regulator of antigen presentation. Additionally, single cell- Assay for Transposase-Accessible Chromatin using sequencing (sc-ATAC-seq) on ~40,000 tumor-associated microglia revealed genes associated with IFN-gamma/IL-12/IL-10 pathway were negatively regulated in IDH^{mut}/IDH^{wt} microglia compared to homeostatic microglia in NGBs.

Conclusions In summary, our study sculpts transcriptional and epigenomic details and re-defines glioma-specific immune contexture for downstream immunogenomics applications. We specifically reveal interferon and TREM2 nodes on microglia-like phagocytic cells as clinically tractable anti-glioma immunotherapy target.

1002 CIRCULATING MYELOID STATES INDUCED WITH ANTI-PD-1 AND GM-CSF COMBINATION THERAPY ARE ASSOCIATED WITH TREATMENT RESISTANCE IN HUMAN BILIARY CANCER

[1]Bridget Keenan*, [1]Elizabeth McCarthy, [1]Arielle Ilano, [1]Diamond Luong, [1]Hai Yang, [1]Li Zhang, [1]Kathryn Allaire, [1]Zenghua Fan, [2]Tony Li, [2]David Lee, [1]Yang Sun, [1]Alexander Cheung, [1]Hewitt Chang, [1]Brandon Chen, [1]Brenna Sheldon, [1]Robin Kelley, [1]Chun Jimmie Ye, [1]Lawrence Fong. *[1]University of California San Francisco, San Francisco, CA, United States; [2]University of Washington, Seattle, WA, United States*

Background Advanced biliary tract cancers (BTC) have a poor prognosis and low rates of response to immune checkpoint inhibition (CPI), with overall response rates ranging from 3-13%.[1-3] The BTC tumor microenvironment contains immunosuppressive immune populations, desmoplastic stroma, and a paucity of tumor infiltrating effector T cells[4,5], but the role of circulating immune cells in response and resistance to CPI is less well-characterized. We aimed to explore circulating immune cells from BTC patients treated with CPI to understand immunotherapy response and resistance.

Methods We used multiplexed multi-omic single cell RNA sequencing and cell surface proteomics (CITEseq) to profile >400,000 circulating immune cells in BTC patients receiving anti-PD-1 with and without GM-CSF as part of a phase II clinical trial (NCT02703714)[6], as well as from age and gender-matched healthy donors. We also evaluated a subset of tumor tissues from BTC patients to investigate the spatial organization of immune cell populations.

Results Using CITEseq, we identified several unique $CD14^+$ monocyte sub-populations in BTC patients' circulation compared to healthy donors. In the circulation of patients with BTC tumors that are CPI-resistant, there was an increased frequency of "$CD14_{CTX}$", a monocyte sub-population expressing high levels of immunosuppressive cytokines and chemotactic molecules, following anti-PD-1 monotherapy. $CD14_{CTX}$ can directly suppress $CD4^+$ T cells and induce SOCS3 expression in $CD4^+$ T cells, rendering them functionally unresponsive. Analogous tumor-associated macrophage populations could also be found within tumor tissues. Consistent with the pleiotropic effects of GM-CSF, we saw changes in the frequency and genomic programs of multiple myeloid populations, including dendritic cells and monocytes, when GM-CSF was combined with anti-PD-1. Within one week of GM-CSF combination therapy, monocyte-derived dendritic cells were induced in the circulation of BTC patients and associated with pro-inflammatory signals, including upregulation of MHC I and II in monocytes and dendritic cells.

Conclusions These results demonstrate the capacity of CPI plus GM-CSF combination therapy to induce monocyte states that both foster and inhibit adaptive immunity. Monocytes arising after anti-PD-1 treatment induced T cell paralysis in a subset of patients with CPI-resistant tumors, as a distinct mode of tumor-mediated immunosuppression. GM-CSF demonstrated the potential to enhance both pro-inflammatory and antigen-processing and presentation-related programs within myeloid cells. These results highlight the importance of identifying pharmacodynamic markers of immune response and targets for combination immunotherapy to overcome CPI resistance in BTC.

Trial Registration NCT02703714

Ethics Approval Peripheral blood mononuclear cells were obtained from patients (per UCSF institutional review board (IRB) #15-18420) from the clinical trial #NCT02703714. Tumor samples were collected from patients biopsied as part of the clinical trial and from patients undergoing standard-of-care resections and consented under the UCSF Hepatobiliary Tissue Bank and Registry (IRB #12-09576). Healthy donor PBMCs were collected from age and gender-matched healthy donors as part of the Cancer Immunotherapy Biobanking protocol and the Immune Cell Census (IRB #15-16385 and #19-27147, respectively). Informed consent was obtained from all patients for participation in the listed trials and for use of blood and tumor samples in research studies.

Consent None of the patient data in this abstract is identifiable; IRB information included as above.

1003 MACROPHAGE ADHESION TO TUMOR CELLS POSITIVELY IMPACTS TUMOR GROWTH

[1]Jovan Nikolic, [2]Joseph Ackerman, [1]Sarah Taheraly, [3]Thierry Rose, [1]Ouardia Aït-Mohamed, [2]Martine Ben Amar, [1]Jean-François Joanny, [1]Philippe Benaroch*. *[1]Institut Curie, Paris, France*; *[2]Ecole Normale Supérieure, Paris, France*; *[3]Institut Pasteur, Paris, France*

Background Myeloid cells are major players of the tumor microenvironment contributing to immune evasion mechanisms and providing pro-tumorigenic effects. Here we aim to analyze at the physical and molecular level, how myeloid cells can impact tumor growth and fate.

Methods Combining quantitative cell biology with the derivation of physical modeling of tumor growth, allow us to extract key parameters and make predictions that are testable both, by simulations in silico and by *in vitro* experiments.

Results We set up an *in vitro* system to follow the growth of tumor spheroids in 3D by real-time microscopy over long periods of time. Importantly, we replicate in this system the strong positive effect of alveolar macrophages on tumor growth and the poor effect of monocytes. From the quantifications and growth curves obtained, we derived mathematical modeling of spheroid growth in 2 and 3D. The semi-continuous model we developed makes use of a particle-based model which allows the treatment of proliferating cells in physical interactions. This model, tested in simulations, fits well with the data obtained in the absence or presence of macrophages. The model predicted that adhesion forces between tumor cells and macrophages are key in the pro-tumoral effect observed. Among the integrins potentially mediating these forces, CD11c stands out as a key candidate since it is expressed by alveolar macrophages but not by monocytes. Anti-CD11c blocking antibodies indeed diminish cell-to-cell adhesion forces as measured by a rupture force assay, prevent spheroid nucleation, and impair spheroid growth.

Conclusions Our results establish that adhesion of macrophages to tumor cells can have a direct impact on tumor growth by modifying key physical parameters. These findings may lead to the identification of new approaches targeting myeloid cells to counteract their pro-tumoral activity within the tumor microenvironment.

1004 SIGNALING PATHWAYS INDUCING TUMORICIDAL PHAGOCYTOSIS IN PANCREATIC CANCER

[1]Li Qiang*, [1]Stephanie Dougan, [1]Samantha Liu, [2]Gabrielle Ro, [3]Michael Dougan, [1]Lestat Ali, [1]Patrick Lenehan, [1]Felix Hambitzer. [1]*Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States*; [2]*University of Utah, Salt Lake City, UT, United States*; [3]*Massachusetts General Hospital, Boston, MA, United States*

Background Macrophages can be repolarized to promote tumor destruction, particularly by triggering tumoricidal phagocytosis of cancer cells. Despite the increasing interest in monoclonal antibody therapies targeting tumor antigens to drive cancer cell elimination via phagocidal macrophages, we still face tremendous challenges in developing adequate therapeutics due to lack of knowledge of the signaling pathways that induce phagocidal macrophages. Our previous work showed that cIAP1/2 antagonism and T cell derived cytokines promote anti-tumor immunity by reprogramming tumoricidal macrophages to phagocytose live tumor cells.

Methods Here we performed transcriptional analysis on both macrophages and tumor cells treated with cIAP1/2 antagonism or vehicle and identified candidate positive and negative regulators of phagocytosis. We are demonstrating how these receptors-ligand pairs on macrophages and tumor cells are induced and the mechanisms by which they effect tumor cell destruction. We also performed an in vitro CRISPR screen on tumor cells cocultured with macrophages, treated with cIAP1/2 antagonism or vehicle, recovered the DNA of phagocytosed tumor cells from within macrophages and compared to non-phagocytosed tumor cells to discover mediators of resistance or sensitivity to both baseline phagocytosis (efferocytosis) and cIAP1/2 antagonism induced phagocytosis. Our screen revealed a striking lack of dependence on MHC class I for tumors treated in vivo. Genes involved in phagocytosis resistance instead converged on regulation of the cytoskeleton and *other candidates which we have now validated in single gene knockout tumor cells and will be discussed*. This study will provide critical insights on tumoricidal macrophages, uncover the key pathways reprogramming these myeloid cells, and decipher the essential tumor-intrinsic pathways resulting in sensitivity and resistance to anti-tumor phagocytosis.

1005 PD-L1 KNOCKOUT NATURAL KILLER CELLS AS A CELLULAR PRODUCT FOR THERAPEUTIC USE IN COMBINATION WITH HUMANIZED ADCC-COMPETENT ANTI-PD-L1

[1]Tayler Croom-Perez*, [2]Jeremiah Oyer, [1]Md Faqrul Hasan, [1]Thomas Dieffenthaller, [1]Liza Robles-Carrillo, [2]Alicja Copik. [1]*University of Central Florida, Orlando, FL, United States*; [2]*University of Central Florida, College of Medicine, Orlando, FL, United States*

Background Immunotherapeutic strategies, such as checkpoint blockade of PD-1/PD-L1, have become a focal point of immunotherapy in oncology. Recent studies highlight the importance of Natural Killer (NK) cells in the success of these immunotherapies and adoptive NK cellular therapy is being explored to enhance response to these treatments. Antibodies targeting PD-L1 are mostly Fc silent but some, such as Avelumab, can engage FcγR (CD16) receptor on NK cells resulting in killing cancer cells via antibody-dependent cellular cytotoxicity (ADCC). PM21-particle expanded NK (PM21-NK) cells are an optimal NK cell product to consider for a combination strategy as these NK cells lack PD-L1 but can induce PD-L1 on tumors cells. Previous reports, however, have shown that PD-L1 can be induced on NK cells. This could potentially lead to fratricide of NK cells in the presence of Fc-competent, PD-L1 targeting antibodies and mitigate their cytotoxic response. This study determined if PD-L1 can be induced on PM21-NK cells and what effect PD-L1 engagement had on their activity and potential for fratricide in both WT and PD-L1 knockout PM21-NK cells.

Methods CRISPR-based Knockout (KO) of PD-L1 in PM21-NK cells was performed and efficiency was determined after overnight incubation of WT or PD-L1 KO PM21-NK cells with cytokines to induce PD-L1 expression. Cancer cells were incubated with NK cells in the presence of non-competent or Fc-competent α-PD-L1 and cytotoxicity was measured using a kinetic live-cell imaging assay. NK cell fratricide was measured in cultures of WT or PD-L1 KO PM21-NK cells induced for PD-L1 expression with non-competent or Fc-competent α-PD-L1.

Results PM21-NK cells were found to express low levels of PD-L1 (< 20%) after exposure to various cancer cell line monolayers or K562 co-culture. Exposure to SKOV-3 spheroids or to a cytokine combination of IL12, IL15, and IL18 led to a significant induction in PD-L1 in WT PM21-NK cells (> 80%). PD-L1 knockout prevented the induction of PD-L1 on NK cells after cytokine exposure and enhanced cytotoxicity. Fratricide was decreased and cytotoxicity increased in PD-L1 KO PM21-NK cells in combination with Fc-competent α-PD-L1.

Conclusions Knockout of PD-L1 in *ex vivo* expanded PM21-NK cells prevented the induction of PD-L1 on NK cells without negative effects on cytotoxicity. PD-L1 KO PM21-NK cell cytotoxicity was further enhanced in combination with Fc-competent α-PD-L1 compared to WT NK cells. PD-L1 knockout PM21-NK cells are a potential cell product for therapeutic use in combination with PD-L1 targeting antibodies.

Background Natural killer (NK) cells are emerging as a promising therapeutic option in cancer. To better understand how cancer cells evade NK cells, we studied interacting NK and blood cancer cells using single-cell and genome-scale functional genomics screens.

Methods We performed multiplexed single-cell RNA-seq (scRNA-seq) on co-cultures of NK cells and 26 cell lines representing diverse blood cancers. Using screens of pooled DNA-barcoded cell lines (PRISM), we quantified the sensitivity of over 60 blood cancer cell lines and integrated the results with CCLE multi-omics to uncover molecular correlates of tumor cell susceptibility to NK cells. We performed 12 genome-scale CRISPR loss-of-function and gain-of-function screens of cancer-cell intrinsic NK cell resistance mechanisms across 7 blood cancer cell lines. Finally, we investigated the mechanisms-of-action of 65 genome-scale screen hits using CRISPR screens with scRNA-seq readout in both tumor and NK cells.

Results At single-cell resolution, interaction of NK and cancer cells induced distinct activation states in both cell types depending on the cancer cell lineage and molecular phenotype. NK cells transitioned either into an activated state characterized by *4-1BB*, *GITR*, *TIM-3*, and *TIGIT* or a state marked by type I interferon signature. Tumor cells responded to NK cell attack by activating interferon gamma (IFNy) signaling, inducing MHC class I. The activation states correlated with sensitivity to NK cells, ranging from more sensitive myeloid to more resistant B-lymphoid cancers. Molecular correlates of increased sensitivity included expression of activating receptor ligands *NCR3LG1*, *PVR*, and *ULBP1* and mutations in the NF-kB regulator *TRAF3*. CRISPR screens uncovered cancer cell-intrinsic genes driving sensitivity and resistance, including antigen presentation and death receptor signaling mediators and adhesion molecules. The screens identified new blood cancer-specific NK cell inhibitory regulators (*SELPLG*, *SPN*, and *MYB*) and genes previously underappreciated in NK cell evasion, including protein fucosylation and transcriptional regulators (e.g. *GFI1B*). CRISPR screens with scRNA-seq readout identified MHC-I, IFNy, and NF-κB regulation as underlying mechanisms. Cancer cell knockout of positive regulators of NK cell response (*CD58, NCR3LG1)* induced an inactive NK cell state, providing experimental evidence how cancer cell-intrinsic genetic alterations can shape the molecular profile of attacking immune cells to promote immune evasion.

Conclusions By integrating diverse functional genomics screens and patient genomic profiles, we provide a comprehensive landscape of potential biomarkers and functionally validated genetic mechanisms which influence how NK cells recognize and kill malignant cells. The results offer a roadmap to facilitate development of NK-cell based immunotherapy for blood cancers and beyond.

Ethics Approval The study was approved by the Helsinki University Hospital ethics committee, (permit number 303/13/03/01/2011), and abided by the principles of the Declaration of Helsinki.

1007 MICROGLIA RECRUIT AND ACTIVATE NATURAL KILLER CELLS TO CONTROL TUMOR PROGRESSION IN BREAST CANCER BRAIN METASTASIS

Timothy McMullen*, Aaron Longworth, Dennis Ma, Devon Lawson, Katrina Evans. *University of California, Irvine, Irvine, CA, United States*

Background Metastatic brain tumors are incurable, rapidly fatal, and five times more common than primary glial or meningeal tumors of the central nervous system (CNS). Up to 30% of metastatic breast cancer patients will develop brain metastasis as a complication of their disease. This represents a significant clinical problem for the 1 in 8 women who will receive a diagnosis of invasive breast cancer during her lifetime. Natural Killer (NK) cells are cytotoxic lymphocytes with strong *in vivo* anti-tumor activity, a native ability to cross the BBB, and a demonstrated role in regulation of metastasis in peripheral organs. NK cells perform critical roles in antitumor immunosurveillance via the expression of germline-encoded activation and inhibition receptors on the cell membrane. These receptors recognize ligands on both normal and transformed cells, and ultimately determine whether an NK cell will be stimulated to kill a neoplastic cell or inhibited from killing a healthy cell. Notably, NK cells are under investigation in clinical trials as both drug targets and adoptive cell therapies.

Methods We have performed single-cell RNA sequencing (scRNA-seq) in conjunction with a fluorescent cytokine screen to determine the cytokine secretion profile of microglia under tumor-bearing conditions. We have also carried out NK cell-depletion experiments using intraperitoneal injections of i.p. injections of anti-Asialo GM1 IgG to determine the functional significance of NK cells in the response to breast cancer brain metastasis.
