Results Our scRNA-seq data and cytokine screen suggest that NK cell activation and recruitment to the brain in BCBM depends on the secretory action of microglia. Furthermore, we observe a complete lack of NK cell infiltration in microglia-knockout mice harboring breast cancer brain metastasis. We confirm with selective antibody-mediated NK cell depletion that NK cells are critical for preventing the outgrowth of disseminated tumor cells in the brain. However, we also observe NK cell dysfunction within the microenvironment of brain metastasis—a clear obstacle to the development of NK cell-based therapies for intracranial metastatic lesions.

Conclusions Microglia appear to play a necessary role in the recruitment of NK cells to the brain under metastatic conditions. An improved understanding of the native functional status of NK cells in the context of brain metastasis, including their interactions with microglia, will inform the development of neuroprotective anti-metastatic therapies aimed at modulating and potentiating the anti-tumor action of both native and adoptive NK cells.

1008 CROSS-SPECIES CHARACTERIZATION OF SPLENIC NATURAL KILLER (NK) CELLS REVEALS ORGAN-SPECIFIC HETEROGENEITY WITH IMPLICATIONS FOR CANCER IMMUNOTHERAPY

Khurshid Iranpur*, Aryana Razmara, Sylvia Cruz, Marshall Lammers, Cyrus Sholevar, Robert Rebhun, Michael Kent, William Culp, Richard Bold, Sean Judge, William Murphy, Robert Canter, Lauren Farley*. *University of California Davis Health, Sacramento, CA, United States*

Background Natural killer (NK) cell immunotherapy is a promising modality for cancer immunotherapy, but questions of optimal donor characteristics for in vivo persistence, engraftment, and effector function remain. Splenic NK cells have been poorly characterized in humans and dogs. Although they are not readily available as a source for adoptive immunotherapy, we hypothesized that splenic NK harbor unique phenotype and function which can inform optimal NK immunotherapy.

Methods Matched NK cells were isolated from spleen and blood of 4 human and 3 dog patients undergoing surgery. Immune phenotype, proliferation, viability, and apoptosis were assessed pre and post 14 days of co-culture with irradiated clone9 K562 feeders. Differential gene expression was assessed using 3'-Tag-RNA-sequencing.

Results NK cell frequencies in resting human spleen were significantly lower compared to PBMCs per live CD45+ cells (9.4±0.3% vs. 16.7±8.8%, P=0.05) whereas the frequencies of NKT, CD3+, and CD8+ were not significantly different (P>0.05 all). Phenotypically, TIGIT expression was higher in resting human spleen NK compared to PBMCs (39.8±2.4% vs. 19.0±8.6%), as was CD69 (23.8±8.7% spleen vs. 14.4 ±7.6% PBMCs). Across both dog and human, spleen cells expanded more significantly than PBMCs with human showing 266-fold versus 105-fold expansion. In human, maximal expansion was also greater for spleen NK cells (690±1080 x 10^6) compared to PBMC NKs (111±165 x 10^6), although not statistically significant. Similar results were obtained with dog NK expansions. Purity of human NK cells at day 14 was similar for spleen and PBMC-expanded NK cells at >90%, and both groups showed similar Ki67 (70-90%) and Granzyme B (97-100%). In killing assays against human sarcoma targets (SAOS2, A673), there was greater cytotoxicity with spleen-expanded NK cells compared to PBMC-expanded at 10:1 E:T (40-50% vs. 30-35%). Day 14 spleen-expanded NK cells from dog showed greater killing compared to PBMC-expanded against osteosarcoma and melanoma targets at 10:1 E:T (45% vs. 25%). At day 14, there was no difference in apoptosis between human spleen and PBMC-expanded NK cells. Sequencing results showed an upregulation of genetic pathways associated with persistence and metabolic fitness for both human and dog spleen-expanded NK cells at day 14.

Conclusions NK cells derived from spleen appear to show greater activation and expansion compared to PBMC-derived in human and dog subjects with no difference in apoptosis. Further characterization of NK cells from the spleen may provide novel insights into mechanisms to overcome barriers to successful NK immunotherapy for solid tumors in both human and canine models.

1009 KNOCKOUT OF THE INHIBITORY RECEPTOR TIGIT ENHANCES ANTI-TUMOR RESPONSE OF *EX VIVO* EXPANDED NK CELLS AND PREVENTS FRATRICIDE WITH THERAPEUTIC FC-COMPETENT TIGIT ANTIBODIES

Md Faqrul Hasan*, Tayler Croom-Perez, Jeremiah Oyer, Thomas Dieffenthaller, Liza Robles-Carrillo, Alicja Copik. *University of Central Florida, Orlando, FL, United States*

Background Antibody blockade of the Natural Killer cells (NK cells) and T cell inhibitory receptor TIGIT has been shown to enhance tumor control and survival in preclinical mouse models and early clinical trials; however, there is a lack of understanding of the effect of TIGIT engagement on anti-tumor functions of activated primary human NK cells. Additionally, the majority of TIGIT antibodies in clinical development have a humanized IgG, which induces antibody-dependent cellular cytotoxicity (ADCC) and likely contributes to their efficacy. However, the potential consequences of these Fc-competent antibodies when binding NK cells, such as fratricide, have not been well characterized. Fratricide could deplete NK cells upon treatment, a detrimental effect to the overall efficacy since NK cells play a critical role in the success of checkpoint blockade immunotherapies. Recent efforts have focused on developing adoptive NK cell therapy and combinatorial immune-oncology therapies in order to enhance response. Adoptive transfer of TIGIT KO NK cells could provide a treatment strategy to mitigate potential negative effects of TIGIT blockade on NK cells. In this study, TIGIT knockout in *ex vivo* PM21-particle expanded human NK cells was performed and the effect on anti-tumor activity alone or in combination with Fc-competent TIGIT antibody blockade was evaluated and compared to WT NK cells.

Methods CRISPR was used to make a targeted TIGIT knockout (KO) in *ex vivo* PM21-particle expanded NK cells (PM21-NK cells). TIGIT KO NK cells were compared to wild type (WT) NK cells to determine changes cytotoxicity, ADCC, and IFNγ, TNFα, and the degranulation marker CD107a expression. Glycolytic rate and mitochondrial stress were measured. TIGIT KO or WT PM21-NK cells were combined with Fc-competent or non-Fc-competent anti-TIGIT and fratricide and cytotoxicity were measured.

Results TIGIT KO PM21-NK cells showed improved killing compared to WT against 3D spheroids from multiple cancer cell lines. ADCC increased proportionally in TIGIT KO NK cells. TIGIT KO PM21-NK cells had increased CD107a surface expression after cancer spheroid exposure and increased basal glycolytic rate after stimulation. TIGIT Knockout prevented Fc-competent anti-TIGIT driven NK cell fratricide and prevented decrease in NK cell cytotoxicity when combined with Fc-competent anti-TIGIT.

Conclusions Knockout of TIGIT in *ex vivo* expanded PM21-NK cells resulted in NK cells with improved anti-tumor activity and metabolic fitness. TIGIT KO prevented ADCC driven NK cell fratricide and inhibition of cytotoxicity when combined with Fc-competent anti-TIGIT. TIGIT KO PM21-NK cells are a potential cellular product for therapeutic use in combination with TIGIT blockade.

1010 A SINGLE-CELL TRANSCRIPTOMIC ATLAS OF HUMAN NK CELLS TO GUIDE CANCER IMMUNOTHERAPY

[1]Ryan King*, [2,3]Azim Amirabad, [1]Amir Bayegan, [1]Joachim Theilhaber, [1]Nicole Acuff, [1,4]Shannon McGrath, [1]Xiangming Li, [2,5]Franck Rapaport, [1,6]Jack Pollard, [1]Donald Jackson. *[1]Sanofi, Cambridge, MA, United States; [2]Digital Data Science, Cambridge, MA, USA; [3]Current Affiliation: Johnson and Johnson, Cambridge, MA, USA; [4]Current Affiliation: Moderna Clinical Biomarker Lab, Cambridge, MA, USA; [5]Current Affiliation: Sanofi Precision Medicine and Computational Biology, Cambridge, MA, USA; [6]Current Affiliation: Moderna Oncology, Cambridge, MA, US*

Background Natural killer (NK) cell can serve as an effective anti-cancer treatment,[1,2] and enhancing NK function has been shown to enhance patient outcomes.[1,2] Therefore, insight into NK cell states and subtypes may lead to new treatment options. Initial characterization of NK cells relied on flow cytometry with surface markers dividing NK cells into less mature $CD56^{bright}$ NKs and more mature $CD56^{dim}$ NKs.[4] More recently, single-cell RNAseq profiling has enabled deeper characterization and revealed three novel subtypes: cytokine-induced memory-like (CIML), adaptive, low ribosomal, and type I IFN responding NKs, which enhanced the previously known $CD56^{bright}$, $CD56^{dim}$, and $CD56^{dim}$ $CD57^{+}$ subtypes.[5] Here, we extend this single cell subtyping by building a cancer-focused NK cell Atlas that integrates 25 public datasets from multiple types of cancers and delineates both the subtypes and states of the NK cells.

Methods Single cell sequencing datasets were downloaded from the studies listed in [table 1]. NK cells were identified using the HaiTam cell type prediction algorithm v1.[6] Harmony v0.1.0[7] was used for batch correction and ACTIONet v3.0.0[8] was used for data integration and cell state identification. Cell state abundance comparisons were performed using 1-way ANOVA with Dunnett's post hoc test.

Results We generated an Atlas of 89,704 NK cells from 281 donors in 21 cancer focused studies, 3 studies using healthy donors, and 1 study of ulcerative colitis [table 1]. We identified 12 unique NK cellular states in our Atlas [figure 1]. Some states recapitulated known NK subtypes such as CIMLs and type 1 IFN responders. By contrast, $CD56^{dim}$ NKs were represented by 2 cellular states and $CD56^{bright}$ NKs were represented by 3 states. We found that one of these $CD56^{bright}$ states is more abundant in blood from renal cell cancer patients than in blood from healthy donors (2.1-fold change; $p < 0.02$). Compared to other $CD56^{bright}$ states, this overrepresented state expresses higher levels of the cytotoxic gene *GZMK* and of migratory markers *CD44*, *CXCR3* and *SELL*.

Conclusions Our Atlas describes 12 NK cell states reflecting maturation, activation, and exhaustion in cancer. These states provide a framework for assessing co-expression of targets for NK modulators and for understanding the effects of treatments on NK cells.

1011 ANTIBODY TARGETING NKG2D LIGANDS MICA/B TO UNLEASH ANTI-TUMOR IMMUNITY OF NK AND ILC1 CELLS

[1]Sizhe Liu*, [1]Tyler Smith, [2]Lisha Zhu, [3]Payal Dhar, [1]Jennifer Wu. *[1]Northwestern University, Chicago, IL, United States; [2]Univeristy of Chicago, Chicago, IL, United States; [3]Northwestern University (*currently affiliated with BMS), Chicago, IL, United States*

Background Natural Killer (NK) cells, the founding member of innate lymphoid cells (ILCs), contribute to tumor control via direct cytolysis and secretion of immune-modulatory cytokines and chemokines. Despite well-characterized roles of NK cells, the involvement of other ILC family members in cancer is less understood. Recent reports indicate that solid tumors are populated by heterogenous ILC subsets.[1] The implication of such heterogeneity for anti-tumor immunity is not entirely clear.

MICA/B serve as ligands for the activating receptor NKG2D on NK and CD8+ T cells. Yet tumor-shed soluble MICA/B are shown to mediate immune suppression via multiple mechanisms.[2] We designed a MIC-targeting antibody B10G5 which was shown to enhance anti-tumor immunity of NK and CD8+ T cells in a murine prostate cancer model recapitulating MIC shedding (TRAMP/MICB).[3,4] In this study we performed single-cell characterization of intra-tumoral ILCs from untreated and B10G5-treated TRAMP/MICB mice (figure 1) to better understand the effects of B10G5 on tumor immune contexture.

Methods We performed single-cell RNA sequencing of CD45+ immune cells from pooled tumors of TRAMP/MICB mice. The samples represent well-differentiated tumors of untreated mice (n = 7), poorly-differentiated tumors of untreated mice (n= 4), and tumors of B10G5-treated mice (n= 3) respectively. CD3-NK1.1+ cells were further sub-clustered into NK and ILC1 subsets, denoted based on their phenotypical and functional profiles. We also measured cytotoxicity of PBMCs from healthy donors stimulated with MIC/B10G5 complexes *in vitro* using calcein release assay.[5]

Results TRAMP/MICB tumors were infiltrated by functionally heterogenous NK and ILC1 subsets. The subsets exhibited distinct expression of genes related with cytotoxicity (*GZMB, PFR1, TNFSF10*) and immunomodulation (*IFNg, XCL1, CCL5*), suggesting their capacity to engage in both cytotoxicity and immune modulation via diverse pathways. Notably, NK cells had higher perforin (*PFR1*) expression, whilst ILC1s exclusively expressed the death ligand TRAIL (*TNSF10*). B10G5 treatment led to NK enrichment and increased heterogeneity of type I ILCs. Lastly, we showed that sMIC/B10G5 complexes enhanced cytotoxicity of PBMCs from healthy donors against tumor cells *in vitro*.

Conclusions Our data elucidated the functional heterogeneity of type I ILCs in prostate tumor microenvironment in a murine model, which has not been previously characterized. Moreover, we showed that targeting MIC with B10G5 could increase heterogeneity of type I innate lymphoid cells *in vivo*, which potentially contribute to better overall anti-tumor responses.

1012 FIBROBLAST ACTIVATION PROTEIN REGULATES HUMAN NATURAL KILLER CELL MIGRATION

[1]Rachael Maynard*, [1]Allison Fitzgerald, [1]Apsra Nasir, [1]Eric Glasgow, [1]Sandra Jablonski, [2]Pieter Van Der Veken, [1]Gray Pearson, [3]Emily Mace, [1]Louis Weiner. *[1]Georgetown University Medical Center, Washington, DC, United States; [2]University of Antwerp, Wilrijk, Belgium; [3]Columbia University Irving Medical Center, New York, NY, United States*

Background Natural killer (NK) cells play a crucial role in both physiologic and pathologic conditions, including cancer. A number of strategies have been employed to utilize the cytolytic properties of NK cells in the treatment of cancer.[1,2] One hurdle to the efficacy of NK-cell based therapy is NK cell infiltration into tumors. [3] The mechanisms NK cells employ for physical migration are not well described.[4,5] We recently found that fibroblast activation protein (FAP) is expressed by human NK cells. FAP is a type-II transmembrane serine protease previously thought to primarily be expressed in reactive stromal fibroblasts. FAP plays a role in tissue remodeling and extracellular matrix digestion to facilitate cell migration.[6]

Methods FAP expression was examined on NK cells by both western blot and immunofluorescence. Compound 60 (CDP60) was used as a specific pharmacological inhibitor of FAP in these assays.

Results We have confirmed that fibroblast activation protein (FAP) is expressed by human NK cells, using both western blot and immunofluorescence. To examine the role of FAP in NK cells we find that following inhibition of FAP activity, NK cells demonstrate decreased migration in 3D culture systems, as well as decreased extravasation from the blood vessels of zebrafish.

Conclusions Future studies include generating an FAP knock-out NK cell line to verify the role of FAP in NK cells identified using CPD60. These findings suggest that FAP is responsible for NK cell migration and may provide a potential novel mechanism to regulate this process. This role in migration can potentially be exploited to enhance NK cell migration into tumors.

1013 PROGNOSTIC VALUE OF NATURAL KILLER CELL ACTIVITY AND DERIVED NEUTROPHILS-TO-LYMPHOCYTES RATIO IN NON-SMALL CELL LUNG CANCER PATIENTS RECEIVING IMMUNE CHECKPOINT INHIBITORS

Line Nederby*, Sara Wen, Christa Nyhus, Lisbeth Bertelsen, Rikke Andersen, Anders Jakobsen, Torben Hansen. *Vejle Hospital, University Hospital of Southern Denmark, Vejle, Denmark*

Background Even though immune checkpoint inhibitors have improved the survival of non-small cell lung cancer (NSCLC) patients, their prognosis is still poor. Natural Killer (NK) cells are lymphocytes with distinct anti-cancer properties, and NK cell activity (NKA) may have a prognostic role. Similarly, derived Neutrophils-to-lymphocyte ratio (dNLR) has been suggested as a prognostic biomarker in cancer patients.

Methods Patients with advanced or recurrent NSCLC eligible for anti-PD-1/PD-L1 treatment were enrolled at the Department of Oncology, Vejle Hospital, Denmark. Blood was sampled at baseline and immediately before the following three cycles of therapy. Interferon gamma (IFNγ) as a surrogate for NKA was measured using the NK Vue® assay (NKMAX, Seongnam-si, South Korea). Normal levels of IFNγ were considered as >250 pg/mL. Neutrophils and leukocytes were quantified by XN-9000 (Sysmex, Kobe, Japan). dNLR was calculated as (neutrophils/(leukocytes-neutrophils)) and dNLR<3 was considered normal. The study was approved by the Regional Committee on Health Research Ethics for Southern Denmark, approval number S-20170063.

Results Baseline level of NKA had no prognostic impact for overall survival (OS) (p=0.1279, NKA-normal n=45 vs NKA-low n=27, logrank). Longitudinal sampling allowed us to determine if dynamics in NKA were of prognostic value. For this purpose, patients were grouped as follows: NKA-low group had NKA <250 pg/mL at all available time-points (n=13), NKA-mixed group had NKA of varying levels (n=34), and NKA-high group had NKA >250 pg/mL at all available time-points (n=29). A logrank test revealed a significant difference between the groups in terms of OS (p=0.0002). Compared to the NKA-high group, the NKA-low group had a poor prognosis with a hazard ratio (HR) of 3.690 (p=0.001). After adjusting for dNLR, histology and performance status it remained an independent prognostic factor (HR=3.581, p=0.005). Interestingly, while dNLR also had prognostic impact for overall survival (OS) (p=0.0274, dNLR<3 n=57 and dNLR>3 n=18, logrank) and dNLR>3 was a prognostic marker for poor OS in univariate analysis (HR=1.908, p=0.03), this was lost in multivariate analysis taking NKA, histology, and performance status into account (HR=1.364, p=0.451).

Conclusions NKA dynamics, and not dNLR, was an independent prognostic marker for OS in NSCLC patients receiving anti-PD-1/PD-L1 treatment. These findings highlight the value of not restricting biomarker evaluation to immune cell enumeration, but rather looking at the ability of these cells to carry out vital immune functions.

Ethics Approval The study was approved by the Regional Committee on Health Research Ethics for Southern Denmark, approval number S-20170063. All participants provided written informed consent.

1014 COMPLEMENT C3 DEFICIENCY INCREASES THE ANTI-TUMOR IMMUNITY OF NK CELLS AND CONTROLS TUMOR GROWTH

Girdhari Lal, Pradipta Pal*, Sourav Paul, Heikrujam Thoihen Meitei, Praneet Wahi, Arvind Sahu. *National Centre for Cell Science, Pune, India*

Background Natural killer cells play an important role in controlling tumor growth. On the other hand, the complement system is known for its protective function in infection and for maintaining cellular homeostasis. It is reported that the complement system promotes tumor growth and metastasis. However, the role of complement and its importance in the anti-tumor function of NK cells is not clearly understood.

Methods Mouse melanoma cell B16F10 was subcutaneously injected in C57BL/6 mice or $C3^{-/-}$ mice, and the growth of the tumor was monitored. The cellular phenotyping of immune cells in the tumor and secondary lymphoid tissues were analyzed using flow cytometry.

Results The transplantation of B16F10 cells in the $C3^{-/-}$ mice showed a significantly reduced tumor growth compared to wild-type mice. Immunohistological analysis of tumor showed increased infiltration of NK cells and CD8 T cells in the $C3^{-/-}$ mice as compared to $C3^{+/+}$ mice. Under the homeostatic condition, analysis of spleen and lymph nodes of $C3^{-/-}$ and $C3^{+/+}$ mice did not show any change in either the frequency or the absolute number of total CD4 T cells, CD8 T cells, NK cells, and NKT cells. However, $CD4^+$ T cells and $CD8^+$ T cells from $C3^{-/-}$ mice secreted significantly higher IFN-g than $C3^{+/+}$ mice and the splenic NK cells from $C3^{-/-}$ mice showed a significantly increased cytotoxic activity compared to $C3^{+/+}$ mice. Further, hepatic NK cells in the $C3^{-/-}$ mice showed significantly lower NKG2A inhibitory receptors, resulting in reduced NKG2D to NKG2A ratio (activating/inhibitory ratio) of molecules per NK cell compared to wild-type NK cells. As expected, NK cells isolated from tumor-bearing $C3^{-/-}$ mice showed a robust cytotoxic activity compared to the tumor-bearing $C3^{+/+}$ mice. Interestingly, $C3^{-/-}$ NK cells showed increased secretion of pro-inflammatory cytokines such as GM-CSF and IFN-g when re-stimulated with IL-2, IL-15, or IL-18 compared to $C3^{+/+}$ NK cells. Depleting NK cells in $C3^{-/-}$ mice with anti-NK1.1 mAb significantly prevented the reduction of tumor growth as compared to isotype control IgG mAb.

Conclusions Our data suggest that complement C3 deficiency alters the effector and cytotoxic function of NK cells, and thereby deficiency of C3 promotes anti-tumor immunity and controls tumor growth. Our data suggest that interfering with the complement system gives a new therapeutic advantage in controlling tumor growth.

1015 NATURAL KILLER CELLS IN IMMUNOTHERAPY-INDUCED MHC-I TUMOR ESCAPE

Eric Miao, Jennifer Poursine-Laurent, Kathleen Sheehan, Robert Schreiber, Wayne Yokoyama, Sytse Piersma*. *Washington University in St. Louis, St Louis, MO, United States*

Background Cancer immunotherapy including immune checkpoint blockade (ICB) has been successful in inducing durable responses in a variety of cancers. However, a proportion of patients who receive ICB undergo tumor relapse, putatively as result of tumor escape. A potential tumor escape mechanism is mutation of the antigen processing and presentation pathway, resulting in decreased surface major histocompatibility complex class I (MHC-I) levels. These escaped tumor cells then become invisible to CD8 T cells, which are central in the anti-tumor immune response to ICB therapy. Indeed, this type of tumor escape has been observed in relapsed patients in longitudinal studies in which mutations in *B2M* (encoding b_2-microglobulin), an essential component of classical and non-classical MHC-I, have been detected. As a result, *B2M*-deficient tumor cells lack cell surface MHC-I expression that should result in activating natural killer (NK) cells through a mechanism termed "missing-self". Yet, the NK cell response does not appear to be strong enough to clear escaped tumor cells in all patients, as mutations in the antigen processing and presentation machinery are detected in relapsed patients. It is unclear why NK cells are unable to eliminate escaped MHC-I-deficient tumors and whether NK cells can be harnessed to prevent emergence of these escaped tumors.

Methods To address these prominent questions, we developed a methylcholanthrene-induced mouse tumor model in which *B2m* loss can be induced with tamoxifen. The selected *B2m* inducible knockout tumor (named BIKOT) lines were validated to lose surface MHC-I in response to tamoxifen administration by oral gavage in vivo.

Results To investigate MHC-I escape in the context of ICB therapy, we treated BIKOT-challenged mice with anti-PD1 and anti-CTLA4. Consistent with established MCA tumor models, tumors grew out progressively in untreated mice, while tumors in ICB-treated mice initially grew out after which they regressed until completely receded. The combination of sub-optimal tamoxifen administration with ICB resulted in initial control of tumor outgrowth, which was followed by progressive outgrowth between week 2-3 in a proportion of animals suggesting immune escape. Indeed, relapsed tumors displayed loss of surface MHC-I.

Conclusions Taken together these preliminary data strongly suggest that the novel inducible MHC-I-deficient tumors are uniquely suited to investigate how tumors can escape T-cell recognition in face of a functional NK cell response, and furthermore provide a platform for development of NK cell-targeting therapeutics that aim to prevent tumor immune escape.

1016 IL-2 EXPANDED TUMOR INFILTRATED NATURAL KILLER (TINK) CELLS FROM CANINE SARCOMAS POSSESS POTENT ANTI-TUMOR CYTOTOXICITY

[1]Weiqing Jing*, [1]Himaly Shinglot, [1]Juliana Chi Kei Ng, [1]Ali Zhang, [2]Bernard Seguin, [3]Jeffrey Bryan, [4]Timothy Fan, [5]Jennifer Wu, [1]Seth Pollack. *[1]Northwestern Medicine, Chicago, IL, United States; [2]Colorado State University, Fort Collins, CO, United States; [3]University of Missouri, Columbia, MO, United States; [4]University of Illinois at Urbana-Champaign, Urbana, IL, United States; [5]Northwestern University, Chicago, IL, United States*

Background Tumor infiltrating NK (TINK) cells are present and linked to prognosis in many solid tumors.[1] While these cells may have potent antitumor effector function, they are thought to be dysfunctional in the tumor microenvironment (TME).[2] Because it is difficult to culture potent TINKs from human tumors, relatively little is known about their interactions with various TME components or their potential for therapeutic applications. Here we report reproducible culture of highly potent TINKs from naturally occurring canine sarcomas for use in modeling the human TME.

Methods Canine sarcoma tumor specimens were cut into fragments and cultured individually in 24-well plates with medium supplemented with 6000 IU/ml of rhIL-2. Expanded wells were maintained separately and autologous tumors were cultured separately. Expanded TINKs and TILs were characterized by flow cytometry and co-cultured with autologous and allogeneic tumor cells at a E:T ratio of 5:1; cytotoxicity of TILs was monitored by tumor confluence in the Incucyte system.

Results Ninety-six individual fragments were derived from soft tissue sarcomas (STS) and 120 fragments were derived from osteosarcoma. 88 (92%) of fragments from STS tumors and 23(19%) from Osteosarcoma were expanded sufficiently for additional analysis. While most TINKs and TILs were able to kill autologous tumor and resulted in increased Granzyme B expression, we surprisingly found that the number of TINKs (NKp46+) was positively corelated with tumor killing, with pure cultures of NKp46+ cells resulting in complete and efficient tumor elimination. Furthermore, the percentage of CD5 + T cells was negatively corelated with tumor killing. By flow cytometry, we found that NKp46+ TINKs were CD5(dim) TCRαβ− TCRγδ− CD4− B220- CD1d-, with some NKp46+ subpopulations co-expressing CD3 or CD8. Compared with the less potent TIL cultures composed of mainly CD5+ T cells, NKp46+ TINKs secreted significantly higher T1 cytokines (IFN-γ, TNF-α and GM-CSF) after co-cultured with tumor. Tumor stimulation preferentially activated the secretion of TNF-α over IFN-γ from TINKs, with concentration levels of TNF-α about 20 folds higher than IFN-γ, suggesting impotent role of TNF-α in TINK mediated tumor killing.

Conclusions Our results demonstrated that functional TINKs can be efficiently expanded from canine sarcoma tumor tissue with little NK cell infiltration seen by immunohistochemistry. Future studies using canine TINKs will explore therapeutic potential for targeting, manipulating, and transferring these cells in human.

1017 **A TUMOR MODEL IN THE HUMANIZED IMMUNO-RECONSTITUTED HIL15 TRANSGENIC MICE REVEALED THE IMPACT OF OTHER IMMUNE COMPONENTS ON THE DEVELOPMENT AND FUNCTION OF NK CELLS AGAINST MALIGNANCIES**

Li Yang*, Chunlei Dai, Hongmei Xu, Hui Qi, Xuzhen Tang, Qingyang Gu, Qunsheng Ji.
WuXi AppTec, Shanghai, China

Background The roles of natural killer (NK) cells, in the process of immunosurveillance and elimination against malignancies, have been increasingly interesting in the space of immuno-oncology. The utilization of humanized mice, reconstituted with human immune cells, improves the translational relevance of animal models in this field. However, it remains a challenge for the effective reconstitution of human NK cells in mice, due to the lack of human cytokines which are essential for the development of NK. Typically, IL-15 humanization could promote the differentiation, function, and survival of NK in such models. Nevertheless, few studies have been conducted to evaluate the impact of IL-15 humanization on a wider range of human immune cell lineages in a comprehensively immuno-reconstituted system.

Methods To understand this, we conducted a study comparing the reconstitution of human NK alone or in a mixture with the autologous PBMC, in the hIL-15-expressing NOD-scid IL2Rg null mice. NCI-H929 human myeloma was established in each mouse, for the evaluation of anti-tumor efficacy by the immunotherapies targeting NK-mediated cell killing. The frequencies of human immune cells in both the circulation and the tumor microenvironment were evaluated by flow cytometry.

Results As a result, the mixed system of NK/PBMC reconstitution achieved a better reconstitution rate of NK cells compared to the NK-alone system. But the anti-tumor efficacy by anti-CD47 or anti-CD38, in contrast to the higher NK frequency, appeared to be poorer in the NK/PBMC-mixed system. To investigate the underlying mechanism, we analyzed the phenotyping of each immune sub-lineages and found an extremely high frequency of hCD4+ cell in the NK/PBMC mixed system.

Conclusions One possible reason for the inversion between NK frequency and drug efficacy might be the enrichment of hCD4+ sub-lineages including Treg, which were promoted by IL-15, suppressed the NK effector function, and compromised the relevant immuno-therapy. Further studies could be suggested including a deeper look into the phenotyping of TILs, combining with a Treg targeting therapy like anti-CTLA4, and studying the mechanism of interaction between Treg and NK. In summary, given the complexity with the function of various immune components co-existing in the system, an appropriate method of immune reconstitution is critical for the evaluation of cancer immuno-therapies utilizing humanized models.

1018 MULTIFUNCTIONAL NATURAL KILLER CELL ENGAGER RELEASING CXCL10 AUGMENTS NATURAL KILLER CELL RECRUITMENT AND ANTI-TUMOR EFFICACY AGAINST GLIOBLASTOMA

Xue Yao*, Sandro Matosevic. *Purdue University, Lafayette, IN, United States*

Background The effectiveness of natural killer (NK) cell-based immunotherapy against solid tumors is limited by the inadequate infiltration of NK cells into the tumors and the heterogeneous immunosuppressive tumor microenvironment (TME), suggesting that a multi-specificity of targeting mechanisms is needed to achieve durable responses.

Methods We isolated and phenotyped tumor-infiltrating NK cells and peripheral blood (PB) NK cells from glioblastoma multiforme (GBM) patients for the expression of chemokine receptor CXCR3. The effect of exogenous CXCL10 on NK cell migration and functions was also established. We further investigated the regulation of the CXCR3-CXCL10 axis on NK cells and tumor cells by establishing CXCR3-knockdown primary NK cells and CXCL10-overexpressing GBM cells. Based on these findings, we designed and synthesized a novel natural killer cell engager (NKCE), which not only targets NKp46 on NK cells and IL13Ra2 on tumor cells but also specifically releases CXCL10 at the tumor sites while sustaining NK cell activation via interleukin (IL)-15.

Results CXCR3 was highly expressed on NK cells in PB from either GBM patients or healthy donors. Although low numbers of tumor-infiltrating NK cells in patients were observed, CXCR3 expression was up-regulated on these cells. CXCL10 induced NK cell migration via CXCR3 but did not affect NK cell functions. Simultaneously, CXCL10 overexpression showed no effect on tumor growth but resulted in enhanced NK cell migration into tumor sites and, in turn, improved the anti-tumor activity of NK cells. Furthermore, our novel NKCE activated NK cells by binding NKp46 and recognized GBM tumor cells via IL13Ra2, thus promoting the contact between NK cells and tumor cells. The engager's CXCL10-releasing domain, which is activated in the local TME, promotes the specific increase in CXCL10 concentration and, in turn, NK cell homing in the TME.

Conclusions The CXCR3-CXCL10 axis contributes to the recruitment of NK cells to GBM. Our novel NKCE within a locally-cleavable CXCL10 domain induced NK cell migration and boosted NK cell anti-tumor activity against solid tumors. Such a multi-specific approach not only activates NK cells locally but promotes their recruitment and retention in the TME.

1019 CSF1R^{+}PD-L1^{+} TUMOR-ASSOCIATED MACROPHAGES TRIGGER MAIT CELL DYSFUNCTION AT THE HCC INVASIVE MARGIN

[1]Benjamin Ruf*, [2]Matthias Bruhns, [2]Sepideh Babaei, [1]Noemi Kedei, [1]Chi Ma, [1]Lichun Ma, [1]Mahler Revsine, [1]Bernd Heinrich, [1]Varun Subramanyam, [1]Jonathan Qi, [1]Simon Wabitsch, [1]Benjamin Green, [1]Kylynda Bauer, [1]Yuta Myojin, [1]Mohamed-Reda Benmebarek, [1]Layla Greten, [1]Justin McCallen, [1]Patrick Huang, [1]Marie Pouzolles, [1]David Kleiner, [1]William Telford, [1]Kimia Dadkhah, [1]Allison Ruchinskas, [1]Merrill Stoffroff, [3]Jiman Kang, [3]Kesha Oza, [4]Mathuros Ruchirawat, [3]Alexander Kroemer, [1]Xin Wang, [2]Manfred Claassen, [1]Firouzeh Korangy, [1]Tim Greten. *[1]National Institutes of Health (NIH), Bethesda, MD, United States; [2]University Hospital Tübingen, Tübingen, Germany; [3]MedStar Georgetown University Hospital, Washington, DC, United States; [4]Chulabhorn Research Institute, Bangkok, Thailand*

Background Hepatocellular Carcinoma (HCC) is considered a prototype of inflammation-derived cancer arising from chronic liver injury. The cellular composition of the HCC tumor immune microenvironment (TiME) has a major impact on cancer biology as the TiME influences tumor initiation, progress, and response to therapy. Mucosal-associated invariant T (MAIT) cells can represent the most abundant T cell subtype in the human liver and are assigned crucial roles in regulating immunity and inflammation in the context of infection, albeit their role in HCC remains elusive.

Methods Study design is displayed in figure 1. High-dimensional flow cytometry (n=37) and scRNA sequencing (n=8) was used to analyze MAIT cell phenotypic changes in patient tissue samples. Highly-multiplexed immunofluorescence microscopy was used to quantify immune cell infiltration in paired human HCC samples. We developed and validated a 37-plex antibody panel and applied CODEX technology to simultaneously profile in situ expression of 37 proteins at sub-cellular resolution in n=15 HCC patient samples using whole slide scanning. We established an image analysis pipeline using a machine learning (ML) algorithm (S^{3}-CIMA) to quantify the MAIT cell interaction network at the HCC invasive front. Murine models of orthotopic HCC using transgenic mouse strains were used for *in vivo* validation, a co-culture system using sorted MAITs from primary human liver cancer tissue was established to gain further mechanistic insight.

Results Hepatic MAIT cells in n=37 patient samples are characterized by impaired infiltration ($p<0.001$) into tumor lesions, increasing dysfunction (e.g. upregulation of PD-1 ($p<0.05$) & reduced IFN-γ ($p<0.01$) within the HCC TiME and show previously underappreciated heterogeneity as seen by scRNA-seq. CODEX imaging revealed the distinct cellular composition of the MAIT neighborhood in human HCC tissue. This allowed for in-depth characterization of cellular interaction networks underlying the MAIT cell dysfunction in HCC. S^{3}-CIMA, a novel ML method, to analyze our spatially resolved immune cell atlas of human liver cancer identified interactions of CSF1R^{+}PD-L1^{+} tumor-associated macrophages (TAMs) and MAIT cells localized in the adjacent (non-tumor) liver as key regulatory elements of MAIT cell dysfunction. Finally, perturbation of this detrimental cell-cell interaction using PD-L1 and CSF1R blocking strategies or depletion of TAMs using *Lysm^{Cre} x Csf1r$^{LsL\text{-}DTR}$* transgenic mice increased MAIT cell infiltration ($p<0.05$) into murine HCC lesions and reinvigorated the cytotoxic MAIT cell phenotype ($p<0.01$).

Conclusions This work provides evidence that MAIT antitumor immunity and response to ICB therapies relies on organized, spatially nuanced interactions between MAITs and PD-L1 +CSF1R+ TAMs within the tumor immune microenvironment.

1020 TARGETING TIM-3 ON T REGULATORY CELLS MAKE NONRESPONSIVE COLD MELANOMA, MORE RESPONSIVE TO IMMUNE MEDIATED TUMOR CONTROL

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1020

[1]Hridesh Banerjee*, [2]Hector Rosado, [1]Benjamin Murter, [1]Lawrence Kane. *[1]University of Pittsburgh, Pittsburgh, PA, United States*; *[2]UPMC Medical School, Pittsburgh, PA, United States*

Background Cold Tumor mouse model study are useful, as a few category of human tumor in breast, brain, prostate, pancreas and ovary are Cold and resistant to Immune checkpoint inhibitors (ICIs) based therapeutic treatments. one of the widely studied model in mouse for cold tumor is B16F10 melanoma, and this model is known to be non-responsive to checkpoint inhibitor therapy. while T regulatory cells have been known to play a major role in cancer immunosupression, targeting T reg cells directly has been a challenge, due to their role in immune homeostasis. we use TIM-3 expressing Tregulatory cells as a significant proportion of Treg cells in various mouse and human tumor model are known to be expressing TIM-3 and this expression is far restricted to the site of Tumor.[1-4]

Methods C57BL 6 mice were injected with Tumor cells subcutaneously, followed by tracking of Size of tumors and also immuno typing of tumor and lymphoid organ. for Treg specific targeting TIM-3 conditional Knockout mouse were generated and Bred to FoxP3 ERT2 Cre model to induce time dependent knocking out of T regulatory cellTIM-3. efficiency of Knock out in various organ and tumor was confirmed by Flow cytometry.

Results MC38(immune responsive) and B16F10(non immune responsive), tumors are both delayed in progression of tumor when Treg cells are incapable of inducing TIM-3.

Frequency of Tregulatory cells goes down in tumors of TIM-3 conditional knockout mouse.

CD8 exhaustion kinetics in TIM-3 Knockout mouse is delayed and knockout mouse survive longer after tumor induction.

Delay in B16F10 melanoma may be a indicative of better immune response in TIM-3 Knockout mice.

Conclusions Targeting TIM-3 in Combination therapy, with their Role in Treg specificity may be a viable and effective strategy. Inability of Treg cells to persist in tumors in absence of TIM-3, indicate to the fact that TIM-3 may be playing a role in survival of Treg cells in tumor microenvironment, and a possibility of role of TIM-3 in T reg cells traffic in tumors can also be not ruled out.

surprisingly along with our previously published Data on MC38 where we have shown that T cell exhaustion kinetics gets delayed , we see the same trend in cold tumor model, B16 F10. suggestive of a possibility of these tumor being more responsive to immune therapy.

1021 A PAN-CANCER SIGNATURE IDENTIFIES TUMOR-REACTING CD8+ TILS AND REVEALS THEIR FUNCTIONAL HETEROGENEITY

[1]Christopher Chamberlain*, [1]Arianna Draghi, [1]Shawez Khan, [2]Katja Harbst, [1]Mario Presti, [1]Aimilia Schina, [1]Agnete Witness Præst Jensen, [1]Anne-Christine Kiel Rasmussen, [1]Torben Lorentzen, [1]Jakob Vasehus Schou, [2]Göran Jönsson, [1]Inge Svane, [1]Marco Donia. [1]*Copenhagen University Hospital, Herlev, Denmark*; [2]*Lund University, Lund, Sweden*

Background Identification of $CD8^+$ tumor-reactive tumor-infiltrating lymphocytes (TILs) is a key focus for understanding TIL:tumor interactions in the tumor microenvironment and improving adoptive cell therapies. Current methods concentrate on the detection of TILs endowed with tumor-specific T cell receptors (TCRs) and largely overlook their functional profiles. In addition, analyses of actively tumor-reacting TIL function are often analyte limited and may not reflect the heterogeneity of TIL responses to stimulation. Therefore, we set out to identify tumor-reacting $CD8^+$ TILs and thoroughly characterize their functional profiles at the single-cell level pan-cancer.

Methods Minimally *in vitro* cultured TILs and matching autologous tumor cell lines (TCLs) were derived from metastatic melanoma (n=6), renal cell carcinoma (n=3), sarcoma (n=2), colorectal cancer (n=1), and ovarian cancer (n=1) patient samples. Bulk TILs were cocultured with their wildtype or a major histocompatibility complex I and II deficient control TCL, sorted for $CD8^+$ (fluorescence-activated cell sorting), and then underwent single-cell RNA sequencing (scRNAseq, 10xGenomics 5' v2/3' v3.1) to form a discovery dataset. Publicly available scRNAseq datasets (n=25, 12 histologies) of fresh tumor biopsies were obtained from online databases (Gene Expression Omnibus, Genome Sequence Archive, European Genome-phenome Archive) or the authors directly and merged into a singular validation dataset. Cell Ranger and Seurat were used for data processing and analysis.

Results Distinct clusters of tumor-reacting $CD8^+$ TILs could be easily bioinformatically identified using known reactivity markers. A tumor-reacting CD8+ TIL signature (TR8S) derived via comparison to non-reacting cells clearly differentiated tumor-reacting and non-reacting $CD8^+$ bulk TILs for all samples and histologies. Deeper characterization of $TR8S^{hi}$ cells revealed diverse sub-populations with distinct and heterogeneous functional profiles, many of which could be re-identified in the validation dataset. In particular, an $XCL1^{hi}XCL2^{hi}$ cluster and a separate $CCL3^{hi}CCL4^{hi}$ cluster dominated the reacting population. The majority of tumor-reacting $CD8^+$ TIL sub-populations were shared across tumor histologies.

Conclusions Our results indicate that the TR8S is an effective pan-cancer tool for identifying and characterizing actively tumor-reacting $CD8^+$ TILs. Furthermore, our data highlight the complexity of the actively tumor-reacting $CD8^+$ TIL population and that deeper investigation of their functional abilities is warranted. Specifically, the prevalence of distinct clusters may have predictive/prognostic strength and could direct future immunotherapies.

1022 TUMOR-INFILTRATING CXCR6-EXPRESSING TISSUE-RESIDENT MEMORY HPV-SPECIFIC CD8$^+$ T CELLS ARE TERMINALLY EXHAUSTED IN HPV-ASSOCIATED HEAD AND NECK SQUAMOUS CELL CARCINOMA

Yang Cheng*, Kathleen Atkinson, Talia Saal, Jean Campbell, Sara Pai. *Massachusetts General Hospital, Boston, MA, United States*

Background Tissue-resident memory T cells (T_{RM}) are important for controlling both infection and tumor growth. We performed comprehensive immunophenotyping of HPV-specific and non-HPV-specific viral bystander (EBV, CMV, IAV, and SARS2-CoV2) CD8$^+$ T_{RM} cells in HPV-associated HNSCCs.

Methods We assessed HPV-specific and non-HPV-specific viral bystander CD8+ T cell frequency and functional states in the primary tumor, tumor-involved lymph node (LN), and peripheral blood mononuclear cells (PBMC) from 34 HPV-associated HNSCC patients. CD8$^+$ T cells were isolated and probed by 89 different pMHC tetramers across three HLA alleles (A*02:01, A*01:01 and A*24:02) using multiplexed combinatorial peptide-MHC (pMHC) tetramer staining and spectral flow cytometry. To interrogate HPV-specific responses, we analyzed 61 HPV16 E6 and E7 epitopes. To compare non-HPV bystander virus-specific T cells, we investigated 11 bystander virus (EBV, CMV and IAV) and 17 SARS2-CoV-2 (spike protein) epitopes. Tetramer$^+$ CD8$^+$ T cells were immunophenotyped by co-staining 20 cellular markers to probe T cell exhaustion and tissue resident phenotypes.

Results 76.4% (26 of 34) of HPV-associated HNSCCs had detectable HPV-specific T cells within their tissue and 82% (28 of 34) had bystander virus-specific T cells. Overall, we identified 26 HPV- (10 HPV16-E6 and 16 HPV16-E7), 11 bystander (non-HPV) virus-, and 8 SARS-CoV-2 spike-specific CD8$^+$ T cell populations. We observed a broader HPV epitope repertoire within LN and PBMC as compared to tumors. However, the frequency of HPV-specific T cells infiltrating the tumor was significantly higher compared to the LN and PBMC. Within the tumor, 13 HPV- (6 HPV16-E6 and 7 HPV16-E7), 6 bystander (non-HPV) virus-, and 3 SARS-CoV-2 spike-specific CD8$^+$ T cell populations were identified. The frequency of tumor-infiltrating HPV-specific T cells ranged from 0.02-3.01% for E6, 0.013-10.9% for E7, 0.013-1.93% for bystander (non-HPV) virus-specific T cells, and 0.014-11.5% for SARS-CoV-2 spike-specific T cells. High-dimensional analysis identified four distinct T_{RM} subsets. Tumor-infiltrating HPV-specific T cells were enriched for two CXCR6$^+$ T_{RM} subsets that were also PD-1^{hi}TIM-3$^+$, suggesting they were terminal exhausted. In contrast, tumor- and LN-infiltrating bystander non-HPV-specific T cells were CXCR5$^+$PD-1^{int} T_{RM} and not exhausted.

Conclusions We report a high frequency of HPV and bystander viral epitopes within HPV-associated HNSCCs, and identified two distinct CXCR6$^+$ terminal exhausted HPV-specific T_{RM} subsets within the tumor. Spatial localization of these two distinct CXCR6$^+$ terminally exhausted T_{RM} to myeloid populations in the primary tumor and tumor draining lymph nodes are ongoing to better understand tumor-specific T cell priming within these two sites.

1023 THE SIGNAL STRENGTH OF SIGNAL 2 AND 3 DURING T CELL PRIMING AFFECT THE FUNCTIONAL FATE OF AN ANTI-TUMOR T CELL RESPONSE

Duncan Morgan, Vidit Bhandarkar, Emi Lutz, K Wittrup, Stefani Spranger, Teresa Dinter*.
Massachusetts Institute of Technology, Cambridge, MA, United States

Background Fate decision in $CD8^+$ T cells refers to the process of differentiation that occurs when a naïve T cell enters into effector, memory, exhausted, or other states. Multiple models of fate decision have been proposed, but the exact determinants of T cell fate are unknown. Evidence in LCMV and cancer models support the notion that signals during T cell priming are especially important in deciding T cell fate and that fate decisions are made early in the priming process. Priming interactions are highly complex, requiring the integration of multiple signals. Each of these signals can vary in strength and it is the sum of these signals that decides the T cell response. Thus, it is unsurprising that we currently do not know the combinatorial specificities and molecular underpinnings of priming interactions. Understanding the factors that drive these different fates could be therapeutically harnessed to reduce exhaustion phenotypes and increase effector functions and memory potential of $CD8^+$ T cells in cancer.

Methods We used therapeutic interventions as a tool to alter the signals received by a T cell during priming and characterized the impact on T cell fate. Using a $BRAF^{V600E}PTEN^{-/-}$ melanoma cell line that expresses the SIYRYYGL (SIY) model antigen, we implanted tumors and provided therapy during priming. We surveyed the effects of checkpoint blockade therapy (anti-PD1 and anti-CTLA4), costimulatory agonists (anti-CD40 and anti-41BB), and Type-I Interferon (IFNa and IFNb) on tumor-reactive $CD8^+$ T cell phenotypes at early timepoints during priming via flow cytometry and single-cell RNA sequencing.

Results All treatments resulted in an increase of effector-like ($TCF1^-TIM3^+$) tumor-reactive T cells. Interestingly however, each intervention induced differential expression of a specific set of transcription factors. For example, expression of Eomes is significantly increased upon IFNb treatment at both protein and RNA level, while it is decreased in T cells exposed to agonistic anti-CD40. Analysis of single-cell RNA sequencing of tumor-reactive $CD8^+$ T cells revealed unsupervised clustering of cells based on the therapeutic intervention administered during priming. Tumor outgrowth and phenotypic studies at later timepoints indicated that $CD8^+$ T cells primed with therapeutic intervention adopt different cell fates.

Conclusions Priming signals are crucial determinants of T cell fate. Changing the signals received by a $CD8^+$ T cell during priming results in an altered phenotypic and transcriptional profile early during priming. These early transcriptional changes appear to generate different $CD8^+$ T cell fates, providing an opportunity to improve anti-tumor immunity in a neoadjuvant setting.

1024 ILLUMINATING STEM MEMORY T CELL (TSCM) HETEROGENEITY IN HUMAN CANCER: CHARACTERIZATION OF A UNIQUE CD45RO+ TSCM POPULATION IN HUMAN OVARIAN CANCER

Erica Brown*, Monika Eiva, Veethika Pandey, Alexander Benton, Stacy Thomas, Wenzhao Meng, Aaron Rosenfeld, Eline Luning Prak, Daniel Powell. *University of Pennsylvania, Philadelphia, PA, United States*

Background Stem memory T cells (Tscm) are a unique T cell subset positioned between naïve and central memory (CM) T cells, that express the surface markers CCR7, CD45RA and CD95, and are CD45RO negative.[1] Tscm cells can self-renew, are multipotent, and appear to be critical for effective antitumor immunity, but little is known about Tscm immunobiology in human tumors.[1-4] Most studies examining canonical Tscm cells are performed using mouse models, expanded tumor-infiltrating lymphocytes (TILs), or peripheral blood T cells, and few studies examine Tscm-like cells directly from human tumors, despite evidence for their crucial role in solid tumor immunotherapeutic treatment.[2-6]

Methods Therefore, we hypothesized that Tscm cells in human ovarian cancer exist and explored Tscm heterogeneity in ovarian cancer tumor digests using flow and mass cytometry. This investigation resulted in the identification of a novel CD45RO + expressing Tscm subset, which was further interrogated using FACS sorted TIL populations to assess self-renewal capabilities and effector function. Additionally, bulk RNA-seq and TCR sequencing were completed on sorted TIL populations to examine the RO+ Tscm subset.

Results Like canonical CD45RO- (RO-) Tscm cells, the RO+ subset can self-renew and is maintained by the homeostatic cytokines IL-7 and IL-15; however, RNA-seq, TCR sequencing, and functional assessment of the RO+ Tscm population position it as a unique subset between RO- Tscm and CM T cell subsets. RNA-seq revealed that RO+ Tscm cells are transcriptionally distinct from other subsets, exhibiting intermediate expression of naïve and effector associated genes. TCR sequencing indicates that the RO+ subset shares a high degree of clones with downstream memory populations and has an intermediate clonality relative to canonical RO- Tscm and CM populations. Notably, our results demonstrate that RO+ Tscm cells exhibit greater effector potential than the RO- Tscm subset, with RO+ Tscm cells producing more IFNγ upon stimulation. These results, paired with the observation that RO+ Tscm cells express CD137, a biomarker of tumor-specificity, more frequently than other differentiation subsets, indicate that this subset may have enhanced anti-tumor capabilities.

Conclusions In conclusion, we (1) demonstrate that a heterogeneous Tscm population exists in human ovarian cancer and (2) identify a distinct RO+ Tscm subset that appears to be transcriptionally, phenotypically, and functionally intermediate between canonical RO- Tscm and CM populations. Importantly, we show that the RO+ Tscm subset is multipotent and exhibits effector-like attributes, making it a desirable target for future research in the setting of cancer immunotherapy.

1025 SINGLE CELL EVALUATION OF COSTIMULATORY AND COINHIBITORY RECEPTORS AND THEIR LIGANDS ACROSS SOLID TUMOR INDICATIONS

Shawn Fahl*, Kerri Colwell, Cavin Ott, Casey Smith, Kayla Williams, Alex Moore. *Discovery Life Sciences, Huntsville, AL, United States*

Background Costimulatory and coinhibitory receptors on T-cells are key mediators of the overall immune response, and the clinical success of checkpoint inhibitor therapies has proven the therapeutic benefits of targeting these pathways. Viable, cryopreserved dissociated tissue provides an opportunity to understand the dynamic expression patterns of these receptor/ligand sets at the single-cell level, providing insights into the differential expression of each receptor/ligand pair across different cancer indications as a means to target new therapeutic interventions.

Methods The study compared expression patterns from two cohorts composed of indications that are clinically approved for checkpoint inhibitor therapy versus indications that are not currently approved for checkpoint therapy. We performed bulk RNA sequencing on both cohorts to understand the global expression of costimulatory and coinhibitory receptors, and their ligands, within the tumor microenvironment. Furthermore, we developed a flow cytometry panel that allows for efficient screening of these receptor/ligand sets on the major cellular subsets (tumor cells, T-cells, B-cells, myeloid cells) within the tumor microenvironment. These data sets were initially evaluated for the expression patterns of PD1/PDL1/PDL2 as the standard for immunomodulatory receptors, and to evaluate the accuracy and sensitivity of the methods for the evaluation of receptor/ligand expression. In addition, we evaluated the expression patterns of two less well-characterized immunomodulatory receptors sets: TIGIT/PVR/PVRL2/CD226 and CD160/HVEM/BTLA/LIGHT to provide new insight into the expression patterns of these potential receptor/ligand sets and to better understand their value as therapeutic targets for specific cancer indications.

Results The protocols developed for this study were able to provide a clear and detailed picture of the receptor-ligand expression patterns across different cancer indications. Consistent with previous reports, PD1 expression was high on T-cell subsets, but low on the other lymphoid subsets within the tumor microenvironment. PDL1, on the other hand, was more differentially expressed on tumor cells across patient samples and was also expressed on myeloid cell populations. The expression patterns for the TGIT and CD160 receptors and their associated ligands demonstrate the distinct differences in expression patterns across cancer indications.

Conclusions Given the varied and distinct expression patterns observed in different cancer indications, it is clear that the successful targeting of immune modulatory therapeutics will require an understanding of the expression of individual receptors and ligands at the single-cell level. This study demonstrates the utility of dissociated tumor cells as a tool to provide detailed insight into, and an understanding of the receptor-ligand expression of different cancer indications.

1027 CHRONIC ANTIGEN IN SOLID TUMORS DRIVES A DISTINCT PROGRAM OF T CELL RESIDENCE

[1]Noah Gavil*, [1]Milcah Scott, [1]Eyob Weyu, [1]Olivia Smith, [1]Stephen O'Flanagan, [1]Sathi Wijeyesinghe, [1]Sahar Lotfi-Emran, [2]Stephen Shiao, [1]Vaiva Vezys, [1]David Masopust. [1]*University of Minnesota, Minneapolis, MN, United States*; [2]*Cedars-Sinai Medical Center, Los Angeles, CA, United States*

Background Resident-memory T cells (T_{RM}) permanently reside in tissues, surveying local environments without recirculating. Surface protein expression (e.g. CD69, CD103) and transcriptional signatures from infection models are used as surrogate markers of T cell residency. Across numerous solid tumor types, T_{RM}-like phenotypes have been identified and correlated with improved prognosis and responsiveness to immunotherapy. However, the migration properties of $CD8^+$tumor infiltrating lymphocytes (TILs) have not been well described, and the reliability of healthy tissue T_{RM} markers for correlating with $CD8^+$ TIL migration properties remains unknown.

Methods In this study, we employed parabiosis migration assays in the context of both acute viral infection and a mouse model of breast cancer. In combination, this system allowed us to simultaneously track both virus-specific memory T cells and tumor-specific T cells.

Results Our migration assays demonstrated that both virus-specific, bystander and tumor-specific $CD8^+$ TILs can be resident. Canonical markers of T_{RM}, including CD69, correlated with tissue residence in healthy mammary tissue, but failed to discriminate between resident cells and recent migrants in tumors. Instead, the expression of markers associated with chronic T cell stimulation (PD-1, CD39, Tim-3) identified a population of resident, tumor-specific cells. We further observed that after tumor entry, $Tcf\text{-}1^+PD\text{-}1^{lo}$ tumor-specific T cells progressively acquired the expression of inhibitory receptors, such as Tim-3, correlating with the phenotypes that represented tumor retention and residence.

Conclusions Thus, T_{RM} exist within tumors, durable intratumoral residence was not informed by common markers associated with pathogen-specific T_{RM} that have been described in healthy tissue, but tumor-specific T cells become resident upon tumor antigen recognition and the subsequent upregulation of CD39 and Tim-3. Together with high-dimensional, single-cell transcriptomics, we propose an integrated view of tumor immunosurveillance in which tissue environments and antigen-specific recognition drive distinct residence programs.

Ethics Approval All mice used in experiments were 5–15 weeks of age and used in accordance with the Institutional Animal Care and Use Committees guidelines at the University of Minnesota.

1028 IL-12 AND IL-27 UPREGULATE CD39 EXPRESSION ON CD8$^+$ T-CELLS AND DIFFERENTIALLY AFFECT CD39$^+$CD8$^+$ T-CELL EFFECTOR FUNCTION

Lara Gerhardt*, Rene Figueredo, Saman Maleki. *Western University, London, ON, Canada*

Background Tumor-specific CD8$^+$ T-cells play a critical role in tumor control, as demonstrated by the success of immune checkpoint inhibitors and adoptive cell therapy. Studies of mice and human tumor-infiltrating lymphocytes (TILs) demonstrate that tumor-specific CD8$^+$ TILs can be defined by CD39 expression on their surface. CD39 is commonly considered an immunosuppressive enzyme, as it depletes ATP. However, CD39 is also associated with mitigating activation-induced cell death and mediating leukocyte trafficking. It is, however, unclear whether CD39 expression on tumor-specific T-cells can be regulated by putative anti-tumor factors such as pro-inflammatory cytokines similar to the phenotype and anti-tumor properties of CD8$^+$ TILs. IL-12 and IL-27 have established roles in promoting effector T-cell differentiation, expansion, and cytotoxic activity. Both cytokines are implicated in the upregulation of CD39 by T regulatory cells, suggesting they may regulate CD39 expression in other cell types, including tumor-specific CD8$^+$ T-cells. We hypothesize that IL-12 and IL-27 induce CD39 upregulation on CD8$^+$ T- cells, modulating their anti-tumor properties.

Methods An engineered immunogenic, syngeneic neuroblastoma (neuro-2a) mouse model was used for *in vitro* and *in vivo* experiments. CD8$^+$ T-cells or bulk splenocytes isolated from naïve or neuro-2a vaccinated mice were stimulated *in vitro* using anti-CD3/CD28 Dynabeads and IL-2 ± IL-12 or IL-27. Flow cytometry was used to determine the phenotype of CD8$^+$ T-cells and assess effector activity. Additionally, we inhibited IL-12 activity *in vivo* to study the effect on CD8$^+$ TIL expression of CD39. An isotype control antibody was administered to a separate group to act as a control.

Results Our *in vitro* results demonstrate that CD8$^+$ T-cells stimulated in the presence of IL-12 or IL-27 had higher expression of CD39 compared to stimulated controls. In addition, we found a higher frequency of CD39$^+$CD8$^+$ T-cells expressing IFNγ and CD107a than CD39$^-$ counterparts. Finally, blocking IL-12 activity *in vivo* reduced CD39$^+$CD8$^+$ TIL frequency compared to the isotype control group.

Conclusions Our results establish that IL-12 and IL-27 induce CD39 expression on CD8$^+$ T-cells and blocking IL-12 reduced CD39$^+$CD8$^+$ TIL frequency. Furthermore, CD39 expression is associated with improved effector CD8$^+$ T-cell function. Future experiments will assess the functionality of CD39$^+$CD8$^+$ T-cells using *ex vivo* cytotoxicity assays. Data generated in this study will provide novel information on the mechanism of CD39 induction and its effect on CD8$^+$ T-cell function, which can be exploited to improve future cancer therapies.

1029 ENGINEERING OF T CELLS WITH CCR10 FOR ENHANCED TRAFFICKING OF ADOPTIVE CELL THERAPY

[2]Hee Jin Lee, [2]Gyung Yub Gong, [3]Kwang Hee Kim, [1]Jong Moo Hong*. *[1]University of Ulsan College of Medicine, Seoul, South Korea, Republic of; [2]Asan Medical Center, Seoul, South Korea, Republic of; [3]NeogenTC Crop, Seoul, South Korea, Republic of*

Background Trafficking T cells into tumor microenvironments is critical to the success of cancer immunotherapy, such as adoptive cell transfer therapy. Chemokines and their receptors play an important role in inducing trafficking and homing of T cells. They activate integrin for T cell adhesion to endothelial cells and help T cells traffic through chemotaxis in microenvironment of cancer. Therefore, the introduction of chemokine receptors that react with tumor-derived chemokines could improve the effectiveness of adoptive T cells. CCR10 is a chemokine receptor for CCL28, which is a high-ranking chemokine secreted from tumor tissue. We engineered T cells with CCR10 to improve trafficking of T cells.

Methods Cloning was performed using vectors containing NY-ESO-1 and HLA-A*02:01 specific (1G4) TCR and CCR10. Transduction of Jurkat cells-NFAT-luciferase (TCR KO) and peripheral blood mononuclear cells (PBMC) was performed after the production of the lentivirus using a lenti-x-293T cell. A375 cell line, which expresses– HLA-A*02:01 and NY-ESO-1, was selected as a target. CCL28 was overexpressed in A375 cell line, and transwell migration assay was performed using CCR10-1G4 TCR-T and 1G4 TCR-T. 1G4 TCR reactivity was measured using luciferase after NY-ESO-1 peptide pulsing in T2 cell.

Results Transduction efficiency of the 1G4 TCR and CCR10 on post-transduction day 7 was more than 90% each in Jurkat and 40% each in CD8+ PBMC. However, when we used the vector containing 1G4 TCR and CCR10 together with T2A linker, the expression efficiency of CCR10 was 30% to 40% in Jurkat and 10% to 20% in CD8+ PBMC. Transwell migration assay was performed using mock Jurkat, CCR10-Jurkat, 1G4 TCR-Jurkat, and CCR10 1G4 TCR-Jurkat. Compared to mock or 1G4-Jurkat, CCR10-Jurkat or CCR10-1G4 TCR-Jurkat had increased migration by more than 10% during 4 h migration period. In addition, migration of CCR10 1G4 TCR-Jurkat increased according to incubation time when transwell assays were performed for 4, 8, and 16 hours. The reactivity of CCR10 1G4 TCR-Jurkat was measured using luciferase. The RLU of the T2 cells without pulsing the NY-ESO-1 peptide was below detection level. When reacted with T2 cells pulsed NY-ESO-1 peptide by diluting 10 times from 1ug to 0.001ug, RLU was 3.40E+04, 5.44E+04, 6.16E+04, and 7.24E+04, respectively.

Conclusions CCR10 engineered TCR-T showed increased in vitro trafficking efficacy. Further studies with application of CCR10 to other T cell therapies would improve quality of adoptive T cell therapy.

1030 PSGL-1-DEFICIENCY SUPPRESSES TUMOR GROWTH OF ORTHOTOPIC PANCREATIC DUCTAL ADENOCARCINOMA TUMORS AND ENHANCES IMMUNE CELL INFILTRATION AND CD8$^+$ T CELL RESPONSES

Jennifer Hope*, Yijuan Zhang, Ashley Palete, Hannah Faso, Sreeja Roy, Dennis Otero, Swetha Maganti, Cosimo Commisso, Linda Bradley. *Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA, United States*

Background Pancreatic ductal adenocarcinoma (PDAC) is an aggressive, poorly immunogenic cancer that is increasing in incidence. PDAC tumors are highly refractory to all currently available treatments including existing immune checkpoint blockade (ICB) therapies, demonstrate limited CD8$^+$ T cell infiltration. Patient prognosis is poor with a 5-year overall survival rate of only 11%. As such, there is a critical need to develop novel approaches to improve patient outcomes. We previously demonstrated that deficiency of P-selectin glycoprotein 1 (PSGL-1) promotes enhanced CD8$^+$ T cell responses that clear chronic LCMV Cl13 virus infection and inhibit the growth of PD-1 blockade resistant melanoma. Here we evaluated if targeting PSGL-1 similarly promotes CD8$^+$ T cell responses to PDAC tumors to inhibit growth and metastases.

Methods 2.5x10^4 KPC.4662 tumor cells suspended in Matrigel were injected orthotopically into the pancreas tail in 6-8 week old C57BL/6 (wildtype control) and PSGL-1$^{-/-}$ male or female mice. PDAC tumors were collected on day 28 post-injection and assessed by flow cytometry and histology. For evaluation of metastatic potential, 2x10^{5}KPC.4662 tumor cells suspended in 1X PBS were injected intravascularly into the tail vein of control and PSGL-1$^{-/-}$ mice. Lung metastases were assessed on day 17 post-injection.

Results At 28 days post orthotopic tumor cell injection, KPC.4662 tumor burden was reduced on average by 45% (0.74±0.27g vs 0.41±0.24g) in PSGL-1$^{-/-}$ mice compared to control mice. Moreover, fewer mice developed non-primary tumor metastases in the intraperitoneal cavity, liver, and lungs. To assess if PSGL-1$^{-/-}$ mice had the capability to reduce metastatic burden, KPC.4662 cells were injected intravascularly and tumor development in the lungs was assessed on day 17. PSGL-1$^{-/-}$ reproducibly developed fewer tumors in the lungs compared to control mice as determined by histological examination. Immune infiltration (CD45$^+$ cells) was markedly increased (10% vs 24%) in orthotopic tumors from PSGL-1$^{-/-}$ mice, including an increase in Thy$^+$T cells (3.1% vs 9.4%). Flow cytometry and immunofluorescence staining confirmed a significant increase in tumor-infiltrating CD8$^+$ T cells in PDAC tumors from PSGL-1$^{-/-}$. Importantly, PSGL-1$^{-/-}$ CD8$^+$ T cells were less functionally exhausted.

Conclusions In the absence of PSGL-1, we observe significantly reduced growth of primary orthotopic PDAC tumors and decreased metastases. These findings were associated with increased CD45$^+$ immune cell infiltration in the tumors and notably, increased CD8$^+$ T cell effector responses. PSGL-1 therefore represents a novel target for promoting immune responses to PDAC tumors.

Ethics Approval These animal studies were conducted at Sanford Burnham Prebys with the approval of the Sanford Burnham Prebys IACUC.

1031 ACETYL COA CARBOXYLASE INHIBITION REWIRES T CELL FATE AND TUMOR IMMUNOTHERAPY OUTCOME

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1031

[1]Katie Hurst, [1]Brian Riesenberg, [1]Elizabeth Hunt*, [2]Alex Andrews, [2]Megan Tennant, [1]Evelyn Gandy, [3]Peng Gao, [2]Lauren Ball, [1]Emily Wallace, [1]David Corcoran, [1]Jessica Thaxton. *[1]University of North Carolina Chapel Hill, Chapel Hill, NC, United States; [2]Medical University of South Carolina, Charleston, SC, United States; [3]Northwestern University, Chicago, IL, United States*

Background Reshaping metabolism improves T cell tumor control [1-3], but direct enzymatic targets that restrict antitumor bioenergetics are poorly defined. Acetyl CoA Carboxylase (ACC) induces carboxylation of cytosolic Acetyl CoA to form Malonyl CoA, a metabolite that restricts the well-defined T cell antitumor program of ß oxidation of fatty acids (FAO).[4-5] Here we tested whether ACC inhibition (ACCi) could act as a molecular switch in CD8 T cells to program lipid catabolism and metabolic efficacy for tumor control.

Methods ACCi-treated T cells were collected and submitted for metabolomics, lipidomics, proteomics, and RNA-sequencing. Seahorse XF Real-Time ATP Rate and Seahorse XF Mito Stress Tests using T cells treated with the ACC1/2 inhibitor ND-646 were performed using the Seahorse XFe96 Analyzer. Spectral flow cytometry was used for T cell phenotyping, using cells stained with 18 fluorophore-conjugated antibodies. To assess ACCi T cell antitumor capability, B16F1-OVA melanomas were established subcutaneously by injecting 2.5×10^5 cells into the right flank of female C57BL/6. After 10 days of tumor growth, 5×10^5 OT-1 T cells conditioned with vehicle or ACCi were infused into tumor-bearing mice. Tumor growth was measured every other day and survival was monitored.

Results Using the compound ND-646 (ACCi), we assessed the effects of ACC inhibition on CD8+ T cell metabolism, lineage, and tumor fate in mouse and human cells. Through metabolomics and metabolic analysis using Seahorse Bioanalysis, we show that ACCi remodels CD8 T cell metabolism, driving FAO and enhancing mitochondrial spare respiratory capacity (SRC) as a result of sustained fatty acid import. Through phenotypic analysis using spectral flow cytometry and RNA-sequencing, we found that alongside this metabolic reprogramming, ACCi also induced transcriptional and functional traits associated with robust tumor control, including sustained production of mitochondrial ATP, allowing for persistent protein and cytokine synthesis. This phenotypic remodeling induced by ACCi resulted in the generation of T cells with prolonged survival and tumor control capabilities.

Conclusions The data indicate that ACC is a molecular switch that impairs FAO in CD8 T cells, driving metabolic, phenotypic, and transcriptional remodeling that confers T cell longevity and robust anti-tumor capabilities. Targeting ACC is an avenue to program therapeutic efficacy of T cells for solid tumors.

1032 UNCOUPLING CD39 AND T CELL ANTIGEN SPECIFICITY IN BRAIN TUMORS

Sierra Kleist, Shawn Musial, Hanna Degefu, Pamela Rosato, Jordan Isaacs*. *Dartmouth College, Lebanon, NH, United States*

Background Tumor-infiltrating lymphocytes have long been thought to encompass a repertoire recognizing primarily tumor antigens. However, our lab and others have found that tumor-infiltrating CD8+ T cells include a population with viral-specificity which can often outnumber tumor-reactive cells. Thus, identifying markers of tumor-reactive T cells are critical for developing ways to target this sub-population and boost anti-tumor immunity. Work to this end has defined CD39 and CD103 as putative markers of tumor-reactive T cells in several solid tumors. CD39+ CD8+ T cells have impaired cytokine production and increased expression of inhibitory receptors, while CD39- CD8+ T cells lack hallmarks of chronic antigen stimulation, highlighting their bystander role.

Methods In contrast, we unexpectedly found that CD39 is highly expressed on functional virus-specific CD8+ T cells in healthy brain compared to other non-lymphoid tissues examined. These findings prompted us to investigate whether the established CD39 antigen-specificity paradigm held true in brain tumors. To test this, we established a mouse model of glioblastoma (GBM) and melanoma brain metastasis harboring virus-specific memory T cells, similar to the observations found in humans.

Results Suprisingly, we found that CD39 expression was uniformly high on all CD8+ T cells in both brain tumor models, including on virus-specific T cells which also co-expressed CD103. Moreover, these CD39+ antiviral T cells remained functionally active and could mediate local inflammation upon recognition of cognate antigen. In contrast, in a mouse model of primary melanoma, bystander virus-specific T cells did not express CD39 while the bulk CD8+ population, including tumor-reactive T cells, expressed high CD39 as has been demonstrated clinically.

Conclusions Our ongoing studies aim to elucidate the functional role of CD39 in T-cell mediated immunity of brain tumors. Overall, these data suggest that CD39 may not stratify tumor-reactive CD8+ T cells in brain tumors as has been demonstrated in other solid tumors. Thus, therapeutic approaches to target CD39/CD103+ T cells or restore anti-tumor immunity through CD39 blockade may have different clinical implications in tumors of the central nervous system.

1033 STEM-LIKE CD8 T-CELLS RESIDING IN ANTIGEN PRESENTING IMMUNE NICHES ARE PROGNOSTIC FOR LOCAL CONTROL IN BRAIN METASTASES AND ARE SUSTAINED FOLLOWING RADIATION THERAPY

[1]Caroline Jansen*, [1]Prasanthi Chappa, [1]Nataliya Prokhnevska, [1]Maria Cardenas, [2]Roshan Prabhu, [1]Jim Zhong, [1]Kimberly Hoang, [1]Subir Goyal, [1]Suzanna Logan, [1]Jeffrey Olson, [1]Edjah Nduom, [1]Luke del Balzo, [3]Kirtesh Patel, [2]Stuart Burri, [4]Anthony Asher, [5]Scott Wilkinson, [5]Ross Lake, [1]Kristin Higgins, [1]Pretesh Patel, [1]Vishal Dhere, [1]Mylin Torres, [5]Adam Sowalsky, [1]Mohammad Khan, [1]Haydn Kissick, [1]Zachary Buchwald. *[1]Emory University, Decatur, GA, USA; [2]Atrium Health, Charlotte, NC, USA; [3]Yale, Atlanta, GA, USA; [4]Atirum Health, Charlotte, NC, USA; [5]National Cancer Institute, Bethesda, MD, USA*

Background While tumor infiltrating T-cells have a prognostic benefit in many tumor types[1-8], the prognostic role of infiltrating immune cells is in patients with brain metastases (BrM) is poorly understood. While patients with 1-2 BrM are treated with resection and stereotactic radiosurgery (SRS), intracranial failure is common, and prognostic biomarkers are needed. Our group recently reported the T-cell response in renal tumors is beneficial for patient outcomes. This response is supported by TCF1+ stem-like CD8 T-cells residing in dense regions of closely clustered antigen presenting cells within the tumor known as the immune niche.[9] Notably, these stem-like T cells are critical for a robust anti-PD-1 response. Here, we wished to determine whether: 1) TCF1+ stem-like CD8 T-cells are present, residing in immune niches, in BrM?, (2) the density of these niches is associated with patient outcomes? and (3) stem-like CD8 T-cells and immune niches persist following SRS?

Methods Tumor tissue was collected from 146 patients with BrM undergoing surgery at two clinical centers. Samples were analyzed by flow cytometry, single cell RNA sequencing, and immunofluorescence. Imaging data was analyzed using custom quantitative pipelines. Together, this allowed for evaluation of the BrM immune microenvironment at baseline or following pre-operative SRS.

Results We describe the presence of TCF1+ stem-like CD8 T-cells in BrM (figure 1A-B), regardless of histology, these stem-like cells reside in dense, antigen-presenting immune niches (figure 1C-D). We find that higher density of these immune niches in BrM correlates with improved local control of BrM (figure 1E). Pre-operative SRS did not decrease immune niche density (figure 1F-G), nor significantly alter the stem-like signature of this population of T-cells. Finally, we also find that a longer time from SRS to resection may lead to increased CD8+ T-cell density in BrM (figure 1H).

Conclusions We have shown that stem-like T-cells are present in BrM in immune niches. The density of this intratumoral immune organization is associated with improved patient outcomes regardless of primary tumor origin. These findings recapitulate the previously reported phenomena of immune organization in tumor tissue, underscoring the trans-tumor/trans-tissue importance of this biology in the anti-tumor immune response. Finally, this niche is maintained following SRS suggesting it is a relatively radioresistant compartment. This has significant implications for combinatorial strategies of immunotherapy and SRS for BrM.

1034 ANALYSIS OF FACTORS ASSOCIATED LESS DIFFERENTIATED T CELLS IN BREAST CANCER FOR IMPROVEMENT OF ADOPTIVE T CELL THERAPY

[1]Jeong-Han Seo, [1]Hyeonjin Lee, [2]Gyungyub Gong, [2]Hee Jin Lee, [3]Sung Wook Jung*. *[1]NeogenTC Corp, Seoul, South Korea, Republic of; [2]Asan Medical Center, Seoul, South Korea, Republic of; [3]University of Ulsan College of Medicine, Seoul, South Korea, Republic of*

Background The survival and proliferative potential of T cells *in vivo* is related to the differentiation status of T cells. Less differentiated cells show prolonged survival duration and effective anti-tumor response for adoptive T cell therapy. To improve *in vivo* sustainability of adoptive T cell therapy, we analyzed factors associated with less differentiated T cells in breast cancer.

Methods We performed a single cell RNA (scRNA) sequence of CD45+ immune cells from 21 breast cancers. Basic analysis was performed using the Seurat package, and immune cells were clustered through UMAP. CD8+ cluster was defined using CD3E, CD8A, and CD8B markers. Differentially expressed genes between differentiated and less differentiated cells were assessed in 3 conditions [SELL-CCR7- (Tem) vs. SELL+CCR7+ (early memory T cell); CD39+CD69+ (terminally differentiated T cell) vs. CD39-CD69- (Tscm phenotype); KLRG1+CD127- (terminal effector cells) vs. KLRG1-CD127+ (pre-memory cell phenotype)]. Genes related to transcription factor and metabolic genes and epigenetic pathways were identified. We also derived data from 5 breast cancer scRNA datasets identified in the NCBI-Gene Expression omnibus and performed the same process as above.

Results 29,102 CD8+ T cells from 6 datasets were analyzed (GSE141665, n=1,767; GSE114724, n=8,400; GSE161529, n=3,023; GSE176078, n=8,036; GSE110686, n=1,214; in house, n=6,662). Based on the 3 conditions in each dataset, up-regulated genes were classified by comparing more and less differentiated phenotypes, and the identified genes were annotated as transcription factors, metabolic genes, and epigenetic genes (transcription factors, n=138, 128, 246, 452, 35, and 546; metabolic genes, n=324, 230, 700, 1,224, 63, and 1,262; epigenetic genes, n=24, 34, 53, 106, 7, and 546 for each dataset, respectively). Total 486 genes, which were up-regulated in less differentiated CD8+ T cells, were obtained by sorting two or more overlapping conditions among the 3 conditions in each dataset (GSE141665, n=141; GSE114724, n=154; GSE161529, n=305; GSE176078, n=840; GSE110686, n=22; in house, n=974). Among 486 genes obtained from 6 datasets, 17 genes including *FOS*, *JUNB*, and *LEF1* were present in all datasets.

Conclusions By combining 21 tumor samples and 5 public datasets, we identified 17 up-regulated genes, which are transcription factors or genes associated with metabolic and epigenetic pathways, in less differentiated CD8+ T cells. Further studies modulating these genes may suggest the possibility of returning terminally differentiated T cells to less differentiated status to improve the T cell therapy.

Ethics Approval The study was approved by the Institutional Review Board of Asan Medical Center, approval number IRB 2016-0935.

1035 HIGH-DIMENSIONAL IMMUNE PROFILING OF PERIPHERAL EPSTEIN-BARR VIRUS-SPECIFIC T CELLS IN NASOPHARYNGEAL CARCINOMA

[1]Nandita Kumar*, [2]Hugh MacMillan, [3]Joe Poh Sheng Yeong, [4]Melvin Chua, [4]Amit Jain, [2]Evan Newell. *[1]University of Washington, Seattle, WA, USA; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [3]Agency for Science, Technology and Research, Singapore, Singapore; [4]National Cancer Centre Singapore, Singapore, Singapore*

Background Nasopharyngeal carcinoma (NPC) is an EBV-driven cancer endemic to East and Southeast Asia with poor survival rates and limited treatment options. While EBV infection plays a key role in NPC pathogenesis, little is known about EBV-specific T cells in the context of immune response to NPC. We, therefore, interrogated the role of EBV-specific T cell responses in NPC immunopathology with the goal of better understanding how the tumor evades immune targeting and identifying new targets for immunotherapy.

Methods We profiled the phenotypes and antigenicity of EBV-specific CD8 T-cells in NPC patient peripheral blood mononuclear cells (PBMCs) from a 51-patient new diagnosis Singaporean NPC cohort using a combined mass cytometry (CyTOF) and multiplexed peptide-MHC tetramer panel. UMAP and clustering analyses were performed to analyze these highly dimensional data and then phenotypic clusters were correlated to patient clinical parameters to identify clinically relevant, NPC-associated EBV-specific phenotypes. Additionally, we performed single-cell multi-omics sequencing (10X Genomics/CITE-seq) on NPC patient PBMCs to dissect the role of peripheral T cells with NPC-associated phenotypes on tumor pathogenesis.

Results We identified that peripheral EBV-specific CD8 T cells in NPC patients are phenotypically distinct from other antigen-specific T cells and differentially express activation, exhaustion, and homing markers, such as CD38, HLA-DR, CD39, and CD103. We found that the frequencies of EBV-specific T cells with these phenotypes are correlated with clinical parameters (i.e., EBV-DNA titer, tumor volume, stage etc.), and observed similar correlations with bulk CD8 T cells with these phenotypes. Finally, we assessed differential gene expression profiles of CD8 T cells with surface expression of NPC-associated phenotypic markers.

Conclusions Overall, we show that the phenotypic profiles of peripheral EBV-specific T cells may be reflective of NPC anti-tumor immune responses, and these phenotypic profiles could potentially be used as biomarkers for immunotherapeutic response.

Ethics Approval All patient samples were obtained from patients who provided informed consent at the National Cancer Centre Singapore, and de-identified patient information from this cohort was obtain through approval by the institutional review board at the Fred Hutchinson Cancer Research Center (IR File#: 6007-1053).

1036 RON KINASE AS POTENTIAL IMMUNOTHERAPEUTIC TARGET FOR AUGMENTING T CELL ACTIVITY IN BREAST CANCER METASTASIS

Alicia Lai*, Alana Welm. *Huntsman Cancer Institute, Salt Lake City, UT, USA*

Background Metastatic breast cancer is the overwhelming cause of mortality among all breast cancers. Harnessing the immune system to eliminate metastasis is appealing because it does not require knowledge of the "drivers" of heterogeneous tumors or specific targeted-therapies. T cells play critical roles in anti-tumor immunity, but they are often dysfunctional in cancer patients. How T cells become dysfunctional during tumor progression is still controversial and requires further investigation. Our lab identified host expression of the receptor tyrosine kinase Ron as a potential target for breast cancer immunotherapy. We discovered that a specific Ron isoform, short-form Ron (sfRon), plays a key role in regulating the anti-tumor immune response. Importantly, genetic deletion of sfRon (Ron SF-/-) in the mouse host nearly eliminates outgrowth of established lung micro-metastases through potent activation of T cell-mediated anti-tumor immune responses. We sought to test the hypothesis that sfRon expression in T cells regulates their function and that inhibiting Ron kinase activity is a viable therapeutic strategy to augment T cell activity against metastasis.

Methods To investigate sfRon in the suppression of anti-tumor immunity, we conducted single-cell RNA sequencing on immune cells isolated from lungs of wild type and Ron SF-/- mice 2 or 4 weeks after tumor injection via tail-vein. To study whether sfRon controls T cell function, T cells from wild type or Ron SF-/- mice were cultured *ex vivo* and T cell activation and exhaustion were examined. Additionally, specific T cell receptors were ectopically expressed on T cells and stimulated with corresponding peptides to access immune modulatory responses. To examine the effector functions, CD8 T cells were stimulated with either specific peptide or co-cultured with antigen-expressing tumor cells and subjected to IFNγ detection by flow cytometry or ELISA. To examine the function of helper T cells, peptide-stimulated CD4 T cells were subjected to intracellular detection of IFNγ, IL4, IL17A, and IL10, which represent helper effector subsets Th1, Th2, Th17, and iTreg, respectively.

Conclusions Our results showed that expression of sfRon causes defects in T cell recruitment into the metastatic site, and deletion of sfRon maintains T cell homeostasis and prevents T cell anergy caused by overactivation. These data strongly advance the field on the mechanism by which sfRon suppresses T cell responses and sheds light on new therapeutic strategies focusing on Ron kinase inhibitors for the prevention and treatment of metastatic breast cancer.

Ethics Approval All animal procedures were reviewed and approved by the University of Utah Institutional Animal Care and Use Committee; protocol number: 21-06006.

1037 SINGLE CELL EVALUATION OF ANTIGEN SPECIFICITY, CLONAL DYNAMICS AND TRANSCRIPTIONAL SIGNATURES OF CD8+ T CELLS IN HEAD AND NECK SQUAMOUS CARCINOMA

Housaiyin Li*, Patricia Santos, Aditi Kulkarni, Alok Joglekar, Lazar Vujanovic, Robert Ferris. *University of Pittsburgh, Pittsburgh, PA, USA*

Background Head and neck squamous cell carcinoma (HNSCC) is caused by high tobacco and alcohol consumption and/or human papillomavirus (HPV) associated.[1-3] Anti-PD-1 immunotherapy only benefits 15-20% of HNSCC patients[4, 5] Thus, there is a need to identify mechanisms involved in resistance to immune checkpoint blockade. Several studies have described the transcriptional phenotypes of tumor infiltrating lymphocytes (TIL) and correlated it with clinical response to ICB.[6-8] It has also been shown that majority of neoantigen-specific CD8+ T cells from the tumor have an exhausted-like phenotype [9-11], but specific targetable epitopes and whether anti-viral T cells dominate in HPV-associated HNSCC immunotherapy have not been determined. Collectively, these studies do not address neoantigen and HPV-antigen specificities of evaluated T cells and their transcriptional and functional status in the HNSCC TME, nor whether these cells re-circulate and demonstrate restoration of function once in the peripheral circulation.

Methods Single cell suspensions were prepared from tumor and blood of 21 treatment-naïve HNSCC patients. T cells were FACS-sorted using barcoded mAbs (CITE-seq) and used to generate single cell RNA sequencing (scRNA), T cell receptor (TCR) and ADT libraries using 10x Genomics workflow. A cell-based method for epitope discovery (SABRs) was used to characterize antigen specificity of selected CD8+ TILs.[12]

Results Clonal expanded CD8 T cells in the tumor express high levels of T cell exhaustion markers (PDCD1, HAVCR2, ENTPD1, LAG3). GSEA analysis show that highly expanded CD8+ TILs share gene signatures with neoantigen-specific CD8+ TILs identified from other cancers. There was no significant overlap observed between TCRs of CD8 T cells with high expression of immune checkpoint receptors in the tumor with peripheral blood CD8+ T cells. TCR analysis show that T cell clones shared between tumor and peripheral blood are found in a cluster of CD8 T cells with an effector memory phenotype expressing distinct granzyme expression in activated versus exhausted tumor reactive cells.

Conclusions In this study, we'd like to evaluate 1). Antigen specificities and transcriptional phenotypes of CD8+ T cells. We found that potential tumor reactive cells express high checkpoints, implying most of tumor reactive cells are dysfunctional within tumor. 2). Clonal dynamics of tumor reactive cells. We observed low clonal overlap between peripheral and tumor resident TCRs, suggesting tumor resident population expanded locally. Shared T cell clones between peripheral CD8+ T cells in effector memory population may reflect an active recruitment and/or exhange of T cells between periphery and tumor.

1038 LOSS OF PD-1 SIGNALS IMPROVES CD8+ TIL FUNCTION IN A CELL INTRINSIC AND CELL EXTRINSIC MANNER

[1]Samuel Markson*, [1]Kristen Pauken, [1]Vikram Juneja, [2]Osmaan Shahid, [1]Kelly Burke, [1]Jared Rowe, [1]Jacklyn Long, [1]Megan Fung, [2]Jacob Luber, [1]Jennifer Judge, [1]Alison Ringel, [1]Marcia Haigis, [2]Meromit Singer, [1]Arlene Sharpe. *[1]Harvard Medical School, Boston, MA, USA; [2]Dana-Farber Cancer Institute, Boston, MA, USA*

Background Blockade of PD-1 or its ligand PD-L1 has led to improved clinical outcomes in diverse cancer types, and has been approved by the FDA for use in over 20 different advanced stage cancers. Though PD-1 pathway inhibitors show great promise, the mechanisms contributing to protective anti-tumor immunity following loss of PD-1 signaling remain incompletely understood.

Methods To elucidate the cell intrinsic consequences of PD-1 loss, as well as the impact of this loss on neighboring PD-1-expressing cells, we developed an inducible PD-1 knockout (KO) model whereby PD-1 could be deleted on roughly half of the $CD8^+$ T cell population.

Results Using paired single cell RNA seq and TCR seq, we found that PD-1-expressing $CD8^+$ T cells in the tumor received much of the same therapeutic benefit as those T cells lacking PD-1. Thus, many of the anti-tumoral changes that occurred in the $CD8^+$ TIL population were not dependent on a cell intrinsic loss of PD-1, but instead were shared between cells that do or do not express PD-1.

Conclusions These data suggest that PD-1 inhibitors can act beyond each individual cell that they contact to promote a heightened anti-tumor state, and can impact T cell functions independent of direct PD-1 blockade.

1040 A POPULATION OF ECTOENZYME EXPRESSING T-CELLS WITH AN IMMUNOSUPPRESSIVE PHENOTYPE ARE ASSOCIATED WITH CHECKPOINT IMMUNOTHERAPY RESISTANCE IN METASTATIC MELANOMA PATIENTS

[1]David Woods*, [1]Carol Amato, [1]Ann Strange, [1]Brian Thompson, [2]Jeffrey Weber, [2]Ankita Mitra. *[1]University of Colorado School of Medicine, Aurora, CO, USA; [2]New York University Langone, New York, NY, USA*

Background Therapies targeting T-cell checkpoints have resulted in anti-tumor responses leading to FDA approval of multiple immunotherapies for metastatic melanoma and an expanding list of other malignancies. Despite having unprecedented efficacy, PD1 and CTLA4 antagonist antibodies still fail to benefit many patients. Critically, an understanding of mechanisms of resistance to immunotherapies is lacking. We recently identified and validated a novel population of peripheral blood T-cells predictive of resistance in nivolumab (αPD1) treated metastatic melanoma patients. This population is defined by the marker set CD3+CD4+CD127-GARP-CD38+CD39+. Based on the co-expression of CD38 and CD39, we have termed the population **e**ctoenzyme **e**xpressing T-cells (T_{eee}).

Methods We utilized high-dimension flow cytometry to assess T_{eee} frequencies in adjuvant immunotherapy treated metastatic melanoma patient peripheral blood samples. To characterize the phenotype of T_{eee}, we utilized flow cytometry and CITE-Seq on melanoma patient tumor specimens. We also evaluated the presence and phenotype of T_{eee} in several l syngeneic murine tumor models.

Results We found that T_{eee} were of low frequency in demographic matched healthy donors and increased in both resected ($p=0.018$) and active disease metastatic melanoma patients ($p=0.003$). Circulating T_{eee} frequencies positively correlated with frequencies of Tregs ($R^2=0.4367$, $p<0.0001$), MDSCs ($R^2=0.2706$, $p=0.0004$) and M2-like monocytes ($R^2=0.1514$, $p=0.0109$). Increases in circulating T_{eee} were associated with relapse in resected melanoma patients treated with adjuvant combination ipilimumab (αCTLA4) and nivolumab ($p=0.0213$). Human tumors showed high frequencies of T_{eee} in tumor infiltrate. We also demonstrated the existence of this population in MC38 and YUMM mouse tumor models. Intratumor frequencies of T_{eee} positively correlated with tumor volume ($R^2=0.96$, $p=0.0006$) and inversely correlated with overall immune infiltrate ($R^2=0.3198$, $p=0.0280$). Our characterization of this population showed an enhanced adenosine generating phenotype (i.e. $CD73^{high}$, $CD26^{low}$), a terminal exhaustion phenotype (i.e. TOX^{high}, $TCF1^{low}$), expression of inhibitory receptors (e.g. CTLA4, TIM3) and ligands (e.g. PDL1, B7-H4), and expression of immunosuppressive cytokines (e.g. IL-8, TGFβ). Supporting a mechanistic relationship to resistance, T_{eee} suppressed autologous T-cell proliferation ($p=0.0278$) and inflammatory function.

Conclusions We have identified a novel population of ectoenzyme expressing T-cells associated with immunotherapy resistance in metastatic melanoma patients. This population of cells had phenotypes associated with immune suppression and suppressed autologous T-cells *in vitro*. Collectively, our data support evaluation of targeting T_{eee} to augment the efficacy of immunotherapy.

Ethics Approval Study was approved by IRB at CU Anschutz and NYU Langone.

1041 PIK3IP1/TRIP IMMUNE REGULATION ON CD8+ T CELLS RESTRICTS ANTI-TUMOR IMMUNITY

Benjamin Murter*, Hridesh Banerjee, Sean Robinson, Andrea Szymczak-Workman, Lawrence Kane. *University of Pittsburgh, Pittsburgh, PA, USA*

Background The signaling pathways involving phosphoinositide-3-kinases (PI3Ks) are highly conserved and tightly regulated to influence the activation, proliferation, and survival of all cell types. PI3K signaling plays a major role in T cell responses to antigen due to its position directly downstream of T cell receptor (TCR)/CD28 ligation.[1, 2] Our lab has shown that the cell surface protein TrIP (**Tr**ansmembrane **I**nhibitor of **P**I3K, gene name: *Pik3ip1*) has a distinctly high expression on T cells and is capable of regulating PI3K signaling in T cells, acting as a negative regulator of T cell immune responses.[3, 4] These studies revealed that $CD4^+$ T cells lacking TrIP expression exhibit a more Th1 inflammatory phenotype compared to WT T cells, both *in vivo* and *in vitro*.[3] These data have led us to propose that TrIP restricts the inflammatory activity of T cells, including $CD8^+$ T cells, and that targeting/knockout of this negative regulator may promote antitumor immunity.

Methods Using a novel conditional TrIP knockout mouse model developed in house, we have performed syngeneic tumor challenges in $CD8^+$ T cell-specific TrIP knockout mice ($TrIP^{fl/fl}E8i^{cre}$). We have also characterized the tumor immune infiltrate of these mice to understand the impact of T cell-specific TrIP deficiency on the immune landscape.

Results Our data show that $CD8^+$ T cell-specific TrIP knockout mice ($TrIP^{fl/fl}E8i^{cre}$) are resistant to growth of syngeneic tumors. In addition to increased tumor resistance, we have also found that tumors harvested from our $TrIP^{fl/fl}E8i^{cre}$ knockout mice contain twice as many infiltrating T cells compared to their WT counterparts. We also found that $CD8^+$ T cells are the major drivers of this infiltration, and importantly don't display any increase in exhaustion.

Conclusions We describe data demonstrating that TrIP, a relatively novel PI3K inhibitor uniquely expressed on the surface of T cells, plays a significant role in the antitumor immune activity of $CD8^+$ T cells. Our $CD8^+$ T cell-specific TrIP knockout mice are resistant to tumor challenge and show more robust tumor $CD8^+$ T cell infiltrate. We are hoping for future/ongoing adoptive transfer experiments will help elucidate if TrIP knockout promotes infiltration/proliferation/survival within the TME. Nevertheless, we propose TrIP as an exciting novel immunotherapeutic target worthy of further investigation.

1042 THE DUAL FUNCTION OF THE ADENOSINE PATHWAY IN THE LIPOSARCOMA TUMOR MICROENVIRONMENT

[1]Jacqueline Oliva*, [1]Younghee Lee, [2]Rebeca Rodriguez, [1]Katarzyna Tomczak, [1]Davis Ingram, [1]Xiao Zhou, [1]Vinod Ravi, [1]Anthony Conley, [1]John Livingston, [1]Joseph Ludwig, [1]Neeta Somaiah, [1]Cara Haymaker. *[1]University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Wellesley College, Houston, TX, USA*

Background Single agent anti-PD1 therapy has shown limited clinical benefit in liposarcoma, but combination with anti-CTLA-4 demonstrated a higher response rate.[1-3] In the MDACC study NCT02815995, combining anti-CTLA4 and anti-PDL1 across multiple soft-tissue sarcomas increased CD73, PD-1, and OX40 expression in T cells early on treatment. The adenosine pathway, which includes CD73 and the A2A receptor, induces immunosuppression[4,5] and protects from antitumoral responses.[6, 7] This pathway is related to immune therapy resistance[8-11], metastasis, and poor prognosis.[12-15] Conversely, CD73+ T cells have long-lived memory and higher proliferation and survival, suggesting a dual role of the pathway.[16-18] We hypothesized that adenosine would negatively correlate with TIL expansion and function.

Methods Surgically resected liposarcoma samples (n=41), are divided for fresh tissue phenotyping by flow cytometry, TIL expansion, and quantification of tissue adenosine, cytokines, and adipokines. The phenotypic analysis included: CD73, A2aR, PD-1, Tim3, CTLA-4, LAG3, OX40, ICOS and 41BB markers. TIL 3.0 expansion protocol[19] was performed, and expanded TIL were assessed for cytotoxicity by IFN-g production and metabolic state (ROS, mitochondrial activity) by flow cytometry.

Results We found high heterogeneity in the frequency of CD45+ cells (0-88.3%), CD4+ and CD8+ TIL infiltrate, and expression of PD-1 (0.66-59.60% and 0.99-76.6% respectively), CD73 (CD4+ 0- 40.97%, CD8+ 0-34.04%), and A2AR (mean CD4+ 0-0.6%, CD8+ 0-17.96%), with no co-expression of CD73 and A2AR. Interestingly adenosine concentration was highly variable (0-84.05 nmol/g tissue) but did not correlate with TIL phenotype or tissue cytokines. Tumors were rich in growth factors and chemokines but lacked a pro-inflammatory profile. The success of TIL expansion was 50% (n=24 cases) in samples with a count of 300 CD3+ events in the fresh tissue by flow analysis. The frequency of CD8 +CD73+ TIL was significantly higher in cases with successful TIL expansion (p=0.041). The expanded TIL phenotype showed CD73 expression (range: CD4+ 0.67-29 % and CD8 + 0.85-13.9%) and upregulation of A2AR (range: 0.2-15.40% and 1.44-87.6%). IFN-g production was related to intrinsic metabolic profiles by mitochondrial mass and ROS production (n=8).

Conclusions A heterogeneous adenosine landscape was found in liposarcoma. A2AR but not CD73 correlated with mitochondrial dysfunction and reduced cytotoxicity. Conversely CD73+ TIL were more likely to expand. Our results indicate a dichotomy in two key members in the adenosine pathway in liposarcoma and suggest that CD73 might play a positive role in TIL function.

1043 HIGH VISTA EXPRESSION ON TUMOR-INFILTRATING LYMPHOCYTES IS PROGNOSTIC OF POOR SURVIVAL IN PATIENTS WITH ENDOMETRIAL CANCER

[1]Sachin Patnaik*, [1]Cassandra Gilmour, [2]Stefanie Avril, [1]Andrelie Branicky, [1]Ajay Zalavadia, [1]Judith Drazba, [1]Li Wang. *[1]Cleveland Clinic Foundation, Cleveland, OH, USA; [2]University Hospitals Cleveland, Cleveland, OH, USA*

Background Immune checkpoint inhibitor therapy has become an effective treatment option for many types of cancers. By enhancing the function of anti-tumor T cells, inhibitors targeting PD1, PDL1, and CTLA4 have shown durable clinical results and increased patient survival. However, the response rate to these checkpoint blockades is generally limited to 30-40% of patients, with the majority failing to respond. This suggests the need to investigate other targets for immunotherapy. One promising candidate is V-domain Immunoglobulin Suppressor of T cell Activation (VISTA), an immune checkpoint protein expressed on several lymphocyte and myeloid lineages, including regulatory T cells, cytotoxic T cells, monocytes, and myeloid-derived suppressor cells. VISTA has been found to potently impair anti-tumor immunity by negatively regulating the activation and function of tumor-reactive T cells. Targeting VISTA has therefore been the focus of several preclinical and clinical studies, with current anti-VISTA antibodies in development as well as in clinical trial. Our study explores the association of VISTA expression on tumor-infiltrating lymphocytes (TILs) with patient outcomes in endometrial cancer.

Methods Pretreatment tissue samples were collected from 121 women diagnosed with endometrial cancer at University Hospitals Cleveland, Cleveland, Ohio, between 2006 and 2012. Tumor microarray (TMA) sections of 4 micron thickness were fixed for multiplex immunohistochemistry using clinically established protocols and stained with a panel of PanCK, CD3, FOXP3, VISTA, TIGIT, and DAPI. TMA measurements were quantified to determine patient subpopulations based on protein expression. Using these data, Kaplan-Meier curves were constructed to analyze overall survival and recurrence-free survival for different groups based on checkpoint protein expression levels in immune cell subsets. Follow-up time for survival outcomes was from 2006 to 2018.

Results We found that the high expression of VISTA on TILs correlates to worse overall survival as well as worse recurrence-free survival. In contrast, TIGIT expression on TILs is not a prognostic factor.

Conclusions Our data elucidate VISTA's importance as a prognostic immune marker for poorer outcomes in patients with endometrial cancer. These results also demonstrate the value of exploring VISTA as a potential immunotherapy target for improving survival.

Ethics Approval Our studies have been approved by the Ethics Committee of the Cleveland Clinic Foundation.

1044 PROTEASOME MEDIATED PROTEIN CATABOLISM FUELS ANTITUMOR IMMUNITY

[1]Brian Riesenberg*, [1]Elizabeth Hunt, [2]Megan Tennant, [1]Katie Hurst, [2]Alex Andrews, [2]Lee Leddy, [2]David Neskey, [2]Elizabeth Hill, [3]Guillermo Rangel Rivera, [3]Chrystal Paulos, [4]Peng Gao, [1]Jessica Thaxton. *[1]University of North Carolina, Chapel Hill, NC, USA; [2]Medical University of South Carolina, Charleston, SC, USA; [3]Emory University, Atlanta, GA, USA; [4]Northwestern University, Chicago, IL, USA*

Background The solid tumor microenvironment (TME) exposes CD8 T cells to metabolic stressors including nutrient and oxygen deprivation coupled with persistent antigen stimulation which work in concert to inhibit cell function.[1-5] Importantly, successful immunotherapy is predicated on CD8 T cells overcoming these hurdles to maintain proliferation and protein secretion. While recent advances in single cell RNA and ATAC sequencing have allowed for identification of genetic and epigenetic traits associated with enhanced antitumor T cell function [6-7], little is known about the mechanisms responsible for controlling the translation of these instructions into effector functions. In this study, we sought to identify the mechanisms responsible for allowing sustained protein translation in the TME.

Methods Protein synthesis was monitored using a flow cytometry-based approach whereby the fluorescent analogue of methionine, L-homopropargylglycine (L-HPG), is incorporated into new forming polypeptide chains and quantified by flow cytometry through Click-IT chemistry.[8-11] Optimal antitumor T cells were generated via cytokine conditioning with IL-15 and then subjected to a series of *in vitro* tumor-T cell coculture systems and *in vivo* tumor growth experiments. Proteasome activity was monitored using a fluorescent activity probe via flow cytometry and pharmacologic intervention using the proteasome inhibitor MG-132 paired with metabolomics. Proteasome stimulator Cyclosporine A was used to validate our findings.

Results Using both human and mouse tumors we found that protein translation is repressed in T cells by the solid TME through activation of the unfolded protein response element p-eIF2a due to competition for glucose. Reprogramming T cells away from glucose dependency alleviated p-eIF2a mediated translation attenuation allowing for sustained translation under TME stress. Using metabolic and pharmacological approaches, we discovered that optimal antitumor T cells mitigate p-eIF2a through enhanced proteasome activity, protecting from translation attenuation enabling sustained cytokine synthesis in solid tumors that resulted in enriched tumor control. Additionally, we found the ability to access protein degradation via the proteasome complex was associated with metabolic programs previously linked to optimal antitumor immunity such as glutathione metabolism and gluconeogenesis.[12]

Conclusions These findings suggest that stress mediated attenuation of translation represents a cellular checkpoint which must be overcome for optimal tumor immunity. Our findings demonstrate protein degradation is a critical component of T cell tumor control and strategies that relieve the misfolded protein burden could be avenues to supplement current immunotherapy approaches.

1045 HIGH DIMENSIONAL PROFILING OF MERKEL CELL POLYOMAVIRUS-SPECIFIC T CELLS IN RESPONSE TO ANTI-PD-1 IMMUNOTHERAPY

[1]Heeju Ryu*, [1]Timothy Bi, [1]Korok Sarkar, [2]Candice Church, [1]Nirasha Ramchurren, [2]Thomas Pulliam, [1]Steven Fling, [2]Paul Nghiem, [1]Evan Newell. *[1]Fred Hutchinson Cancer Center, Seattle, WA, USA; [2]University of Washington, Seattle, WA, USA*

Background Merkel cell carcinoma (MCC) is an aggressive skin cancer often associated with clonal integration of Merkel cell polyomavirus (MCPyV) and expression of T antigen oncoproteins in 80% of cases with the remainder of cases caused by UV mutations.[1,2] PD-1 blockade is effective in treating both etiologies of MCC patients, however, only ~60% of patients respond.[3] MCPyV-specific T cells are implicated in immunotherapeutic responses[4], yet further qualitative and quantitative analysis of those cells among responders and non-responders is needed.

Methods We analyzed MCPyV-specific T cells in blood from responders (CR, n=13) and non-responders (n=6 for partial responses, PR; n=5 for stable and progressive disease, SD/PD) before, during and after anti-PD-1 immunotherapy (from trial NCT02267603) using a mass cytometry (CyTOF)-based multiplexed peptide-MHC tetramer staining approach. This allowed us to simultaneously assess 76 MCPyV epitopes and 34 control epitopes derived from viruses such as CMV, EBV, Flu, and HSV, in parallel with 34 cellular phenotyping markers of differentiation, trafficking, and exhaustion. We also performed deep TCR sequencing of sorted T cell populations from the blood samples to track T cell clonotypes between the periphery and tumor.

Results Combinatorial tetramer staining with CyTOF allowed us to detect T cells specific for 11 previously reported and 5 novel MCPyV-specific epitopes. Frequencies of MCPyV-specific cells were higher in patients with CR (mean = 0.103% of $CD8^+$ T cells) than those with PR (mean = 0.021%; P=0.007) and SD/PD (mean = 0.003%; P<0.0001) at the baseline, and decreased over the course of immunotherapy in patients with CR. Strikingly, the phenotypes of MCPyV-specific $CD8^+$ T cells were enriched for an activated/exhausted ($CD71^+PD\text{-}1^+CD39^+$) phenotype. Those cells also highly expressed cutaneous lymphocyte-associated antigen (CLA), a marker of skin trafficking, and CD103, a marker of tissue-recirculating cells. Informed by these phenotypes, high-dimensional profiling of bulk $CD8^+$ T cells revealed correlations of the frequencies of $CD39^+$ cells co-expressing CLA or CD103 with both the baseline tumor burden and magnitude of clinical outcome. TCR sequencing was used to assess clonal sharing between tumor infiltrating T cells and these subpopulations of $CD8^+$ T cells from blood.

Conclusions Although these findings need to be confirmed in an independent cohort, our high-dimensional analysis and immune profiling of MCC patients suggest that MCPyV-specific cells and $CD39^+$ cells co-expressing CLA or CD103 in blood are enriched for tumor-reactive TCRs and potentially useful as blood-based biomarkers of response to immunotherapy or for novel cellular therapeutic strategies.

1046 TARGETING NOVEL PATHWAYS IN CHRONICALLY ACTIVATED T CELLS PREVENTS FUNCTIONAL EXHAUSTION

Justyna Rzepecka*, Andrew Hall, Mark Barbour, Emma Mallon, Marija Bedaj, Lucia Janicova, Xabier Cortes-Lavaud, Frances Acklam, Joanne Hay, Hayley Gooding, Darryl Turner, Preeti Singh, Aaron Crawford. *Concept Life Sciences, Edinburgh, UK*

Background In cancer, persistent antigenic challenge leads to T cells acquiring a hyporesponsive cell state, also referred to as T cell exhaustion. We have previously demonstrated that human $CD3^+$ T cells repeatedly stimulated *in vitro*, via their TCR, develop phenotypical characteristics of exhausted T cell found *in vivo*, including increased expression of inhibitory receptors PD-1, TIM-3 and LAG-3 and diminished responsiveness to dendritic cell activation and cancer cell cytotoxicity. We showed that PD-1 blockade with nivolumab and treatment with an IKZF3 inhibitor, lenalidomide, reinvigorated the exhausted T cells. We next wished to evaluate if blocking of IKZF3 during the development of T cell exhaustion could protect them from acquiring the exhausted phenotype.

Methods Human $CD3^+$ T cells, isolated from healthy PBMC donors, were repeatedly stimulated with anti-CD3/anti-CD28 coated beads to mimic chronic antigenic challenge. The stimulations were conducted in the presence or absence of lenalidomide. T cells, both $CD4^+$ and $CD8^+$, were assessed for changes in expression of inhibitory receptors and cytokine release was quantified. Following the final round of TCR stimulation, T cells were co-cultured with allogeneic dendritic cells to determine if their functionality has been altered by lenalidomide treatment. T cell proliferation and IFN-g release were assessed as well as changes in inhibitory receptor expression at the end of the co-culture.

Results We demonstrated that lenalidomide had no impact on T cell viability or $CD4^+/CD8^+$ ratio in repeatedly stimulated cultures. Lenalidomide did however affect inhibitory receptor expression and impacted cytokine secretion from chronically stimulated T cells. Lenalidomide led to increased PD-1 expression on $CD8^+$ T cells and LAG-3 expression on $CD4^+$ T cells whereas TIM-3 expression was downregulated on both T cells subsets in the presence of compound. Lenalidomide enhanced production of cytokines in repeatedly stimulated T cells. To assess if lenalidomide-driven changes had any impact on T cell functionality, we cultured lenalidomide-treated and untreated repeatedly activated T cells with allogeneic dendritic cells. Whilst repeatedly stimulated T cells not exposed to lenalidomide showed diminished ability to proliferate and secrete IFN-g, consistent with their exhausted cell state, lenalidomide treated T cells displayed increased IFN-g secretion suggesting that lenalidomide protected repeatedly stimulated T cells from acquiring an exhausted phenotype.

Conclusions The *in vitro* assays described herein offer the opportunity to investigate the effect of candidate therapeutics, including combination therapies, on exhausted T cell development and function.

1047 FROM EXHAUSTION TO MEMORY: ALTERING T CELL FATE IMPROVES IMMUNOTHERAPEUTIC RESPONSES TO CANCER

Nicole Scharping*, Allison Cafferata, Maximilian Heeg, Quynhanh Nguyen, Ananda Goldrath. *University of California San Diego, San Diego, CA, USA*

Background In cancer, $CD8^+$ T cells have the power to target and kill tumor cells with precision but often fail due to chronic activation from the immunosuppressive tumor microenvironment (TME), differentiating into a dysfunctional cell state known as exhaustion. In healthy tissues, T cells differentiate into tissue-resident memory cells (T_{RM}) in response to infection, which remain lodged in tissues to provide protection from reinfection. When T_{RM} cells are found in patient tumors, they correlate with improved responses to immunotherapy and patient outcomes. Understanding how to manipulate T cell fates to avoid exhaustion and favor T_{RM} characteristics could benefit cancer immunotherapy.

Methods To explore differences between these cell states, we screened the core T_{RM} gene expression signatures for genes downregulated as T cells differentiate to terminal exhaustion. Targets were then overexpressed in antigen-specific T cells and adoptively transferred into tumor-bearing mice for analysis.

Results We found many genes related to protein regulation were identified, including multiple E3 ubiquitin ligases with not well-described targets. When these genes are individually overexpressed in tumor-specific T cells, we found the transduced T cells express less inhibitory receptors and showed enhanced anti-tumor function: increased accumulation in the TME, upregulation of T_{RM} markers, and polyfunctional cytokine production, which resulted in controlled tumor growth and increased mouse survival in multiple cancer models.

Conclusions These results highlight the understudied field of negative regulation of T cell function by protein degradation in T cell differentiation fate and function, and uncovers potential gene targets for immunocellular therapies to favor functional T cell fates in cancer.

1048 INTERPLAY OF IL-12 AND IFNG TO INDUCE T_{REG} FRAGILITY WITHIN THE TUMOR MICROENVIRONMENT

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1048

Ellen Scott*, Angela Gocher, Creg Workman, Dario Vignali. *University of Pittsburgh, Pittsburgh, PA, USA*

Background Immune cells play an integral role in the prevention as well as the progression of cancers. Within the T cell compartment, regulatory T cells (T_{regs}) suppress the anti-tumor T cell response through use of direct and indirect mechanisms.[1,2] However, under some circumstances T_{regs} can lose their suppressive activity while retaining expression of their master transcription factor, Foxp3, a phenomenon our lab has termed T_{reg} fragility.[3] A hallmark of T_{reg} fragility is production of IFNg, a pleiotropic cytokine necessary for response to cancer immunotherapies such as anti-PD1.[4] However, it is unknown the exact mechanism that leads to T_{reg} fragility as well as the consequences of T_{reg}-produced IFNg. By using a novel transgenic mouse with a conditional deletion of IL-12Rb2 (*Il12rb2.Thy1.1*$^{L/LhNGFR}$ *Foxp3*$^{Cre.YFP}$) in T_{regs} we were able to test the effect of IL-12 signaling on T_{reg} function and response to different immunotherapies during tumor progression.

Methods We inoculated wildtype mice with MC-38 adenocarcinoma or B16 melanoma and determined the amount of IL-12 and IFNg induced by different immunotherapies. We also inoculated mice with a T_{reg}-specific IL12R deletion with MC-38 or B16 and characterized the effect of IL-12R loss on T_{reg} function after immunotherapy treatment by measuring tumor growth and flow cytometric analyses of intratumoral T_{regs}.

Results We have found that anti-PD1 therapy is able to cause modest increases in IFNg and IL-12 levels within the tumor. In contrast, when using an IL-12 inducing therapy (anti-CD40 agonism) there was a larger amount of IL-12 intratumorally along with very large increases of IFNg levels in both tumors and serum of wildtype mice. However, when mice with IL-12R deficient T_{regs} were treated with either of these therapies, tumor growth was not affected. Additionally, flow cytometric analyses of these mice after anti-CD40 agonist treatment suggests that these T_{regs} are still sensitive to fragility induction.

Conclusions These data suggest that IL-12 is not necessary for the induction of T_{reg} fragility. More specifically, these data may indicate that the increase in IFNg that is induced by immunotherapy may circumvent the IL-12 signaling loss in our mouse model and induce T_{reg} fragility. While the mechanism of how IL-12 is effecting these changes still unknown, this evidence suggests that IL-12 can indirectly induce fragility in T_{regs} and therefore augment the TME and the response to immunotherapy.

1049 RECONSTRUCTION OF GENE REGULATORY NETWORKS DISSECTS TRANSCRIPTIONAL CONTROL OF INTRATUMORAL REGULATORY T CELLS

[1]Feng Shan*, [1]Anthony Cillo, [1]Carly Cardello, [1]Daniel Yuan, [1]Sheryl Kunning, [1]Jian Cui, [1]Robert Ferris, [1]Tullia Bruno, [1]Creg Workman, [2]Panayiotis Benos, [1]Dario Vignali. *[1]University of Pittsburgh, Pittsburgh, PA, USA; [2]University of Florida, Gainesville, FL, USA*

Background Regulatory T cells (T_{reg}) -targeted therapy exhibit clinical benefit and has been reported as a promising strategy. However, many gaps remain in our understanding of T_{reg} biology within the context of tumor microenvironment (TME). The autoimmune toxicity and restricted efficacy are major limitations of T_{reg} therapies in the clinic, when T_{reg} depletion occurred not only in the tumor but in other organ systems, or concurrent downregulation of antitumor effector T cells.[1, 2]

Methods We profiled 51,195 single-cell transcriptomes of $CD4^+$ T cells in tumors and peripheral blood from patients with head and neck squamous cell carcinomas (HNSCC)[3], in inflamed tonsil tissues and in healthy peripheral blood. Canonical genes, gene sets and RNA Velocity[4] were used to define cell states of T_{reg}. Cibersortx[5] and bulk RNA sequencing data in The Cancer Genome Atlas were used to infer the association between the enrichment of T_{reg} subpopulations and progression-free survival of patients with solid tumors. SCENIC[6] and Causal mixed graphical modeling[7] were used to reconstruct the gene regulatory network (GRN). Knockout of *BATF* with CRISPR-Cas9[8] in conjunction with bulk RNA sequencing, immunophenotyping and in vitro functional assays were used to interrogate the roles of BATF in human activated T_{reg}.

Results We identified an activated subpopulation of T_{reg} expressing multiple tumor necrosis factor receptor (TNFR) genes, including *OX40* and *4-1BB*, which is highly enriched in solid TME compared with non-tumor tissues. These TNFR-activated T_{reg} were associated with worse prognosis across solid tumors. Notably, we found *BATF* is a central component of a GRN that controls the transcriptional signature of TNFR-activated T_{reg}. Consistent with single-cell analyses, BATF was co-expressed with 4-1BB, OX40, CD96 and CD39 that highly enriched in HNSCC intratumoral T_{reg} at protein level. CRISPR-editing results revealed an enhancement of immunosuppression in *BATF* KO T_{reg} and activation in *BATF* KO T_{reg} accompanied with increased expression of genes including 4-1BB, OX40, ICOS, LAG3 and neuropilin-1, indicating that BATF functions as a transcriptional nexus in human activated T_{reg} that essential for T_{reg} activation, function and stability.

Conclusions We identify a unique intertumoral subpopulation of T_{reg} characterized by BATF-driven expression of tumor necrosis factor receptor family expression and associated with survival across solid tumors, suggesting a possibility to target suppressive intratumoral T_{reg} without causing overt autoimmunity in normal tissues. A deeper understanding of transcriptional network in T_{reg} biology will provide novel mechanisms for immunotherapies in cancer, but also for T_{reg} engineering in autoimmunity.

1050 SINGLE CELL TRANSCRIPTOME AND EPIGENOME PROFILING REVEALS THE DIVERSITY OF T CELL STATES IN *EX VIVO* GROWN TUMOR-INFILTRATING LYMPHOCYTES FROM MALIGNANT PLEURAL MESOTHELIOMA

Katarzyna Tomczak*, Carlos Ramos, Nathaniel Deboever, Nicolas Zhou, Jacqueline Liszeth Oliva, Chang-Jiun Wu, Chad Strange, Annikka Weissferdt, David Rice, Reza Mehran, Jianjun Zhang, Mehmet Altan, Anne Tsao, Boris Sepesi, Cara Haymaker. *University of Texas MD Anderson Cancer Center, Houston, TX, United States*

Background Malignant pleural mesothelioma (MPM) is a rare and aggressive cancer associated with exposure to asbestos that lacks effective treatment options.[1] Immunotherapy approaches remain challenging with a current paucity of knowledge on the tumor-infiltrating lymphocyte (TIL) landscape.[2] We aimed to generate a reference transcriptomic and epigenomic atlas of MPM T cell subpopulations that could inform on cellular features and states of propagated *ex vivo* cells to allow new immunotherapy design.

Methods TIL were expanded utilizing the MDACC 'TIL 3.0' method from surgically managed MPM patients (n=8, 6/8 cases received chemotherapy with treatment ending an average of 82 days prior to surgery).[3] Cells were processed for 10x Genomics 5' single cell (sc) RNA- and scATAC-seq profiling. Analysis was performed using 10x Genomics cell ranger pipelines. Downstream analysis was performed in R utilizing Seurat and Signac packages, following Monocle3 trajectory analysis.[4–6] The significant expression of key defining genes was used to label cell states. Wilcoxon Sum Ranking test was applied for determination of statistical significance of genes (adjusted p-value significance: 0≤*** <0.001≤** <0.01).

Results Profiling revealed 18 clusters: one CD4+ T cell cluster (CD4-CD40LG), twelve clusters representing different CD8+ states (CD8-CD27, CD8-MIF, CD8-ZNF683, two MAIT, IL9R-Tcells, five CD8-MKI67 and CD8-TOX), four gamma-delta T cell clusters (?d-TRDC), and one unique cluster (MALAT1). scATAC-seq analysis of the MPM TIL paired with their transcriptomic clusters validated the presence of existing cell states with trajectory analysis confirming the separation of the distinct cell states. Activation and inhibitory markers showed heterogenous pattern. Upregulation of activation markers OX40 (*TNFRSF4****) and ICOS*** was present in CD4-CD40LG and OX40 (*TNFRSF4****) marker in IL9R-Tcells. Moreover, CD4-CD40LG showed high upregulation of CTLA4*** and GITR (*TNFRSF18****), whereas, among CD8+ subsets, GITR *** expression was observed only in γδ-TRDC and IL9R-Tcells. γδ-TRDC also displayed heterogenous upregulation of other inhibitory markers as TIGIT, LAG3 and TOX. Progenitor exhausted state transcription factor TCF7*** was only observed in CD8-CD27 and across CD8-MK67 populations. Transcription factors *PRDM1****, *MAF**** promoting T cell exhaustion were present within MALAT1 cluster.

Conclusions As expected, CD8+ TIL states predominated the grown TIL products. The expression of signature genes suggested presence of several activated and proliferating CD8+ states, tissue resident memory CD8+, an effector CD4+ state and a γδ+ T-cell state. The presence of inhibitory receptors is heterogenous and informs the dysfunctional states of cells, which may be of use for design of novel immunotherapy strategies.

1051 RADIATION DOSE-RELATED TEMPORAL CHANGES IN STING-ASSOCIATED IMMUNE GENES IN MURINE CD8 T CELLS

Ana Torres*, Amanda Shea, Wonjong Jin, Caroline Kerr, Kaleb Schroeder, Paul Clark, Zachary Morris. *University of Wisconsin-Madison, Madison, WI, USA*

Background Systemic lymphopenia from radiation results in poor outcomes for patients. Clinical interventions can reduce lymphopenia; however, more efficient treatments could drastically improve patient outcomes, particularly when receiving immunotherapeutic treatments. Interactions of T cells, radiation, and the tumor microenvironment remain largely unknown, and in this study, we examined modulation of CD8 T cell transcriptional activity after radiation at various doses and time points.

Methods Five spleens of C57BL/6 mice were disaggregated into single cell suspensions and positively sorted with a CD8 T cell isolation kit. The $CD8^+$ cell suspensions were expanded *in vitro* for 9 days with CD3/CD28 plate-bound stimulation and then left unirradiated (0Gy control) or administered 2Gy, 8Gy, 12Gy, or 20Gy. At 24-, 48-, and 72-hours post-irradiation, the cells were collected for RNA, followed by expression analysis using qPCR. Fold-change (with relation to 0Gy) expression data were compared among multiple cohorts using a two-way ANOVA with a post hoc Tukey test.

Results We identified several immune genetic changes in irradiated CD8 T cells compared to unirradiated controls. *Ifn*-??, a direct stimulator of type 1 IFN response, expression was highest at 72 hours post radiation, with all doses exhibiting >10-fold increases ($p<0.006$). *Irf3*, a transcription factor of type 1 interferons, was increased in 8Gy, 12Gy, and 20Gy conditions, and expression levels were highest 48 hours post radiation in the 8Gy condition ($p=0.0009$).*Trex1*, a potential negative regulator of STING-response, increased in a dose dependent manner with the highest expression being a 14-fold increase at 48 hours post radiation (p-values for all conditions <0.0001, except 2Gy ns). Interestingly, *Ifn*-??, a Type 2 interferon response and activated T cell interferon, was also increased ($p<0.0001$) at 8Gy 48 hours post radiation. *Pd-L1* and *Mhc-1* expression both increased at all radiation doses with highest expression at 48 hrs (*Mhc-1*: 2-10 fold increase; *Pd-L1*: 2-7 fold increase).

Conclusions Radiation dose-related and temporal changes in transcription of various immune genes (*Ifn*-??, *Irf3*, *Trex1*, *Ifn*-??, *Pd-L1*, *Mhc-1*) suggests CD8 T cells play a role in activation, maintenance, and regulation of immune response, at least partially via the STING pathway. Changes included actionable targets such as *Pd-L1* and *Mhc-1* that could inform timing of immunotherapies to patients such as immune checkpoint inhibitors and CAR-T cells.

Ethics Approval All animal experiments were performed with the approval of UW Madison Institutional Animal Care and Use Committee (IACUC). PI Zachary Morris M005670. No human materials were used in the experiment described. All experiments were conducted under BSL-1 conditions with the approval of the UW Institutional Safety Board (B00000510).

1052 TISSUE-SPECIFIC INTERFERON-GAMMA DRIVES REGULATORY T-CELLS TO RESTRAIN DC1-MEDIATED PRIMING OF CYTOTOXIC T-CELLS AGAINST LUNG CANCER

[1]Maria Zagorulya*, [1]Leon Yim, [1]Duncan Morgan, [2]Austin Edwards, [1]Elen Torres-Mejia, [1]Noor Momin, [1]Chloe McCreery, [1]Izabella Zamora, [1]Brendan Horton, [1]K Wittrup, [1]J Love, [1]Stefani Spranger. [1]*Massachusetts Institute of Technology, Cambridge, MA, United States*; [2]*University of California San Francisco, San Francisco, CA, United States*

Background Although failure to respond to checkpoint blockade immunotherapies is frequently associated with a lack of T-cell infiltration into the tumor, clinical data suggests that in patients with lung cancer, T-cell-inflamed tumors can also be resistant to therapy.[1] Work by us identified that checkpoint blockade immunotherapy resistance in T-cell-inflamed lung cancer is driven by lung cancer-specific $CD8^+$ T-cell dysfunction, characterized by reduced cytolytic capacity and established during priming in the mediastinal lymph nodes (mLN).[2] In this study, we sought to uncover lung-specific mechanisms that blunt priming of anti-tumor cytotoxic T-cell responses.

Methods To study T-cell priming against lung cancer, we implanted a syngeneic lung cancer cell line (KP) orthotopically in the lungs or subcutaneously in the flanks of C57BL/6 mice. Immune subsets were profiled using flow cytometry, immunofluorescence staining and RNA-sequencing. Immunological mechanism was dissected using adoptive T-cell transfers, bone marrow chimeras and *ex vivo* co-cultures.

Results Both lung and flank KP tumors resulted in type-1-conventional dendritic cell (DC1)-dependent expansion of tumor-reactive T-cells, however, $CD8^+$ T-cells primed in response to lung tumors in the mLN failed to upregulate key markers of effector $CD8^+$ T-cell differentiation, namely CD25 and Granzyme B. Comparing DC1 from tumor-draining inguinal (iLN) and mLN revealed equivalent antigen load, but reduced expression of CD80, CD86 and IL-12 on mLN-derived DC1. Regulatory T-cell (Treg) depletion rescued both stimulatory molecule expression on DC1 and cytotoxic T-cell priming in the tumor-draining mLN, suggesting that lung $CD8^+$ T-cell dysfunction required the local presence of Treg during priming. *Ex vivo* co-cultures validated that DC1 and Treg were required and sufficient to induce dysfunctional $CD8^+$ T-cells. This immunosuppression was spatially coordinated within tissue-specific LN microniches and required antigen-specific contact between DC1 and Tregs, as abrogating MHCII-dependent Treg:DC1 interactions restored DC1 capacity to prime cytotoxic T-cell responses against lung tumors. The lung-specific suppression was associated with clonally expanded $CXCR3^+$ T_H1-like effector Tregs, which were induced upon interferon sensing in the mLN. Consequently, interferon-gamma neutralization early during tumor induction could prevent the immunosuppression and restore cytotoxic T-cell priming in the mLN. Similarly, in cancer patients, interferon-sensing $CXCR3^+$ Tregs but not $CD8^+$/Treg ratios correlated with resistance to checkpoint blockade immunotherapy.

Conclusions Our work suggests that the functional quality of Tregs, specifically the interferon-induced $CXCR3^+$ T_H1-like effector state, rather than Treg quantity, is instrumental in restraining tumor-reactive T-cell responses and represents a critical barrier to productive anti-tumor immunity.

1053 IDENTIFICATION OF DISTINCT IMMUNE LANDSCAPES OF INFILTRATING T CELLS IN COLON CANCER USING MULTIPLEX IMMUNOFLUORESCENCE STAINING

[1]Hehuan Zhu*, [1]Jessica Roelands, [2]Eiman Ahmed, [1]Imke Stouten, [1]Rachel Hoorntje, [1]Ronald Vlierberghe, [1]Marieke Ijsselsteijn, [1]Noel Miranda, [1]Rob Tollenaar, [2]Wouter Hendrickx, [2]Davide Bedognetti, [1]Peter Kuppen. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Sidra Medicine, Doha, Qatar*

Background The immune system recognizes foreign microorganisms as "non-self" and reacts to destroy these disease-causing agents, playing a similar role in protecting the body from malignancies. The spatial distribution of T cell subsets in tumor tissues, like colon cancer, may provide information on the role of the immune system in tumor development. To gain novel insights into different types of T cells including cytotoxic T (Tc) cells, helper T (Th) cells, and regulatory T (Treg) cells, a seven-color multiplex immunofluorescence (mIF) panel was used to study the number and spatial distribution of these T cell subsets in a panel of colon tumors.

Methods We simultaneously assessed CD3, CD8, Foxp3, Ki67, Granzyme B and pan cytokeratin in ninety colon cancer cases using a tyramide signal amplification based mIF approach. Using dedicated image analysis software, we analyzed the multiple cell phenotypes and their spatial distribution inside tumor stromal and epithelial regions of interest. Moreover, in a previous study, next-generation sequencing was performed on the same samples, resulting in consensus clustering based on the immunologic constant of rejection (ICR) genes,[1] segregating colon cancer patients in three different groups: ICR low, medium and high. Statistical analyses were conducted to determine associations between the density of T cell subsets and their spatial location.

Results All T cell subtypes were more prevalent in the stromal fraction than in the epithelial fraction, but the proportion of Ki-67+ or Granzyme B+ T cells was significantly higher in the tumor epithelium than in the tumor stroma. In both tumor epithelium and tumor stroma, T cell densities were significantly higher in those with high ICR than in those with low ICR. Meanwhile, the median distance between immune cells and epithelial cells was significantly smaller in ICR-high than in ICR-low. Interestingly, patients with an ICR high/Th cells high experienced improved overall survival ($p = 0.016$).

Conclusions In this study, we quantified the spatial distribution of T cell subsets and highlight the tumor infiltration of Th cells, which can improve the prognostic value of T cell immune signatures in colon cancer.

1054 MYELOID AND T CELL SUBSETS DEFINED IN BLADDER CANCER USING SINGLE-CELL RNA SEQUENCING AND PAIRED PROTEIN PROFILING

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1054

[1]Viktor Sincic*, [2]Ashfaq Ali, [1]Alar Aab, [1]Thoas Fioretos, [1]Carl Borrebaeck, [1]Fredrik Liedberg, [1]Kristina Lundberg. *[1]Lund University, Lund, Sweden; [2]National Bioinformatics Infrastructure Sweden, Lund, Sweden*

Background Muscle-invasive bladder cancer (MIBC) has a 5-year survival of only 50% despite preoperative chemotherapy and radical cystectomy. For non-muscle-invasive bladder cancer (NMIBC), the 5-year survival rate is > 80%, but the local recurrence rate is very high. Immune checkpoint inhibitors can drastically increase survival, however only a fraction of bladder cancer patients is currently responding. We have performed single-cell RNA sequencing (scRNAseq) of tumor-infiltrating immune cells from NMIBC and MIBC biopsies as well as full-length scRNAseq with parallel protein profiling of T cells in MIBC, to pinpoint novel targets for immunomodulatory therapy.

Methods Tumor biopsies obtained from untreated patients with MIBC (N= 14) and NMIBC (N=4) were mechanically and enzymatically digested into single cell suspensions and either $CD45^+$ or $CD3^+$ cells were sorted. Parallel protein assessment (index sorting) was performed for $CD3^+$ cells. In total, 30 000 $CD45^+$ and 4061 $CD3^+$ cells were processed according to the 10x Genomics and Smart-seq3 protocols, respectively.

Results Approximately 1600 and 4000 genes per cell were detected using the 10x and Smart-seq3 methodologies, respectively. The transcriptomic immune cell landscape in NMIBC and MIBC was delineated and within the myeloid compartment, e.g. $SPP1^+$tumor associated macrophages (TAMs) were identified and shown to correlate with response to checkpoint blockade in the IMvigor210 cohort.[1] Within the T-cell compartment, populations including cytotoxic $CD4^+$ and $CD8^+$ T cells and exhausted $CD8^+$ T cells were identified and their transcriptional profiles were defined. Of note, using protein-level data from the index sorting, two populations of cytotoxic $CD4^+$ T cells with remarkable similarity to $CD8^+$ counterparts were identified. Furthermore, $CD56^+$ T cells were found to differentially populate certain T cell clusters, including Treg and cytotoxic T cell clusters.

Conclusions Our results provide new insights into the myeloid and lymphocyte compartment in the microenvironment of bladder cancer. This understanding can give clues for designing novel treatment strategies.

1055 IMMUNE CELL SUBTYPES ASSOCIATED WITH THE LEVEL OF TUMOR-INFILTRATING LYMPHOCYTES IN BREAST TUMOR MICROENVIRONMENT

[1]Su Min Cha*, [1,2]Jeong-Han Seo, [2,3]Jung-Wook Park, [2]Hee Jae Lee, [1,2]Hee Jin Lee. *[1]University of Ulsan College of Medicine, Seoul, South Korea, Republic of; [2]NeogenTC Corp., Seoul, South Korea, Republic of; [3]Sungkyunkwan University, Seoul, South Korea, Republic of*

Background The level of tumor-infiltrating lymphocytes (TILs) is a predictive and prognostic factor for improved clinical outcomes in breast cancer. To identify immune cell subtypes associated with the level of TILs, we compared composition of immune cells between breast cancers with high or low level of TILs using single cell RNA sequencing (scRNA-seq).

Methods The scRNA-seq was performed with dissociated and CD45+ sorted cells from 21 breast tumor tissues. Among them, 12 samples with high TIL (≥ 40%, n=6) or low TIL (≤ 2%, n=6) were compared. Standard procedures were performed by the Seurat package in R. T cells, B cells, monocytes, and dendritic cells (DCs) were separated using the Azimuth package. Differentially expressed genes (DEGs) were computed according to the level of TILs for pathway analysis using ReactomePA package (p value < 0.05, abs(log2 fold change) ≥ 1).

Results The proportion of T cells (60.6% vs 41.8%) and B cells (9.8% vs 3.9%) in the high TIL group were higher than the low TIL group. Monocytes (16.3% vs 29.3%) and DCs (4.6% vs 4.5%) in the high TIL group were lower or not different. In each immune cell type, cell subtypes and clusters were compared by proportion in the high and low TIL groups. T cell subtypes showed no difference between the high and low TIL groups. However, B cells, monocytes, and DCs had different composition of cell subtypes between the high and low TIL groups [B intermediate (22.2% vs 35.8%), B memory (14.2% vs 36.6%), plasmablast (57.1% vs 19.1%), cDC2 (54.5% vs 66.7%), pDC (39.0% vs 27.8%), and 4 monocyte clusters (11.1% vs 19.6%, 12.7% vs 20.1%, 18.8% vs 13.8%, and 14.9% vs 7.5%)]. DEGs derived from differential subtypes between the high and low TIL groups were used for pathway analysis. Upregulated pathways including interleukin and interferon signaling pathways in the high TIL group were shared by several immune subtypes.

Conclusions Composition of immune cell subtypes and their signaling pathways were different between breast cancers with the high or low level of TILs. Further researches for better understanding and modulation of immune cell subtypes associated with high level of TILs are needed to heighten the level of TILs in breast cancer microenvironment.

Immune-Stimulants and Immune Modulators

1056 ZG033, A NOVEL CD137 AGONIST, INDUCES SUPERIOR ANTI-TUMOR ACTIVITY WITHOUT HEPATOTOXICITY RELY ON FC-MEDIATED CROSSLINKING

[1]Liansheng Cheng, [1]Wenting Liu*, [1]Dayan Zhang, [1]Xiaoli Zeng, [2]Guodong Shen. *[1]Hefei Hankemab Biotechnology Co., LTD, Hefei, Anhui, China; [2]The First Affiliated Hospital of University of Science and Technology of China, Hefei, Anhui, China*

Background CD137 (TNFRSF9, 4-1BB) is a member of the tumor necrosis factor receptor superfamily that functions as a costimulatory molecule of immunocytes. Agonistic antibodies against CD137 have shown promising therapeutic activity in mouse tumor models. However, molecules in clinical development have shown limitations due to either dose-dependent severe liver toxicity or modest antitumor activity. We developed ZG033, a fully human IgG4 agonist of CD137 that engages with an exclusive epitope, to achieve a better efficacy and safety profile for immunotherapy.

Methods The biophysical properties and activities were determined using multiple *in vitro* assays, incuding enzyme-linked immunosorbent assay (ELISA), surface plasmon resonance (SPR), cell-based and reporter gene assays. *In vivo* antitumor activities were assessed in human 4-1BB transgenic mice transplanted with human colon cancer cell line MC38. The pharmacokinetic (PK) behavior and safety profiles of ZG033 were characterized in cynomolgus monkeys.

Results ZG033 is a safe and potent antibody injection associated with a differentiated pharmacology and toxicology profile. The structure of the ZG033/CD137 complex was determined by X-ray crystallography. The Fab of ZG033 binds CD137 at an obvious competitive epitope with the CD137 ligand, which differs from the currently known agonist antibodies of CD137. The residues T61A and I64R play a vital role in the formation of the complex, which was demonstrated by affinity assays. The binding affinity to human 4-1BB of ZG033 determined by surface plasmon resonance (SPR) was moderate (KD=10 nM). ZG033 increased CD137-driven NFκB reporter gene activation and the production of IFN-γ by human T cells in an FcγR–dependent manner. In human 4-1BB transgenic mice, ZG033 showed robust single-agent antitumor activity and induced durable antigen-specific immunological memory that prevented the tumor formation in the rechallenged mice. To determine the safety of ZG033, we incubated ZG033 with peripheral blood mononuclear cells (PBMCs) from healthy donors (n=4) and proved that it does not induce nonspecific production of proinflammatory cytokines. The results in 5-week I.V. repeated-dose (3, 10 and 30 mg/kg) and single-dose toxicity studies (60 and 180 mg/kg) suggested that ZG033 was well tolerated in cynomolgus monkeys with no abnormal hepatic or renal function and hematological index.

Conclusions These data demonstrate that ZG033 acts as an FcγR crosslinking-dependent CD137 agonist that displays a favorable safety profile and has potential in either mono- or combinational immunotherapies.

1057 HBM7008, A FIRST-IN-CLASS BISPECIFIC ANTIBODY TARGETING BOTH B7-H4 AND 4–1BB, EXHIBITS ROBUST ANTI-TUMOR IMMUNITY AND LOW TOXICITY THROUGH B7-H4-DIRECTED 4–1BB ACTIVATION

Bing Huang*, Fangfang Du, Xiaocheng Lv, Jianxun Zhao, Fei Chen, Zailian Lu, Yang Zhang, Victor Chen, Xin Gan, Jiuqiao Zhao, Yun He, Xiaodong Wu, Yiping Rong. *Harbour BiMed Co., Ltd, Shanghai, China*

Background 4-1BB is an immune costimulatory receptor. Anti-4-1BB agonistic monoclonal antibodies have high potential of therapeutic efficacy in cancers. However, 4-1BB agonistic antibody urelumab shows dose-limiting hepatotoxicity in clinical trials. B7-H4 is a member of the B7 superfamily. It shows limited expression in most normal tissues but high expression on the surface of tumor cells in breast, ovarian, and endometrial cancers. B7-H4 also inhibits the proliferation and activation of T cells. Blockade of B7-H4 demonstrates some efficacy in mouse models. To overcome the hepatotoxicity of systemically active 4-1BB agonist and to improve the anti-tumor activity of B7-H4 antagonist, HBM7008, a B7-H4x4-1BB bispecific antibody specifically activated in tumor microenvironment, has been developed.

Methods B7-H4 expression of multiple tumor tissues was evaluated by immunohistochemistry staining. Anti-B7-H4 fully human IgG antibodies and anti-4-1BB fully human heavy chain only antibodies (HCAb) were generated from H2L2 and HCAb Harbour Mice®, respectively. HBM7008 was developed from Harbour BioMed HCAb based bispecific immune cell engager (HBICE®) platform. It is composed of anti-B7-H4 IgG1 monoclonal antibody and anti-4-1BB HCAb variable domain fused at the C-terminus of heavy chain constant region with LALA (L234A and L235A) mutations. Its proposed mechanism of action and nonclinical pharmacology were characterized by a series of *in vitro* and *in vivo* assays.

Results B7-H4 showed high prevalence of expression on breast, ovarian, cervical, endometrial cancers, and squamous non-small-cell lung carcinoma. HBM7008 can bind to B7-H4 and 4-1BB simultaneously. HBM7008 robustly induced T cell activation *in vitro* in a B7-H4-dependent manner with activity comparable to that of urelumab. HBM7008 demonstrated potent antitumor activity with complete response and resistance to tumor rechallenge in a mouse model. It also increased proliferation of tumor infiltrating lymphocyte (TIL) cytotoxic CD8+ T and effector memory CD8+ T cells. HBM7008 is a first-in-class bispecific T cell engager targeting both B7-H4 and 4-1BB and enhances T cell function by dual mechanisms: (1) blockade of the B7-H4 mediated T cell inhibition and (2) activation of 4-1BB+ T cells only in a B7-H4 cross-linking dependent manner. In a good laboratory practice-compliant non-human primate 4-week repeat dose toxicity study, HBM7008 was well tolerated up to 100 mg/kg with no discernable drug-related toxicity.

Conclusions HBM7008 demonstrated comparable biological activity to urelumab and improved safety profile characterized by *in vitro* functional assays, *in vivo* antitumor efficacy model, and TIL analysis. These preclinical data support the clinical investigation of HBM7008 for the treatment of cancers.

Ethics Approval The cancer tissue microarray was purchased from Fanpu Biotech, Inc. The company ensured ethical approval from the patients, and patient consent for publication. The anti-tumor efficacy and pharmacodynamics studies in mice were approved by the internal ethics board of the respective contract research organization (CRO). The good laboratory practice-compliant toxicity studies in non-human primate were approved by Ethics Board of an appropriate contract research organizations (CROs).

1058 YH32364 (ABL104), A NOVEL EGFR/4–1BB BISPECIFIC ANTIBODY EXHIBITS POTENT ANTITUMOR EFFICACY WITH AN EXCELLENT SAFETY PROFILE

[1]Eunjung Lee*, [2]Hyejin Chung, [2]Yangsoon Lee, [1]Young Bong Park, [1]Eun-Jung Lee, [1]Hyunmo Koo, [1]Mikyeong Ju, [1]Ju Young Park, [1]Sujin Ahn, [1]Junhwan Kim, [2]Kyeongsu Park, [2]Wonjun Son, [2]Jaehyun Eom, [2]Hanbyul Lee, [2]Jaeho Jung, [2]Jonghwa Won, [1]Se-Woong Oh. *[1]Yuhan Corporation, Seoul, South Korea, Republic of; [2]ABL Bio Inc., Gyeonggi-do, South Korea, Republic of*

Background Epidermal growth factor receptor (EGFR) is a key factor in cellular proliferation, differentiation, and survival, which has been considered as a main target in the treatment of malignancies. Although treatment with EGFR-targeted therapy and chemotherapy improved outcomes for EGFR overexpressing cancer, its clinical application is limited due to drug resistance. Therefore, there is an urgent *unmet* medical *need for new* therapies that can *overcome drug resistance*, particularly for EGFR overexpressing cancer. Combination with immunotherapy would be one of the new treatment options to resolve drug resistance. 4-1BB (CD137) is a key costimulatory receptor expressed on activated T cells and natural killer (NK) cells, which is a promising therapeutic target in cancer. A novel YH32364 (ABL104) has been generated to overcome the challenges with EGFR-drug resistance via tumor-directed 4-1BB agonism and EGFR signal blocking.

Methods YH32364 is EGFR/4-1BB-bispecific antibody with an engineered IgG1 isotype. Its activity was determined using cell-based 4-1BB bioassay and co-culture assay with human peripheral blood mononuclear cells (hPBMC). *In vivo* antitumor efficacy of YH32364 and the infiltrated-immune cells into tumor were assessed in h4-1BB knock -in (KI) mice models. Three-week repeated dose toxicity study of YH32364 for dose range finding (DRF) was conducted in cynomolgus monkeys at the dose of 30 and 100 mg/kg.

Results YH32364 binds to EGFR and 4-1BB with high affinity. YH32364 not only blocked EGFR signaling of tumor cells, but also activated T cells as indicated by IFN-γ secretion, leading to tumor cell lysis in co-culture assay using hPBMC and EGFR-expressing tumor cells. YH32364 exhibited superior efficacy on tumor regression and anti-tumor immunity in MC38/hEGFR-bearing h4-1BB KI mouse models, compared to the equimolar dosing of cetuximab. *In 3*-week toxicity study in monkey, there were no YH32364-related toxicological findings including skin toxicity, mortality, body weight, hematology, clinical chemistry etc., indicating a favorable safety profile.

Conclusions YH32364 exhibited potent *in vitro* and *in vivo* efficacy and it was well tolerated and safe potentially due to tumor-localized T cell activation. These results suggest that YH32364 could be a promising therapeutic for EGFR-overexpressing cancer patients, especially with EGFR drug resistance.

1059 ON203: A NEW ANTIBODY TARGETING THE OXIDIZED FORM OF MACROPHAGE MIGRATION INHIBITORY FACTOR (OXMIF) EXERTS ANTITUMORIGENIC ACTIVITY AND MODULATES THE TUMOR MICROENVIRONMENT

Barbara Maurer, Irina Mirkina, Julia Mayer, Christine Landlinger, Alexander Schinagl, Michael Thiele, Randolf Kerschbaumer*. *OncOne Research and Development GmH, Vienna, Austria*

Background Immunotherapy success in solid cancers is largely dependent on the tumor microenvironment (TME) and its modulation is central to improve clinical outcomes. One of the key players regulating the TME is the macrophage migration inhibitory factor (MIF), which contributes to an immunosuppressive environment. MIF induces polarization of macrophages to the M2 subtype, suppresses cytotoxic T cells and correlates with poor response to immune checkpoint therapy. MIF expression is associated with tumor aggressiveness, metastasis, and disease progression, but due to its ubiquitous nature is considered an elusive target for therapeutic intervention. In contrast, the disease-related structural isoform of MIF, termed oxMIF, is specifically present in solid tumor tissue. We now determined the antitumorigenic and TME-modifying potential of the new oxMIF-specific antibody ON203.

Methods In 3D tumoroids retaining an intact TME, which were isolated from colorectal carcinoma patients, tumor cell killing (high-content 3D computational bioimaging) and TME modulation (immune cell composition and activation, secretome analysis) induced by ON203 were analyzed. *In vivo* tumor penetration was assessed by infrared-labeled ON203 injected in tumor-bearing mice. Efficacy was assessed in human cancer cell-line (PC3) xenografted mice and ON203's effects on tumor cell proliferation, vascularization and infiltrating immune cells were evaluated by immunohistochemistry.

Results Four out of five ON203-treated, freshly isolated tumoroids from colorectal carcinoma patients responded with significant tumor cell death. In the responding tumoroids a clear immunomodulatory effect on the tumor-associated immune cells was detected: ON203 activated NK and NKT cells (upregulation of Granzyme B and CD107a) and supported M1 polarization, correlating with reduced IL-10 levels in the secretome of ON203-responding tumoroids.

ON203 accumulated and retained in the tumor tissue *in vivo* and treatment of immunocompromised mice xenografted with human PC3 tumors led to significantly reduced tumor volumes. Tumor cell proliferation (assessed by Ki67 staining quantification) and tumor vessel density (CD31 staining quantification) were strongly decreased and currently ongoing analysis of tumor-infiltrating immune cells by immunohistochemistry and flow cytometry will provide further insights on the immunomodulatory therapeutic effects of ON203.

Conclusions The anti-oxMIF antibody ON203 demonstrated antitumorigenic effects by (i) reducing tumor cell proliferation, (ii) reducing angiogenesis and intravasation and (iii) by modulating the TME towards immunosupportive functions. In the upcoming clinical Phase 1 trial ON203's safety, tolerability, pharmacokinetics, and pharmacodynamics in patients with solid tumors will be analyzed to evaluate its potential as a standalone or combinatorial therapy with immune checkpoint inhibitors, kinase inhibitors or antiangiogenic agents.

1060 EVOLVE™: A NOVEL COSTIMULATORY T CELL ENGAGER PLATFORM ENGINEERED FOR THE TREATMENT OF IMMUNE SUPPRESSIVE TUMORS

Jeremy Myers*, Mohosin Sarkar, Abudukadier Abulizi, Eric Tam, Guixian Jin, Xingyue An, Evelyn Teran, Shu Shien Chin, Danielle Klaskin, Nana Adjoa Pels, Maria Hackett, Oksana Sergeeva, Hayden Karp, Julio Rodriguez, Sonali Dhindwal, Changqing Yuan, Zengzu Lai, Jennifer Zeiger, Amber Fearnley, Louis Matis, Jay Fine. *EvolvImmune Therapeutics, Branford, CT, USA*

Background CD3-bispecifics are antibody-based therapies that can simultaneously bind to a tumor cell surface antigen and T cells to establish a synapse between the tumor and T cell and activate T cell to induce specific killing of the tumor cell. CD3-bispecifics have demonstrated clinical success in B cell acute lymphoblastic leukemia and follicular lymphoma with approvals of that blinatumomab (Blincyto®) and mosunetuzumab (Lunsumio®) that target B cell lineage antigens CD19 and CD20, respectively. However, clinical progress in deploying CD3-bispecifics for positive patient outcomes in solid tumors has been slow, due to tumor microenvironmental factors such as induction of T cell exhaustion, as well as the potential of CD3-bispecifics to mediate T cell anergy and dysfunction in the absence of adequate costimulation.

Methods Here we describe the development and preclinical validation of the EVOLVE platform, a tumor-targeted biologic that induces the formation of a synthetic synapse that simultaneously activates the T cell receptor complex and the CD2 receptor to optimize CD8 T cell effector phenotype and improve tumor cell killing *ex vivo* and *in vivo*, compared to matched CD3-bispecifics.

Results We demonstrate that CD2 costimulation is superior to other forms of T cell costimulation in its ability to promote cytolytic costimulation, T cell cytokine production and T cell expansion. Furthermore, CD2 receptor expression is markedly elevated in tumor infiltrating lymphocytes across a broad set of tumor types, relative to the CD28 and 4-1BB costimulatory receptors. EVOLVE-mediated T cell activation is conditionally dependent on tumor antigen binding and can be tuned to promote optimal costimulation without increasing cytokine release relative to matched CD3-bispecifics. We also demonstrate the modular nature of the EVOLVE platform across diverse tumor antigens including B7H4 (VTCN1), the B cell lymphoma antigen CD20 and a novel squamous tumor antigen ULBP2.

Conclusions Our data highlight the broad applications of the EVOLVE platform to improve CD8 T cell-mediated anti-tumor immunity and suggest its potential as an emerging, first-in-category immunotherapeutic strategy to address unmet medical needs in oncology.

1061 CLN-617 IS AN INTRATUMORALLY INJECTED AND LOCALLY RETAINED FUSION OF IL-2 AND IL-12 THAT DRIVES SYSTEMIC ANTI-TUMOR ACTIVITY

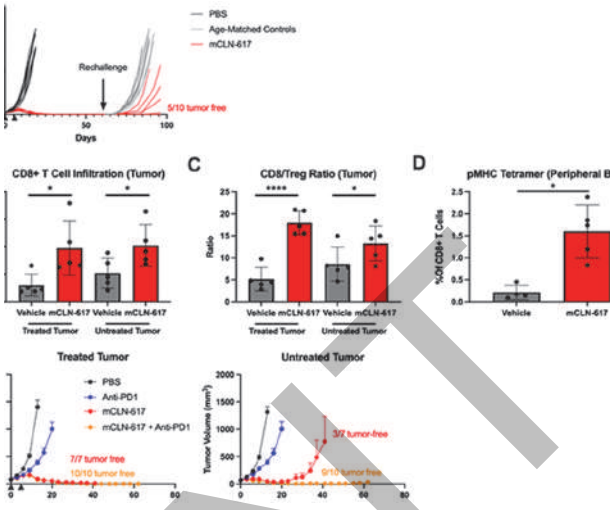
[1]Mehta Naveen*, [1]Kavya Rakhra, [1]Kristan Meetze, [1]Irina Shapiro, [2]Karl Wittrup, [1]Patrick Baeuerle, [1]Jennifer Michaelson. *[1]Cullinan Oncology, Inc., Cambridge, MA, USA; [2]Massachusetts Institute of Technology, Cambridge, MA, USA*

Background IL-2 and IL-12 synergistically trigger the stimulation and proliferation of T and NK cells to mediate anti-tumor immunity. Although aldesleukin (recombinant IL-2 for high-dose infusion) has been approved for the treatment of melanoma and renal cell carcinoma, adoption has been hindered by frequent grade 3 and 4 severe adverse events. No IL-12 therapy has been approved yet due to dose-limiting toxicities. CLN-617 is comprised of IL-2, leukocyte-associated immunoglobulin-like receptor 2 (LAIR2), human serum albumin (HSA), and IL-12, and is designed for intra-tumoral (IT) administration. Upon injection, tumor retention is enabled by LAIR2, which binds to collagen, and by HSA, which increases the molecular weight, to reduce toxicity and enhance efficacy.

Methods Proteins were expressed in HEK293 or CHO cells. Collagen binding was measured by ELISA. Cytokine bioactivity was evaluated by treating PBMCs with CLN-617 followed by flow cytometry and protein microarray analysis. In vivo studies were conducted in B16F10 and MC38 murine syngeneic tumor models. Cytokine concentrations were determined by Mesoscale Discovery, and immunophenotyping was performed in blood and digested tissue samples.

Results CLN-617 triggered signal transducer and activator of transcription 4 and 5 (STAT4 and STAT5) signaling pathways in T cells and NK cells *in vitro* comparable to recombinant IL-2 and IL-12. When a murine surrogate of CLN-617 (mCLN-617) was injected IT in MC38 tumors, IT concentrations of mCLN-617 were >20x serum concentrations. In the checkpoint-refractory B16F10 and MC38 tumor models, mCLN-617 demonstrated 95% tumor growth inhibition and 100% CRs, respectively. All mice cured of their primary MC38 tumors were either protected from re-challenge or showed delayed tumor growth kinetics (figure 1A). In mice bearing two MC38 tumors, only one of which was treated IT, the number of CD8+ T cell infiltrates more than doubled (figure 1B) and the CD8+ to T regulatory cell ratio increased to >10 (figure 1C) in both treated and distal untreated tumors. The frequency of tumor-specific T cells in the periphery increased >7-fold (figure 1D). 100% of treated tumors and 90% of untreated tumors were eliminated when mCLN-617 was combined with an anti-PD1 antibody (figure 1E), demonstrating a robust abscopal response.

Conclusions Fusion to LAIR2 and HSA enables well-tolerated and effective IT delivery of IL-2 and IL-12 in a single multifunctional molecule. Despite local administration and retention, CLN-617 mobilizes systemic immunity to drive abscopal responses. CLN-617 is currently in IND-enabling studies.



Abstract 1061 Figure 1 CLN-617 drives memory responses and systemic immunity.A) MC38 tumors were treated IT with mCLN-617. Surviving mice were re-challenged with MC38 tumors after two months. B-D) Mice were implanted with two MC38 tumors, and one was treated IT. Treated and untreated tumors (B,C) as well as peripheral blood (D) were evaluated by flow cytometry. E) In a dual flank MC38 tumor model, one tumor was treated with mCLN-617 IT with or without systemic anti-PD1 administered intraperitoneally. For B-D, statistics were analyzed by t-test, *p<0.05 ****p<0.0001

1062 ES009, A LILRB2-SPECIFIC BLOCKING ANTIBODY, REPROGRAMS MYELOID CELLS INTO PRO-INFLAMMATION PHENOTYPE AND POTENTIATES T CELL ACTIVATION

Xiaofeng Niu, Chunnian Wang, Jinfeng Zhao, Jiahui Hu, Yanfen Hu, Jun Sun, Xiaoyan Zheng, Yuting Qiu, Zhihao Wu, Yangsheng Qiu, Quan Qiu, Hongtao Lu*. *Elpiscience Biopharma, Shanghai, China*

Background The ITIM-containing inhibitory receptor leukocyte immunoglobulin-like receptor B 2 (LILRB2, also known as ILT4) is predominantly expressed on myeloid-lineage cells, including monocytes, macrophages, dendritic cells and granulocytes, and is emerging as a key immune checkpoint for tumor immunotherapy. Human LILRB2 broadly binds to multiple ligands including classical MHC-I, HLA-G, angiopoietin-like (ANGPTL) family members, myelin-associated glycoprotein (MAG), and contributes to immune suppression in the tumor microenvironment (TME). Accumulating evidence has demonstrated that blocking LILRB2 reprograms tumor-associated myeloid cells and promotes anti-tumor efficacy in combination with PD-1 antibody in clinical setting. In this study, we seek to further investigate LILRB2 biology and have developed a LILRB2 blocking antibody called ES009 with high affinity and specificity that potently reprograms myeloid cells into pro-inflammation phenotype and potentiates T cell activation.

Methods LILR family homologue binding properties were evaluated by ELISA and FACS. Antigen binding affinity was determined by surface plasmon resonance system (Biacore). Blocking activity was determined by competition assay. Functional activity was evaluated by *in vitro* monocyte activation assay, dendritic cell (DC) differentiation assay, macrophage polarization assay, M2 macrophages-T cells (M2-T) co-culture assay, and an *ex vivo* study with malignant ascites in ovarian cancer patients. Epitope analysis was performed by competitive ELISA and hydrogen deuterium exchange mass spectrometry (HDX-MS). Lead clone was humanized via CDR grafting and back mutation screening.

Results ES009 specifically recognizes human LILRB2 with high affinity. It binds to a unique epitope on LILRB2 that is distinct from known competitor molecules. ES009 potently blocks LILRB2 binding to multiple HLA ligands (HLA-A2, HLA-G) as well as non-HLA ligands (ANGPTL1, ANGPTL2, ANGPTL4, ANGPTL7, MAG). Through blocking ligand interaction and receptor activation, ES009 can promote human monocytes and human monocytes derived DCs into a pro-inflammatory status, reprogram human monocyte derived M2 macrophages into pro-inflammatory M1 phenotype, and restore T cell activity from M2 macrophage-mediated suppression. Most importantly, in an *ex vivo* study, ES009 demonstrated very potent ability in reprogramming primary macrophages from malignant ascites of ovarian cancer patients into a pro-inflammatory status.

Conclusions In summary, the anti-LILRB2 mAb ES009 has demonstrated great potential in the reversion of immune suppression in the TME, leading to promotion of anti-tumor immunity. We are currently advancing the development of ES009 into a clinical candidate.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1062

1063 ANTI-4–1BB X PD-1, A BISPECIFIC ANTI-CANCER THERAPEUTICS

Byoung S Kwon, Hanna Lee*, Jin Sung Park, SeungHee Han, Sungmin Park, Sun Woo x Im, HyunTae Son, Joseph H Jeong. *Eutilex Co. Ltd., Seoul, South Korea, Republic of*

Background 4-1BB and Programed cell death protein-1(PD-1) are both T cell costimulatory receptors/immune checkpoint regulators. 4-1BB/4-1BBL provides stimulatory signals while PD-1/PD-L1, suppressive ones to T lymphocytes. Various forms of agonists to 4-1BB or blockers to PD-1 have shown a potent anti-cancer activity by modulating mainly $CD8^+$ T cells. Thus, synergistic or additive anti-cancer effect may be achieved by combining the agonists to 4-1BB and blockers to PD-1.

Methods We have tested various combinations of antibodies and proteins with consideration of overall size of the therapeutic candidates. To obtain molecularly-evolved PD-1 we first used the 3D complex between PD-1 and PD-L1 to select the major contributing PD-1 amino acids, a library targeting selected amino acids and random mutations were constructed and screened using yeast surface display. To demonstrate functions of EU505, Cell binding assay, 4-1BB bioassay and cytotoxicity assay have been conducted. Furthermore, 4-1BB/PD-1 double Knock-in(DKI) mouse and humanized mouse tumor models were used to evaluate the inhibitory activity of EU505.

Results The best anti-cancer activities were obtained by combination of an agonistic anti-4-1BB antibody and soluble PD-1 that binds to PD-L1 with high affinity. we confirmed that EU505 binds both targets independently at the same time. The result of 4-1BB bioassays, a biologically relevant MOA-based assay, showed that potent PD-L1-dependent T cell activation with EU505. *In-vitro* killing assays showed that EU505 selectively activated T cells which in turn killed high PD-L1-expressing cells, but not low-PD-L1-expressing ones. EU505 demonstrated much stronger tumor-killing effect compared with each component alone when we tested against human PD-L1-expressing tumor cells in a 4-1BB/PD-1 DKI mouse model and humanized mouse model. Furthermore, it was observed that number of effector $CD8^+$ T cells increased in the peripheral blood upon EU505 injection and consequently tumor size was reduced.

Conclusions EU505, a promising anti-cancer drug, appears to enhance CD8+ T cell infiltration and activate T cells *in situ* at the tumor sites by binding two different targets of 4-1BB and PD-L1 simultaneously.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1063

1064 EXERCISE INDUCED HORMONE IRISIN INHIBITS INTEGRIN αV-TGF-β AXIS IN TUMOR MICROENVIRONMENT TO IMPROVE CD8$^+$ T CELL MEDIATED TUMOR CONTROL

No-Joon Song*, Yuzhou Chang, Anqi Li, Yi Wang, Kelsi Reynolds, Kevin Weller, Chelsea Bolyard, Gang Xin, Qin Ma, Zihai Li. *The Ohio State University, Upper Arlington, OH, USA*

Background It has been reported multiple times that exercise can prevent cancer development, help anti-tumor therapies, and lower relapse rate after successful cancer treatment. However, an underlying molecular mechanism for these beneficial effects remained elusive. Recent studies revealed that cytotoxic immune cell populations contribute to exercise mediated effects, and exercise induced hormones including insulin, cortisol, testosterone, and epinephrine have been studied in this context, especially related to CD8$^+$ T cell function. Exercise also induces secretion of another myokine irisin, which was originally discovered in 2012. Role of irisin has been primarily studied in metabolic disease including obesity and diabetes. However, the role of irisin in tumor immunology has not been studied.

Methods To address this point, multiple pre-clinical tumor models including colon, skin, bladder, and lung cancer were utilized. After tumor implantation, irisin was intraperitoneally injected for every 2 days starting at day 7. Tumor growth was monitored to check anti-tumoral effect of irisin. To address immunological changes within the tumor microenvironment (TME), high-dimensional flow cytometry panels were applied and analyzed. To confirm our findings, publicly available scRNA-seq data sets were re-analyzed and web-based TCGA database was utilized for further validation.

Results Irisin displayed anti-tumoral activity when tested in multiple pre-clinical models. High-dimensional flow cytometry analysis revealed that irisin treatment reduced accumulation of regulatory T cells (Tregs) in TME. Suppressive marker expressions in Tregs were also decreased and led to better CD8$^+$ T cell function with evidence of less dysfunctional signature. Integrin αv-TGF-β axis was identified for responsible mechanism, and myeloid cell specific knockout of integrin αv further confirmed importance of this pathway. Our findings were validated using publicly available scRNA-seq, spatial-transcriptomics, and TCGA data sets. Integrin αv was specifically expressed in myeloid cells, and TGF-β signaling pathway was higher in integrin av adjacent spots. Also, overall survival rate and immunotherapy response rate was lower in patients with high expression of integrin complex and TGF-β. This was experimentally validated in pre-clinical model by combining irisin with PD-1 blocking antibody; the combination group exhibited better tumor control.

Conclusions We conclude that irisin treatment reduced tumor growth in multiple tumor models and this outcome was mediated by T cells. Integrin αv-TGF-β axis in the TME was responsible for this effect, and blocking this pathway exhibited better tumor control. Re-analysis of publicly available data sets further validated importance of this signaling pathway, implying therapeutic potential of irisin in treating cancer.

1065 ACTM-838, A MICROBIAL-BASED IMMUNOTHERAPY THAT ENRICHES IN SOLID TUMORS AFTER IV DOSING, REVERSES THE IMMUNOSUPPRESSIVE TME TO PROMOTE DURABLE ANTI-TUMOR IMMUNITY, ALONE AND IN COMBINATION WITH ANTI-PD1 IN MICE

Akshata Udyavar*, Hailey He, John Brandenburg, Julie Janes, Oanh Pham, Sara Tribble, Ryan Daroy, Keith Cheung, Haixing Kehoe, Bret Peterson, Emily Miyashita-Lin, Omkar Joshi, Nick Eisele, Christopher Thanos, Chan Whiting. *Actym Therapeutics, Hayward, CA, USA*

Background Effective treatment of metastatic cancers requires reversal of the immunosuppressive tumor microenvironment (TME) and priming a broad repertoire of tumor-specific CD8 + T cells. ACTM-838 is an attenuated, precision genome-engineered, ***S.*Typhimurium-Attenuated Cancer Therapy** (STACT) strain carrying a DNA plasmid that encodes payloads consisting of IL-15plex and engineered, constitutively active STING (eSTING). ACTM-838 is designed to colonize the TME and deliver payloads to phagocytic APCs, inducing a durable anti-tumor immune response, after IV dosing.

Methods STACT was developed through genome editing of the parental strain, VNP20009. Single payload (IL-15plex or eSTING) STACT strains and ACTM-838 were bactofected into immune cell lines and primary immune cells. Uptake, payload expression and activity were measured *in vitro* using ELISAs, MSD, and flow cytometry. ACTM-838 was evaluated in multiple murine tumor models for efficacy as a monotherapy or in combination with anti-PD1 antibodies. Modulation of immune responses in the TME and payload effects were assessed using IHC, RNAseq, flow cytometry and ELISA. ACTM-838 tolerability studies were performed in NHPs and mice.

Results Expression of encoded IL-15plex and eSTING payloads led to IFN-b expression and IL-15 secretion in cell lines and primary M2 macrophages. Furthermore, primary human M2 macrophages polarized toward a novel, co-stimulatory and phagocytic M1/M2 hybrid phenotype. ACTM-838 preferentially colonizes tumors in mice upon IV administration and is well tolerated in NHPs, with enhanced safety compared to VNP20009 in mice. ACTM-838 is selectively taken up by phagocytic APCs in vitro and by tumor-resident APCs in vivo. ACTM-838 treatment showed dose- and payload-dependent anti-tumor efficacy in an anti-PD1 refractory, myeloid rich and T cell excluded, orthotopic EMT6 mouse model as a single agent, and induced a durable anti-tumor CD8+ T cell-dependent memory response upon tumor re-challenge. ACTM-838 induced profound immune reprogramming and remodeling of the TME through increased myeloid cell activation and CD8+ T cell infiltration. Synergistic combination anti-tumor activity was observed when dosed with anti-PD1.

Conclusions ACTM-838 delivers IL-15plex + eSTING payloads to phagocytic APCs in the TME after systemic administration, leading to potent immune reprogramming. Indeed, myeloid cell repolarization, T-cell activation and recruitment promotes durable anti-tumor efficacy as a monotherapy and in combination with anti-PD1. IV-delivered ACTM-838 possesses a compelling safety profile in mice and primates, and is currently in IND-enabling, preclinical development.

Ethics Approval All animals were used according to protocols approved by an Institutional Animal Care and Use Committee and maintained in specific pathogen-free conditions in a AAALAC accredited barrier facility.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1065

1066 PHARMACOLOGIC INHIBITION OF DGKα ACTIVATES T CELLS AND ENHANCES ANTI-TUMOR IMMUNITY

Adele Wang*, Lance Stapleton, Jean-Philippe Belzie, Weimei Xing, Gladys Muiru, Dmytro Kornyeyev, Edward Hsieh, Albert Liclican, Pamela Toy, Mengshu Xu, Kei Kim, Jacob Lee, Michelle Kuhne, Latesh Lad. *Gilead Sciences, Inc., Foster City, CA, USA*

Background Immunotherapies blocking checkpoint receptors on T cells have demonstrated impressive activity in cancer patients, however, a significant population of patients do not respond to these therapies or develop acquired resistance over time. Therefore, alternate approaches to enhance T cell immunity are needed to broaden and deepen the current clinical response rates in patients. A potential promising approach is to target intracellular negative regulators of T cell receptor (TCR) signaling. Diacylglycerol (DAG) is a key second messenger that links TCR signal strength to the intensity and duration of signaling by the RAS-extracellular signal-regulated kinase (ERK)- and protein kinase C (PKC)-dependent pathways. Diacylglycerol kinase α (DGKα) is an intracellular lipid kinase that is enriched in T cells and functions as a key negative regulator of TCR signaling by catalyzing the conversion of DAG to phosphatidic acid (PA), thus attenuating DAG-mediated signaling. Inhibition of DGKα maintains levels of DAG following TCR stimulation and potentiates T cell activation. Here we describe a potential first-in-class, potent, highly selective and orally bioavailable inhibitor of DGKα.

Methods The proximal activity and specificity of Gilead's inhibitor for enhancing the main TCR-driven transcriptional nodes was measured in Jurkat cell lines containing a luciferase reporter under the control of NFAT, NF-kB, or AP-1. To assess anti-tumor activity of the inhibitor in vitro, a three-dimensional GFP-expressing human breast tumor spheroid co-culture assay with $CD8^+$ T cells was established. Tumor lysis was determined by assessing the reduction of GFP signal and supernatants were collected to measure IFN-γ and granzyme B production. In parallel, to further confirm the activation of T cells by the inhibitor, splenocytes from OT-I mice were stimulated and supernatants were collected for IL-2 quantification. Furthermore, Gilead's inhibitor was evaluated in multiple mouse tumor models to assess anti-tumor efficacy as monotherapy and in combination with checkpoint antibodies.

Results Gilead's DGKα inhibitor enhanced DAG-mediated TCR signaling pathways (AP-1 and NF-kB), leading to augmented T cell activation, as measured by increased IL-2, IFN-γ and granzyme B secretion, that resulted in increased T cell-dependent killing of tumor cells in vitro. In colorectal (CT26 and MC38) and melanoma (B16F10) mouse tumor models, the inhibitor demonstrated tumor growth inhibition as a monotherapy and improved the efficacy of α-PD-1 and α-CTLA-4.

Conclusions Specific inhibition of DGKα by Gilead's inhibitor enhances effector T cell function, leading to robust tumor growth inhibition in mouse tumor models as a monotherapy and potentiating the activity of checkpoint blockade.

1067 SYNERGISTIC COMBINATION OF NATURAL KILLER CELL ENGAGERS (NKES) WITH PROINFLAMMATORY CYTOKINES

Tian Zhang*, Matthew Faber, Erik Pong, Ke Liu, Matthew Bernett, Christine Bonzon, Juan Diaz, Dong Hyun Nam, Kendra Avery, Jing Qi, Rumana Rashid, Rena Bahjat, John Desjarlais, Katrina Bykova. *Xencor Inc., Monrovia, CA, USA*

Background While promoting antigen-dependent T cell responses has proven successful in a subset of patients and in certain tumors, the emergence of resistance and tumor heterogeneity with respect to MHC class I expression suggests additional approaches be considered. Expanding the anti-tumor response to include natural killer (NK) cell activation could broaden the clinical impact against tumors with heterogenous MHC I status. Our aim was to develop a new format capable of stimulating both the innate and adaptive arms of immunity, to induce direct tumor elimination while also eliciting multicellular responses to promote durable tumor control. NK cells' intrinsic anti-tumor activity and low toxicity profile make them an attractive effector cell population for immunotherapy. We designed tumor antigen targeted NK cell engaging antibodies (NKEs) that synergistically activate NK cells via NKG2D or NKp46 agonism with simultaneous engagement of Fc gamma receptors via the Fc domain. In addition to stimulating NK cells, NKG2D targeting NKEs also provide co-stimulation to CD8 T cells.

Methods Expanding on Xencor's XmAb protein engineering platform, we developed tumor-targeted NKE molecules agonizing multiple activation pathways including NKG2D or NKp46, together with FcγRIIIa engagement through the intrinsic Fc domain interaction. Functional activity of these novel NKE molecules was evaluated through assessment of anti-tumor cytotoxicity, production of proinflammatory cytokines, and activation of NK and T cells.

Results Co-engagement of activating receptors, NKG2D or NKp46, with FcγRIIIa enhanced production of IFNγ and increased cytotoxicity towards tumor cells. These activities were further enhanced in the presence of proinflammatory cytokines, including IL-15. One of the challenges associated with targeting multiple receptors expressed on effector cells is a potential induction of effector cell fratricide. To address this, we tuned NKG2D and FcγR affinities to balance the desired anti-tumor activity with the off-target activity against effector cells. In a parallel approach, we developed NKEs targeting NKG2D ligands MICA/B. MICA/B NKEs activate effector cells by co-targeting a tumor associated antigen and MICA/B on the surface of target cells, facilitating their interaction with NKG2D on effector cells. MICA/B NKEs showed potent anti-tumor activity in vitro and induced production of IFNγ by effector cells.

Conclusions XmAb NKE molecules designed to activate NK and T cells show potent tumor cell lysis and cytokine production activities that are further enhanced in the presence of proinflammatory cytokines. Future directions include evaluation of in vivo activity and establishment of safety profile.

1068 A ROR1 SPECIFIC CD3 BISPECIFIC T-CELL ENGAGER ENGINEERED FOR SOLID TUMORS WITH AN EXPANDED THERAPEUTIC WINDOW

Brian Rabinovich*, Xueyuan Zhou, Jeffrey Takimoto, Paul Song, Evren Alici, Nikhita Khanna.
Fuse Biotherapeutics, Winchester, MA, USA

Background T cell engagers (TCEs) activate T cells by bridging the CD3 complex to a tumor associated antigen (TAA). TCEs have shown clinical efficacy for hematological malignancies and hold promise for solid-tumors. Dose limiting toxicities, including Cytokine Release Syndrome (CRS) and Tumor Lysis Syndrome (TLS) remain major concerns.

Methods We engineered two ROR1 specific TCEs with properties to increase the size of their therapeutic windows using a unique ROR1 specific VHH from Camelus bactrianus (clone 5A1) that contains a non-canonical disulfide-bond between CDR1 and CDR3 and ROR1 specific valency that (1) decouples cytotoxicity from cytokine release and (2) facilitates the discrimination between ROR1 cell surface density on normal versus tumor cells.

Results When 5A1 was paired with an anti-CD3 Fab in two orientations that include a half-life extending Fc domain, we were able to establish a T cell/tumor synapse that resulted in sufficient activation to induce degranulation/tumor-killing at TCE concentrations of 10-30 pM (EC50 ~ 150-200 nM). In contrast, expression of CD69, CD25 and IFNg, the latter of which is directly upstream of CRS, was not observed until the concentration of TCEs reached ~1 nM (EC50 ~ 5-10 nM). Compared to the non-decoupling control TCE, 5A1 TCEs demonstrated 3.5-4.5 fold greater decoupling. In the context of JeKo1 CD19+/ROR1+ tumor targets, the 5A1 TCEs were 6-7.5 fold better decoupled compared to blinatumomab. We also observed an EC50-cytotoxicity for blinatumomab of below 100 fM, suggesting that the risk of both CRS and TLS are multiple folds higher than for 5A1 TCEs. Compared to the non-decoupling control TCE, the 5A1 TCEs mediated superior cytotoxicity/serial killing at an effector to target ratio (E:T) as low as 1:16, more consistent with solid-tumors. The 5A1 TCEs were also utilized ROR1 specific binding valency to discriminate between cell surface densities of ROR1 typical to tumor cells (>15k molecules/cell) versus normal cells (generally <10,000 molecules/cell). The concentration of TCEs required for maximum IFNg release and killing of tumor cells registered in the pM range, as opposed to the supraphysiologic nM/uM range that was insufficient to induce more than 25% and 35% of IFNg release and cytotoxicity, respectively, on cells expressing <10,000 molecules of ROR1.

Conclusions We hypothesize, that our ROR1 TCEs will provide a superior therapeutic index and safety profile associated with reduced risks of CRS and TLS, the capacity to dose higher, avoid continuous infusion and potentially mediate better efficacy in solid tumors.

1069 OX40/CD137 DUAL AGONISM POTENTIATES ANTI-TUMOUR IMMUNITY BY DRIVING FUNCTIONAL REPROGRAMMING AND INSTABILITY OF REGULATORY T (T_{REG}) CELLS

[1]Charlotte Imianowski, [1]Paula Kuo, [2]Edmund Poon, [2]Matthew Lakins, [2]Michelle Morrow, [1]Rahul Roychoudhuri*. [1]*University of Cambridge, Cambridge, UK*; [2]*F-Star Therapeutics Ltd, Cambridge, UK*

Background Immunomodulatory therapies targeting the effector T (T_{eff}) cell inhibitory signalling pathways PD-1/PD-L1 and CTLA-4 induce striking objective clinical responses in patients with certain cancer types, but are ineffective at inducing durable responses in a majority of patients.[1] $CD4^+$ regulatory T (T_{reg}) cells, dependent on the transcription factor Foxp3, powerfully suppress T_{eff} cells and prevent immune-mediated rejection of tumours.[2,3] Low T_{reg} to T_{eff} cell ratios in humans are associated with favourable survival in multiple cancer types and murine models show that ablation of T_{reg} cells results in activation of $CD4^+$ or $CD8^+$ T_{eff} cells and rejection of tumours. T_{reg} cells therefore represent an attractive target for immunostimulatory therapy.

FS120 is a novel tetravalent bispecific antibody targeting OX40 and CD137 (4-1BB), both tumour necrosis factor (TNF) receptor superfamily members which are expressed on activated and memory T-cell subsets, T_{reg} and NK cells. Preclinically, an FS120 mouse surrogate antibody has demonstrated significant anti-tumour immunity in syngeneic tumour models.[4] FS120 is currently being evaluated in a Phase 1 trial (NCT04648202) which aims to identify a well-tolerated and pharmacologically active dose of FS120 for exploration as monotherapy, and in combination with anti-PD-1.[5]

Methods We elucidate mechanisms of action of OX40/CD137 dual agonist therapy with a mouse-specific FS120 surrogate molecule, using syngeneic tumour models, in conjunction with genetic T_{reg} lineage tracing, high-dimensional flow cytometry, transcriptome analyses and functional studies.

Results FS120 treatment invokes profound anti-tumour immune responses resulting in substantially reduced growth of syngeneic MC38 colorectal adenocarcinoma tumours. FS120 treatment induces two distinct phenomena within tumours: 1) T_{reg} lineage instability, marked by accumulation of 'ex-T_{reg}' cells from T_{reg} progenitors, which gain the ability to express IFN-γ and TNF-a, and 2) T_{reg} functional reprogramming, where Foxp3+ T_{reg} cells are induced to produce effector cytokines IFN-γ and TNF-a. The ability of FS120 surrogate to drive T_{reg} instability and functional reprogramming are not shared by anti-PD-1 therapy, suggesting a mode of therapeutic efficacy distinct from anti-PD-1. Accordingly, FS120 treatment synergises with PD-1 checkpoint blockade therapy to induce profound anti-tumour responses.

Conclusions Treatment with FS120 surrogate causes lineage instability and functional reprogramming of T_{reg} cells, resulting in their ability to produce effector cytokines and drive tumour regression. This mode of action is distinct from anti-PD-1 therapy. These findings support a combination therapy approach exploiting the distinct anti-tumour immune activities of FS120 and anti-PD-1 in cancer patients.

1070 HEXABODY-CD27 ENHANCES T-CELL ACTIVATION, PROLIFERATION, CYTOKINE SECRETION AND CYTOTOXIC ACTIVITY INDEPENDENTLY OF FC GAMMA RECEPTOR-MEDIATED CROSSLINKING

[2]Kristina Nürmberger, [2]Andrea Imle, [2]Aras Toker, [1]Kristin Strumane, [2]Sina Fellermeier-Kopf, [1]Andreea Ioan-Facsinay, [2]Alexander Muik, [2]Mustafa Diken, [1]Frank Beurskens, [1]Rob De Jong, [2]Sebastian Kreiter, [1]David Satijn, [2]Friederike Gieseke, [1]Janine Schuurman, [3]Tahamtam Ahmadi, [2]Oezlem Tuereci, [3]Kate Sasser, [1]Esther Breij, [2]Ugur Sahin, [1]Isil Altinas*. [1]*Genmab B.V., Utrecht, Netherlands*; [2]*BioNTech SE, Mainz, Germany*; [3]*Genmab US, Inc., Plainsboro, NJ, USA*

Background Clustering of CD27 on the plasma membrane of T cells induces T-cell activation, proliferation, and differentiation. Therefore, this costimulatory receptor represents a target for cancer immunotherapy. Multiple monoclonal antibodies (mAbs) targeting CD27 are being explored in the clinic, which require Fc gamma receptor (FcγR)-mediated crosslinking to induce CD27 agonism. HexaBody-CD27 (GEN1053/BNT313) is a novel anti-CD27 mAb with an IgG Fc domain engineered to induce CD27 agonist activity independently of FcγR-bearing cells, which may be scarce in tumors. The Fc domain was further modified to silence Fc-mediated antibody effector functions, with the aim to prevent T-cell depletion. Here we present preclinical characterization of the mechanism of action of HexaBody-CD27.

Methods Target binding characteristics and functional activity of HexaBody-CD27 were analyzed *in vitro* using flow cytometry, cell-based reporter assays and primary human lymphocyte assays. The capacity of HexaBody-CD27 to induce tumor-infiltrating lymphocyte (TIL) proliferation was assessed *ex vivo* using non-small cell lung cancer (NSCLC) tissue resected from patients. HexaBody-CD27 activity *in vivo* was investigated in human CD27 knock-in mice that were immunized with ovalbumin and treated with HexaBody-CD27 by characterizing peripheral blood and splenic T cells using flow cytometry.

Results HexaBody-CD27 exhibited dose-dependent CD27 agonist activity in reporter assays, independent of crosslinking via FcγR-expressing cells. In contrast, agonist activity of benchmark anti-CD27 antibody analogs was dependent on FcγR-mediated crosslinking. HexaBody-CD27 did not functionally engage with FcγRs, and membrane-bound HexaBody-CD27 was unable to bind C1q, confirming functional silencing of the IgG Fc domain. *In vitro*, HexaBody-CD27 enhanced activation, proliferation, and proinflammatory cytokine secretion of TCR-stimulated human $CD4^+$ and $CD8^+$ T cells as well as $CD8^+$ T-cell mediated cytotoxic activity towards cognate antigen-expressing tumor cells. In TIL assays with human NSCLC tumor tissue, HexaBody-CD27 promoted expansion of $CD8^+$ T cells. In human CD27 knock-in mice, HexaBody-CD27 enhanced expansion and IFN-γ secretion of antigen-specific $CD8^+$ T cells. No decrease in percentages of circulating or splenic T cells was detected *in vivo* after treatment with HexaBody-CD27, whereas treatment with a benchmark anti-CD27 mAb analog resulted in a marked reduction of T cells.

Conclusions HexaBody-CD27 has a functionally inert Fc domain and exhibits FcγR-crosslinking-independent CD27 agonist activity, a unique mechanism of action that distinguishes HexaBody-CD27 from benchmark mAbs targeting CD27. In preclinical studies *in vitro* and *in vivo*, HexaBody-CD27 increased T-cell activation, proliferation, cytokine secretion, and cytotoxic activity. A first-in-human clinical trial has been initiated to evaluate HexaBody-CD27 in patients with advanced solid tumors (NCT05435339).

Ethics Approval The use of resected tumor tissue was approved by BioNTech SE's Ethics Board, approval number 837.309.12 (8410-F).

All mouse studies were performed at Crown Bioscience Inc. in China. Animals were housed and handled in accordance with good animal practice as defined by the regulations of the Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC).

1071 AUTOLOGOUS TUMOR CELL IMMUNOTHERAPEUTIC PLATFORM INDUCES STRESS-CORRELATED IMMUNOGENIC CELL DEATH LEADING TO IMMUNE ACTIVATION WITHIN THE DRAINING LYMPH NODES

[1]Christopher Cultrara*, [1]Kenneth Kirby, [1]Essam Elrazaq, [1]Christopher Uhl, [1]Amelia Zellander, [2]Lorenzo Galluzzi, [1]Mark Exley, [1]Jenny Zilberberg. *[1]Imvax, Philadelphia, PA, USA; [2]Weill Cornell, New York, NY, USA*

Background Imvax is developing a novel personalized immunotherapeutic platform combining irradiated patient-derived tumor cells and insulin-like growth factor type-1 receptor antisense oligonucleotide (IMV-001) in biodiffusion chambers (BDC; 0.1-micron pores). The combination product IGV-001 was recently evaluated in a newly diagnosed glioblastoma (GBM) phase 1b clinical trial[1]. Median overall survival of highest exposure IGV-001-treated 'Stupp-eligible'[2]patients (n=10) was 38.2 months compared with 16.2 months in recent standard-of-care-treated patients (P=0.044)[1] [NCT02507583]. Imvax also reported anti-tumor activity of IGV-001 in the GL261-luc GBM murine model[3]. Here, we show that IGV-001 is associated with activation of stress-related pathways and the release of immunogenic cell death (ICD) molecules capable of stimulating myeloid and T cell subsets with potential anti-tumor activity in the draining lymph nodes (DLN) proximal to the BDCs.

Methods GL261-IGV-001 was formulated and BDCs were incubated at 37°C and 5% CO2 for 48h. Supernatants were analyzed for extracellular ATP (eATP) and high mobility group box 1 (HMGB1) protein as indicators of ICD, along with flow cytometric analysis of viability, surface calreticulin exposure, and reactive oxygen species (ROS). Stress-related pathways were analyzed by immunoblotting. DLN from mice receiving GL261-IGV-001 and s.c. tumor-challenge were isolated for immunophenotyping.

Results GL261-IGV-001 cells in BDCs showed significant increase in cell death in vitro (>80%, P<0.001) after 48h incubation. eATP was present after cell preparation. HMGB1 was present in BDCs containing dying cells, while surface calreticulin was undetectable. Immunoblot analysis showed induction of the integrated stress response pathway via eif2α activation and upregulation of the ATF4-CHOP axis. ROS levels were elevated after 24h with subsequent activation of the JNK pathway and downregulation of the anti-apoptotic marker BCL-2. Importantly, similar levels of cell death were observed in in vivo implanted BDCs. Phenotyping analyses showed increased CD45+CD11b+CD11c+MHCII+ DCs in the DLN compared to the contralateral control site without BDC (P<0.001). Likewise, the percentage of effector (P<0.001) and effector memory (P<0.0001) in $CD4^+$ T cells and effector memory $CD8^+$ T cells (P=0.006) were also higher in the DNL, as were CD8+Tim3+, CD8+PD1+, and CD4+PD1+ T cells (P=0.03, P=0.0024, P<0.0001, respectively).

Conclusions Cell death in IGV-001 correlated with the detection of ICD damage-associated molecular patterns (eATP and HMGB1), was characterized by stress-mediated activation of apoptosis pathways, and induced immune responses detected in the DLNs. These data suggest a potential mechanism of action of IGV-001 in GBM via ICD.

1072 INTRAVENOUS BCG ADMINISTRATION IN MICE STIMULATES NK AND T CELL-MEDIATED ANTITUMOR IMMUNITY IN THE LUNG AND OVERCOMES RESISTANCE TO IMMUNOTHERAPY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1072

Eduardo Moreo Lapieza*, Santiago Uranga, Carlos Martín, Nacho Aguiló. *University of Zaragoza, Zaragoza, Spain*

Background Intravesical administration of the tuberculosis vaccine Bacillus Calmette-Guérin (BCG) was the first immunotherapy to be approved by the FDA and is still nowadays the treatment of choice for a subset of non-muscle invasive bladder cancer patients. Intravenous (IV) administration of BCG has been recently reported to be highly effective at preventing tuberculosis infection in macaques by inducing strong T cell responses in the lung[1], as well as to alter myelopoiesis, generating "trained" macrophages which confer protection against tuberculosis infection in the lung[2]. Therefore, in this work we set out to characterize the therapeutic application of IV BCG in mouse models of lung cancer.

Methods We used mouse models of tumors growing in the lung based on IV inoculation of B16-F10 melanoma and LLC lung carcinoma tumor cells to study the therapeutic effect of IV BCG. We performed immune cell profiling by flow cytometry to study the mechanism of action, as well as functional assays such as NK and T cell cytotoxicity assays.

Results First, we observed that therapeutic IV BCG administration extended mice survival in models of B16-F10 lung metastasis and orthotopic LLC lung tumors (figure 1). Immune cell depletion studies revealed that NK cells and $CD4^+$ and $CD8^+$ T cells were required for IV BCG efficacy against lung tumors (figure 2). IV BCG induced a tumor-specific $CD8^+$ T cell response in the lung in a process relying on type 1 conventional dendritic cells (cDC1s). Mechanistically, BCG stimulated lung NK cells (figure 3A), which participated in the recruitment of cDC1s to the tumor (figure 3B) and initiated tumor-specific T cell responses (figure 3C) by favoring the loading of cDC1s with tumor-associated material by killing tumor cells in a perforin-dependent manner (figure 4). Remarkably, IV BCG reduced tumor growth in B16-F10 and LLC lung tumors in which MHC-I expression was ablated (figure 5). Finally, we observed that IV BCG upregulated PD-L1 in multiple immune cells in the tumor microenvironment (TME), suggesting the generation of an inflamed TME. Combination of IV BCG and antiPD-L1 antibodies further increased mouse survival in mouse models of lung tumors, which were otherwise resistant to checkpoint blockade as a monotherapy (figure 6).

Conclusions Here we describe a therapy based on IV BCG administration which enabled antitumor immunity in the lung by coordinating multiple immune cell populations, including both T and NK cells as well as *Batf3*-dependent cDC1s. Remarkably, IV BCG sensitized lung tumors to antiPD-L1 checkpoint blockade therapy.

1073 COSTIMULATORY CD28 TRISPECIFIC ANTIBODIES TARGETING PDL1 AND PDL2 ENHANCE T CELL ACTIVATION IN SOLID TUMORS

Veronica Zeng*, Juan Diaz, Jing Qi, Thuy Truong, Matthew Dragovich, Rumana Rashid, Christine Bonzon, Panida Lertkiatmongkol, Ruschelle Love, Michael Hackett, Kendra Avery, Norman Barlow, John Desjarlais, Michael Hedvat, Gregory Moore. *Xencor, Inc., Monrovia, CA, USA*

Background T cells in the tumor micro-environment require TCR/MHC engagement and co-stimulatory receptor engagement to achieve optimal activation. Tumor cells lack expression of CD28 ligands, so we hypothesized that activation of CD28 signaling at the T cell/tumor cell interface could enhance anti-tumor activity. We designed PDL1 x PDL2 x CD28 trispecific antibodies that conditionally costimulate CD28 only in the presence of PDL1 or PDL2 expression, and TCR engagement. As PD1 signaling has been shown to directly inhibit CD28 costimulation, this novel bispecific modality has potential to promote CD28 costimulation while simultaneously preventing the suppression of the same signal. Furthermore, since CD3 bispecific T cells engagers are known to indirectly promote PDL1 expression, PDL1 x PDL2 x CD28 trispecific antibodies can potentially be applied in combination to CD3-bispecific T cell engagers to enhance their activity.

Methods We developed a CD28 antibody that is agonistic only under the context of TCR engagement. We paired this CD28 binding domain with PDL1 and PDL2 Fab binding domains that share a common light chain to generate PDL1 x PDL2 x CD28 trispecifics monovalent for each of the three antigens. We optimized the affinity for each of the antigens for potent blockade of PDL1 and PDL2 and enable CD28 costimulation across a range of PDL1 and PDL2 cell surface densities. Cell based assays with different TCR engagement modalities were utilized to describe the function of trispecifics including, CD3-stimulated T cells cocultured with cancer cell lines, CMV+ T cells recognizing cancer cells expressing pp65-derived NLV peptide, and Mixed Lymphocyte Reactions. Cell based assays measured IL2 and IFNγ release, T cell proliferation and cancer-cell death as readouts for activity.

Results PDL1 x PDL2 x CD28 trispecifics block PDL1 and PDL2 binding to PD1 in both solid phase and cell-based assays. PDL1 and PDL2 blockade led to enhanced cytokine secretion from human mixed lymphocyte reactions. Target cell expression of either PDL1 or PDL2 was shown to be sufficient to promote CD28 co-stimulation leading to acute IL2 release of cocultures of CD3-stimulated PBMC with cancer cell lines. In a more physiologically relevant model of TCR engagement, PDL1 x PDL2 x CD28 trispecifics enhanced T cell activation in a CMV-recall assay. When in combination with CD3-targeted T cell engagers, PDL1 x PDL2 x CD28 trispecifics enhanced T cell proliferation and TDCC activity.

Conclusions Data warrant further development of PDL1 x PDL2 x CD28 trispecifics for treatment of solid tumors.

1074 A NOVEL FULLY HUMAN CD28 ANTIBODY THAT CROSS-REACTS WITH CTLA-4 AND MOUSE CD28 FOR POTENTIAL APPLICATIONS IN CANCER IMMUNOTHERAPY

[1]Abdullah Elsayed*, [1]Frederik Peissert, [1]Louis Plüss, [2]Franziska Ulrich, [1]Emanuele Puca, [1]Roberto De Luca, [2]Cornelia Halin, [3]Dario Neri. *[1]Philochem AG, Otelfingen, Switzerland; [2]Swiss Federal Institute of Technology, Zurich, Switzerland; [3]Philogen Spa, Otelfingen, Switzerland*

Background T cell activation is initiated through engaging T cell receptor (TCR)/CD3 complex upon recognizing antigenic peptides presented by major histocompatibility complex (pMHC).[1,2] However, TCR/CD3 complex alone is not sufficient for full T cell activation. In fact, the absence of an additional signal induces T cell exhaustion and thus impaired activation of T cells.[3] CD28 is a crucial co-stimulatory receptor that enhances T cell proliferation, survival and production of key cytokines such as IL-2, IFN- γ, and TNF- α.[4–7] Despite the potential key role of CD28 in cancer immunotherapy, there have been safety concerns following the TeGenero disaster in 2006.[8] Here we describe the generation of a fully human anti-CD28 antibody named "VE19ZH". VE19ZH features a unique combination of desirable properties in comparison to other currently available mAbs such as TGN1412.

Methods We isolated a new fully human antibody (VE19ZH) against human CD28 by phage display technology. Binding was validated by flow cytometry on primary human T cells. The co-stimulatory effect in combination with anti-CD3 (OKT3) was assessed *in vitro* by proliferation of human PBMCs and cytokine release. To rule out the undesirable super-agonistic effect observed by TGN1412, VE19ZH was tested for its capability to activate human PBMCs in the absence of TCR/CD3 signaling. Cross-reactivity against CTLA-4 and mouse CD28 were evaluated by ELISA and flow cytometry. Finally, the binding epitope of VE19ZH was revealed using PepSpot™ technology.

Results VE19ZH is a fully human antibody that binds selectively to both human and murine CD28. VE19ZH IgG_4 exhibited a strong and significant co-stimulatory effect on human PBMCs when combined with anti-human CD3 (OKT3). Unlike TGN1412, VE19ZH did not activate T cells without TCR/CD3 signaling. In addition, VE19ZH was shown to bind to CTLA-4. VE19ZH binds to an epitope similar to the natural ligand (CD80/CD86) as revealed by PepSpot™ technology. *In vitro* killing activity was validated using BiTE formats and showed synergism with low concentrations of CD3 bispecifics.

Conclusions VE19ZH is a promising module for cancer immunotherapy with unique properties: **(i)** Fully human mAb for minimal immunogenicity **(ii)** Potent co-stimulator for full T cell activation **(iii)** Conventional agonist of CD28 and not super-agonistic like TGN1412 **(iv)** cross reacts with mouse CD28 for better assessment in immunocompetent mouse models **(v)** Binds to human CTLA-4 for potential checkpoint inhibition. The potential of VE19ZH to boost T cell response via CD28 activation and CTLA-4 blockade is currently being investigated *in vitro* and *in vivo*.

1075 HBM1020 IS A FULLY HUMAN NOVEL ANTI-B7H7 ANTIBODY WITH EXCELLENT PRECLINICAL EFFICACY AND SAFETY PROFILE

Xiaodong Wu*, Yongqiang Wang, Jonna Liu, Xiaocheng Lv, Fei Chen, Izzie Wang, Jiuqiao Zhao, Yiping Rong. *Harbour BiMed Co., Ltd, Shanghai, China*

Background Immunotherapeutic targeting immune checkpoints such as programmed death-1 receptor (PD-1)/PD1 ligand (PD-L1) and cytotoxic T-lymphocyte antigen-4 (CTLA4) offer effective treatment alternatives to traditional cancer therapies. However, a considerable proportion of patients remains unresponsive to treatment indicating that a more complex immune inhibitory tumor microenvironment is involved. B7H7 is a novel B7 family member and reported to be highly expressed on a variety of human cancers such as colon, kidney, bladder, lung cancers; and is associated with metastatic disease and poor survival. B7H7 can inhibit T cell and NK cell activation and its co-inhibitory function makes it a new checkpoint and candidate for cancer immunotherapy other than PD-L1 or other immune checkpoints.

Methods Fully human Anti-B7H7 antibodies were generated from H2L2 Harbour Mice® transgenic platform. The binding and blocking activities were tested by fluorescence-activated cell sorting (FACS) method. *In vitro* function of the antibodies was tested for their abilities to activate T cell and NK cell. *In vivo* efficacy was tested on multiple NOD-Prkdc^{em26Cd52}Il2r-g^{em26Cd22}/NjuCrl (NCG) mouse models engrafted human PBMC tumor. The dose range-finding (DRF) tox study was evaluated on a non-human primates (NHP) 4-week repeat-dose toxicity study.

Results HBM1020, a fully human anti-B7H7 antibody, bound specifically to cell lines that over-express either human B7H7 or cynomolgus monkey B7H7, as well as human tumor cell lines that express endogenous B7H7, with high selectivity against other B7 family members. HBM1020 blocked the interaction between B7H7 and its receptors and potently promoted T cell activation and NK cell cytotoxicity *in vitro*. Furthermore, HBM1020 showed potent anti-tumor activity in multiple murine tumor models. In DRF 4-week repeat-dose NHP toxicity study (20, 60, 147 mg/kg), HBM1020 was well tolerated up to 147 mg/kg dosed weekly (total 5 doses) with no notable test article-related adverse finding but increased anti-KLH IgG and IgM after KLH immunization at $\geq$ 60 mg/kg.

Conclusions HBM1020 is a fully human novel anti-B7H7 antibody with potent activity on T cell activation, NK cell cytotoxicity, excellent *in vivo* anti-tumor efficacy, and excellent safety profile. HBM1020 may present a promising novel anti-tumor agent as monotherapy and/or combination therapy with currently established immune-oncology agents.

Ethics Approval The anti-tumor efficacy studies in mice were approved by the internal ethics board of the respective contract research organization (CRO). The dose-range finding toxicity studies in non-human primates were approved by Ethics Board of an appropriate contract research organizations (CROs).

1076 ANCHORED IMMUNOTHERAPY WITH INTRATUMORALLY ADMINISTERED ALUMINUM HYDROXIDE-TETHERED IL-12 INDUCES POTENT ANTI-TUMOR IMMUNE RESPONSE

[1]Sailaja Battula, [1]Gregory Papastoitsis, [1]Howard Kaufman, [2]K Wittrup, [1]Michael Schmidt*. *[1]Ankyra Therapeutics, Lexington, MA, USA; [2]Massachusetts Institute of Technology, Cambridge, MA, USA*

Background Interleukin-12 (IL-12) is a potent cytokine that can promote innate and adaptive anti-cancer immunity, but its clinical development has been limited by toxicity when delivered systemically.[1] Intratumoral (IT) administration can expand the therapeutic window of IL-12 and other cytokines but is in turn limited by rapid clearance from the tumor, thereby reducing efficacy, necessitating frequent administration, and increasing systemic accumulation. We recently described an approach called 'anchored immunotherapy'[2] in which an engineered IL-12 variant is complexed with the vaccine adjuvant aluminum hydroxide (alum) to form a locally retained cytokine depot that induces potent therapeutic activity in syngeneic murine tumors after only 1 or 2 IT injections. Here, we provide additional characterization of the retention kinetics and mechanism of action of alum-complexed IL-12.

Methods Human or murine IL-12 was genetically fused to a phosphorylated alum-binding peptide (IL-12-ABP) and mixed with aluminum hydroxide to form the therapeutic complexes ANK-101 (human) or mANK-101 (mouse). Local retention and biodistribution of labeled mANK-101 after IT administration in syngeneic murine tumors was measured by IVIS and SPECT imaging. Intratumoral immune changes were detected by flow cytometry, IHC, Nanostring, and scRNA-seq to characterize mANK-101's mechanism of action. Safety of ANK-101 was assessed in cynomolgus macaques after subcutaneous injection. Statistical comparisons between groups were performed using one-way ANOVA.

Results ANK-101 induces IFNγ expression from human PBMCs, purified T-cells, and NK-cells with similar potency as native IL-12. Following IT administration in murine tumor models, mANK-101 complexes are retained locally for multiple weeks while unanchored IL-12-ABP protein is cleared within hours as detected by IVIS or SPECT imaging. This extended retention leads to prolonged expression of IFNγ and other pro-inflammatory cytokine and chemokines for >1 week. We hypothesized that this would result in improved CD8+ T cell recruitment, which was tested by intratumoral immunophenotyping by IHC and flow cytometry. We found that mANK-101 treatment led to robust CD8 T-cell infiltration and an increased CD8/Treg ratio that correlated with anti-tumor efficacy. Gene expression and scRNA-seq analyses suggested a profound remodeling of the tumor microenvironment after mANK-101 treatment with T-cell and NK-cell activation, shifts to pro-inflammatory myeloid cell phenotypes, and increased markers of antigen presentation and co-stimulation. Subcutaneous administration of ANK-101 in cynomolgus macaques was well tolerated.

Conclusions Anti-tumor activity of locally retained IL-12/alum is mediated by recruitment and activation of lymphocytes and myeloid immune cells. Anchored immunotherapy may represent a general approach to improve the therapeutic potential of immuno-oncology agents.

1077 DEVELOPMENT OF A MOLECULAR TARGETED CYTOKINE THAT SPECIFICALLY EXPANDS VGAMMA9VDELTA2 T CELLS AND POTENTIATES ANTI-TUMOR ACTIVITY

Bryan Becklund*, Kaitlyn Robinson, Kyle Jones, Angelica Sanabria, Elisebeth Torretti, Andrew Eckles, Abrahim Hussain, Sae Jeong Ahn, Rajay Pandit, Florian Sulzmaier, John Timmer, Brendan Eckelman. *Inhibrx, La Jolla, CA, USA*

Background Vgamma9Vdelta2 (Vg9Vd2) T cells are an ideal target for cancer immunotherapy due to their ability to recognize stress-related ligands from transformed cells and eliminate them with broad, potent cytotoxicity.[1] One limitation restraining the ability of Vg9Vd2 T cells from eliminating tumors is that they are a rare population in peripheral blood. Efforts to expand Vg9Vd2 T cells *in vivo* have typically relied on treatment with bisphosphonates and low-dose interleukin-2 (IL-2). This combination is limited by rapid clearance of the molecules, competition for IL-2 and dose-limiting toxicities.[2] Using our molecular targeted cytokine (MTC) platform, we developed an alternative strategy to specifically expand Vg9Vd2 T cells utilizing a detuned IL-2 variant targeted to the Vg9Vd2 T cell receptor.

Methods Human IL-2 was engineered to eliminate CD25 binding and have reduced affinity for CD122.[3] A high-affinity single-domain antibody specific to the Vg9-subunit of the Vg9Vd2 T cell receptor targets this cytokine to cells expressing the target antigen and thereby restricts IL-2 activity to Vg9Vd2 T cells. The ability of this Vg9Vd2-targeted MTC (anti-Vg9xIL2-X) to selectively bind and activate Vg9Vd2 T cells was assessed *in vitro* utilizing human PBMCs from healthy donors and dissociated tumor cells (DTCs) from various indications. IL-2 signaling and cell proliferation were analyzed by flow cytometry. Cancer-specific target cell killing was determined by coculturing Vg9Vd2 T cells with labeled tumor cells or healthy B cells. Expansion of Vg9Vd2 T cells *in vivo* was analyzed in NSG-B2M KO mice engrafted with human PMBCs.

Results Anti-Vg9xIL2-X bound Vg9Vd2 T cells and activated STAT5 signaling in a target-dependent manner. Treatment with anti-Vg9xIL2-X led to a dramatic increase in proliferation and accumulation of Vg9Vd2 T cells in healthy human PBMCs and DTCs. Anti-Vg9xIL2-X-driven expansion of Vg9Vd2 T cells increased expression of cytotoxic effector molecules, including IFNg and granzyme-B, leading to potent *in vitro* anti-tumor activity across numerous cancer cell types. The killing activity was selective for transformed cells as healthy cells were largely spared. Treatment with anti-Vg9xIL2-X also improved antibody dependent target cell killing by Vg9Vd2 T cells. Finally, dosing of human PBMC-engrafted mice with anti-Vg9xIL2-X was well-tolerated and resulted in an increased prevalence and specific expansion of Vg9Vd2 T cells.

Conclusions Utilizing our MTC platform, we have developed a targeted cytokine that specifically activates and expands Vg9Vd2 T cells. By restraining IL-2 activity to this subset, we hope to limit IL-2-mediated toxicity and enhance Vg9Vd2 T cell anti-tumor activity across numerous cancer types.

1078 CONDITIONALLY ACTIVATABLE INTERFERON-ALPHA 2B IMPROVES TOLERABILITY AND EXHIBITS PREFERENTIAL ACTIVITY IN TUMORS

Alexey Berezhnoy*, Hsin Wang, Nicole Lapuyade, Na Cai, Carol LePage, Michael Winter, Michael Krimm, Kenneth Wong, Robert Dunn II, Sean McAlister, Leila Boustany, Madan Paidhungat, Marcia Belvin, Erwan Le Scolan, Dylan Daniel. *CytoX Therapeutics, South San Francisco, CA, USA*

Background Despite its potential, the toxicity of interferon alpha has limited its clinical use. CytomX proprietary Probody® Therapeutics (Pb-Tx) technology allowed us to create a conditionally active IFN-a2b (Pb-IFN-a2b) with minimal activity in its prodrug form. The prodrug is activated in the tumor microenvironment (TME), leading to preferential activity in the TME but not in healthy tissues. Pb-IFN-a2b demonstrated a substantially enhanced tolerability profile compared to standard IFN therapy without compromising its antitumor effects.

Methods The Pb-Tx platform technology attenuates activity of a molecule by blocking its active regions through affinity or steric interference. Such blockade, termed masking, is reversed upon proteolytic cleavage of a linker between the molecule and the mask by tumor associated proteases.

Results Pb-IFN-a2b demonstrated considerable reduction (1000-fold or more) of interferon signaling in vitro and significantly reduced immune cell activation. Exposure to viable tumor tissues or tumor-associated proteases in vitro fully restored its bioactivity, including the ability of Pb-IFN to stimulate tumor-infiltrating immune cells.

Antitumor activity of the Pb-IFN-a2b in xenograft studies is equal to or greater than Peg-IFN-α2b. In syngeneic mouse tumor models, Pb-IFN demonstrated significant antitumor activity that was further enhanced by PD-(L)1 blockade. Activation of lymphocytes by the molecule was observed in tumors but not in secondary lymphoid organs.

Toxicology studies performed in hamsters demonstrated enhanced tolerability of the molecule compared to its unmasked control. In addition, Pb-IFN-a2b suppressed growth of hamster melanoma tumor model RPMI1846 at dose levels that were above the tolerated dose of the unmasked control.

Biomarkers of IFN signaling were greatly attenuated in non-human primates compared to the unmasked control. In cynomolgus monkey, Pb-IFN-a2b demonstrated linear pharmacokinetics, extended half-life, and was well tolerated at weekly doses up to 60 mg/kg.

Conclusions Pb-IFN-a2b shows improved tolerability and antitumor activity in preclinical studies compared to traditional IFN treatment. These data support Probody cytokine therapeutics as a promising addition to current immunotherapy regimens, potentially expanding their benefits to patients with typically unresponsive tumors.

Ethics Approval All animal experiments were reviewed and approved by CytomX's Institutional Animal Care and Use Committee (IACUC Protocol AP303).

1079 LAG3-TARGETED IL15/IL15Rα-FC (LAG3 X IL15) FUSION PROTEINS FOR PREFERENTIAL TIL EXPANSION VIA CIS DELIVERY OF IL15 TO LAG3+ CELLS

Matthew Bernett*, Suzanne Schubbert, Michael Hackett, Lukasz Ochyl, Lizett Scott, Christine Bonzon, Rumana Rashid, Kendra Avery, Nicole Rodriguez, Irene Leung, Norman Barlow, Rena Bahjat, Umesh Muchhal, John Desjarlais. *Xencor, Inc., Monrovia, CA, USA*

Background Therapeutic approaches utilizing IL2 or IL15 have suffered from low tolerability, fast clearance, and limited therapeutic window due to extensive activity on peripheral T and NK cells. Conversely, selective targeting of tumor-reactive lymphocytes (TIL) may improve tolerability and anti-tumor activity while simultaneously improving drug PK. We hypothesized that we could selectively target tumor-reactive TILs by combining a reduced potency IL15/IL15Rα heterocomplex with an immune checkpoint(CP)-targeting arm to bias binding and activation to CP-positive TILs, potentially improving therapeutic index. Lymphocyte activation gene 3 (LAG3) was chosen as the CP targeting-arm due to its frequent co-expression with PD1, bias to CD8+ T cells, ability to easily combine with anti-PD1 agents, and recent promising results with anti-LAG3 agents in the clinic.

Methods First, potency-reduced IL15/IL15Rα were created by engineering amino acid substitutions in IL15 – at the IL2Rβ/γc interface – that reduced in vitro potency by at least 1000-fold. We then designed LAG3 x IL15 fusion proteins containing single-chain IL15/IL15Rα and LAG3-targeting arms attached to a heterodimeric-Fc region, relying on targeting avidity (in cis) to recover potency on LAG3+ cells. In vitro proliferation of lymphocytes in human PBMCs, stimulated with sub-optimal concentrations of anti-CD3 to induce LAG3 expression, was monitored by CFSE dilution or by counting Ki67+ cells after incubation with LAG3 x IL15. In vivo activity was evaluated using a humanized mouse tumor model. Lead LAG3 x IL15 were evaluated in non-human primates (NHP).

Results LAG3 x IL15 showed >500-fold selectivity compared to a non-targeted IL15 in an in vitro proliferation assay of lymphocytes stimulated for induced LAG3 expression. In vitro potency was greatest on effector memory CD8 T cells. LAG3 x IL15 were 3-fold more potent on CD8 T cells compared to CD4 T cells and had very weak activity on NK cells, consistent with minimal LAG3 expression on this population. In mouse tumor models, LAG3 x IL15 had single-agent anti-tumor activity and promoted significantly increased numbers of T cells. Moreover, LAG3 x IL15 combined productively with anti-PD1 to promote additional anti-tumor activity and T cell expansion. In NHP, LAG3 x IL15 has superior PK compared to native IL15-Fc and showed selective targeting of LAG3+ peripheral T cells.

Conclusions LAG3 x IL15 shows a promising profile of selective delivery to LAG3+ cells with minimal peripheral activity and may help to preferentially expand LAG3+ TIL in patients with cancer, while potentially avoiding systemic toxicity due to off-target activation and expansion of peripheral lymphocytes.

1080 USING SITE-SPECIFIC CHEMICAL CONJUGATION TO GENERATE SUPERIOR HALF-LIFE EXTENDED OR PD-1-TARGETED FORMATS OF A POTENT IL-18 VARIANT RESISTANT TO IL-18 BINDING PROTEIN

Jean Carralot*, Camille Delon, Rubén Alvarez Sanchez, Roy Meoded, Philipp Moosman, Kea Martin, Arnaud Goepfert, Andrew Chi, Vijaya Pattabiraman, Bertolt Kreft. *Bright Peak Therapeutics, Basel, Switzerland*

Background Interleukin-18 (IL-18) is a pro-inflammatory cytokine able to trigger both innate as well as adaptive immune responses. IL-18 is a potent amplifier of IFNg signaling which induces pleiotropic Th1 responses, making it an attractive cytokine for cancer immunotherapy. However, the clinical efficacy of wild-type (wt) IL-18 was limited, potentially due to the upregulation IL-18 binding protein (IL-18BP). IL-18BP is a secreted IFNg-induced antagonist that binds IL-18 with high affinity, prevents its interaction with the IL-18 receptor, and neutralizes IL-18 activity. Hence, we aimed to generate a potent IL-18BP-resistant IL-18 ”payload” that can be turned into optimal therapeutic formats with superior pharmacologic properties or leverage synergistic mechanisms of action (MOA).

Methods By introducing of a minimal set of mutations we generated an optimized human IL-18 that, compared to wt-IL-18, shows enhanced potency and significant resistance to IL-18BP. We further engineered the enhanced IL-18 variant to create a versatile “payload” that can be chemically conjugated in a site-specific manner. Conjugation to polyethylene glycol (PEG) resulted in a half-life extended agent, while conjugation to an anti-PD-1 antibody yielded a PD1-IL18 immunocytokine (IC) allowing exploitation of synergistic MOAs. We then characterized the pharmacologic and anti-tumor properties of these two therapeutic formats *in vitro* and *in vivo*.

Results Compared to wt-IL-18, the conjugatable payload is 300-fold more potent and >600-fold less sensitive to IL-18BP inhibition. Conjugation to a 30 kDa PEG yields a molecule with significantly improved PK properties in mice that is able to strongly activate CD8+ T and NK cells and to potently trigger the release of pro-inflammatory cytokines. PEGylated IL-18 showed strong anti-tumor efficacy which was enhanced in combination with an anti-PD-1 antibody. For the PD1-IL18 IC, the basic properties of the anti-PD-1 antibody and the cytokine payload were largely preserved after chemical conjugation. The PD1-IL18 IC exhibited potent antitumor activity *in vivo* inducing complete responses in the large majority of animals.

Conclusions We generated a potent and IL-18BP-resistant IL-18 payload that can be chemically conjugated to distinct chemical or biological entities in a site-specific manner to generate unique IL-18-based therapeutic formats with desirable pharmacological properties. Both the PEGylated half-life extended IL-18 and the PD1-IL18 IC are well tolerated, show encouraging efficacy in pre-clinical models, and have the potential to be next-generation enhanced IL-18 therapeutics.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1080

1081 EXENOKINE-2: A HALF-LIFE EXTENDED NO-α-IL-2 WITH IMPROVED PRECLINICAL PHARMACOLOGICAL PROPERTIES SUPPORTS FIRST-IN-HUMAN CLINICAL DEVELOPMENT

[1]Lili Cheng*, [1]Fan Ye, [1]Sandra Chen, [1]Jianing Huang, [1]Jenny Jiang, [1]Henry He, [1]Shirley Shi, [1]Mingxing Yang, [1]Qiang Fu, [1]Ark Xia, [1]Yudan Hong, [1]Wang Xin, [1]Karen Yuan, [2]Hongchuan Liu, [2]Hui Feng, [1]Eugene Liu, [1]Ziyang Zhong. [1]*Anwita Biosciences, San Carlos, CA, USA*; [2]*Junshi Pharma, Shanghai, China*

Background IL-2 is a critical cytokine driving immune mediated killing of tumor cells by stimulating both the innate and adaptive immune cells. High-dose IL-2 (aldesleukin) has been approved for the treatment of metastatic melanoma and metastatic renal cell carcinoma, however, the practical use of aldesleukin in the clinic is limited. The short half-life of aldesleukin necessitates a frequent and burdensome treatment schedule for patients. In addition, binding to IL-2Rα on endothelial cells and type 2 innate lymphoid cells is thought to induce severe adverse events associated with vascular leak syndrome. Furthermore, the efficacy of aldesleukin is compromised due to strong activation of immunosuppressive regulatory T cells (Treg) expressing the high-affinity IL-2Rαβγ. To overcome the major limitations of wild-type (WT) IL-2, Exenokine-2 (Exn-2), a fusion protein comprised of a no-α-IL-2 linked to a humanized anti-human serum albumin (HSA) single domain antibody (sdAb), was designed using Anwita's discovery platform technology.

Methods Binding affinities were determined using Bio-Layer Interferometry. *In vitro* potency was assessed using a human primary immune cell-based pSTAT5 assay. *In vivo* efficacies were assessed in MC38 and B16F10 syngeneic as well as N87 and Raji xenograft mouse models.

Results The no-α-IL-2 in Exn-2 is a chimera between IL-2 and IL-15 cytokines. The lack of binding with IL-2Rα resulted in limited activation of Treg while retaining the high potency on NK cells and $CD8^+$ T cells. The addition of an anti-HSA sdAb in Exn-2 resulted in prolonged systemic exposure with a 30-fold longer half-life in mice as compared to WT IL-2. In syngeneic mouse tumor models, Exn-2 showed strong dose-dependent antitumor efficacy as a single agent with up to 95% reduction in tumor growth, as well as an enhanced efficacy with a high rate up to 66% of complete response when combined with an anti-PD-1 monoclonal antibody. In xenograft models of gastric cancer and lymphoma, Exn-2 significantly potentiated the antitumor activity of Trastuzumab and Rituximab, respectively, demonstrating clinical potential as a combination therapy with ADCC-competent antibodies. In cynomolgus monkeys, Exn-2 was well tolerated and induced robust and sustained expansions of lymphocytes and $CD8^+$ T cells while showing negligible effects on eosinophils and Tregs.

Conclusions Collectively, *in vivo* efficacies from mouse tumor models as well as the desired pharmacodynamic effects and safety profile observed in cynomolgus monkeys support the first-in-human clinical development of Exn-2. IND-enabling studies for Exn-2 is nearing completion, with GMP lot production completed for the Phase 1 study.

Ethics Approval The protocol of animal studies has been reviewed and approved by IACUC

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1081

1082 IL-27 EXPRESSED IN THE TUMOR MICROENVIRONMENT IS CORRELATED WITH PD-L1 LEVELS AND CAN INDUCE PD-L1 EXPRESSION ON IMMUNE AND TUMOR CELLS

Karin Golan*, Ricard Masia, Yu Yang, Yue Ren, Kerry White, Benjamin Lee, Vito Palombella, Jonathan Hill. *Surface Oncology, Cambridge, MA, USA*

Background Interleukin (IL)-27 is a heterodimeric cytokine expressed by myeloid cells that is known to reduce the intensity and duration of immune responses. IL-27 signaling via IL-27RA receptor augments the expression of co-inhibitory molecules (PD-L1, LAG-3, TIM-3, and TIGIT) on immune cells and reduces proinflammatory cytokines in the tumor microenvironment. Blocking IL-27 activity by SRF388, a first-in-class monoclonal antibody, enhances immune function and demonstrates monotherapy activity in patients with cancer (NCT04374877). This study further characterizes the expression of IL-27 in primary solid tumors.

Methods Gene expression profiles from published datasets were analyzed to identify *IL27* and *IL27RA* transcripts. Immunohistochemistry (IHC) and flow cytometry were used to quantify IL-27, PD-L1, and IL-27RA expression in primary tumors. IL-27 levels were measured in cell culture media of primary tumor cells and activated peripheral blood mononuclear cells (PBMCs) by ELISA.

Results Primary tumor samples showed IL-27 expression by IHC within morphologically defined tumor-associated macrophages (TAMs) in several cancers, including lung, liver, renal, gastric, and head and neck. This is consistent with single-cell RNA-seq transcriptional data showing predominant expression in macrophages from several tumor types. Interestingly, IL-27$^+$ TAMs are localized in the vicinity of PD-L1–expressing cells in gastric, lung, and liver tumors, where the highest IL-27$^+$ TAM density is associated with the highest expression of PD-L1. Expression of IL-27RA in tumor tissues was also explored by IHC. IL-27RA expression was identified on tumor cells in several cancers and included examples where tumor cell expression of the receptor was maintained at sites of lymph node metastasis. In vitro cultures of activated PBMCs showed that IL-27 increased PD-L1 expression on immune cells, an effect that was further amplified in the presence of dissociated primary tumors co-cultured with activated PBMCs. IL-27 levels were higher in co-cultures of activated PBMCs and dissociated primary tumors than in cultures of PBMCs alone. Finally, IL-27 was shown to upregulate PD-L1 expression on tumor cell lines that express IL-27RA.

Conclusions IL-27 is expressed by TAMs and plays a role in immune suppression. IL-27$^+$ cells are found in close proximity to PD-L1$^+$ cells in patient tumors, and IL-27 can regulate levels of PD-L1 expression in immune cells and tumor cell lines, suggesting cross-talk between these molecules to diminish immune activation within the tumor microenvironment. Combined blockade of IL-27 and PD-(L)1 to enhance antitumor immune responses is currently being evaluated in clinical trials.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1082

1083 AB821 IS A CD8+ T CELL SELECTIVE IL-21 WITH ENHANCED BIOAVAILABILITY THAT MEDIATES POTENT ANTI-TUMOR ACTIVITY, CYTOTOXICITY, AND EXPANSION OF MEMORY CD8+ T CELLS

[1]Renee Greer, [1]Henry Nguyen, [1]Paul Mesko, [1]Ruth Lan, [1]Wei Wei Prior, [2]Hussein Sultan, [1]Meghana Sukthankar, [1]Irene Ni, [1]S Michael Chin, [1]Kelly Moynihan, [3]Ton Schumacher, [2]Robert Schreiber, [1]Andy Yeung, [1]Ivana Djuretic*. *[1]Asher Biotherapeutics Inc., South San Francisco, CA, USA; [2]Washington University, St. Louis, MO, USA; [3]The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background IL-21 is a clinically validated cytokine that showed monotherapy activity in melanoma[1] and renal cell carcinoma[2]. Further clinical development of IL-21 was discontinued, likely due to limitations such as short half-life and poor bioavailability, a result of IL-21's low molecular weight and highly positive charged nature, respectively. The pleiotropic effects of IL-21 may have also limited its effectiveness in the clinic. While IL-21 can activate STAT3 in CD8+ T cells to promote anti-tumor immunity, STAT3 activation in NK cells and myeloid cells may be associated with toxicity and immunosuppression, respectively[3,4]. To maximize the potential of IL-21, we developed AB821, a cis-targeted IL-21 that selectively activates CD8+ T cells and exhibits improved bioavailability.

Methods AB821 was generated by fusing a CD8 targeting antibody to an IL-21 mutein which has attenuated binding to IL-21 receptor and a reduced positive charge profile. AB821 and its murine surrogate, muAB821, were characterized alongside WT IL-21 in multiple in vitro and in vivo studies.

Results In STAT3 assays with human PBMCs, whereas IL-21 indiscriminately activated CD8+ T cells and non CD8 cells with almost equivalent potency, AB821 demonstrated high potency of 0.5nM on CD8+ T cells and 1000-fold selectivity over other IL-21 target cell types such as B cells, NK cells and CD4+ T cells. Selective activation of STAT3 in CD8+ T cell was also observed following AB821 dosing in cynomolgus monkeys. Besides selectivity, AB821 showed enhanced in vivo exposure with reduced non-specific consumption compared to WT IL-21. Functionally, AB821 largely recapitulated the gene expression signatures of WT IL-21 in both resting and antigen-activated CD8+ T cells. Notably, AB821 induced minimal gene expression changes in resting CD8+ T cells but synergized with antigen stimulation and induced a larger set of genes in activated CD8+ T cells, consistent with IL-21's primary role in the context of antigen activation. Furthermore, in hematopoietic stem cell-humanized mice, a single dose of AB821 resulted in a persistent increase in Granzyme B+ CD8 + T cells and marked increases in the memory compartment. Finally, muAB821 demonstrated remarkable monotherapy activity in multiple tumor models, with muAB821 significantly outperforming mouse IL-21. Furthermore, muAB821 showed synergistic anti-tumor activity with anti-PD1 antibody in multiple PD1-resistant tumors.

Conclusions AB821 is a next-generation IL-21 with superior anti-tumor activity and enhanced bioavailability over WT IL-21. AB821 promotes cytotoxicity and memory CD8+ T cells in the context of antigen activation and synergizes with PD1 blockade in PD1-resistant tumors. Clinical development of AB821 is planned.

1084 NTX-0250, A MULTIMODAL MRNA-BASED IMMUNOTHERAPY, ERADICATES LARGE ESTABLISHED TUMORS IN A STRINGENT MOUSE MODEL OF HPV16-DRIVEN CANCER

[1]Ole Haabeth*, [2]Diane DaSilva, [1]Colin McKinlay, [1]Weiqun Liu, [1]Edward Lemmens, [1]Christopher Rae, [1]Adrienne Sallets, [1]Daniel Frimannsson, [1]Sangeeta Nath, [1]Nicole Peck, [1]Ou Li, [1]Nicole Fay, [2]Ruben Prins, [1]Meredith Leong, [2]W Martin Kast, [1]Samuel Deutsch. *[1]Nutcracker Therapeutics, Emeryville, CA, USA; [2]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA, USA*

Background Human papillomavirus (HPV) is a contagious cause of anogenital and oropharyngeal cancers developing from persistently infected and subsequently transformed basal keratinocytes of mucosal epithelium. More than 90% of cervical cancers and pre-cancerous cervical intraepithelial neoplasia (CIN) are linked to infections with high-risk HPV, with more than 50% of cancers linked to HPV16.[1,2] At least 25% of women with high-grade CIN lesions progress to in situ or invasive cancer, if untreated.[3] Current treatments for high-grade CIN can remove abnormal tissue but do not address underlying HPV infection, and 15% of women treated develop residual or recurrent high-grade CIN or cervical cancer.[4] Long-term efficacy may require induction of tumor-specific T cell responses combined with alleviated local immune suppression and increased tumor immune cell infiltration. Multimodal mRNA-based immunotherapies that deliver both antigens and immunomodulators in a single drug product represent a promising new approach for treatment of CIN and cervical cancer that can address current disease as well as the underlying cause (HPV infection). Here we report on pre-clinical efficacy of NTX-0250, a nanoparticle-formulated, multi-component mRNA drug that co-delivers a novel HPV16 antigen design with two potent immunomodulators.

Methods To test efficacy, we utilized the well-established, clinically relevant, C3.43 tumor model (5). C3.43 is a progressive subclone of C3, HPV16-transformed B6 mouse embryo cell line that expresses HPV16 E6 and E7 antigens under the natural promoter.[5] Therapeutic efficacy of NTX-0250 was assessed in mice with large (>120mm^3) C3.43 tumors. HPV16-specific T cells were assessed by flow cytometry on peripheral blood mononuclear cells (PBMCs). Mechanistic studies were performed by post-treatment tumor microenvironment characterization. To assess translational potency of NTX-0250, induction of HPV-specific T cell responses in cynomolgus monkeys was measured by flow cytometry and IFNg ELISpot on PBMCs

Results In tumor challenged mice, administration of NTX-0250 induces complete regression of large tumors resulting in long-term, tumor-free survival of 100% of treated animals (figure 1A). Complete responses are accompanied by strong tumor immune infiltration of CD8+, CD4+ APCs and NK cells and upregulation of IFNγ in the tumor microenvironment (figure 1B). In cynomolgus monkeys, administration of NTX-0250 induces strong HPV16-specific responses (figure 2).

Conclusions Here we report for the first time robust pre-clinical efficacy of a multimodal, mRNA-based therapeutic combining antigen- and immunomodulator-encoding mRNAs in a novel nanoparticle formulation. NTX-0250 treatment resulted in complete regression of large established murine tumors and robust induction of HPV-specific T cell responses in non-human primates.

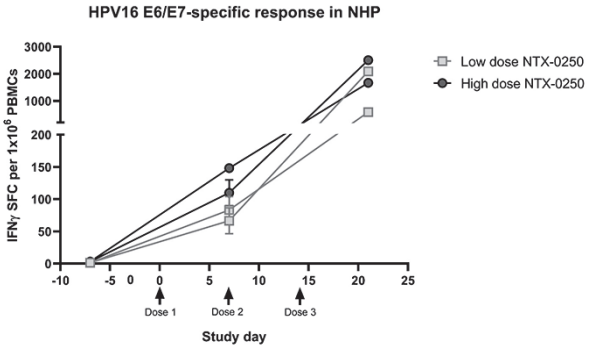
Abstract 1084 Figure 1 NTX-0250 induces complete regression of large tumors in mice
A) 10 C57/BL6 mice per group were inoculated with 1x106 C3.43 cells in the subcutaneous compartment. NTX-0250 or Mock-treatment, was initiated when tumors were >120mm3 (18 after tumor inoculation). Mice received 3 doses of 1.5µg NTX-0250 with 7 days interval. Tumor growth was monitored for 90 days. B) Representative immunohistochemistry staining of C3.43 tumors 3 days post treatment with vehicle control (Mock treated) or NTX-0250. Slides were stained for infiltrating CD8+ T cells (Brown).



Abstract 1084 Figure 2 NTX-0250 induces robust HPV16-specific responses in NHPs.
Cynomolgus monkeys (n=2) were immunized three times with low or high dose of NTX-0250. Induction of HPV16 E6 and E7-specific T cells responses were measured by IFNγ ELISpot after one and three doses.

1085 THE NAD+ DEPENDENT DEACETYLASE SIRT2 IS A NEGATIVE REGULATOR OF THE JAK/STAT PATHWAY IN EFFECTOR T CELLS

[1]Imene Hamaidi*, [2]Lin Zhang, [1]Pingyan Cheng, [1]Min-Hsuan Wang, [1]Erika Johnson, [1]Bin Fang, [1]Sungjune Kim. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Medical University Cancer Institute, Tianjin, China*

Background The Janus kinase (JAK)-signal transducer and activator of transcription (STAT) pathway plays critical roles in orchestrating the immune system through cytokine receptors by modulating T cell polarization and effector functions. Cytokine binding to the cognate receptors activates JAKs that phosphorylates STATs which in turn translocate to the nucleus in order to activate or suppress the transcription of genes. This pathway is regulated by an array of regulator proteins, determining the initiation, duration, and termination of the signaling. However, the roles of these protein regulators other than phosphorylation-dephosphorylation remain unclear.

Sirt2 is an (NAD+)-dependent histone deacetylase with conflicting reports on its tumor suppressor or oncogenic roles. We previously showed that Sirt2 is a suppressor of T cell metabolism that deacetylates key metabolic targets and negatively impacts their enzymatic activity. Accordingly, Sirt2 deficient T cells exhibited a hyper-metabolic status with a profound upregulation of glycolysis.

Methods The role of Sirt2 in T cell immune response was investigated using RNA-sequencing, CFSE proliferation assay, DAPI/AnnexinV staining, IFN-γ ELISpot assay, intracellular staining of effector molecules and LDH cytotoxicity assay in Wild-type and Sirt2 knockout mice. Sirt2 interactome was identified via mass spectrometry (MS) and immunoprecipitation/Wb analyses. Phosphorylation and acetylation of JAK/STAT effector molecules following cytokine stimulation were assessed by Wb. Pharmacologic inhibition of Sirt2 in human T cells was achieved using Thiomyristoyl, a Sirt2 selective inhibitor.

Results Sirt2 expression is induced following T cell activation. Our molecular studies revealed that Sirt2 directly interacts with JAK1/2/3 and STAT1/3/5 and negatively impacting their acetylation status.

Strikingly Sirt2 inhibition resulted in increased phosphorylation of JAK1/2/3 and STAT3/5 following IL2 stimulation and increased phosphorylation of JAK1/2 and STAT1 following IFN-γ stimulation in murine and human T cells.

Accordingly, RNA-sequencing analysis revealed upregulation of IL-2 signaling and IFN-γ response with Sirt2 deficiency in activated T cells.

As a consequence of enhanced JAK/STAT activation, Sirt2 deficient T cells displayed enhanced T cell proliferation and effector functions.

Conclusions Our findings indicate Sirt2 as a suppressor of JAK/STAT pathways and show that protein acetylation plays an important role in the modulation of cytokine signaling and T cell fate. Therefore, Sirt2 constitutes a potential target to manipulate the immune response and to treat immune-related diseases or enhance antitumor immunity.

1086 NKTR-288, A POLYMER-CONJUGATED INTERFERON GAMMA MUTEIN FOR THE TREATMENT OF SOLID TUMORS

[1]Damon Hamel*, [2]Marlene Hennessy, [3]Sarah Ingersoll, [1]Olga Zemska, [1]Phi Quatch, [1]Rhoneil Pena, [1]Thomas Chang, [2]David Doherty, [4]Guifen Xu, [1]Arkopal Choudhury, [1]Danni Yu, [4]Werner Rubas, [1]Christie Fanton, [1]Brian Vuillemenot, [1]Saul Kivimae, [1]Takahiro Miyazaki, [1]Jonathan Zalevsky. *[1]Nektar Therapeutics, San Francisco, CA, USA; [2]Exelixis, Alameda, CA, USA; [3]Amgen, South San Francisco, CA, USA; [4]Sutro BioPharma, South San Francisco, CA, USA*

Background Interferon gamma (IFNg) cytokine induces cellular antigen presentation and has great potential in cancer treatment through enhancement of tumor antigen specific cytotoxic T cell response. However, the unfavorable pharmacokinetics (PK) and the pleiotropy of native IFNg have limited its therapeutic potential. NKTR-288 is a polymer-conjugated IFNg mutein, designed to improve exposure by increasing hydrodynamic radius and reducing receptor and heparin binding affinity to provide optimized on-target pharmacodynamics (PD). Here, we report on the discovery of NKTR-288 and investigate its pharmacological properties.

Methods Binding of NKTR-288 to interferon gamma receptor 1 (IFNGR1) and heparin was measured by surface plasmon resonance. The biological activity of NKTR-288 was measured by pSTAT1 induction in tumor cell lines and primary myeloid cells in vitro and in vivo. PK/PD was measured in nonhuman primates (NHP), and human xenograft mouse models. Antitumor efficacy and enhancement of checkpoint blockade was measured in the mouse syngeneic B16F10 tumor model using a mouse IFNg polymer conjugate as a surrogate for NKTR-288.

Results NKTR-288 has increased hydrodynamic radius to slow renal clearance and binds to IFNGR1 and heparin with reduced affinity compared to recombinant IFNg1b, thereby reducing clearance due to target-mediated drug deposition. In vitro, NKTR-288 maintains the maximum potential (Emax) for pSTAT1 induction on target cells. In vivo, NKTR-288 shows durable exposure in tumor bearing mice (half-life [T½] 18.2 to 24.2 hr) and NHP (T½ 31.6 to 37.3 hr) and is well tolerated at pharmacologically active doses. NKTR-288 has a desirable PK/PD profile that can attain greater induction and duration of MHCI than can be achieved with the native cytokine. NKTR-288 also upregulates PD-L1 in tumor tissue supporting combination therapy with checkpoint inhibitors. In a syngeneic tumor model, a surrogate mouse conjugate exhibited significant anti-tumor efficacy (57% TGI), and increased efficacy when combined with anti-PD-1 (73% TGI) or anti-PD-L1 (68% TGI). Treatments were well tolerated and tumor growth inhibition was immune system mediated, requiring T cells.

Conclusions NKTR-288 is a novel IFNGR agonist with optimized pharmacological properties for tolerable and sustained induction of tumor antigen presentation, potentially increasing tumor cytotoxic T cell response, immune infiltration, and TME modification. As evidence, a mouse surrogate conjugate demonstrated T cell-mediated anti-tumor activity, and enhanced checkpoint blockade efficacy in a low-MHCI "cold" tumor model. These results highlight the potential of NKTR-288 as a novel cytokine immunotherapy in cancer patients, with the potential to enhance PD-1/PD-L1 checkpoint blockade efficacy and broaden the responsive patient population.

Ethics Approval Animal studies were performed under protocols approved by the Institutional Animal Care and Use Committee of Nektar Therapeutics and the Canadian Council on Animal Care. All studies met the ethical and humane criteria for transportation, housing, and care established by the US NIH guidelines or Canadian animal care regulators.

1087 ADDITION OF IL-2 OVERCOMES LUNG TUMOR RESISTANCE TO IL-12 BY COORDINATING CYTOTOXIC AND REGULATORY T CELL RESPONSES

Brendan Horton*, Maria Zagorulya, Noor Momin, Yash Agarwal, K Wittrup, Stefani Spranger. *Massachusetts Institute of Technology, Cambridge, MA, USA*

Background IL-12 is a pleiotropic cytokine with potent T cell stimulatory ability that can induce tumor regression in preclinical models. Translation of IL-12 has been hampered by high toxicity and a lack of efficacy. While many efforts have been made to engineer IL-12 to be less toxic and more effective, our understanding of resistance to IL-12 is limited due to a lack of appropriate model systems. We have identified a model of IL-12-resistant lung cancer that allows us to probe mechanisms of IL-12 response and resistance.

Methods We utilized the syngeneic, transplantable murine lung cancer KP cell line to analyze the response to extended half-life IL-12 or IL-2 fused to murine serum albumin (IL12-MSA, MSA-IL2). Expression of the $CD8^+$ T cell antigen SIY in KP cells (KP.SIY) allowed the tracking of antigen-specific anti-tumor immune responses.

Results IL12-MSA induced significant tumor control and improved survival of mice with subcutaneous KP flank tumors. However, mice inoculated intravenously with KP cells to form metastatic lung tumors derived no survival benefit from IL12-MSA. Using KP.SIY cells, we determined that successful IL12-MSA immunotherapy in the flank setting involved significant expansion and effector differentiation of SIY-reactive$CD8^+$ T cells in the tumor-draining lymph node (TdLN), and the depletion of $CD4^+$ regulatory T cells (T_{reg}) from the tumor microenvironment. In the lung tumor setting, however, T cells were unresponsive to IL12-MSA, as SIY-reactive T cells did not expand in lung TdLNs and did not upregulate the effector molecules CD25, GzmB, and TIM-3. Using fluorescently labeled IL12-MSA, we found significantly reduced IL-12 binding by SIY-reactive $CD8^+$ T cells and T_{reg} in the lung tumor setting, explaining the lack of IL12-MSA efficacy against lung tumors. However, combed MSA-IL2 and IL12-MSA improved lung tumor control and synergistically enhanced $CD8^+$ T cell activation. In lung tumors and lung TdLNs, the addition of MSA-IL2 increased the binding of IL12-MSA by T_{reg}, suggesting that IL-2 sensitized lung tumors to IL-12 through a coordinated enhancement of tumor-reactive $CD8^+$ T cell activation with a concomitant inhibition of T_{reg}.

Conclusions Resistance to IL-12 can be mediated by tumor-reactive T cells with low IL-12 receptor expression, therefore IL-12 receptor expression should be considered when administering IL-12-based therapies. IL-2 can sensitize T cell responses to IL-12 through a feed-forward mechanism of $CD8^+$ T cell activation and concurrent T_{reg} inhibition.

Ethics Approval The experiments in this abstract were approved by the Massachusetts Institute of Technology Committee on Animal Care, Protocol Number 0220-006-23, NIH Assurance Number D16-00078.

1088 A HIGHLY POTENT ANTI-LAG-3-IL-2C THAT SELECTIVELY TARGETS TUMOR-SPECIFIC CD8+ T CELLS

Zoey Huang, Jianing Huang, Fan Ye*, Sandra Chen, Danny Huang, Michael Hua, Ella Li, Jenny Jiang, Hanna Lin, Shirley Shi, Bella Yue, Henry He, Mingxing Yang, Qiang Fu, Ziyang Zhong. *Anwita Biosciences, San Carlos, CA, USA*

Background Interleukin 2 (IL-2) is an essential link in immune activation and heavily contributes to tumor eradication. Clinically, IL-2 has shown impressive efficacy in various tumor types. However, the abundant and ubiquitous expression of IL-2 receptors made IL-2 pleiotropic and hence limits its application as the sole agent for immunotherapy. LAG-3 emerged as the next-generation inhibitory immune checkpoint (ICP) following CTLA-4, PD-1, and PD-L1. Simultaneous blockade of LAG-3 and PD-1 has shown favorable clinical outcomes in PD-1/PD-L1 resistant melanoma patients. In addition to its ICP role, the expression pattern of LAG-3 has made it an appealing target to be used in combination with IL-2 as a bifunctional fusion protein for tumor immunotherapy as LAG-3 is highly expressed on tumor-specific $CD8^+$ T cells. A LAG-3^+-T-cell-targeting IL-2 has strong anti-tumor efficacy and minimal systemic toxicity, as well as the compatibility to be combined with PD-1 blockade. We herein proposed the use of an αLAG-3-IL-2c fusion protein which consists of a LAG-3 binding domain and IL-2c, a chimeric molecule that contains a fragment from IL-15 and does not bind to IL-2 receptor alpha, to achieve the aforementioned purpose.

Methods The *in vitro* potency was determined with pSTAT5 signaling assay and human PBMC proliferation assay. The *in vivo* efficacy was evaluated in syngeneic CT26 mouse model with a surrogate molecule. A humanized αLAG-3-IL-2c fusion protein was tested on hLAG-3-knocked-in (KI) mice with MC-38 model, as well as in combination with mesothelin-targeted CAR-T on NSG mice with N87 gastric cancer xenograft model.

Results αLAG-3-IL-2c induced a greater pSTAT5 activation signal in LAG-3^+ T cells than in LAG-3^- T cells. Additionally, αLAG-3-IL-2c enhanced *in vitro* proliferation in LAG-3^+ T cells compared to untargeted IL-2c by approximately 1000 folds. Furthermore, among the LAG-3^+ cell population, αLAG-3-IL-2c expanded $CD8^+$ T cells to a greater extent compared to $CD4^+$ T cells. In the syngeneic CT26 model and hLAG-3 KI model, αLAG-3-IL-2c induced a much stronger anti-tumor response compared to LAG-3 mAb, IL-2c, or LAG-3 mAb in combination with IL-2c. Moreover, αLAG-3-IL-2c showed enhanced intratumoral $CD8^+$ T cells proliferation and anti-tumor efficacy in a CART model, demonstrating the promising usage of αLAG-3-IL-2c to combine with CART therapy.

Conclusions Altogether, these results indicate that αLAG-3-IL-2c is a potent tumor-infiltrating $CD8^+$ T agonist without notable peripheral toxicity.

Ethics Approval The protocol of animal studies has been reviewed and approved by IACUC.

1089 IMMUNOPHERESIS®: A NOVEL IMMUNOTHERAPY PLATFORM FOR EXTRACORPOREAL REMOVAL OF SOLUBLE TARGET MOLECULES IN ONCOLOGY

Steven Josephs, Robert Segal, Steve Prince, Mathew Ong, Amir Jafri, Lawrence Florin, Victoria Manax, Michael Matho, Sameera Bilgrami, Annette Marleau*. *Immunicom, Inc., San Diego, CA, USA*

Background Immunopheresis® is a novel immunotherapeutic approach for treating cancer that employs Immunicom, Inc.'s proprietary technology platform for extracorporeal removal of soluble target molecules from plasma. The technology platform consists of patent-protected apheresis columns containing an affinity matrix to which customized ligands are coupled for capturing one or more cytokines, cytokine receptors and/or growth factors. The lead product, the LW-02 Column, selectively removes soluble tumor necrosis factor receptors (sTNF-Rs) from plasma, which are shed by tumors to neutralize TNF-α and evade its anti-tumor activities. Performance of the LW-02 Column demonstrates the effective and selective target molecule capture that is achievable using the Immunopheresis platform.

Methods The LW-02 Column comprises a trimeric single-chain TNF-a molecule covalently conjugated to an agarose bead matrix to form a proprietary high affinity resin. Laboratory performance testing of the LW-02 Column includes: 1) Capture efficiency and binding capacity for sTNF-Rs (sTNF-R1 and sTNF-R2) measured using MSD assays; 2) Leaching of ligand from the affinity matrix evaluated using MSD assays; 3) Potential off-target binding assessed by measuring plasma protein profiles and cytokine concentrations pre- and post-column exposure using HPLC and immunoassays

Results In laboratory testing, the LW-02 Column has a capture efficiency of >80% removal of both sTNF-R1 and sTNF-R2, during recirculation of 1L test plasma through the column to model a clinical apheresis procedure. The column binding capacity exceeds the sTNF-R quantities that are typically present in cancer patients' plasma (approximately 30 micrograms total). The quantities of TNF-a ligand that leach from the affinity matrix (equivalent to < 1 microgram per procedure) are significantly lower than TNF-a levels reported to cause clinical adverse events. The LW-02 Column exhibits selectivity for sTNF-Rs with negligible off-target binding of cytokines, immunoglobulins, or other plasma components.

Conclusions LW-02 Column Immunopheresis has a highly specific and selective mechanism of action and offers a novel subtractive therapy approach for treating cancer that avoids the typical toxicities associated with systemic drug therapy. Clinical performance of the LW-02 Column is currently being monitored as part of three ongoing clinical trials as monotherapy or as an adjunct to chemo- or immunotherapy for various solid tumors. The technology platform is being leveraged with novel high-affinity capture ligands to address other clinically relevant target molecules in immuno-oncology.

1090 OVERCOMING SYSTEMIC TOXICITY OF IL-12-BASED IMMUNOTHERAPY BY TUMOR-TARGETING AND IL-12 ATTENUATION

Jihoon Chang*, Donggeon Kim, Dahea Lee, Dongsu Kim, Soomin Ryu, Byoung Lee. *Kanaph Therapeutics, Seoul, Korea, Republic of*

Background Cytokines are well-known immunomodulators. Thanks to recent success of immune checkpoint inhibitors there is a renewed interest in cytokines as a promising cancer immunotherapy option. Several inflammatory cytokines including IL-12 showed potent anti-tumor activities but severe immune adverse events when administered systemically greatly hindered using them as anti-tumor agents.

Methods Previously (*SITC 2020*) we showed that IL-12 activity was reduced by our introduced mutation (termed as mut1) if measured by pSTAT4 AlphaLISA assay. But when it was treated in human immune cells IFNg production was not reduced as expected. Thus, we further attenuated IL-12 activities by protein engineering and created our candidate molecule KNP-101.

Results We showed that KNP-101 maintained potent anti-tumor activities in vivo but gained greatly improved toxicity profiles. When we measured pSTAT4 signals, KNP-101 showed about 30-fold attenuation in IL-12 activities compared with rIL-12. IFNg production from human PBMC was also reduced. Although the IL-12 activity was weakened in order to reduce its systemic toxicity, our KNP-101 mouse surrogate still maintained good anti-tumor potency in various mouse syngeneic models with a single intravenous injection as low as 2 ug/head. In combination with anti-PD-L1, KNP-101 surrogate showed a synergistic anti-tumor effect and further FACS analysis of tumor infiltrated lymphocytes demonstrated that the effects were mediated by immune cell infiltration. Importantly, in CD1 naïve mouse toxicity test, KNP-101 surrogate was tolerable up to 50 ug/head and no survival issue was observed. However, that was not the case with the control group, non-tumor-targeting null/IL-12 showing survival issues with all tested dose levels. Compared with the control, KNP-101 surrogate also showed much safer profiles in terms of organ weight and serum chemistry such as ALT level. We also performed similar toxicity study in tumor-bearing mice. KNP-101 surrogate again showed a very safe profiles being tolerable up to 500 ug/head and no survival issue. Noticeably, when serum IFNg was measured in tumor-bearing mice, our KNP-101 surrogate induced far less IFNg in serum compared to null/IL-12 suggesting that systemic toxicity was greatly reduced.

Conclusions Together, we demonstrated that systemic toxicity of IL-12 cytokine therapy can be overcome by tumor-targeting and IL-12 attenuation. Our KNP-101 has a widen therapeutic window by maintaining potent anti-tumor activities and showing much improved safety profiles. We hope that KNP-101 can benefit patients in the future who suffer from primary and acquired resistance of the current anti-PD-1/PD-L1 treatments.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1090

1091 CGC-601, A NOVEL βγ-ONLY IL-2 VARIANT, ENHANCES MODERATE IMMUNE ACTIVATION WITHOUT TREG EXPANSION, AND EXHIBITS A SUPERIOR SAFETY EVIDENCE IN VIVO

Lei Zhao*, Rong Wang, Chuan Feng, Yongji Jiang, Patrick Liu, Yuan Liu. *Cure Genetics Co., LTD, Suzhou, China*

Background IL-2 was first approved by FDA for the solid tumor treatment. However, the therapeutic window of IL-2 (low dose suppresses immune system by Treg activation and high dose represents toxicity) limited its clinical use. The major dose-limiting toxicity IL-2 is vascular leak syndrome (VLS). The mechanism of VLS is mainly considered as the direct interaction of IL-2 with IL-2Rα expressed on endothelial cells in vivo[1, 2] or by over-stimulation of immune cells.[3, 4] To get rid of the IL-2Rα interaction, non-α IL-2 muteins were designed to deplete the Treg expansion which may contributes to its anti-tumor efficacy (figure 1). However, they still remain the risk of overstimulated immune response.

Here, we introduce our IL-2 variant, CGC-601, which abolished its binding to IL-2Rα, while obtained a structural twist on four α-helix (figure 2). This brand new molecule was designed as a non-suppressive and moderate immune agonist, through the strategy of de-coupling the IL-2 binding pattern to "βγ-only".

Results CGC-601 does not bind to IL-2Rα or IL-2Rβ alone, while only binds to βγ complex with the similar affinity to wtIL-2 in a "fast-on, fast-off" feature (figure 3). Moreover, CGC-601 shows a low Treg response and mild CD8 T and NK activation in human PBMC (figure 4). For T cell expansion, upon 50nM treatment, CGC-601 holds a similar T cell expansion capacity with rhIL-2 (figure 5A). Meanwhile, CGC-601 expands both CD8 T cells and NK cells, but Treg expansion dramatically constrained after PBMC *ex vivo* expansion (figure 5B). Thus, compare with rhIL-2, CGC-601 gives "young" and less differentiated T cells after expansion (figure 6).

In the toxicity test, CGC-601 dose as high as 30 mg/kg, mice stay in good health conditions, while 10 mg/kg rhIL-2 showed a severe weight loss and a reduced activity since Day 3, suggesting CGC-601 has a much safer profile than rhIL-2 (figure 7A). Pulmonary edema is significantly reduced even CGC-601 dose reached 30mg/kg (figure 7B). CGC-601 treatment did not elevate serum IL-5 levels 6 hrs after the first dose (Fig. 7C). CGC-601 prefers C8 T cells and NK cells expansion, on the contrary, CGC-601 does not expand Tregs in vivo (figure 8).

Conclusions CGC-601 with a unique βγ-only binding property, promotes moderate CD8 T and NK expansion and diminishes immunosuppressive Tregs in vivo, has a great potential in immune-stimulation indications. CGC-601's safety evidence sets up a platform allowing multiple application scenarios (figure 9).

1092 THE CD8+ T CELL SELECTIVITY OF AB248 IS ESSENTIAL FOR OPTIMAL ANTI-TUMOR ACTIVITY AND SAFETY IN NONCLINICAL MODELS

[1]Kelly Moynihan*, [1]Danielle Pappas, [2]Hussein Sultan, [1]Terrence Park, [1]Manu Kumar, [1]Ruth Lan, [1]Irene Ni, [1]Jessie Chen, [1]Michael Chin, [3]Ton Schumacher, [1]Andy Yeung, [2]Robert Schreiber, [1]Ivana Djuretic. *[1]Asher Biotherapeutics, South San Francisco, CA, USA; [2]Washington University in St. Louis, St.Louis, MO, USA; [3]The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background AB248 is a fusion of an affinity-attenuated IL-2 mutein and an antibody targeting CD8+ T cells designed to overcome the limitations of wild-type IL-2 and second-generation IL-2Rβγ agonists, "not-α" IL-2 and IL-15 variants. Like "not-α" IL-2, AB248's IL-2 mutein does not bind IL-2Rα and thus avoids IL-2Rα-associated vascular leak syndrome (VLS) and preferential Treg activation in nonclinical models. Further, the IL-2 mutein in AB248 has reduced IL-2Rβ affinity, and its cis-targeting to CD8+ T cells enables AB248 to avoid the biased expansion of IL-2Rβ^{high} NK cells and IL2Rβγ-mediated activation of Tregs associated with untargeted IL2Rβγ agonists. Thus, AB248's design enables robust IL-2 pharmacology on CD8+ T cells, key effectors with IL-2-based therapy[1-2], while avoiding cell types that may promote toxicity or oppose anti-tumor activity. Here, the mechanisms by which AB248 achieves enhanced nonclinical activity and safety profiles over untargeted IL-2-based therapies are elucidated.

Methods In vitro activation and cytokine release assays were performed on human immune cells. Tumor immune profiling including scRNAseq was performed in mice treated with AB248's surrogate, muAB248. Cynomolgus monkeys were dosed with AB248.

Results We previously showed that IL-2 and "not-α" IL-2 triggered antigen-independent cytokine release from PBMCs in vitro, which was mitigated by the depletion CD56+ cells, which are largely NK cells, and that AB248 avoided this non-selective cytokine release. Studies with sorted PBMC subsets further interrogated this observation and demonstrated the necessity of dual IL-2Rα and IL-2Rβγ affinity reduction as well as CD8+ T cell cis-targeting to avoid antigen-independent cytokine release. Strong anti-tumor activity was elicited by muAB248 in multiple murine models without body weight loss. In contrast, "not-α" IL-2 could not achieve meaningful activity without accompanying NK cell-dependent weight loss. Bypassing the NK cell sink was also important for optimal expansion of intratumoral CD8+ T cells. Comprehensive analysis following treatment with muAB248 demonstrated profound impacts to the tumor immune infiltrate, including activation of unique CD8+ T cell clusters by muAB248 compared to "not-α" IL-2, which may explain muAB248's superior anti-tumor activity. In cynomolgus monkeys, repeated doses of AB248 that selectively expanded CD8+ T cells >20-fold were well tolerated, without evidence of cytokine release syndrome or VLS.

Conclusions AB248 exhibited strong anti-tumor activity in mice, profound pharmacodynamic effects in primates, and a favorable nonclinical safety profile. CD8+ T cell restriction was essential for optimal anti-tumor activity and safety in nonclinical models. Collectively, this data demonstrates AB248's differentiation from broadly acting IL-2-based therapies and supports AB248's clinical development.

1093 A NOVEL IL12-BASED IMMUNOCYTOKINE TARGETING FIBROBLAST ACTIVATION PROTEIN (FAP) FOR THE TREATMENT OF CANCER

[1]Lisa Nadal, [1]Frederik Peissert, [1]Abdullah Elsayed, [2]Tobias Weiss, [2]Thomas Look, [2]Michael Weller, [3]Geny Piro, [3]Carmine Carbone, [3]Giampaolo Tortora, [1]Mattia Matasci, [1]Nicholas Favalli, [1]Riccardo Corbellari, [1]Cesare Di Nitto, [1]Eleonora Prodi, [4]Chiara Libbra, [4]Simone Galeazzi, [4]Claudiopietro Carotenuto, [5]Cornelia Halin, [1]Emanuele Puca, [4]Dario Neri, [1]Roberto De Luca*. *[1]Philochem AG, Otelfingen, Switzerland; [2]University Hospital Zurich, Zürich, Switzerland; [3]Catholic University of the Sacred Heart, Rome, Italy; [4]Philogen S.p.A, Siena, Italy; [5]ETH Zurich, Zurich, Switzerland*

Background Fibroblast Activation Protein (FAP) has been described as the "next billion-dollar nuclear theranostics target"[1], since more than 28 different tumor types have successfully been imaged in patients with radiolabeled FAP ligands. [2-3] FAP can be found in the tumor microenvironment (TME) of most malignant solid tumors, while being absent in most healthy tissues. Thus, it is an attractive target for both imaging and therapeutic applications. Monoclonal antibodies targeting TME antigens have been considered for the delivery of bioactive payloads, such as proinflammatory cytokines. Antibody-cytokine fusions (also called immunocytokines) may exploit the tumor-homing properties of the antibody moiety, in order to concentrate the cytokine payload at the site of disease and enhance the therapeutic index.[4] Interleukin-12 (IL12) have been extensively studied in oncology. IL12 strongly promotes NK cells, CD4+ and CD8+ T cells to produce interferon-gamma (IFN-g), one of the most relevant mediators of anti-cancer immunity.[5]

Methods In this work, we describe the generation of a novel anti-FAP antibody, called 7NP2. The tumor recognition properties of the antibody were validated by immunofluorescence procedures performed on cancer biopsies from human patients. A fusion protein consisting of the 7NP2 antibody linked to interleukin-12 was generated and the anti-cancer activity of the murine surrogate product (named mIL12-7NP2) was evaluated in mouse models. To prepare for future clinical trials, a fusion protein consisting of human IL12 linked to the 7NP2 antibody was further investigated in a toxicology study in *Cynomolgus* monkeys.

Results Biodistribution analysis in tumor bearing mice confirmed the ability of the product to selectively localize to solid tumors while sparing healthy organs. Encouraged by these results, therapy studies were conducted *in vivo*, showing a potent anti-tumor activity in immunocompetent and immunodeficient mouse models of cancer, both as single agent and in combination with immune checkpoint inhibitors. The fully human product was tolerated when administered to non-human primates.

Conclusions The results obtained in this work provided a rationale for future clinical translation activities using IL12-7NP2.

1094 **FAVORABLE PRECLINICAL EFFICACY AND SAFETY PROFILE OF AVB-001 A NOVEL IL-2 CELL-BASED IMMUNOTHERAPY THAT ERADICATES OVARIAN CANCER IN MOUSE TUMOR MODELS AND SUPPORTS FIRST IN HUMAN CLINICAL DEVELOPMENT**

[1]Guillaume Carmona*, [2]Amanda Nash, [1]Ryan Newman, [1]Jake Schladenhauffen, [2]Maria Jarvis, [2]Samira Aghlara-Fotovat, [2]Sudip Mukherjee, [2]Andrea Hernandez, [2]Andrew Hecht, [3]Peter Rios, [2]Shirin Nouraein, [4]Rahul Sheth, [5]Weiyi Peng, [3]Jose Oberholzer, [4]Amir Jazaeri, [2]Omid Veiseh. *[1]Avenge Bio, Natick, MA, USA; [2]Rice University, Houston, TX, USA; [3]Celltrans, Chicago, IL, USA; [4]University of Texas MD Anderson Cancer, Houston, TX, USA; [5]University of Houston, Houston, TX, USA*

Background Aldesleukin, recombinant human IL-2 has been approved by the FDA for the treatment of melanoma and renal cancer. However, effective cytokine therapy is limited by its short half-life in circulation and the severe adverse effects associated with high systemic exposure when administered iv. To overcome these limitations, Avenge Bio has developed a localized cytokine delivery LOCOcyte™ platform comprised of polymer encapsulated epithelial cells that produce potent immune effector molecules for loco-regional delivery with temporal regulation. AVB-001 is engineered to produce native IL-2, for the treatment of ovarian cancer.

Methods Safety, PK and PD testing of AVB-001 using a combination of rodent and NHP animal models.

Results Tumor-adjacent local administration of AVB-001 demonstrated that mIL-2 local concentration (intraperitoneal space) was 100x higher than the systemic concentration (blood) demonstrating the ability of the LOCOcyte™ platform to deliver native cytokines in vivo and create a high locoregional concentration of cytokines with limited peripheral exposure. Additional studies in mice demonstrated dose-dependent levels of IL-2 in the IP cavity in mice. Treatment of solid tumors using a single administration of AVB-001 demonstrated complete responses as monotherapy and provided sustained eradication of peritoneal tumors in ID8 ovarian cancer mouse model. Our data in mice confirmed that AVB-001 leads to a local increase in activation and proliferation of cytotoxic T-cells within the IP space in comparison to sham mice. In addition, in MC38 colorectal cancer rechallenge model it was observed that a single local administration of AVB-001 leads to complete tumor eradication as a single agent and was accompanied by systemic antitumor immune responses. A single administration of AVB-001 in NHP led to therapeutic levels of IL-2 in the IP cavity and produced local and systemic T-cell biomarker profiles that predict efficacy. In safety assessments of AVB-001, no signs of cytokine storm and vascular leak syndrome and no evidence of adverse pathologic effects on local or systemic tissue were observed with administration of AVB-001 expressing up to 16.7 µg hIL-2/kg in mice and 12.8 µg hIL-2/kg in NHP giving a sufficient safety window for the planning of our first clinical study.

Conclusions It was demonstrated that the AVB-001 is dose adjustable, safe and efficacious in preclinical animal models. Avenge Bio aims to pursue a Phase 1 First in Human study of AVB-001 in ovarian cancer patients. The LOCOcyte™ platform enables delivery of a diverse set of cytokines alone or in combination which is presently being explored.

1095 IL-12-BASED CYTOKINE FACTORIES MODULATE TUMOR MICROENVIRONMENT TO ERADICATE PANCREATIC TUMORS IN MICE AND ARE WELL TOLERATED IN NON-HUMAN PRIMATES

[1]Amanda Nash*, [1]Samira Aghlara-Fotovat, [1]Andrea Hernandez, [2]Sofia Ghani, [2]Ira Joshi, [2]Douglas Ira, [2]Peter Rios, [1]Omid Veiseh. [1]*Rice University, Houston, TX, USA*; [2]*Cell Trans Inc, Chicago, IL, USA*

Background Pancreatic cancer is often diagnosed at advanced stages and responds poorly to chemotherapy.[1] Because high tumor T cell infiltration corresponds with better clinical outcomes in pancreatic cancer patients, immunotherapy has gained significant interest for treatment. IL-12 is a proinflammatory cytokine that activates CD8+ T cells and NK cells.[2] Unfortunately, systemic high dose IL-12 administration led to severe toxicities in clinical trials which limited further development of this cytokine as a cancer therapeutic. To address this limitation, we developed an implantable cytokine delivery platform for local administration of IL-12. These cytokine factories, composed of genetically engineered cells encapsulated in biocompatible polymers, allow for safe and controlled dosing *in vivo*.

Methods

Cytokine PK Studies Supernatant from individual capsules were assayed at 1-, 2-, 4-, or 24-hours using ELISA (n=6).

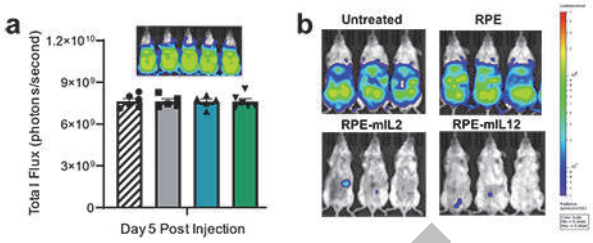
Mouse Studies For IP tumors, 1e6 pan02 cells were injected in the IP space of mice. Cytokine factories were implanted 7 days post tumor injection.

Primate Studies Cytokine factories were administered to cynomolgus macaques (n=1). Complete blood count and blood chemistry analysis were performed for 28 days after administration.

IVIS Imaging Mice were injected in the IP space with D-luciferin (300 µg/mL, PerkinElmer). Photographs and luminescent images were acquired 10 minutes after injection.

Results Local administration of IL-12-based cytokine factories caused reduction of pan02 tumor burden by 80% after 1 week of treatment in mice (figure 1). Single cell RNAseq of the tumor adjacent immune cells showed 2x more T cells in IL-12 treated mice than untreated mice suggesting immune cell infiltration. Importantly, the IL-12 dose was well tolerated in all mice for 180 days. In efforts to evaluate the translatability of this platform, we further tested IL-12-based cytokine factories in a non-human primate. The cytokine factories produced a high local IL-12 concentration without substantial leakage into the systemic circulation and were well tolerated by the primates as shown by the lack of fever or weight loss, as well as the lack of renal or liver toxicity.

Conclusions Our findings highlight the therapeutic potential of IL-12 treatments when administered locally via cytokine factories in preclinical animal models. Further, these findings provide rationale for future clinical testing of cytokine factories in a wide range of metastatic cancers in humans.



Abstract 1095 Figure 1 IL-12 cytokine factories reduce mice pancreatic tumor burden a) Total flux calculated from IVIS imaging prior to treatment with RPE-mIL2, RPE-mIL12, RPE only, or untreated (n=5). b) Representative IVIS images of each treatment group 5 days post treatment.

1096 MWTX-330, AN IL-12 INDUKINE MOLECULE, SELECTIVELY ACTIVATES TUMOR INFILTRATING LYMPHOCYTES AND REPROGRAMS THE TUMOR MICROENVIRONMENT IN MURINE SYNGENEIC TUMOR MODELS

Christopher Nirschl*, Heather Brodkin, Connor Dwyer, Daniel Hicklin, Nesreen Ismail, Celesztina Domonkos, Cynthia Seidel-Dugan, Philipp Steiner, Zoe Steuert, Jenna Sullivan, William Winston, Andres Salmeron. *Werewolf Therapeutics, Watertown, MA, USA*

Background Cytokines are powerful modulators of the immune system, making them a promising target for novel cancer immunotherapies. IL-12 is a pleotropic cytokine that acts on various immune cell populations, including professional APCs as well as adaptive and innate effector cells. Furthermore, recombinant IL-12 generates robust anti-tumor activity in murine models. However, its clinical use has been impeded by a poor pharmacokinetic profile and severe, sometimes fatal, adverse events following systemic administration. mWTX-330 is a selectively inducible IL-12 containing pro-drug (INDUKINE™ molecule) that is comprised of chimeric IL-12 (human p40, mouse p35) linked to a half-life extension domain and an inactivation domain by protease cleavable linkers. Following systemic administration, the inactivation domain keeps the molecule inactive in the periphery, while selective processing of the linkers in the tumor microenvironment results in the local release of chimeric IL-12.

Methods Mice bearing syngeneic tumors were treated with mWTX-330, and tumor growth and body weight were monitored over time. In some experiments tissues were harvested at various timepoints, and analyzed by flow cytometry, NanoString analysis, or other downstream techniques.

Results mWTX-330 generated robust anti-tumor immunity in multiple syngeneic tumor models, including MC38, CT26, B16-F10, and EMT-6. Antibody based depletion of the CD8+ T cells resulted in a loss of late tumor control, while depletion of CD8+ T cells, CD4+ T cells, and NK cells resulted in a complete loss of tumor control following mWTX-330 treatment. Furthermore, mWTX-330 treated mice that rejected primary tumors were protected against later rechallenge with the same tumor cell line. Systemic mWTX-330 treatment selectively activated tumor infiltrating immune cells, with little evidence of immune cell activation in the peripheral blood or secondary lymphoid tissues. Likewise, mWTX-330 was better tolerated than chimeric IL-12, while maintaining efficacy at a similar dose, resulting in a significant expansion of the therapeutic window due to the INDUKINE design of this molecule. Additionally, mWTX-330 treatment increased the frequency of polyfunctional CD8+ T cells, skewed CD4+ non-Tregs towards a TH1 phenotype, robustly drove NK cell production of effector cytokines within the tumor and triggered a metabolic re-invigoration of effector cells.

Conclusions These data highlight the preclinical potency and selective inducibility of mWTX-330 in various murine syngeneic tumor models. More importantly, they demonstrate the feasibility of the INDUKINE approach to address the clinical roadblocks seen with IL-12 therapy and support the ongoing clinical development of our IL-12 INDUKINE molecule containing a fully human payload, WTX-330.

1097 MDK1654: A BRANCHED SYNTHETIC PEPTIDE THAT ACTIVATES BOTH THE IL-7 RECEPTOR AND THE βγC FORM OF THE IL-2/15 RECEPTOR

Inkyung Angie Park*, Steven Cwirla, Alice Bakker, Ronald Barrett, Michael Needels, Praechompoo Pongtornpipat, Blake Williams, Prarthana Joshi, William Dower. *Medikine, Menlo Park, CA, USA*

Background Derivatives of IL-2, IL-15, and IL-7 are in clinical development as immuno-oncology agents. IL-2 and IL-15 stimulate proliferation and enhance the function of effector T cells and natural killer cells, whereas IL-7 acts on naïve and memory T cells and is crucial for persistent effector T cell generation. Combining these complementary effects on immune cells may offer benefits over either mechanism alone. We have previously described small synthetic peptidyl agonists (PEPTIKINES), unrelated to IL-2, IL-15, or IL-7, that selectively activate either IL-2/15Rβγc or IL-7Rαγc.

Methods Here we report the creation and pharmacology of a synthetic branched peptide, MDK1654, comprised of three peptide ligands binding to IL-7Rα, IL-2/15Rβ, and γc separately and linkers that are engineered to provide appropriate spatial orientation of the ligands. The *in vitro* pharmacology of MDK1654 was compared to non-alpha IL-2/15 or IL-7 mono-specific PEPTIKINES by signaling and immune cell proliferation.

Results MDK1654 can activate both IL-2/15Rβγc and IL-7Rαγc signaling pathways as measured by phosphorylation of STAT5 and showed full agonist activity for both receptors with EC50s <10 nM in naturally γc-expressing TF-1 cells engineered to overexpress either IL-2Rβ or IL-7Rα.

In *ex vivo* studies with PBMCs from 5 healthy donors, MDK1654 exhibited additive and complementary effects of IL-2/15Rβγc and IL-7Rαγc signaling among various lymphocyte subpopulations. The mono-specific non-alpha IL-2/15 and IL-7 PEPTIKINEs produced signaling patterns in lymphocyte subsets similar to those induced by IL-2v (a "non-alpha" mutant of IL-2) and IL-7, respectively. In the resting PBMCs, MDK1654 induced pSTAT5 and cell proliferation response profiles in CD8, CD4, and naïve and memory subpopulations similar to the IL-7 PEPTIKINE, including expansion of Tscm cells. In PBMCs activated with anti-CD3 antibody, a treatment known to increase IL-2/15Rβ expression, MDK1654 behaved similarly to the non-alpha IL-2/15 PEPTIKINE in most cell populations except for the Tscm population. NK cells were expanded by MDK1654 and the non-alpha IL-2/15 PEPTIKINE but not by the IL-7 PEPTIKINE.

Conclusions These data indicate that MDK1654 mimics the effect of the non-alpha binding form of IL-2/15 or IL-7, depending on the cell type. To our knowledge, this is the first demonstration of a synthetic peptide with agonist activity for two different cytokine receptors and offers an exciting new modality for cancer immunotherapy.

1098 TARGETING WILDTYPE IL-2 TO CD8 T CELLS INDUCES POTENT ANTI-TUMOR IMMUNE RESPONSES AND DECREASES IL-2 MEDIATED TOXICITY

Selvi Ramasamy*, Joanathan Nardozzi, Shannon Boi, Joanna Swain, Anthony Coyle, Stefano Gulla. *Repertoire Immune Medicine, Cambridge, MA, USA*

Background High dose IL-2 treatment in metastatic renal cell carcinoma and metastatic melanoma patients induced complete remission in 5%–10% of patients without recurrence for over 25 years and potentially cured 70% of these patients.[1] Although FDA approved for treatment of metastatic melanoma and renal cell carcinoma, the clinical utility of high-dose IL-2 is limited by significant multisystem toxicity, treatment-related mortalities in up to 4% of patients, and a lack of response in some patients. As a pleiotropic cytokine, IL-2 not only boosts the desired proliferation and effector function of T and NK cells, but also enhances detrimental immune suppression by expanding high affinity IL-2R($\alpha\beta\gamma$) expressing T_{reg} cells. Contributing to its toxicity, IL-2 also activates innate lymphoid cells (ILC) and IL-2Rα^+ endothelial cells to cause vascular leak syndrome. A key challenge in developing IL-2 as a safe and efficacious cancer therapeutic is uncoupling its efficacy from its toxicity. Here, we present data to support that this could be achieved by linking wildtype IL-2 to an anti-CD8 antibody and selectively delivering IL2 to CD8 T cells.

Methods We separately linked wild type human IL-2 to anti-murine and anti-human CD8 or untargeted RSV antibodies for studies in murine and human systems, respectively. *In vitro* pharmacology was studied with mouse splenocytes and human PBMC. *In vivo* pharmacodynamics, efficacy, and toxicity were assessed in naive mice, B16F10 and MC38 syngeneic tumor models.

Results Incubating respective CD8-IL2s with mouse splenocytes and human PBMC selectively loaded IL2 on CD8 T cells. This resulted in potent pSTAT5 activation downstream of the IL-2R and CD8 T cell expansion compared to incubating with untargeted IL-2 antibody fusions. CD8-IL2 localization is driven by CD8 antibody affinity where as untargeted IL2 localization is driven by IL-2 affinity for its receptors. In naïve mice, CD8-IL2 preferentially expanded CD8 T cells over T_{reg} and NK cells. In contrast, untargeted IL-2 primarily expanded high-affinity IL-2R positive T_{reg} and NK cells. In B16F10 syngeneic tumor bearing mice, untargeted IL-2 induced a dose dependent increase in inflammatory cytokines responsible for high toxicity and body weight loss. In contrast, treatment with CD8-IL2 significantly reduced toxicities but potently inhibited B16F10 and MC38 syngeneic tumor growth.

Conclusions Our data supports that selective targeting of IL-2 to CD8$^+$ T cells minimizes exposure of other cell types to IL2 and reduce IL2 mediated toxicity. CD8-IL2 is expected to be a safe and effective cancer immunotherapy.

Ethics Approval All experimental animal procedures were approved by the Institutional Ethics Review Board.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1098

1099 **ANV419 IS A NOVEL CD122-BIASED IL-2/ANTI-IL-2 FUSION PROTEIN SHOWING INCREASED EFFICACY IN COMBINATION WITH CHECKPOINT INHIBITORS AND TREATMENTS ACTING THROUGH ANTIBODY DEPENDENT CELLULAR CYTOTOXICITY**

Christoph Huber*, Kirsten Richter, Laetitia Petersen, Nicole Egli, Patrizia Murer. *Anaveon AG, Basel, Switzerland*

Background ANV419 is an antibody-cytokine fusion protein with natural affinity to the heterodimeric IL-2Rβ/γ, but no affinity for IL-2Rα/β/γ. As a result, ANV419 preferentially stimulates CD8 T cells and NK cells over regulatory T cells. ANV419 is currently being investigated in a phase I dose finding study in patients with solid tumors. The goal of this study is to evaluate the activity of ANV419 on NK and CD8 T cells and investigate the potential synergy of ANV419 with complementary immune-activating mechanisms. We also evaluated pharmacological combination partners enhancing the therapeutic potential of ANV419.

Methods The signaling properties of ANV419 were compared to recombinant hIL-2 and hIL-15 in human PBMCs. NK cell killing was analyzed in combination with trastuzumab. Mechanistic studies were performed to test the combination of ANV419 with checkpoint inhibitors using the H22 syngeneic tumor mouse model. The impact of checkpoint inhibitor combination on safety was tested in human whole blood.

Results To assess the impact of ANV419 treatment, human PBMCs were analyzed. NK and CD8 T cells showed comparable STAT5 phosphorylation kinetics upon treatment with ANV419, hIL-2 and hIL-15. Combination of ANV419 with the antibody-dependent cellular cytotoxicity (ADCC) inducing anti-HER2 antibody trastuzumab showed additive effects in NK cell killing compared to single trastuzumab treatment supporting clinical combination of ANV419 with treatments promoting NK cell mediated killing.

To assess the role of ANV419 in indications where T cells are involved in tumor resolution, ANV419 combination with the checkpoint inhibitors anti-PD1 or anti-CTLA4 was tested and showed additive effects in inducing tumor growth retardation in mice bearing H22 tumors compared to mice treated with single agents. Analysis of tumor infiltrating lymphocytes indicated intra-tumoral accumulation of NK and CD8 T cells. Treatment of whole blood with a combination of ANV419 and pembrolizumab (anti-PD1) or ipilimumab (anti-CTLA4) induced only slightly increased cytokine secretion compared to ANV419 alone and is therefore considered to have a reasonable safety profile.

Conclusions The data presented here further elucidate the *in vitro* and *in vivo* effects of ANV419 and support the rationale for clinical development in indications where NK and CD8 T cells are involved in tumor resolution as well as in combination with ADCC inducing treatments or checkpoint inhibitors.

1100 IL-15 ENHANCES CYTOTOXICITY OF SIPULEUCEL-T FROM METASTATIC CASTRATION-RESISTANT PROSTATE CANCER PATIENTS BY ACTIVATING CD8+ T AND NK EFFECTOR CELLS

Muhammad Saeed*, Kevin Kim, Russell Pachynski. *Washington University School of Medicine, Saint Louis, MO, USA*

Background Prostate cancer is the most commonly diagnosed non-skin cancer in men, and metastatic castration-resistant prostate cancer (mCRPC) represents the most lethal form of the disease. Sipuleucel-T (sip-T) is an autologous active cellular immunotherapy approved by FDA for patients with mCRPC and has been shown effective in improving overall survival (OS) among individuals with mCRPC. To date, detailed analysis of the sip-T product has not been studied using an advanced mass cytometry approach. Here, we present high dimensional data describing the phenotype of sip-T in detail. Furthermore, we show the effects of IL-15 on the anti-tumor efficacy of sip-T using in vitro and in vivo and studies.

Methods We performed a comprehensive assessment of sip-T (n=13 samples) from 10 patients with mCRPC, using high-throughput mass cytometry (CyTOF) comprised of 37 different antibodies/markers. Furthermore, we performed CyTOF on control and IL-15 stimulated sip-T and identified changes in leukocyte subsets as well as markers of activation and exhaustion. Finally, we examined the effects of IL-15 on cytotoxicity of sip-T against human prostate cancer cells (LNCaP and DU145) using in vitro cytotoxicity assays and in vivo studies in NSG mice.

Results CyTOF analysis revealed that CD3+ T-cells (including CD4+ and CD8+) constituted the highest proportion (median, range: 63%, 9-89%) of unstimulated sip-T, followed by CD19+ B-cells (4%, 1-82%), CD3-CD14-CD56+ natural killer (NK) cells (4%, 1-18%), and CD3-CD19-CD56-HLA-DR+CD11c+CD14+ monocytes (1%, 1-37%). Following sip-T stimulation with IL-15, a significant expansion and activation (increase in IFNγ+, CD95+, CD107+, and CD69+ cells) of CD8+ T-cell and NK cell populations was seen. A significant increase in signature cytokines (e.g. IFNγ and granulolysin) in cell supernatants was also seen after IL-15 stimulation. Furthermore, IL-15 stimulated sip-T showed significantly higher cytotoxicity of LNCaP and DU145 cells in vitro. Adoptive transfer of IL-15 stimulated sip-T into LNCaP-bearing NSG mice resulted in significantly reduced tumor growth compared with those receiving untreated sip-T. Evaluation of tumor-infiltrating lymphocytes revealed a significant expansion of CD8 T-cell/NK populations and reduction in exhausted (PD1+, TIM3+) T-cell/NK cells in the IL-15-sip-T group compared to controls.

Conclusions This is the first comprehensive study to evaluate the composition of sip-T from mCRPC patients using high dimensional CyTOF analysis, and serves as an important reference source for further modification and improvement of sip-T efficacy. Furthermore, our data is the first to show that the addition of IL-15 to sip-T could potentially enhance the efficacy of sip-T in mCRPC patients.

1101 ASKG315 – AN IL-15 PRODRUG WITH ANTIBODY-LIKE PK, ENHANCED SAFETY AND EXPANDED THERAPEUTIC WINDOW

[1]Chunxiao Yu*, [1]Kurt Shanebeck, [2]Jieye Sun, [2]Chao Wang, [1]Shiguang Yu, [1]Jeannie Luiz, [1]Ray Chuang, [1]Ming Li, [2]Yong Wen, [1]Jeff Lu, [1]Yuefeng Lu. *[1]AskGene Pharma Inc., Camarillo, CA, USA; [2]Aosaikang Biotherapeutics Co Ltd, Nanjing, China*

Background AskGene has established a proprietary cytokine prodrug platform (Smartkine®) to achieve its overarching objective of modulating immune reactions at a disease site in a selective and controlled manner. Cytokines are potent molecules, yet their broad application as therapeutics has been hampered due to short PK, severe systemic toxicity, and narrow therapeutic window. To improve the therapeutic potential of cytokines, AskGene has developed several cytokine prodrugs using its proprietary SmartKine® platform. To our knowledge, ASKG315 is the first IL-15 prodrug moving into clinical development.

Methods The in vitro activities of ASKG315 were evaluated using reporter assay and PBMC-based assays. The anti-tumor activities were tested in human PBMC-engrafted tumor xenograft models. The PK/PD properties and safety profiles of ASKG315 were assessed in non-human primates (NHPs) following three IV injections every two weeks.

Results ASKG315 showed minimal activity prior to protease-dependent activation and significantly enhanced activity after protease-dependent activation in vitro. It selectively stimulated NK cells and CD8+ T cells in vitro. In in vivo efficacy studies, ASKG315 at 0.3 mg/kg showed similar potency and better safety compared to a reference IL-15 molecule (unmasked) at 0.5 mg/kg, suggesting that ASKG315 had an expanded therapeutic window. These results also showed that, compared to the reference molecule, ASKG315 had similar or higher immune stimulation in the tumor while having significantly reduced immune stimulation in the periphery. In NHPs, ASKG315 demonstrated prolonged and antibody-like PK profiles. It selectively induced proliferation of NK cells and CD8+ T cells while showing minimal effect on CD4+ T cells in vivo. In addition, ASKG315 was well tolerated at the highest dosage tested in NHPs, with no cytokine release syndrome (CRS) and minimal immune reaction at injection sites.

Conclusions Activated ASKG315 showed selective stimulation for NK cells and CD8+ T cells in vitro and in vivo. ASKG315 in vivo showed less periphery immune activation and higher anti-tumor activity compared to the reference molecule. In addition, it had extended antibody-like PK in NHPs and was well tolerated at the highest dosage tested in the GLP safety study. It also showed a significantly expanded therapeutic window. A first-in-human (FIH) study for ASKG315 is expected to start in the second half of 2022.

Ethics Approval The uses of the animals in the in vivo studies were approved by the ethics committees of the CROs who performed the studies.

1102 A SINGLE SPARK CAN START A PRAIRIE FIRE – RE-THINK THE COMBINATION STRATEGY AND CLINICAL SETTING OF IL-12 WITH ANTI-PD-1

[1]Pei-Yi Tsou, [1]Wan-Ying Lin, [1]Meng-Na Lee*, [2]San-chi Chen. *[1]Libo Pharma Corp., New Taipei City, Taiwan; [2]Taiwan Veterans General Hospital, Taipei, Taiwan*

Background Immune-checkpoint inhibitors have become the standard therapy in many types of cancers. The combination of anti-PD-1 and anti-CTLA4 demonstrated better anti-tumor response, but toxicity is a concern. Cytokines including IL-2, IL-12, IL-15, IL-21 that target immune cells have been developed to enhance immune response against tumors. IL-12, a multifunctional and potency cytokine, regulates both innate and adaptive immunity. IL-12 is considered to: (1) promote the proliferation and survival of T cell; (2) upregulate the chemokine and adhesion molecule to facilitate lymphocyte trafficking; (3) and trigger the T cell:DC crosstalk in combination with aPD1 treatment which might could potently enhance antitumor immunity. Therefore, this study aims to explore the synergistic anti-tumor immune response of IL-12 and anti-PD-1.

Methods Demonstrate the combination tumor growth inhibition effect in 11 (MBT-2, MC38, CT-26, B16F10, 4T1, RENCA, B16F10, Hepa1-6, EMT-6, LL/2, J558) syngeneic mice tumor bearing model. Dose dependent effect, dosing sequential effect, and immunophenotyping in tumor microenvironment (TME) is conducted in CT26 and MC38 tumor bearing model. Mixed lymphocyte reaction (MLR) assay of Keytruda and human recombinant IL-12 (rHu-IL12) combination is conducted for *in vitro* lymphocyte proliferation and activation assessment.

Results MBT-2, MC38, EMT-6, Hepa 1-6, and J558 is moderate to high responding to mIL-12 monotherapy (TGI 30 ~ 90%); CT-26 and 4T1 is slight responding to mIL-12 monotherapy (TGI 10 ~ 20%); LL/2, RENCA and B16F10 is non-responding to mIL-12 monotherapy. Anti-PD-1 combine with mIL-12 has permissive effect in MC38 (TGI 70% vs. 70% vs. 95%) and J558 (TGI 10% vs. 30% vs. 30%); has synergetic effect in CT26 (TGI 20% vs. 25% vs. 60%); and indifference in B16F10 and 4T1. Immunohistochemical and flow cytometric analyses confirmed that CD8+ T cells accumulate at the tumor margin and infiltrate the tumor mass in response to the combination therapy, resulting in favorable effector and regulatory T-cell ratios (12.33% : 4.64% to 18.40% : 2.03%), M1/M2 ratios (0.07%:0.08% vs. 0.1%:0.01%). In the MLR assay, rHu-IL12 could enhance the T cell proliferation combined with Keytruda; the T cell activation biomarker (CD25, CD69, HLA-DR) is also induced higher in rHu-IL12 combination group.

Conclusions Systemic mIL-12 administration could show the robust tumor growth inhibition effect under specific TME setting, and reshape the tumor microenvironment even at extremely low concentration (20~50ng/mice). It gives us a hint to re-think the clinical setting and combination strategy of rHu-IL12 with anti-PD-1.

1103 HALF-LIFE EXTENDED, CONDITIONALLY ACTIVE IFNA PRODRUG INDUCES TUMOR-SELECTIVE ACTIVATION AND POTENT ANTITUMOR RESPONSE

Alice Yam*, Kshama Doshi, Krishna Bajjuri, Millicent Embry, Frank Xiao, Grace Lee, Stephanie Armstrong, Daniel Calarese, Xiaofan Li, Gang Yin, Kristin Bedard, Trevor Hallam.
Sutro Biopharma, South San Francisco, CA, USA

Background Type-1 Interferons (IFN) are known to elicit both direct antitumor effects as well as modulate tumor microenvironment (TME) to induce antitumor immune responses. Combination of IFNa with PD-1 blockade has shown promising outcomes in patients with melanoma. However, clinical use of currently marketed IFNa products is limited due to poor systemic tolerability. Using our breakthrough XpressCF+TM cell-free technology we have developed a conditionally active IFNa-2b prodrug designed to widen the therapeutic window by virtue of limited systemic activation and preferential tumor-selective activation.

Methods IFNa-2b was prodrugged via site-specific conjugation of releasable polyethylene glycol (PEG) molecules, enabling both half-life extension (HLE) and tumor-selective demasking of the interferon molecules. PEG molecules were attached via a tumor selective linker, taking advantage of specific protease enrichment in the TME across a broad range of cancer indications. The size of PEG and sites of conjugation were chosen to enable an optimal balance of HLE, prodrug attenuation, demasking and potency of released catabolite.

Results In-vitro human IFNa-2b prodrug (IFNa-2b-prodrug) was greater than 1000-fold attenuated compared to recombinant IFNa-2b, thus supporting reduced systemic activation. However, on release of PEG activity of the catabolite is fully restored and comparable to wild-type protein. Site-specific PEG conjugation also conferred significant HLE supporting less frequent systemic administration. In mouse xenograft model MDA-MB-231 grown in immunocompromised mice, IFNa-2b-prodrug induced greater antitumor activity compared to control IFNa-2b variant with a non-releasable PEG mask. At equivalent doses, antitumor activity of the prodrug was significantly greater in mice engrafted with human peripheral blood mononuclear cells. This suggests IFNa-2b-prodrug elicits antitumor response both via direct action on tumor cells and by engaging the immune system. Mouse surrogate for IFNa-2b-prodrug induced potent tumor growth inhibition in both immunogenic and less immunogenic syngeneic tumor models. Response in syngeneic models was associated with increased expression of cytotoxic effector molecules in TME. Finally, we used hamsters to assess tolerability and showed that single dose of IFNa-2b-prodrug is well tolerated up to 45 mg/kg with no body weight loss and minimal liver enzyme induction. In contrast, both HLE-IFNa-2b variant and IFNa-2b-prodrug masked with a more permissible PEG linkage, exhibited poor tolerability associated with significant systemic activation.

Conclusions In summary, these preclinical data suggest this novel HLE, tumor-selective human IFNa-2b prodrug has the potential to improve therapeutic index of IFNa therapies. Moreover, the results also support further development of this molecule as a single agent and in a combination setting.

1104 A SAFE AND HIGHLY POTENT PD-1-IL-2 FUSION (AWT020) THAT DECOUPLES THE EFFICACY AND TOXICITY OF IL-2 THERAPY

[1]Fan Ye*, [1]Zoey Huang, [1]Lili Cheng, [1]Jianing Huang, [1]Sandra Chen, [1]Michael Hua, [1]Danny Huang, [1]Ella Li, [1]Jenny Jiang, [1]Hanna Lin, [1]Xin Wang, [1]Bella Yue, [1]Shirley Shi, [1]Henry He, [1]Karen Yan, [2]Binfeng Lu* , [1]Ziyang Zhong. *[1]Anwita Biosciences, Mountain View, CA, USA; [2]University of Pittsburgh, Pittsburgh, PA, USA*

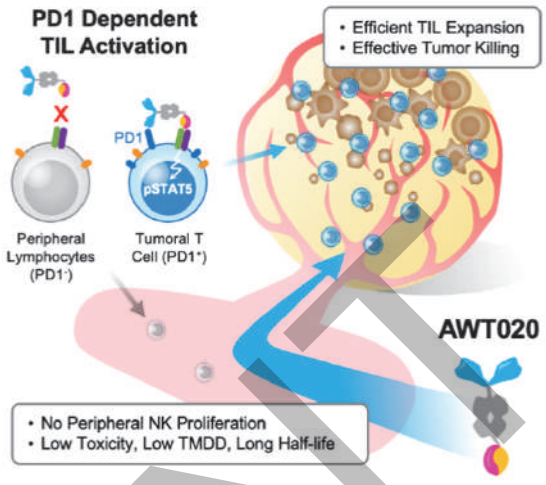
Background Interleukin 2 (IL-2) is a pivotal immune agonist for tumor immunotherapy that has demonstrated its clinical efficacies in melanoma and renal cell carcinoma. Nevertheless, its pleiotropic effect has led to severe side effects and its anti-tumor activity is compromised by its activation of regulatory T cells. In contrast, the PD-1 blockade-based cancer immunotherapy has good safety profiles by targeting and sustaining the activity of tumor-antigen specific T cells within cancer tissues. To take advantage of the complementary antitumor activity of PD-1 monoclonal antibody (mAb) and IL-2, a bifunctional fusion protein composed of PD-1 mAb and IL-2c mutein (AWT020) is designed to enhance the therapeutic efficacy while reducing the IL-2 related toxicity (figure 1).

Methods The in vitro activity of AWT020 was verified using STAT5 signaling assays and human PBMC proliferation assays. A mouse surrogate of AWT020 (mAWT020) was tested in multiple syngeneic tumor models including colon carcinoma models (MC38 and CT26), melanoma model (B16F10), and breast carcinoma model (EMT6). The tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of AWT020 were accessed in cynomolgus monkeys.

Results AWT020 stimulated much greater pSTAT5 activation and proliferation in PD-1$^+$ T cells than PD-1$^-$ T cells. The high specificity of AWT020 on PD1+ T cells not only minimizes the systematic toxicity but also improved the anti-tumor efficacy. In PD-1 resistant B16F10 and EMT6 models, mAWT020 achieved >90% TGI, while in CT26 tumor, mAWT020 treatment achieved 70% complete response (CR). In MC38 model, mAWT020 achieved 100% CR with a single dose at 0.3 mg/kg. Cell phenotyping studies showed that mAWT020 specifically and significantly expands tumor-infiltrating CD8$^+$ T cells but has minimal effects on peripheral T cells and NK cells. Global gene expression profiling studies showed that mAWT020 significantly elevated expression levels of Cd3d, Cd3e, Cd8a, Il2rα, Cxcr3, Cxcr6, Zap70, Lck, and Pdcd1 inside tumor tissues, indicating a specific expansion and activation of T cells. Single dose study at up to 10 mg/kg in cynomolgus monkeys showed that AWT020 was well tolerated, with good exposure and long half-life.

Conclusions The high target specificity of AWT020 significantly mitigates the IL-2 related adverse side effects and allows it to be dosed at a much higher level compared to IL-2 therapy, achieving full blockade of PD-1 and optimal activation of intratumoral CD8$^+$ T cells.

Ethics Approval The protocol of animal studies has been reviewed and approved by IACUC.



Abstract 1104 Figure 1 MOA of AWT020
AWT020 is highly specific to tumor infiltrated T cells

1105 A NOVEL TRIPLE ACTION AND PRE-CLINICAL SAFETY PROFILE OF SLC-3010 PREDICT ITS FAVORABLE TRANSLATION IN THE PHASE I CLINICAL STUDY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1105

Woong Hee Yoon*, Junhyeok Heo, Daeun Kim, Geona Kim, Kyungmi Han, Jun-Young Lee.
Selecxine, Seoul, Korea, Republic of

Background SLC-3010 is a noncovalent conjugate of IL-2 and anti-IL-2 antibody (TCB2) that can preferentially stimulate CD8 T cells and NK cells over Tregs. It is achieved by blocking the binding of IL-2 to the IL-2Rα, which is predominantly expressed on the Tregs. Previously we have reported that SLC-3010 exhibited strong anti-tumor activity in various mouse tumor models.[1] Notably, the dissociated TCB2 persisted in serum for several weeks despite the clearance of SLC-3010 within 72 h. We hypothesized that the dissociated TCB2 can intercept the endogenous IL-2, thereby suppressing the Tregs while stimulating the CD8 T cells and NK cells. Such versatility was termed as the triple action, and the proof-of-concept studies were conducted. GLP toxicity and pharmacodynamic studies were also performed, which provided promising results for the safety and efficacy.

Methods GMP batch of SLC-3010 was manufactured at GenScript Probio. POC studies for the triple action were performed in mice either by administrating the anti-mouse IL-2 antibody (S4B6, functional substitute of TCB2 in mice) after the SLC-3010 to measure the Treg suppression, and by injecting the TCB2 several weeks ahead of IL-2 to validate the reconjugation of TCB2 with the endogenous IL-2. GLP PK, PD, and toxicology assessments were conducted in mice or cynomolgus monkeys after i.v. injecting various doses of SLC-3010 or TCB2.

Results The potency of the dissociated TCB2 to enable the additional anti-cancer mechanisms was studied in mice. Cotreatment of SLC-3010 and S4B6 reduced the number of Tregs and Foxp3 expression, which is a functional indicator of Treg. In addition, TCB2 remained for weeks and reinitiated the immunostimulatory function upon the IL-2 encounter. GLP PK and PD studies in the cynomolgus monkeys demonstrated the selective expansion of CD8 T cells and NK cells. Adverse effects were unobserved in all dose groups of mice and monkeys in the pathological aspects. Half-lives of SLC-3010 were approximately 14 and 8 hours in mice and monkeys, respectively.

Conclusions

- SLC-3010 is a noncovalent conjugate of IL-2 and TCB2, of which nature enables the "triple action" including the selective stimulation of anti-cancer immunity, disruption of Treg homeostasis, and re-boosting the immune system through the conjugation with the endogenous IL-2.
- Favorable GLP toxicity results provided a large safety margin, with the NOAEL being over 30 folds greater than the initial dose (DL1) of the phase 1 clinical trial.

1106 HZ-S506, A SELECTIVE AND ORALLY BIOAVAILABLE HPK1 DEGRADER, IS EFFICACIOUS AS A SINGLE AGENT OR IN COMBINATION WITH PD-1 ANTIBODY

Yizhe Wu*, Xinglu Zhou, Tingting Jin, Xinxin Jin, Yizhe Wu. *Hangzhou HeaZen, Hangzhou, China*

Background Hematopoietic Progenitor Kinase 1 (HPK1/MAP4K1) has been demonstrated to restrain T cell activation through phosphorylation of SLP-76 at Serine 376 leading to TCR signal blocking. The negative feedback role of HPK1 in TCR signaling makes it a promising target for immunooncology therapy. Several HPK1 inhibitors have entered into phase 1 clinical trial. However, the HPK1 selectivity against other MAP4Ks family protein is still challenging, which may lead to the weakening of HPK1-targeted therapy. Recently, PROteolysis TArgeting Chimera (PROTAC) is a bifunctional molecule that can bring the target protein and E3 enzyme closer for ubiquitination labeling, and the target protein can be degraded by UPS system. Therefore, in theory, it can reduce the generation of drug resistance and avoid the problem of off target inhibition to further enhance subtype selectivity.

Methods HZ-S506 was discovered based on our team's unique DaTProD® platform. Western blot and HPK1 biochemical assay were used to analyze HPK1 degradation and inhibition. T cell activation and SLP-76 phosphorylation were also conducted. The in-vivo anti-tumor efficacy was assessed in C57BL/c mice which were engrafted with CT-26 cell line.

Results We found that **HZ-S506** potently inhibited HPK1 kinase activity (IC_{50} = 4.6 nM) under Km concentration of ATP, and it also had good selectivity against other MAP4K family members. **HZ-S506** catalyzed the degradation of HPK1 in Jurkat and PBMC (DC_{50} < 10 nM). **HZ-S506** treatment of jurkat T cell demonstrated robust HPK1 degradation without significant downregulation of other off-target proteins in the proteomics experiment. **HZ-S506** had stimulatory effect on immune response by increasing in IL-2 production (EC_{50} =279.1nM) in Jurkat cell with stimulation with anti-CD3 and anti-CD28, which was more significantly more potent. Treatment with **HZ-S506** also can overcome PGE2 mediated immune-suppression. Interestingly, **HZ-S506** possessed excellent pharmacokinetic properties, the exposure of which is higher than its parent inhibitor (~2 folds). In efficacy studies, **HZ-S506** exhibited anti-tumor activity CT26 tumor model as single agent and in combination with an anti-PD1 antibody, demonstrated robust anti-tumor activities of anti-PD1 efficacy in 4T1 and MC38 syngeneic tumor models.

Conclusions In summary, **HZ-S506** is a potent and selective degrader of HPK1 with good ADME properties and efficacy. These results support further development of **HZ-S506** as a single-agent or combinational therapy with the current checkpoint inhibitors.

1107 ANTI-HVEM MAB THERAPY IMPROVES ANTITUMORAL IMMUNITY BOTH *IN VITRO* AND IN A NOVEL MICE MODEL EXPRESSING HUMAN HVEM AND BTLA MOLECULES USING HVEM EXPRESSING TUMORS

[1]Demerle Clemence, [1]Laurent Gorvel, [2]Marielle Mello, [3]Sonia Pastor, [3]Clara Degos, [2]Ana Zarubica, [2]Frederic Fiore, [3]Geoffrey Guittard, [4]Bernard Malissen, [2]Herve Luche, [5]Jacques Fieschi-Meric, [6]Laurent Greillier, [7]Fabrice Barslesi, [1]Daniel Olive*. *[1]Institute Paoli Calmettes, Marseille, France; [2]CiPHE, Marseille, France; [3]Cancer Research Center Marseille, Marseille, France; [4]Centre d'Immunologie de Marseille-Luminy, Marseille, France; [5]Veracyte, Marseille, France; [6]Assistance Publique- Hopitaux Universitaires de Marseille, Marseille, France; [7]Gustave Roussy, Paris, France*

Background TNFRSF-14/HVEM is a molecule that is the ligand for BTLA and CD160 immune co-inhibitory molecules as well as viral proteins. Its expression is dysregulated with an overexpression in tumors and a connection with tumors of adverse prognosis

Methods We developed models expressing huBTLA and huHVEM in C57/bl6 mice as well as mAbs that completely prevent the interactions of HVEM with its ligands. We also generated mutants of HVEM devoid of the binding sites for BTLA and CD160 binding

Results Here, we show that anti-HVEM18-10 increases primary human alpha beta T cells activity alone (Cis-activity) or in presence of HVEM expressing lung or colorectal cancer cells in vitro (Trans-activity). HVEM18-10 synergizes with anti-PDL1 antibody to activate T cells in presence of $HVEM^{+}PDL\text{-}1^{+}$tumors, but is sufficient to trigger T cell activation in presence of $PD\text{-}L1^{-}$cells. In order to better understand HVEM18-10 effect in vivo and especially CIS and TRANS effects, we developed cutting edge Human BTLA expressing mouse model (BTLA hu KI) and a mouse model expressing both human BTLA and human HVEM ($BTLA^{huKI}$/$HVEM^{huKI}$or DKI). *In vivo*pre-clinical experiments performed in both mouse models showed that HVEM18-10 treatment was efficient to decrease human $HVEM^{+}$ tumor growth. This effect was more pronounced in DKI mice and linked to an increase in $CD8^{+}$cytotoxic T cells tumor infiltration. Interestingly, in both settings, tumor free mice appeared (± 20%) and did not develop tumors upon re-challenge, therefore showing a marked T cell memory effect.

Conclusions Altogether, our preclinical models validate anti-HVEM18-10 as a promising antibody to use in clinics alone or in combination with existing therapies such as anti-PD-L1.

Trial Registration The study presented here is part of the clinical trial PIONeeR BioMarqueurs registered under the number NCT03493581 and part of the RHU PIONeeR ANR-17-RHUS-0007.

Ethics Approval Animal housing and experimental procedures have been conducted according to the French and European Regulations (Parlement Européen et du Conseil du 22 Septembre 2010. Décret n°2013-118 du 1er Février 2013 relatif à la protection des animaux utilisés à des fins scientifiques). All animal procedures (including surgery, anesthesia and euthanasia as applicable) used in the current study have been submitted to the Institutional Animal Care and Use Committee of CIPHE approved by French authorities (CETEA DSV -APA-FIS#6151- 201607202339418-V5).

1108 SCREENING FOR IMMUNE RESPONSE INDICATORS AFTER P53 GENE TRANSFER AND CABAZITAXEL TREATMENT IN HUMAN PROSTATE CARCINOMA *IN VITRO*

[1]Nadine Assis*, [2]Bryan Strauss. [1]*Universidade de São Paulo, São Paulo, Brazil*; [2]*Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil*

Background Prostate cancer is among the most common cancers in men worldwide[1] and despite current treatment options, patients with metastatic disease have a five-year survival rate of only 31% in the United States.[2] Taxane chemotherapy is the standard of care for metastatic Castration-Resistant Prostate Cancer (mCRPC) with cabazitaxel as second-line treatment, however, it causes grade $\geq$ 3 adverse effects such as neutropenia, leukopenia and anemia.[3] Our group has previously shown that p53 gene transfer sensitized prostate cancer cells to cabazitaxel, permitting the application of lower drug doses, thus avoiding toxicity, while still achieving complete inhibition of tumor progression in a mouse model.[4] Integrating our encouraging results with recent findings on the relevance of p53 reinstatement in initiating an anti-tumor immune response[5,6] here we present data related to the validation of experimental conditions, examination of cell death and gene expression analysis of indicators of immune response in human mCRPC cells *in vitro*.

Methods PC3 human carcinoma cells were transduced with AdRGD-PG-p53, AdRGD-PG-eGFP or AdRGD-PG-Luc non-replicative serotype 5 adenoviral vectors and treated with the 25% inhibitory concentration (IC_{25}) of cabazitaxel. Flow cytometry was used for assessment of vector transduction efficiency after transduction with the GFP vector as well as evaluation of hypodiploid cell population after p53 gene transfer and treatment with low-dose cabazitaxel, which was complemented with MTT assay for determination of cell viability. Screening for indicators of immune response was performed by quantitative PCR for genes involved in recognition of tumor cells by immune cells, IFN signaling and antigen processing and presentation in the tumor cells after combined treatment.

Results Combined treatment led to an approximately 50% reduction in cell viability, showing a potentiation of the cytotoxic effects of each treatment alone. Induction of p53-target genes (e.g. CDKN1A, HDM2 and NOXA1) was confirmed together with the modulation of genes of immune activation pathways (e.g. TLR3, IRF1, ISG15 and TAP1). Genes involved in the recently described Viral Mimicry Response (e.g. HERV-E and DNMT1) were also shown to be modulated, mainly as a result of p53 restoration in our model.

Conclusions Both cabazitaxel treatment and p53 gene transfer were shown to display important reduction in viability of PC3 cells, especially when combined. Modulation of important immune response mediators, at least at the mRNA level, encourages us to proceed to protein and immunology assays.

1109 PROGESTERONE IMPACTS THE GROWTH AND IMMUNE CELL INFILTRATION OF MURINE MAMMARY GLAND TUMORS

[1]Lauryn Werner*, [1]Eilidh Chowanec, [1]Julio Tinoco, [1]Harmony Saunders, [1]Dominika Helm, [1]Sean Holloran, [1]Richard Hastings, [1]Junping Wei, [2]Gangjun Lei, [2]Xiao-Yi Yang, [1]Mary Markiewicz, [1]Prabhakar Chalise, [3]Justin Balko, [2]Zachary Hartman, [1]Christy Hagan. *[1]University of Kansas Medical Center, Kansas City, KS, USA; [2]Duke University School of Medicine, Durham, NC, USA; [3]Vanderbilt University Medical Center, Nashville, TN, USA*

Background Clinical studies have linked usage of progestins (synthetic progesterone) to breast cancer risk. However, little is understood regarding the role of native progesterone (P4), signaling through the progesterone receptor (PR), in breast tumor formation. Recently, we demonstrated that P4 treatment or PR overexpression can drive changes in immune cell populations in the murine mammary gland and that PR overexpression leads to increased development of mammary gland tumors in mice. Given these findings, we sought to investigate whether P4 impacts tumor growth and immune cell infiltration of mammary gland tumors.

Methods To evaluate the effect of P4 on PR+ mammary gland tumor growth, orthotopic syngeneic mammary gland tumors were utilized. Briefly, mice were implanted with P4 (30mg) or placebo pellets and were injected with mammary gland tumor cells. After 28 days, tumors were excised and immunophenotyping was performed via flow cytometry. To determine the effect of anti-progestin treatment on mammary gland tumor growth and immune cell infiltration, two syngeneic mammary gland tumor models were used, in which mice were implanted with onapristone (30mg) or placebo pellets followed by mammary gland tumors. After 28 days, tumors were excised and immunophenotyping was performed via flow cytometry. The experiment was repeated in SCID mice to determine if effects of onpristone were immunologically mediated.

Results In syngeneic mammary gland tumor models, P4 promoted tumor growth and impacted immune cell infiltration of PR+ mammary gland tumors. Numbers of tumor-infiltrating dendritic cells were decreased and exhausted T cells and regulatory T cells were increased with P4 treatment in PR+ tumors. Onapristone treatment led to significantly decreased tumor volumes in two syngeneic mammary gland tumor models and reversed the effect that P4 had on tumor-infiltrating regulatory T cells. To determine if inhibition of tumor growth by onapristone was immunologically mediated, SCID mice bearing PR+ mammary gland tumors were treated with onapristone. Results revealed a decreased ability of onapristone to inhibit tumor growth in SCID mice compared to immunocompetent mice, suggesting that inhibition of tumor growth is, in part, immunologically mediated.

Conclusions These findings offer a novel mechanism of P4-driven mammary gland tumor development and provide rationale in investigating the usage of anti-progestin therapies to promote immune-mediated elimination of mammary gland tumors.

1110 EFFECT OF SUB-ABLATIVE HYPERTHERMIA ON PD-1/PD-L1 AXIS MODULATION IN THE TUMOR MICROENVIRONMENT

Md Raihan Chowdhury, Mohamed Farghaly Ramadan, Vassiliki Boussiotis, Muneeb Ahmed, Marwan Moussa*. *Beth Israel Deaconess Medical Center, Boston, MA, USA*

Background Lack of intratumoral immune checkpoint receptor (ICR) expression results in resistance to immune check point inhibitors (ICIs), limiting their clinical efficacy in many patients. Here we investigate the modulatory effect of percutaneous sub-ablative hyperthermia (SA-HT) on PD-1/PD-L1 axis as a potential strategy to modulate ICR expression towards ICI responsiveness.

Methods A three phase experiment was performed. In phase 1, an *in-vitro* experiment was performed using breast adenocarcinoma R3230 cells, exposed to variable thermal doses (41, 43 and 45 all ± 1 °C) for variable durations (5- 60 min, 5 times). Cells were propagated, and supernatant and cells were collected at 0-11d (6 times) post-treatment. Soluble PD-L1 (sPD-L1) in supernatant was analyzed using ELISA. In phase 2, 3 cell lines of different species and cell type (R3230/rat, Hepa 1-6/mouse and HeLa/human) were treated with effective thermal doses (41°C x 60 mins (HT41), 43°C x 30 mins (HT43) & 45°C x 15 mins (HT45)), informed by phase 1 results. Propagated cells were collected up to 14d post-treatment and evaluated for c-Met (a potent PD-L1 regulator) and PD-L1 expression by flow cytometry. Finally, a phase 3 *in-vivo* validation was performed by using 6 Fisher rats with 10-12 mm R3230 tumors, randomized to hyperthermia (HT; SA-HT @ 45°C x 15 mins) (n=3) or control (n=3). Animals were sacrificed at 7d and tumors harvested for FC.

Results In phase 1, specific SA-HT doses demonstrated effective PD-L1 modulation. Specifically, sPD-L1 demonstrated significant decrease in comparison to control at days 2, 4 and 7-9 at a treatment of HT45, HT43 and HT41, respectively, $p < 0.05$ for all. In phase 2, response to SA-HT varied by tumor type. R3230 cells demonstrated downregulation of cMet/PD-L1 in HT45 at 7 days of post treatment ($p<0.05$). However, HeLa cells demonstrated upregulation of cMet/PD-L1 in HT43 and HT45 treated cells at 7 days post treatment ($p<0.03$) compared to control. Moreover, Hepa 1-6 cells demonstrated upregulation of cMet/PD-L1 in HT41 at day 16, but downregulation in HT45 at days 7 & 14, when compared to control ($p<0.05$ for all). Interestingly, all treatment groups demonstrated significant correlation of cMet and PD-L1 expression. In phase III, HT45 resulted in increased intratumoral CD8/PD-1^+ cells, and upregulation of cMet$^+$ and PanCK/PD-L1^+ cells compared to sham, $p < 0.05$.

Conclusions Sub-ablative hyperthermia effectively modulates PD-1/PD-L1 axis and may be a vaible adjuvant against ICI resistance. Furthermore, SA-HT PD-L1 modulation may vary based on tumor type and strongly correlates with intratumoral cMET expression.

1111 IMMUNE MODULATION OF MELANOMA BRAIN METASTASES BY IRAK-4 INHIBITION

Christina Von Roemeling, Erica Matich, Tyler Elliot, Vincent Archibald, Duane Mitchell, Kelena Klippel, Vrunda Trivedi, Lan Hoang-Minh, Bently Doonan*. *University of Florida, Gainesville, FL, USA*

Background Melanoma brain metastases (MBM) remain the primary driver of melanoma associated mortality. With improved survival from current therapy, the rate of MBM is expected to rise and it is already estimated that up to 60% of patients with metastatic disease will develop MBM during the course of their disease.[1] With dual agent immunotherapy or dual RAF/MEK targeted therapy, the intracranial response rate can reach 50%.[2] This leaves half of patients in a position of either partial, temporary, or no response to treatment in their area of highest risk disease. Additionally, these sites lose response to both immunotherapy and targeted therapy sooner than areas of peripheral disease.[3] Novel strategies are needed to improve the treatment of MBM patients. We propose the targeting of IRAK-4 as a mechanism of immune modulation in combination with immune checkpoint inhibition in MBM.

Methods We analyzed human MBM samples for expression of IRAK-4 and components of the inflammatory myddosomal pathway of activation through advanced immunohistochemistry (IHC) and protein array. We then modeled MBM in aggressive, PD-1 refractory mouse MBM model system B16.F10. Following implantion of B16.F10 tumor both intracranially and into the flank of C57BL6 mice we treated mice with the oral IRAK-4 inhibitor CA-4948 with or without anti-PD-1 mAb therapy or vehicle control. Mice were treated for 7 days and then the tumor microenvironment of both intracranial and flank tumors was analyzed through IHC and flow cytometry.

Results We show here human MBM samples express high level of IRAK-4 and downstream target proteins in the NF-KB pathway of activation. We additionally show oral CA-4948 is capabable of rapid passage across the blood brain barrier and reaches therapeutically signficant levels. We further show the addition of the novel oral IRAK-4 inhibitor CA-4948 to immune checkpoint inhibition has a tumor growth restriction capacity through downregulation in MAPK, NF-KB, and pERK and this results in a survival advantage of combination treatment. We also show the combination has a secondary effect of enhanced T cell activation and T cell infiltration in MBM tumors.

Conclusions Though IRAK-4 sits on the pathway of innate inflammation and suppression acts to restrict inflammation, this actually enhances anti-tumor T cell activity unlike traditional anti-inflammatory agents like steroids. We posit IRAK-4 inhibition as a mechanism of restoring the inflammatory balance in MBM to improve immune checkpoint inhibition. We propose the further investigation of IRAK-4 inhibition with combination immunotherapy approaches in MBM patients.

1112 PARP INHIBITION INCREASES IN THE SUPPRESSIVE CAPACITY OF TUMOR-ASSOCIATED TREGS IN A BRCA1-DEFICIENT MODEL OF OVARIAN CANCER

Daniel Falcon*, Ichiko Kinjyo, Sarah Adams. *University of New Mexico, Albuquerque, NM, USA*

Background Emerging evidence indicates that tumor-directed anticancer agents have immunomodulatory effects that contribute to therapeutic outcomes. Targeted therapy by inhibition of poly(ADP-ribose) polymerase (PARPi) has had a profound effect on disease outcomes in ovarian cancer. The cytotoxic effects of PARPi are attributed to inhibition of single-stranded DNA repair pathways resulting in accumulation of DNA-damage in BRCA-deficient cells. While PARP is commonly associated with DNA repair, it has also been linked to a variety of other processes including cell division and inflammation. Published data using PARP1-KO mice suggests that PARP impairs circulating regulatory T cell (Treg) function through modulation of FoxP3, however, the impact on tumor-associated Tregs is unclear. As in many cancers, Tregs accumulate in the ovarian cancer tumor microenvironment (TME) and represent a key mechanism of immune escape. With growing interest in testing combinations of PARPi and immunotherapy, we sought to examine the impact of PARPi on peripheral and tumor-associated Tregs.

Methods To isolate viable Tregs we used FoxP3-eGFP co-expressing transgenic mice. Female mice (8-10 wk) were challenged with BRCA1-deficient ID8 cells (i.p.) and treated daily with ABT-888 (40 mg/kg) for six weeks. Tumor-associated Tregs were sorted from total peritoneal cells pre-enriched for CD4+ T cells. In separate experiments, peripheral Tregs were sorted from CD4+ spleen and lymph node cells and pre-treated with ABT-888 for 24 hours prior to use. Standard proliferation assays using naïve T cells were used to assess Treg suppressive function. Flow cytometry was used to measure cell divisions and expression of FoxP3 and CTLA-4.

Results Ex-vivo treatment of Treg from non-treated, tumor-naïve mice showed that ABT-888 pre-treatment significantly reduced the suppressive capacity of Tregs in a dose-dependent manner ($P < 0.05$). Similarly, ABT-888 treatment resulted in decreased expression of FoxP3 and CTLA-4 in a dose-dependent manner ($P < 0.05$). Conversely, tumor-associated Tregs from PARPi-treated mice had superior suppressive capacity compared to those from non-treated mice ($P < 0.05$). No differences between treated and non-treated groups were observed in Tregs isolated from the spleen.

Conclusions Taken together these data highlight the immunomodulatory effects of PARPi on tumor-associated Tregs. Here we present evidence that PARPi treatment promotes the suppressive capacity of Tregs in the TME and also identify a potential interaction between PARPi and response to immunotherapy in BRCA-deficient ovarian cancer. Future studies will include PARP inhibitors with varying degrees of DNA trapping ability as well as non-BRCA mutated tumors.

1113 EPIGENETIC MODIFICATIONS INFLUENCE IMMUNE REGULATORY PATHWAYS IN MURINE AND HUMAN NEUROBLASTOMA AND MELANOMA TUMOR MODELS

Arika Feils*, Lizzie Frankel, Ankita Shahi (De), Alina Hampton, Paul Sondel, Amy Erbe.
University of Wisconsin-Madison, Madison, WI, USA

Background Immunotherapy for the treatment of various cancers has substantially improved the clinical outcome for many patients. Yet, some cancers classified as immunologically "cold", including high-risk neuroblastoma (HR-NBL) and melanoma (MEL), still have a poor response to immunotherapeutic intervention. These tumors are characterized by low tumor mutation burden, poor immune infiltrate, and/or low MHCI expression. As a potential route of immune escape, these cold NBL/MEL tumors may have induced epigenetic modifications to regulate expression of MHCI/II. Here, we investigated the ability of epigenetic modifiers (EMs), including inhibitors of DNA methyltransferases (DNMTis), histone deacetylases (HDACis), and histone methyltransferases (HMTis), to restore MHCI/II expression in murine and human NBL/MEL models.

Methods To determine the doses of various EM inhibitors (EMis) (n=8), human and murine NBL/MEL cell lines (n=14) were treated with various concentrations of EMis and monitored for proliferation and apoptosis via an Incucyte. Optimal doses were then used to treat NBL/MEL cells with single-agent EMis, or combinations, +/- IFNg. Following treatment, cells were assessed by qPCR and flow cytometry for changes in MHCI/II, PD-L1, and other genes [e.g., antigen presenting machinery (APM)].

Results With increased doses of EMis, we observed reduced proliferation and increased apoptosis across the NBL/MEL cell lines. Using doses of EMis that we found did not alter proliferation or apoptosis (in an effort to focus on the potential immune modulation), we found that certain combinations of EMis with IFNg restored MHCI/II surface expression. Accordingly, we observed increased transcription of genes involved in the APM and chemokines known to influence immune cell infiltration, following guadecitabine (DNMTi) and entinostat (HDACi) treatment. Moreover, the combination of guadecitabine and entinostat resulted in co-expression of MHCI and MHCII on several of the cell lines tested.

Conclusions These findings suggest that certain combinations of EMis may allow us to turn these cold NBL/MEL tumors "hot" by reversing the loss of MHCI/II. By combining guadecitabine and entinostat with current immunotherapeutic regimens, there is potential to reinvigorate the activity of T cells in the anti-tumor response through T cell engagement with MHCI/II. Future studies are aimed to investigate the *in vivo* ability of guadecitabine and entinostat to restore MHCI/II expression.

1114 IMMUNOTHERAPEUTIC ACTIVITY OF OX425 AGAINST PD-1 RESISTANT HR$^+$HER2$^-$ BREAST CANCER

[1]Claudia Galassi, [2]Wael Jdey, [1]Lorenzo Galluzzi*. *[1]Weill Cornell Medicine, New York, NY, USA; [2]Onxeo, Paris, France*

Background Hormone receptor (HR)$^+$ breast cancer is a cold tumor that responds poorly to immune checkpoint blockers targeting PD-1[1,2], calling for the development of therapeutic strategies that inflame the HR$^+$ tumor microenvironment to restore PD-1 sensitivity. OX425 is a second-generation poly (ADP)-ribose polymerase 1 (PARP1)-targeting decoy oligonucleotide (ODN) that drives PARP1 hyperactivation coupled to exhaustion of the DNA damage response, ultimately killing cancer (but not normal) cells as a function of metabolic breakdown.[3] PARP1-targeting decoy ODNs have been shown to mediate multiple immunostimulatory effects, standing out as promising combinatorial partners for PD-1 blockers in cold tumors.[3]

Methods We harnessed a unique endogenous mouse model that recapitulates key immunobiological features of human HR$^+$HER2$^-$ breast cancer, as driven by subcutaneous, slow-release medroxyprogesterone acetate (MPA) pellets combined with 7,12-dimethylbenz[a]anthracene (DMBA) gavage[4], to investigate the therapeutic efficacy of OX425 delivered intraperitoneally 1X or 2X per week at 100 or 500 μg/mouse, optionally combined with a mouse PD-1 inhibitor (delivered intraperitoneally in 2 doses of 200 μg/mouse 3 days apart from each other). Tumor growth, mouse-adapted RECIST score assessments, progression-free survival, overall survival and other clinically relevant parameters were monitored until ethical endpoint.

Results OX425 at the highest dose (500 μg/mouse 2X per week) was associated with weight loss across treated mice (irrespective of PD-1 blockage) and premature mortality in 10% of the mice, calling for dose reduction to 100 μg/mouse 2X per week. At all other administration schedules, OX425 was well tolerated, effective at controlling tumor growth and extending overall survival in mice bearing MPA/DMBA-driven carcinomas (which are intrinsically resistant to PD-1, similar to HR$^+$ breast cancer in women).[1,2,4] Blocking PD-1 increased the therapeutic activity of OX425 when delivered 2X per week at 100 μg/mouse as it inhibited the development of secondary tumors.

Conclusions OX425 at doses < 500 μg/mice 2X per week is well tolerated in mice and mediates single-agent immunotherapeutic activity in models of PD-1-resistant HR$^+$HER2$^-$ breast cancer, with a potential for synergy with PD-1. Further investigation of the immunostimulatory and therapeutic properties of OX425 is warranted.

1115 T-DXD INCREASES IMMUNE CELL INFILTRATION AND ENHANCES ACTIVITY OF IMMUNE CHECKPOINT BLOCKADE IN MURINE TUMOR MODELS

[1]Liam Jenkins*, [1]Matt Wilson, [2]Jerome Mettetal, [2]Theresa Proia. *[1]AstraZeneca UK Ltd, Cambridge, UK; [2]AstraZeneca Pharmaceuticals LP, Waltham, MA, USA*

Background The combination of antibody-drug conjugates (ADCs) and immunotherapeutic agents has gained attention due to impressive activity demonstrated in bladder and triple-negative breast cancer. Trastuzumab deruxtecan (T-DXd) is an ADC composed of an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a cytotoxic topoisomerase I inhibitor approved for HER2+ metastatic breast and gastric cancer. T-DXd has been shown to induce PD-L1 and MHC-I upregulation and demonstrated activity in combination with immune checkpoint inhibitors.[1,2] We report the result of mechanistic studies of the immune response profile to T-DXd and immune checkpoint inhibitor combinations, utilizing an MMAE containing ADC as a comparator.

Methods Human PBMCs were treated with DXd, MMAE, T-DXd, and T-MMAE (trastuzumab-vc-MMAE) with and without CD3/CD28, and viability measured. Supernatant for co-culture assays was collected from human cancer cell lines treated *in vitro* with T-DXd or T-MMAE. *In vivo*, BALB/c mice bearing human HER2 expressing EMT6 tumors were treated with T-DXd or T-MMAE +/- anti-PD-L1 mAb and evaluated for pharmacodynamic changes and efficacy.

Results *In vitro*, treatment of human PBMCs with free DXd caused anti-proliferative effects (IC50 = 0.06uM); however, conjugation of DXd to trastuzumab (T-DXd IC50 = 60ug/mL) mitigated the anti-proliferative effects and was comparable to T-MMAE (IC50 = 12ug/mL). Incubation of human macrophages with supernatant collected from T-DXd treated, but not T-MMAE treated cancer cells resulted in greater than 1.5-fold increase in HLA-DR and CD86 expression, without notable increases in CD163 expression. *In vivo*, both compounds exhibited anti-tumor activity in a human HER2-EMT6 tumor model, with treatment resulting in tumor growth inhibition (TGI) of 25.7% (P = 0.001) for T-DXd, and 11.6% (P = 0.123) for T-MMAE. In combination with anti-PD-L1 treatment, T-DXd (TGI = 55.4%, P <0.001) but not T-MMAE (TGI = 10.8%, P = 0.280) significantly delayed tumor growth compared to anti-PD-L1 monotherapy (TGI = 16.5%, P = 0.063). Flow cytometric analysis of T-DXd-treated tumors revealed a significant increase in total $CD45^+$ cells (1.9-fold, P = 0.028) and $CD8^+$ T cells (2.8-fold, P = 0.018) that was not observed in T-MMAE-treated tumors. T-DXd treatment also promoted a significant increase in tumoral abundance of macrophages (2.2-fold, P = 0.001), Th cells (2.2-fold, P =0.028) and Tregs (2.6-fold, P = 0.018).

Conclusions These data demonstrate that T-DXd treatment enhances the immunogenicity of human cancer cell lines, promotes tumoral immune cell infiltration, and can be effectively combined with immune checkpoint blockade to enhance anti-tumor immune responses.

1116 OXPHOS INHIBITION OFFSETS THE METABOLIC ADVANTAGE OF PANCREATIC CANCER AND PROMOTES A PRO-INFLAMMATORY TUMOR MICROENVIRONMENT

Madeline Steiner*, Arthur Liu, Sayan Alekseev, Charlotte Dahlem, Michael Curran. *MD Anderson Cancer Center, Houston, TX, USA*

Background Cancer cells must reprogram their metabolic state to adapt to the heightened energy demands needed for tumorigenesis.[1] Aberrant tumor metabolism rapidly exhausts the tumor microenvironment of oxygen and key nutrients, creating a hypoxic, immunosuppressive landscape that limits T cell infiltration and renders immunotherapy ineffective.[2] We have previously shown that targeted hypoxia reduction restores effector T cell infiltration and sensitizes tumors to *anti*-CTLA-4/*anti*-PD-1 blockade.[3] Inhibitors of tumor oxidative metabolism (OxPhos) are also promising strategy to offset the tumor metabolic advantage over the immune system by reducing the oxygen utilization of tumor cells and combating tumor hypoxia. Metformin, a mitochondrial complex 1 inhibitor, has been reported to improve tumor control when combined with PD-1 blockade by alleviating tumor hypoxia and improving T cell activation.[4] While targeting tumor oxidative metabolism has shown promising results, studies have mainly focused on the impacts of complex I inhibition, leaving the impact of inhibition on downstream components of the electron transport chain poorly understood.

Methods Napyradiomycin A1 (OxPhos complex I and II inhibitor), αTOS (OxPhos complex II inhibitor) and Atovaquone (OxPhos complex III inhibitor) were used to assess the differential impact of OXPHOS inhibition on mT4-2D PDAC tumor cells (derived from $Kras^{+/G12D}TP53^{+/R172H}$*Pdx1-Cre* (KPC) organoid cultures) (5) versus on T cells *in vitro* and *in vivo*.

Results We found that MT4-2D cancer cells treated with OxPhos complex II/III inhibitors *in vitro* showed no significant decrease in viability or proliferative capacity, however Atovaquone treatment decreased mitochondrial respiration potential based on reduced MitoRed staining in treated cells. We also found Ovalbumin-specific $CD8^+$ T cells treated with Atovaquone during activation *in vitro* showed no significant reduction of T cell activation markers (CD44 and 4-1BB), as well as a minimal increase in T cell exhaustion marker expression (PD-1 and LAG3). Additionally, complex III inhibition during $CD8^+$ T cell activation did not adversely impact IFN-γ production. OxPhos inhibitor treatment *in vivo* reduced the frequency of MDSCs within the tumor microenvironment and elicited increased $CD8^+$ T cell infiltration.

Conclusions Here we show that inhibition of the complex II/III components of the mitochondrial OxPhos chain has the potential to offset the tumor metabolic advantage of the murine pancreatic cancer cell line MT4-2D. We found that these complex II/III inhibitors limit the metabolic fitness of MT4-2D while minimally compromising the activation state and function of cytotoxic T cells. Additionally, OxPhos inhibition repolarized the immunosuppressive tumor microenvironment, showing favorable potential for synergy with immune checkpoint blockade.

1117 A PATIENT-DERIVED TUMOR ORGANOID PLATFORM TO INVESTIGATE RADIATION-INDUCED NEOANTIGEN EXPOSURE

[1]Samantha Van Nest*, [1]Jared Capuano, [1]Tuo Zhang, [1]Bhavneet Bhinder, [1]Xi Zhou, [1]Adriana Irizarry, [1]Laura Martin, [1]Silvia Formenti, [1]Olivier Elemento, [2]Nils-Petter Rudqvist, [1]Sandra Demaria. *[1]Weill Cornell Medicine, New York, NY, USA; [2]The University of Texas MD Anderson Cancer Center, Houston, TX, USA*

Background The level of expression of a mutation-associated neoantigen (MANA) is a critical determinant of effective T cell priming.[1] Thus, interventions that increase the expression of a protein containing a MANA could increase responses to immune checkpoint inhibitors (ICI), especially for tumors with relatively low mutation burden like microsatellite stable (MSS) colorectal cancer (CRC).[1] We have shown that radiation therapy (RT) upregulates the expression of genes containing MANA in a preclinical model, resulting in enhanced presentation of the derived MANA.[2] We also found expansion of CD8 T cells against a MANA upregulated in expression by RT in a lung cancer patient with complete response to RT +ipilimumab.[3] Here we set out to test if MANA upregulation is a common response of human tumors to RT.

Methods Patient-derived tumor organoids (PDO) from colorectal (CRC) (n=3) (figure 1a) and lung (n=4) cancer were characterized for radiation response[4] (figure 1b). PDOs were then irradiated with doses of 5-8 Gy daily for 3 days (RT) or left untreated (UT) and RNAseq performed 24h post-RT. Differentially expressed genes were identified using DESeq2 differential expression analysis. Ingenuity Pathway Analysis (IPA) was used to identify pathways modulated by RT.

Results In the CRC PDO, 2034 and 362 genes were found to be concordantly upregulated and downregulated, respectively, by RT (figure 1c). Upregulated genes were associated with p38 MAPK signaling and innate immune signaling pathways (figure 1d). This RT-modulated gene set was used to interrogate predicted MANA dataset from CRC patients [1]. We found that ≥1 MANA-encoding gene was predicted to be significantly upregulated by RT in 263/266 patients from the TCGA COADREAD MSS cohort (figure 2a). The median number/patient of upregulated MANA was 11 (range 0-79), while for downregulated MANA it was 0 (range 0-15, figure 2b). In the lung PDO, 439 and 117 genes were found to be concordantly upregulated and downregulated, respectively, by RT. Upregulated genes were largely associated with DNA damage response pathways. We found that ≥1 MANA-encoding gene was predicted to be significantly upregulated by RT in 29/35 patients from a lung cancer dataset.[5] The median number/patient of upregulated MANA was 3 (range 0-25), while for downregulated MANA it was 0 (range 0-14).

Conclusions Our data support the novel concept that RT can uncloak neoantigens in tumors like MSS CRC where low neoantigen expression may preclude effective T cell priming and contribute to ICI resistance.

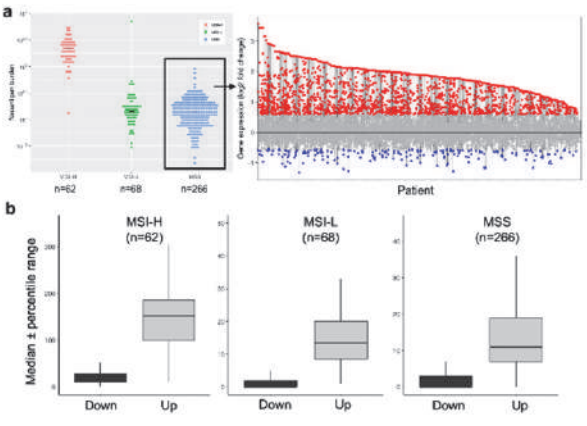
Abstract 1117 Figure 1 a. Representative H&E images showing morphological similarity between carcinoma cells in the original resection and organoid culture for two CRC PDOs. b. Radiation response for each CRC organoid studied. Surviving fraction was evaluated based on ATP levels as measured using the CellTiter-Glo Assay, in irradiated compared to unirradiated PDO samples at 1 week following exposure to single radiation doses between 2 Gy and 12 Gy.[4] c. Volcano plot showing 2,034 genes upregulated (red), 362 genes downregulated (blue) and 13,717 genes unchanged (grey) concordantly in all three PDOs at 24 hours following RT (5Gy x 3). Differential expression analysis was applied to a pooled dataset of three CRC PDOs, each with n=4 biological replicates per treatment condition. Cutoffs corresponding to a fold change in gene expression of 1.5 and adjusted p-value of 0.05 as determined from DESEQ2 were used to define the threshold between genes that are unchanged vs modulated by RT. d. Ingenuity Pathway Analysis (IPA) identified a total of 79 pathways enriched (-log(p-value)>2) by RT in the transcriptome, in all three CRC PDOs. Twelve representative pathways are shown.



Abstract 1117 Figure 2 a. Neoantigen burden associated with MSI-H (n=62), MSI-L (n=68) and MSS (n=266) patient subsets in the TCGA COADREAD cohort as reported by Westcott *et al* [1] and overlay of the RT-modulated gene set derived from CRC PDOs with MANA encoding genes on a patient-by-patient basis for the MSS subset. Only neoantigens with binding affinity (IC50)<500 nM and upper quartile normalized FPKM>0 are included. b. Box plots (outliers removed) showing the median and percentile range of MANA predicted to be

upregulated and downregulated based on the PDO-derived RT-modulated gene set.

1118 IMMUNOLOGICALLY RELEVANT EFFECTS OF PT-112 ON CANCER CELL MITOCHONDRIA

[1]Takahiro Yamazaki*, [1]Lorenzo Galluzzi, [2]Christina Yim, [2]Tyler Ames. *[1]Weill Cornell Medical College, New York, NY, USA; [2]Promontory Therapeutics Inc., New York, NY, USA*

Background PT-112 is a novel platinum-pyrophosphate conjugate[1] under clinical development for cancer therapy.[2-5] Besides mediating cytostatic and cytotoxic effects in numerous human and mouse cancer cells, PT-112 elicits various danger signals that are linked to immunogenic cell death (ICD), such as calreticulin exposure, as well as ATP and HMGB1 secretion.[3,6,7] Accordingly, mouse cancer cells succumbing to PT-112 *in vitro* efficiently protect immunocompetent, tumor-naïve mice from challenge with living cancer cells of the same type.[6,7] Moreover, PT-112 synergizes with PD-1 or PD-L1 blockade to control mouse tumors developing in immunologically competent hosts.[6,7] In some tumor models, robust type I interferon (IFN) signaling is required for ICD[8-10] However, the role of type I IFN signaling in the immunogenicity of PT-112 remains unclear.

Methods We used wild-type, mitochondrial DNA (mtDNA) depleted (rho^0), as well as *Casp2*$^{-/-}$ and *Casp3*$^{-/-}$ mouse TS/A cells.[11] ELISA, flow cytometry and immunofluorescence microscopy were employed to monitor type I IFN levels, reactive oxygen species (ROS) generation, mitochondrial polarization, cell death, and cytosolic dsDNA accumulation driven by PT-112 and underlying regulatory mechanisms.

Results In cultured TS/A cells, PT-112 induced mitochondrial dysfunction, as demonstrated by ROS generation and mitochondrial hyperpolarization, as well as cytosolic accumulation of dsDNA that was abrogated in rho^0 TS/A cells. Type I IFN secretion by wild-type TS/A responding to PT-112 was not observed. Both *Casp2* and *Casp3* deletion provided TS/A cells with some protection from PT-112-driven ROS generation and mitochondrial hyperpolarization, but only *Casp3* deletion afforded robust protection against the acute cytotoxicity of PT-112. Importantly, both *Casp2* and *Casp3* deletion augmented cytosolic dsDNA accumulation driven by PT-112.

Conclusions PT-112 causes pronounced mitochondrial dysfunction in cancer cells coupled with cytosolic mtDNA accumulation, which generally leads to type I IFN secretion.[8] PT-112-driven caspase activation, however, possibly prevents mtDNA-driven type I IFN secretion, likely reflecting CGAS cleavage by active CASP3[12] and/or the rapid CASP3-dependent transition of dying cancer cells into metabolically inert corpses.[13,14] In line with this possibility, both *Casp2*$^{-/-}$ and *Casp3*$^{-/-}$ TS/A cells exhibited increased cytosolic mtDNA accumulation upon PT-112 treatment. As PT-112 is a potent inducer of ICD in vaccination assays[6,7] CASP3 activation elicited during the cytotoxic response to PT-112 may not influence the ability of PT-112 to drive prophylactic anticancer immunity in tumor-naïve hosts. Additional studies with established tumor models are needed to clarify the impact of caspases on the immunogenicity of PT-112 in clinically relevant settings.

1119 GLUTAMINE ANTAGONIST PRODRUG JHU083 REPROGRAMS IMMUNOSUPPRESSIVE TUMOR-ASSOCIATED MACROPHAGES TO DRIVES TUMOR IMMUNITY IN UROLOGIC CANCERS

[1]Monali Praharaj*, [1]Fan Shen, [1]Thomas Nirschl, [1]Alee Lee, [1]Xiaoxu Wang, [1]Liang Zhao, [2]Alok Singh, [1]Debebe Theodros, [1]Laura Sena, [1]Elizabeth Thompson, [1]Ada Tam, [1]Srinivasan Yegnasubramanian, [1]Edward Pearce, [1]Robert Leone, [1]Jesse Alt, [1]Rana Rais, [1]Barbara Slusher, [1]Andrew Pardoll, [3]Jonathan Powell, [1]Jelani Zarif. *[1]Johns Hopkins School of Medicine, Baltimore, MD, USA; [2]University of Pennsylvania, Philadelphia, PA, USA; [3]Calico Labs, South SF, CA, USA*

Background Tumor metabolism is emerging as a regulator of immune mediated anti-tumor responses. Previously, we reported increased infiltration of immunosuppressive tumor associated macrophages (TAMs) with disease progression in prostate adenocarcinoma.[1] Glutamine metabolism has been implicated in immunosuppressive TAMs as well as mCRPC[2] and radioresistant urothelial carcinoma[3]. To harness the potent anti-tumor effects of 6-Diazo-5-oxo-L-norleucine (DON) which targets glutamine utilizing enzymes and to mitigate known significant toxicities, we here use a novel pro-drug moiety of DON, i.e., JHU083. We hypothesize that JHU083 will enhance anti-tumor immunity by simultaneously targeting both TAMs and cancer cells.

Methods Using a scRNA-seq dataset from prostate cancer bone metastatic patients we investigated the importance of glutamine metabolism in TAMs in the tumors.[4] We utilized a novel pro-drug JHU083 to treat two urological syngeneic immunogenic mouse tumor models *in vivo*; B6CaP (prostate cancer) and MB49 (bladder cancer). We studied the direct effect on tumor cells, as well as the required immune compartment for drug efficacy *in vivo* using antibody targeted depletions or adoptively transferred treated TAMs. Moreover, we used RNA-sequencing, multi-parameter flow cytometry and targeted LC-MS/MS metabolic profiling to characterize the effect of JHU083 on sorted TAMs transcriptional programming, proteomic expression profiles and metabolite flux *in vivo*. Lastly, we assessed the functional phagocytotic capacity of TAMs with flow cytometry and IF microscopy.

Results Enriched expression of glutamine utilizing enzymes was observed in increased TAMs in the tumor relative to bening tissue from patient samples. JHU083 showed significant tumor regression in both urologic cancer models. Using *in vivo* depletion of CD4 or CD8 T cells, or adoptively transferring previously *in-vivo* JHU083 treated TAMs we established a direct anti-tumor role of TAMs. These TAMs were inflammatory. Strikingly, in the TME we also observed an metabolic flux of glycolytic metabolites which corresponded with increased of Glut1 and Hexokinase II in their protein expression indicating metabolic reprogramming towards glycolytic phenotype. Importantly, JHU083-treated TAMs showed significantly increased phagocytic activity, providing direct evidence of functional reprogramming.

Conclusions We found that JHU083 has two distinct functions *in vivo;* first, it directly impairs cancer cells which are glutamine dependent and second, it reprograms TAMs from an immunosuppressive to an inflammatory state. These macrophages convert to a highly glycolytic state, have increased TNF production, and have improved phagocytic activity against tumor cells. As urologic cancers are heavily infiltrated with immunosuppressive TAMs, JHU083 is an excellent preclinical candidate.

1120 NEOADJUVANT *IN SITU* INTRATUMORAL VACCINATION WITH EMPTY COWPEA MOSAIC VIRUS NANOPARTICLES IS EFFECTIVE AGAINST CANINE MAMMARY CANCER

[1]Daniel Alonso-Miguel*, [1]Guillermo Valdivia, [2]Barbara Zimmermann, [1]Lucia Lucia Barreno, [1]Angela Alonso-Diez, [1]Maria Dolores Perez-Alenza, [3]Veronique Beiss, [1]María Suárez-Redondo, [4]Nicole Steinmetz, [5]Steven Fiering, [2]Johannes Vom Berg, [1]Laura Laura Peña, [5]Hugo Arias-Pulido. *[1]Complutense University of Madrid, Madrid, Spain; [2]University of Zurich, Schlieren, Switzerland; [3]Case Western Reserve University Schools, Cleveland, USA; [4]University of California San Diego, Cleveland, CA, USA; [5]Geisel School of Medicine at Dartmouth, Lebanon, NH, USA*

Background Approved anti-PD-1/PD-L1 immunotherapy has demonstrated clinical benefits for breast cancer (BC) mostly in triple-negative breast cancer (TNBC) patients. Developing effective immunotherapies for breast cancer is slow in part due to the lack of appropriate models to evaluate novel agents. In this study, we evaluated efficacy, safety, and effect on survival of neoadjuvant *in situ* intratumoral immunotherapy with noninfectious empty cowpea mosaic virus (eCPMV) nanoparticles in spontaneous canine mammary cancer (CMC) patients. CMC shares clinical, pathologic, biologic, and immune similarities to human BC.

Methods Eighteen companion CMC patients were enrolled in the study approved by the Ethics Committee *(*Study #04/2018). Dogs with poor prognosis received adjuvant medical therapy (oral metronomic cyclophosphamide and firocoxib). Seven dogs received surgery, and eleven dogs received neoadjuvant *in situ* intratumoral eCPMV immunotherapy (0.2 mg per injection in the target tumor) at day 0 (D0) and at D6-D9, surgery at D12-D17, and adjuvant medical therapy. Efficacy was evaluated by tumor growth inhibition (TGI), safety by hematologic, and biochemistry changes in blood, and patient outcome by survival analysis. eCPMV-induced changes in blood cells were analyzed by flow cytometry.

Results Two neoadjuvant *in situ* intratumoral eCPMV injections generated tumor reduction of injected tumors in all patients by surgery day without systemic adverse events. TGI ranged from 6% to 63%. Remarkably, TGI was also observed in non-injected lesions (abscopal effect) both in the ipsilateral (TGI=1% to 96%) and contralateral (TGI=10% to 78%) mammary chains. Efficacy was independent of tumor size, clinical stage, histopathologic grade, and tumor receptor status (eight cases were luminal A, one luminal B, and two TN). Values stayed within normal range for hematocrit and hemoglobin and biochemistry (total proteins, glucose, creatine, alanine aminotransferase, and urea), confirming that eCPMV immunotherapy is not toxic. eCPMV injections induced a significant increase in the number of mature and immature blood neutrophils at D6-D9 ($p<0.05$ for both relative to D0). Flow cytometry of circulating immune cells identified minor fluctuations induced by eCPMV injections in various immune cell subsets (not significant). eCPMV-treated patients had a statistically significant ($p=0.006$) improved overall survival compared to patients not treated with eCPMV.

Conclusions Neoadjuvant *in situ* intratumoral eCPMV immunotherapy demonstrated anti-tumor efficacy and improved survival in CMC patients without systemic adverse effects. This novel immunotherapy could be a groundbreaking immunotherapy for CMC patients and a potential future immunotherapy for human BC patients beyond the current TNBC subtype.

Acknowledgements We would like to thank all canine owners who were very generous and supportive of the present study and the personnel of the Veterinary Teaching Hospital Complutense for their help and support.

Ethics Approval The study was approved by the Animal Experiment Ethics Committee (Study #04/2018)

1121 TIGILANOL TIGLATE IS A NATURALLY OCCURRING SMALL MOLECULE ONCOLYTIC THAT EFFECTIVELY ABLATES TUMORS VIA INTRATUMOURAL INJECTION AND CAN ENHANCE RESPONSE TO IMMUNE CHECKPOINT BLOCKADE

[1]Jason Cullen*, [1]Pei-Yi Yap, [1]Blake Ferguson, [1]Zara Bruce, [2]Motoko Koyama, [1]Herlina Handoko, [3]Jacinta Simmons, [1]Jenny Johns, [1]Marjorie D'Souza, [1]Natasa Broit, [4]Praphaporn Stewart, [4]Daniel Shelley, [4]Tracey McMahon, [5]Steven Ogbourne, [6]Yi Chieh Lim, [7]Giovanni Appendino, [5]Victoria Gordon, [5]Paul Reddell, [1]Glen Boyle, [1]Peter Parsons. *[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [3]Queensland University of Technology, Brisbane, Australia; [4]University of the Sunshine Coast, Sippy Downs, Australia; [5]QBiotics Group Ltd., Brisbane, Australia; [6]Danish Cancer Society Research Center, Copenhagen, Denmark; [7]Università del Piemonte Orientale, Novara, Italy*

Background Tigilanol Tiglate (TT) is a novel small molecule under development for local treatment of solid tumours via intratumoral (I.T.) injection. TT is a protein kinase C (PKC)/C1 domain activator that disrupts tumour vasculature, leading to haemorrhagic necrosis of the lesion.[1] Strikingly, in both preclinical syngeneic mouse models and cutaneous/subcutaneous tumours presenting in the veterinary clinic, I.T. injection of TT results in complete and enduring ablation of target tumours in >70% of patients.[1,2,3] TT has completed a Phase I/IIa dose-escalation trial in humans (ACTRN12614000685617), with strong evidence of local anticancer efficacy and signs of abscopal effects in some patients.[4] However, the underlying mechanism of action (MOA) of TT, together with its immunotherapeutic potential in oncology, is not fully understood.

Methods A combination of microscopy, immunofluorescence, immunoblotting, subcellular fractionation, intracellular ATP assays, LDH release assays and mixed lymphocyte reactions were used to probe the MOA of TT *in vitro*. TT-mediated damage associated molecular pattern (DAMP) release/externalization was assessed using luciferase (ATP), ELISA (HMGB1), flow cytometry and immunohistochemical (calreticulin) approaches. *In vivo* experimentation with TT utilized CT-26 and B16-F10-OVA tumor bearing mice, with or without anti-PD1/anti-CTLA4 treatment.

Results Our data demonstrates that therapeutic concentrations of TT induce death of cancer and endothelial cell lines, both *in vitro* and *in vivo*, via oncosis. Whilst largely PKC-independent, PKC/C1 domain signaling appears necessary for timely oncolysis *in vitro* and efficacious tumor ablation *in vivo*. Our results also show that TT binds to ER membranes, causing ER stress with subsequent activation of the integrated stress response. This is followed by mitochondrial membrane potential loss, ATP depletion, organelle swelling, oncosis and terminal necrosis. We also found that TT treatment promoted the release/externalization of DAMPs (HMGB1, ATP, calreticulin) from cancer cells *in vitro* and *in vivo*, characteristics indicative of immunogenic cell death (ICD). Confirmation of ICD *in vivo* was obtained through rechallenge experiments using CT-26 tumour bearing mice, which also demonstrated that TT promoted the development of tumour-specific T cells. In addition to stimulating immune cell infiltration into tumours, TT significantly improved treatment response in the B16-F10-OVA mouse melanoma model when combined with immune checkpoint blockade.

Conclusions These data indicate that TT is an oncolytic small molecule with the potential to enhance responses to immunotherapy. TT is currently undergoing Phase I/II trials in head and neck cancers (ACTRN12619001407189), soft tissue sarcomas, Stage III melanoma in-transit (NCT05234437) and non-resectable Stage IIIB to IV M1c melanoma (TT/pembrolizumab combination: NCT04834973).[5]

1122 RADIOTHERAPY-ACTIVATED NBTXR3 NANOPARTICLES INDUCE INTERFERON BETA SECRETION BY CANCER CELLS

Jordan Da Silva*, Sebastien Paris. *Nanobiotix, Paris, France*

Background The first-in-class radioenhancer NBTXR3 is composed of hafnium oxide nanoparticles, design to be delivered to patients by a single intratumor injection. When exposed to radiotherapy (RT), NBTXR3 nanoparticles increase radiation dose deposition from within the cancer cells. Results from a phase II/III clinical trial in patients with locally advanced Soft Tissue Sarcoma demonstrated significant superiority and clinical benefits of NBTXR3 activated by RT compared to RT alone, with a very good safety profile. Several preclinical studies have established the immunomodulatory capacities of NBTXR3 (e.g., increase of CD8 infiltrates in tumors, restoration of anti-PD1 sensitivity, induction of abscopal effect, etc.). Nonetheless, few data are currently available to understand the biological mechanisms triggered by NBTXR3+RT at the cancer cell level which could explain these results. Here, we investigated the impact of NBTXR3 activated by RT (NBTXR3+RT) on the interferon beta (IFN-beta) secretion by cancer cells.

Methods The impact of NBTXR3 activated by radiotherapy on IFN-beta production by cancer cells was evaluated by ELISA assay in the supernatant of CT26.WT cells (a murine colorectal cancer cell line). Six-wells plates containing plated cells were treated (or not) with 400µM of NBTXR3. The following day, cells were irradiated (or not) by a single dose of 4Gy. After 3 days, supernatants were collected, and the IFN-beta secretion was analyzed by ELISA assay. The efficacy of each treatment modality on cell viability was also measured by MTT assay.

Results ELISA analyses showed no effect of NBTXR3 without RT. In contrast, RT alone induced a significant increase of IFN-beta secretion. Interestingly, NBTXR3+RT significantly increased IFN-beta secretion by treated cells, compared to RT alone. MTT assay also show the superior capacity of NBTXR3+RT to destroy cancer cells, compared to RT alone.

Conclusions It has been previously reported that NBTXR3 +RT (3 fractions of 4Gy) produced a significant abscopal effect in competent mice bearing CT26.WT tumors. Our in vitro data show that NBTXR3+RT can significantly enhance the secretion of IFN-beta by these cells, with only a single dose of 4Gy. These results suggest that the immunomodulatory capacities of NBTXR3+RT measured in vivo could be explained, at least in part, by a greater secretion of IFN-beta, a cytokine known to play a central role in the priming of immune response.

1123 PRECLINICAL ACTIVITY AND SAFETY PROFILE OR JANX008, A NOVEL EGFR-TARGETING TUMOR-ACTIVATED T CELL ENGAGER FOR TREATMENT OF SOLID TUMORS

Shahram Salek-Ardakani*, Thomas DiRaimondo, Natalija Budimir, Lina Ma, Simon Shenhav, Vanessa Cicchini, Hua Wu, Renee Jocic, Fabrece Roup, Calvin Cambell, Carolina Caffaro, Hans Aerni, Ugur Eskiocak, Wayne Godfrey, Charles Winter, Marc Nasoff, Neil Gibson, David Campbell. *Janux Therapeutics, San Diego, CA, USA*

Background Epidermal growth receptor (EGFR) is the most expressed membrane oncogenic protein in human cancers. KRAS and BRAF mutations are significant drivers of resistance to EGFR-targeted therapies. Unlike other treatments, EGFR-targeting, CD3 bispecific T cell engagers (TCEs) can potentially retain activity against tumors bearing resistance mutations. However, cytokine release syndrome (CRS), on-target off-tumor toxicities, and poor pharmacokinetics (PK) properties present significant clinical limitations for these potent immunomodulators. To overcome these challenges, Janux has developed JANX008, an EGFR- and CD3-targeted tumor-activated T cell engager (TRACTr). JANX008 is a humanized trispecific protein that contains EGFR- and CD3-binding domains, an albumin binding domain to extend circulating half-life, and two different peptide masks fused to the molecule through tumor protease cleavable linkers. One peptide mask inhibits EGFR engagement on target cells, and the other inhibits CD3 engagement on T cells. Once the cleavage sequences undergo proteolysis by tumor proteases, the EGFR and CD3 masks are released, and the resulting active molecule can bind EGFR and CD3 on target cells.

Methods Peptide masks against EGFR- and CD3-binding domains were identified via phage display. The efficiency of the masks was evaluated using human EGFR and CD3 ELISAs. JANX008-induced cleavage-dependent T cell killing was evaluated in human PBMC/tumor cell co-culture assays. Anti-tumor efficacy of JANX008 was tested in multiple preclinical models, including EGFR antibody-resistant KRAS- and PIK3CA-mutant mouse colon cancer model (HCT116) and a fully human primary colorectal cancer (CRC) tumoroid system. The pharmacokinetic and safety profile of JANX008 was evaluated in non-human primate studies.

Results JANX008 target engagement was cleavage-dependent, where masking reduced EGFR and CD3 binding by >300x and >1,000x, respectively. JANX008 exhibited potent cleavage- and dose-dependent activity in multiple preclinical models, including EGFR antibody-resistant tumor and T cell co-culture assays, humanized mouse CRC model, and a human primary CRC tumoroids with an intact tumor microenvironment. JANX008 showed a significantly enhanced safety profile in NHPs compared to non-masked EGFR-TCE, including decreased CRS-associated cytokines and healthy tissue toxicities at high exposures. Clinical chemistry, hematology, and pathology measurements supported No-Observed-Adverse-Effect-Level $\geq$ 0.6 mg/kg/dose. Finally, the cleavable albumin-binding domain extended the half-life of JANX008 to ~94h, relative to the ~1.3h half-life of non-masked TCE, supporting its weekly clinical dosing.

Conclusions Preclinical data demonstrate key characteristics of JANX008, including cleavage-dependent activity, half-life extended PK, the potential for superior safety, and manufacturability properties that could mitigate significant limitations of TCEs and support JANX008 clinical development.

1124 INTRATUMORAL ADMINISTRATION OF VAX014 COOPERATES WITH CHECKPOINT BLOCKADE TO REPROGRAM TUMOR IMMUNE MICROENVIRONMENTS AND CLEAR INJECTED AND NONINJECTED TUMORS

[1]Matthew Giacalone, [1]Katherine Reil*, [1]Shingo Tsuji, [1]Kinsey Nelson, [2]Elsa Molina, [3]Kathleen McGuire. *[1]Vaxiion Therapeutics, San Diego, CA, USA; [2]University of California San Diego, San Diego, CA, USA; [3]San Diego State University, San Diego, CA, USA*

Background Immunologically "cold" tumors, which lack tumor infiltrating lymphocytes (TILs), are minimally responsive to immune checkpoint blockade (ICB). VAX014 is a novel clinical stage targeted oncolytic agent based on recombinant bacterial minicells and previous preclinical work demonstrated intratumoral (i.t.) administration of VAX014 increased TILs and led to effective lymphocyte-dependent clearance of immunologically cold tumors.[1,2] When combined with systemic ICB against PD-1 (αPD-1) and CTLA-4 (αCTLA-4) (tripartite combination), this treatment effect was enhanced and systemically expanded to control or eliminate distal noninjected tumors in most mice. Here, we more deeply explored the underlying immune mechanisms in injected and noninjected tumors following VAX014 treatment alone and in combination with systemic ICB by evaluating tumor immunotranscriptomes, TIL populations/phenotypes, and the potential development of protective immunologic memory.

Methods The syngeneic B16F10 model (immune desert phenotype) was used for these studies. Initial changes in immunotranscriptomes of injected tumors were evaluated 24 hours following i.t. treatment with VAX014 in mice bearing a single intradermal (i.d.) tumor. A bilateral variation of the i.d. B16F10 model was then used to systematically evaluate changes in immune gene signatures in both injected and noninjected tumors after addition of systemic αCTLA-4, and again after the further addition of αPD-1. Noninjected tumors from the same series of combination treatment groups were then evaluated by flow cytometry to assess and compare changes in TIL populations/phenotypes. Finally, mice surviving tripartite combination treatment were rechallenged with a second round of i.d. B16F10 tumors to evaluate protective long-term immunologic memory.

Results Immunotranscriptome analysis of injected tumors following i.t. treatment of VAX014 resulted in upregulation of multiple immune gene networks, including Type I/II interferon, dendritic cell function/activation, Natural Killer cell function/activation, antigen processing/presentation, and T cell lymphotaxis and effector function. In distal noninjected tumors, the dual combination of VAX014 with αCTLA-4 resulted in slower tumor growth, upregulation of the same pathways, but also indicated upregulation of *Pdcd1* (PD-1). Addition of αPD-1 to the treatment regimen led to clearance of noninjected tumors, coinciding with an increased cytotoxic cell gene signature and increased cytotoxic and effector memory CD8+ TILs. Finally, mice exhibiting complete response following tripartite combination treatment could limit tumor growth or completely protect against B16F10 tumor rechallenge.

Conclusions VAX014 stimulated rapid local immune activation and lymphocyte-mediated clearance of injected tumors following i.t. administration. When combined with systemic ICB blockade, this treatment effect was systemically expanded to control or eliminate distal noninjected tumors while promoting protective antitumor immunologic memory.

1125 INTRATUMORAL ADMINISTRATION OF SARS-COV-2 REDUCES TUMOR PROGRESSION AND ALTERS THE TUMOR IMMUNE MICROENVIRONMENT SIMILAR TO THAT OF THE SEASONAL INFLUENZA VACCINE

Eileena Giurini*, Kajal Gupta. *Rush University Medical Center, Chicago, IL, USA*

Background A significant challenge in using immunotherapies to treat solid tumors is that these treatments are largely ineffective due to lack of immune cell infiltration or are dominated by suppressive immune cell populations. To overcome this, we previously demonstrated that intratumoral administration of influenza converts an immune barren tumor to a tumor that is loaded with inflammatory factors, thus can be targeted by the immune system. With the onset of the COVID-19 pandemic, and there being several shared characteristics between the influenza and SARS-CoV-2 we sought to determine the cancer immunotherapeutic potential of SARS-CoV-2. Here, we have shown that inactivated SARS-CoV-2 can reduce tumor growth in murine tumor models and can shift composition of the tumor microenvironment paralleling that of treatment using the influenza vaccine.

Methods To determine the anticancer response, 4T1 breast cancer and B16 melanoma tumors were induced in BALB/C and C57BL/6 mice, respectively. Tumors were treated with inactivated SARS-CoV-2, seasonal influenza vaccine, or PBS via intratumoral injection. Tumor growth was evaluated via caliper measurements. Determination of immune cell population changes within the tumor following each treatment was determined via flow cytometry analysis.

Results Intratumoral injection of inactivated SARS-CoV-2 and the influenza vaccine showed significant reduction in tumor growth compared to a PBS control ($p < 0.001$) in both 4T1 and B16 tumor models. Within B16 tumors, both SARS-CoV-2 and influenza vaccine increased CD45+ cell populations ($p < 0.0001$) compared to PBS. Notably, both B16 and 4T1 tumors treated with SARS-CoV-2 and influenza experienced a significant increase in CD8+ T-cell infiltration ($p < 0.05$, $p < 0.01$). Additionally, CD11b+ Ly6G/Gr-1+ myeloid derived suppressor cell populations were decreased in B16 melanoma tumors following inactivated SARS-CoV-2 or influenza vaccine treatment.

Conclusions These findings indicate that introducing inactivated SARS-CoV-2 into the tumor microenvironment reduces tumor progression and is able to shift the immune profile of a tumor from an immune-suppressed to a more inflamed, immunologically targeted status. Further, the changes in immune cell populations within the tumor as well, paralleling those of influenza vaccine treated tumors.

1126 MOLECULAR MECHANISMS OF DC ACTIVATION BY MELANOMA CELLS RESPONDING TO LTX-315

[1]Xiao-Qing Li, [2]Takahiro Yamazaki*, [1]Tianzhen He, [1]Md Masud Alam, [1]Jia Liu, [1]Anna Trivett, [3]Baldur Sveinbjørnsson, [3]Øystein Rekdal, [2]Lorenzo Galluzzi, [1]De Yang, [1]Joost Oppenheim. *[1]NCI Center for Cancer Research, Frederick, MD, USA; [2]Weill Cornell Medical College, New York, NY, USA; [3]Lytix Biopharma, Oslo, Norway*

Background Oncolytic peptides are emerging as attractive candidates for the development of novel anticancer regimens[1], reflecting broad cytolytic activities against a variety of malignant (but not normal) cells and a pronounced potential for immunostimulation.[2] LTX-315 is a synthetic nonameric cationic peptide derived from bovine lactotransferrin[3] that has been associated with a pronounced capacity to elicit tumor-targeting immune responses in various preclinical models of cancer.[2] Specifically, LTX-315 has been shown to (1) cause immunogenic cell death (ICD) [4] coupled to the release of immunostimulatory cytokines and damage-associated molecular patterns (DAMPs)[5,6], (2) deplete the tumor microenvironment (TME) of immunosuppressive cells such as $CD4^+CD25^+FOXP3^+$ regulatory T (T_{REG}) cells and myeloid-derived suppressor cells (MDSCs)[7], and (3) synergize with immunogenic chemotherapy[8] or immune checkpoint inhibitors (ICIs)[7] in the control of syngeneic mouse tumor models. However, the effects of tumor cells responding to LTX-315 on dendritic cells (DCs) remain to be precisely elucidated.

Methods Human A375 and mouse B16F10 cells were used as models of melanoma, *in vitro* (A375, B16F10) and *in vivo* (B16F10) upon subcutaneous injection in immunocompetent C57BL/6 mice. Flow cytometry, ELISA, RT-PCR and immunoblotting were used to assess DC maturation *in vitro* and *in vivo*, immunoblotting was employed to investigate the molecular mechanisms underlying DC activation, knockout and knockdown systems were harnessed to demonstrate mechanistic involvement. Therapeutic assays with B16F10 melanoma cells growing in immunocompetent vs *Myd88*$^{-/-}$ mice coupled to tumor rechallenge were employed to confirm activation of tumor-targeting immunity coupled to the establishment of immunological memory.

Results LTX-315 mediated the release of immunostimulatory DAMPs and nucleic acids (NAs) from melanoma cells that drove robust DC activation as monitored by surface immunophenotyping for CD80, CD83, CD86 and MHC class II and cytokine (TNF, IL-1β) secretion. This immunostimulatory effect mechanistically depended on TLR9 (detecting LTX-315-DNA complexes), TLR8 (detecting LTX315-RNA complexes) and TLR7 (which was activated by LTX-315 per se), as well as on the common TLR signal transducer MYD88. Accordingly, the *in vivo* anticancer activity of LTX-315 against B16F10 melanoma cells was significantly reduced in *Myd88*$^{-/-}$ mice, and *Myd88*$^{-/-}$ mice eradicating B16F10 tumors upon LTX-315 treatment remained susceptible to a rechallenge with B16F10 cells.

Conclusions In addition to induce immunogenic cell death, LTX-315 also activates DC via MYD88-dependent pathways that mediate optimal immunostimulatory effects coupled to the establishment of cancer-specific immunological memory in preclinical melanoma models.

1127 CALCIUM PHOSPHATE BIOMATERIALS ENHANCE IMMUNOTHERAPEUTIC MRNA DELIVERY IN MELANOMA

Hannah Martin*, Joshua Choe, Iris Baurceanu, William Murphy. *University of Wisconsin-Madison, Madison, WI, USA*

Background Messenger ribonucleic acid (mRNA) is a powerful tool for transferring genetic information. Its advantages include potent but transient gene expression without risk of genomic insertion, tailorable immunogenicity to match therapeutic application, and the potential for efficient, scalable manufacturing.[1] The recent success of mRNA-based SARS-CoV-2 vaccines has inspired interest in mRNA as a cancer therapy to deliver immunostimulatory molecules and tumor antigens. However, clinical translation is limited by mRNA instability at physiological conditions and inefficient *in vivo* delivery.[2] A reliable, non-toxic, and stabilizing *in vivo* delivery system for immunotherapeutic mRNA would help to advance mRNA as a viable cancer therapy. Here, we utilized calcium phosphate mineral-coated microparticles (MCMs) as a delivery system for mRNA-lipid complexes (lipoplexes) to transfect melanoma cells.

Methods MCMs were prepared as previously described[3] by suspending β-tricalcium phosphate particles in modified simulated body fluid under rotation for 7 days at 37°C, refreshing the media daily. MCMs were then washed in deionized water and freeze dried. Custom-synthesized reporter or therapeutic mRNA constructs were complexed with a lipidic transfecting agent through mixing, then resulting lipoplexes were incubated briefly with MCMs to facilitate electrostatic binding to the porous CaP coating (figure 1a). Loaded MCMs or soluble lipoplexes were added to B16F10 murine melanoma cell culture, and transfection was measured through various assays, including fluorescence microscopy, bioluminescence, and enzyme-linked immunosorbent assays.

Results Scanning electron microscopy was used to verify plate-like, porous coating morphology following MCM fabrication (figure 1b). MCMs enhanced transfection of B16F10 melanoma cells compared to soluble mRNA lipoplex delivery. This was demonstrated with reporter constructs encoding enhanced green fluorescent protein (eGFP, figure 1c) and Gaussia luciferase (G-Luc), as well as with a therapeutic construct encoding interleukin 15 (IL-15), a T cell growth factor. Timelapse imaging also revealed more rapid transfection with MCMs. A close proximity of cells to MCMs was observed as necessary for transfection.

Conclusions We demonstrated that MCMs efficiently and locally deliver mRNA lipoplexes to melanoma cells and cause elevated levels of protein expression compared to soluble lipoplex delivery. This enhanced delivery profile makes MCMs a potential drug delivery platform for future *in vivo* tumor studies and clinical translation.

1128 NEW VIRAL-DELIVERY OF GLYCAN-MODIFYING SIALIDASE INDUCES ANTI-TUMOR IMMUNITY

[1]Natalia Rodrigues Mantuano*, [1]Michael Sandholzer, [1]Andreas Zingg, [2]Heinz Läubli.
[1]*University of Basel, Basel, Switzerland*; [2]*University Hospital Basel, Basel, Switzerland*

Background Recent advancements in the stimulation of the immune microenvironment and anticancer immune responses with immune checkpoint inhibitors (ICI) has improved the outcome of cancer patients. However, primary and acquired resistance significantly diminish the success of ICI and only a minority of patients benefit. Thus, new strategies are urgently needed in order to induce long-term remissions with cancer immunotherapy. Changes of glycosylation have a significant impact on cancer biology and cancer progression. New therapies that aim to remodel the tumor glycosylation and reactivate the immune system are being explored. In particular, approaches that target the sialoglycan-Siglec glyco-immune checkpoint showed very promising results in pre-clinical animal models and are currently under investigation in early clinical trials.

Methods An adeno-associated virus (AAV) was constructed to express influenza sialidase under a CMV promoter (AAV-sia). Efficacy of sialidase production in transduced cells and the sialidase activity were tested in *in vitro* assays and mouse tumor models after intratumoral injection. In addition, efficacy of immune reactivation against tumors and cancer control was tested in various transplantable, syngeneic mouse models. Immune reactions were further characterized by flow cytometry and single cell RNA sequencing.

Results Upon AAV-sia treatment, cancer cells express sialidase on the cell surface and are able to cleave sialic acid in the tumor microenvironment in mouse models. We are further able to show an inhibitory effect on tumor growth and survival in syngeneic tumor models responsive and unresponsive to PD-1 blockade. Furthermore, a relevant synergism combining AAV-sia and anti-PD-1 treatment was observed. Mechanistic studies demonstrate an increased activation of $CD8^+$ T cells, a polarization of myeloid cells towards a less immune-suppressive phenotype and an increase in conventional dendritic cell infiltration. In addition, scRNAseq data shows an increase in a macrophage population that up-regulate M1-like genes as TNF-alfa, CD80, MHCII, NOS2, IL1-beta and CXCL9. Despite local injection and desialylation, we observed also a growth inhibition on distant tumor sites and an increase in tumor-specific T cells suggesting a systemic immune activation.

Conclusions Taken together, AAV-sia removes the immune-suppressant carbohydrate sialic acid from the tumor microenvironment and cancer cells rendering them more vulnerable for destruction by immune cells.

Ethics Approval All mouse experiments were approved by the local ethics committee (Approval 3036, Basel Stadt, Switzerland) and performed in accordance with the Swiss federal regulations

1129 A NOVEL CPG MOTIF INTRODUCED INTO A BISPECIFC AM003 COMPOUND FOR THE TREATMENT OF SOLID TUMORS

Neta Zilony- Hanin, Erez Lavi, Zohar Pode, Sapir Dahan, Vitaliy Buravenkov, Leeron Shefet Carasso, Ido Bachelet, Raanan Berger, Irit Carmi Levy*. *Aummune, Tel Aviv, Israel*

Background Despite clinical activity of immunotherapy agents in a broad range of cancer indications, there is still a substantial percentage of patients who fail to respond to those therapies, and hence, an unmet need to address mechanisms of tumor immune resistance. One of the most promising approaches is to turn a "cold" tumor into "hot" tumor.

CpG motif is a DNA sequence rich in unmethylated Cytosine- phosphate Guanine (CpG) nucleotides, prevalent in bacterial DNA, eliciting host immune reaction.

AM003 is a Bispecific Personalized Aptamer comprised of a T cell engager arm and a tumor-targeting arm, which is the outcome of Aummune's innovative tailored therapeutic platform that identifies functional aptamers capable of killing tumor target cells. The two ssDNA aptameric arms of AM003, when hybridized, are designed to form a novel immunostimulant CpG motif

Methods In vitro evaluation of the AM003 CpG mode-of-action was performed using B cell and dendritic cells (DC) flow cytometry analyses, cytokines measurements and co-culture assays. Moreover, in vivo immunologic effects were investigated in syngeneic mice tumor models.

Results The AM003 CpG motif induced a potent stimulation of antigen presenting cells. Stimulated dendritic cells (DC) had an increased cell surface expression of different co-stimulatory receptors and elevated TNF-a secretion.

DC cultured with AM003 demonstrated enhanced CD4 T cells stimulation in a mixed lymphocyte reaction (MLR) model with higher levels of IFN-gamma detected. Furthermore, anti-PD1 led to a synergistic effect when combined with AM003 in the MLR assay, where IFN gamma levels were further elevated, compared with both single agents.

In line with the observed results of innate immune stimulation, in vivo, intratumoral injection of AM003 effectively transformed the immune landscape of the injected tumor, with increased infiltration of CD8+ CD4+ T cells and of B cells.

Conclusions Our findings suggest that AM003 addresses the challenges of immune resistance by activating the innate immune system, improving T cell infiltration and enabling a follow-on effective T cell activation by the compound's T cell engager arm.

These data provide a framework for the clinical development of this novel personally tailored immunotherapy. Aummune has initiated a first-in-human clinical study of AM003 in subjects with solid tumors.

1130 INVESTIGATING MACROPHAGE MODULATION IN A MURINE MODEL OF SOFT TISSUE SARCOMA

Kurt Hildebrand*, Karys Hildebrand, Franz Zemp, Carolina Salazar Arcila, Michael Monument. *University of Calgary, Calgary, Canada*

Background Soft tissue sarcomas (STSs) are a heterogeneous group of malignancies that arise from mesodermal tissue. Generally, STSs are treated with morbid surgical resection and radiation therapy.[1] The STS tumour microenvironment (TME) contains an abundance of macrophages[2] and few lymphocytes.[3] In many malignancies, macrophages can be associated tumour progression[4] and suppression of lymphocytes.[5] The role of macrophages in STSs needs further investigation. Therefore, the purpose of this study was to modulate macrophages in an immune competent model of STS, and assess the changes in tumour growth and the immune landscape.

Methods Two models were used to modulate macrophages in an immune competent murine STS model; the Macrophage Fas-Induced Apopotosis (MaFIA) model[6], and the C-C chemokine receptor-2 Knockout (CCR2 KO) model.[7] MaFIA mice express a transgene and can be given a pharmacological agent to induce cell death in CSF1R+ cells. The CCR2 KO model shows a deficiency in recruiting monocytes to inflamed tissue. Both models have reduced tumour macrophages in other murine models.[8, 9] MaFIA and CCR2 KO mice were engrafted with STS cells in the right hindlimb.[10] Tumour volume, macrophages ($CD45^+$, $CD11b^+$, $F4/80^+$, and $CD80^+$ or $CD206^+$), as well as lymphocytes ($CD45^+$, $CD3e^+$, and $CD4^+$ or $CD8^+$) were assessed using flow cytometry.

Results MaFIA mice showed a ~84% decrease ($p<0.01$) in tumour volume, whereas the CCR2 KO mice and control mice showed no differences in tumour volume. MaFIA mice showed a significant reduction of CSF1R+ macrophages (53%; $p<0.01$) and CSF1R+, CD206+ macrophages (54%; $p<0.05$), but no changes to total macrophages. Interestingly, the CCR2 KO mice showed a significant decrease in tumour macrophages (47%; $p<0.01$), as well as CD206+ macrophages (41%; $p<0.01$). The MaFIA model showed no differences in lymphocytes, but the CCR2 KO model showed a significant increase in CD8 T cells (360% increase; $p<0.01$). Interestingly, CSF1R+ ablative treatment was associated with an increased expression of PD1 in the MaFIA model (211%; $p<0.01$).

Conclusions Both CSF1R and CCR2 modulation diminished macrophage subtypes, but CSF1R modulation did not diminish the total macrophage population. However, only the CCR2 KO model improved lymphocyte (CD8 T cell) infiltration, which did not improve disease outcome. Additionally, CSF1R modulation was associated with an increased PD1 expression. Thus, modulating the CCR2 axis influenced the TME but did not change tumour burden. The CSF1R axis diminished STS tumour burden and macrophage subtypes, and could potentially also sensitize STS tumours to anti-PD1 therapy.

1131 GRWD5769: A FIRST-IN-CLASS INHIBITOR OF ERAP1, GENERATING NOVEL CANCER ANTIGENS TO DRIVE DE NOVO ANTI-TUMOR T CELL RESPONSES

[1]Peter Joyce*, [1]Andrew Leishman, [2]Asolina Braun, [1]Mitul Patel, [1]Michael Pinggera, [1]Jessica Sette, [1]Kate Anderton, [3]Edd James, [1]Valeriya Shunina, [2]Anthony Purcell, [4]Nicola Ternette, [5]Jason Shiers, [1]Martin Quibell, [4]Wayne Paes, [1]Tom McCarthy. *[1]Grey Wolf Therapeutics, Oxford, UK; [2]Monash University, Melbourne, Australia; [3]University of Southampton, Southampton, UK; [4]University of Oxford, Oxford, UK; [5]Sygnature Discovery, Nottingham, UK*

Background Immune checkpoint inhibitors (ICI) have changed the cancer treatment paradigm, yet significant unmet need remains. Clinical data demonstrates increased antigen presentation diversity, genomic instability, tumor mutational burden and HLA diversity are all factors that improve clinical response to ICI.[1,2,3] Further, the effectiveness of ICI is limited by the permanent exhaustion of pre-existing cytotoxic T cells, caused by chronic cancer antigen stimulation.[4] Endoplasmic reticulum aminopeptidase 1 (ERAP1) trims peptides loaded into classical and nonclassical MHC Class I.[5] In cancer, knockout or inhibition of ERAP1 changes a proportion of the antigen repertoire, generating and up-regulating cancer antigens.[6,7] This leads to the activation of de novo anti-tumor T cell responses, causing tumour growth inhibition and bypassing a key resistance mechanism in immuno-oncology (IO), T cell exhaustion. We report the preclinical development, characterisation and mechanistic analysis of the first-in-class ERAP1 inhibitor, GRWD5769.

Methods Immunopeptidomics was used to assess the impact of ERAP1 inhibition on the cancer antigen repertoire, thus determine proof of mechanism. T cell receptor (TCR) repertoire sequencing, RNAseq and immunohistochemistry established the ability of ERAP1 inhibition to drive a differentiated T cell response in syngeneic mouse models and primary human immune cell co-cultures.

Results Extensive analysis of the immunopeptidomes of diverse cancer cell lines robustly showed that GRWD5769 modulates the cancer-related antigen repertoire across genotypes and cancer-type backgrounds. Novel or upregulated neoantigens generated by ERAP1 inhibition are conserved across cancer cell types and genetic backgrounds. ERAP1 inhibition diversified the TCR repertoire, up-regulated prognostic immune gene markers in the tumor, including markers for recently activated (thus non-exhausted) T cells, and drove infiltration of T cells into syngeneic mouse model tumours. ERAP1 inhibition is efficacious across syngeneic models, including different mouse strains. Importantly, the effects of ERAP1 inhibition on the T cell response correlate with efficacy. Further, ex vivo human T cell co-cultures demonstrate that novel and upregulated neoantigens generated by ERAP1 inhibition drive tumour cell killing.

Conclusions Grey Wolf Therapeutics' first-in-class, ERAP1 inhibitor clinical candidate, GRWD5769, drives novel anti-tumor T cell responses through neoantigen creation, circumventing T cell exhaustion, a key resistance mechanism in IO. GRWD5769 has completed GLP toxicology studies, has a very good safety profile and clear path forward to first patient dosed. Extensive biomarker development has resulted in development of proof of mechanism and proof of principle biomarkers that will be used to establish the activity and efficacy of GRWD5769 in patients in 2023.

1132 **IMPACT OF INTRALESIONAL ONCOLYTIC VIRAL THERAPY TARGETING *IN SITU* ACTIVATION OF CD40 AND TYPE 1 INTERFERON SIGNALING PATHWAYS ON THE TME AND SYSTEMIC T CELL IMMUNITY IN MURINE MODELS AND CANCER PATIENTS**

[1]Andreas Saltos*, [1]Hong Zheng, [2]Christy Arrowood, [2]Georgia Beasley, [2]James Ronald, [1]Ghassan El-Haddad, [2]Uzma Khan, [1]Luiziane Guerra-Guevara, [2]Steven Wolf, [2]Lin Gu, [2]Xiaofei Wang, [3]Mark Cantwell, [2]Scott Antonia, [1]Amer Beg, [2]Neal Ready. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Duke University, Durham, NC, USA; [3]Memgen, Inc, Meadow Vista, CA, USA*

Background Oncolytic viral therapies are thought to act through both direct killing of tumor cells and activation of conventional dendritic cells (cDCs), resulting in an enhanced T cell response. However, cDC activation has not been optimized with current therapies. MEM-288 is a conditionally-replicative oncolytic adenovirus encoding transgenes for human interferon beta (IFNβ) and a recombinant membrane-stable form of CD40-ligand (MEM40), two potent activators of the immune response and cDCs.

Methods We evaluated intralesional adenoviral delivery of MEM40 and IFNβ to activate cDCs in mouse melanoma and lung tumor models. Flow cytometry and scRNA-seq were used to determine treatment impact on cDCs and T cells. Clinical translational research also investigated the immune response of intralesional administration of MEM-288 in patients with select solid tumors in an ongoing Phase 1 dose-escalation, multi-center, open-label trial (NCT05076760). Patient pre- and on-treatment tumor biopsies and peripheral blood were collected before and after MEM-288 treatment for immunologic evaluation.

Results In preclinical studies, MEM40 and IFNβ in situ co-expression induced higher cDC activation than either molecule alone, in addition to a dramatic increase in lymph node migration, a systemic anti-tumor $CD8^+$ T cell response, and regression of established tumors in a manner dependent upon type 1 cDCs. MEM40 and IFNβ expression enhanced generation of both Granzyme B^+ $CD8^+$ T cell effectors as well as $TCF1^+$ stem-like $CD8^+$ T cells that are known to be strongly associated with response to immune checkpoint inhibitors (ICIs). Intralesional therapy with MEM40 and IFNβ expressing adenovirus synergized with ICIs, leading to effective control of distant tumors and lung metastases. Notably, these preclinical results are translating into the clinical setting. Pre- and on-treatment biopsies from the initial 2 non-small cell lung cancer (NSCLC) patients on study were evaluated for TME impact of MEM-288 treatment. A single intralesional injection of low dose cohort MEM-288 (1e10 viral particles) resulted in shrinkage of the injected tumor (-31 and -53%), concomitant with substantial increases in overall $CD8^+$ T cells and $TCF1^+$ stem-like $CD8^+$ T cells. Studies to determine systemic effects on T cells are ongoing.

Conclusions MEM40 and IFNβ expression induces strong remodeling of the TME in both murine models and solid tumor patients. Preliminary safety, antitumor, and immune response data in the ongoing MEM-288 clinical trial is also encouraging. Following completion of the monotherapy study, an expansion arm is planned where MEM-288 will be combined with anti-PD1 antibody in patients with advanced NSCLC refractory to ICI.

Ethics Approval The studies described received IRB approval (Moffitt: Adverra IRB, # Pro00060205, Duke: DUHS IRB, #Pro00109517) prior to commencement, and in the clinical trial described all participants gave informed consent before taking part.

1133 REMODELING THE IMMUNOSUPPRESSIVE TUMOR MICROENVIRONMENT WITH ONCOLYTIC VIRUS-MEDIATED DELIVERY OF A POTENT TGF-B INHIBITOR

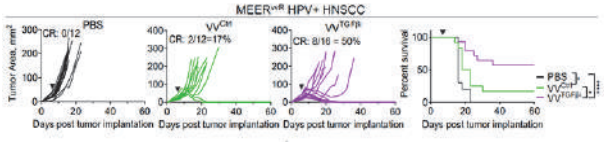
Kristin DePeaux*, Dayana Rivadeneira, Kevin Quann, Konstantinos Lontos, Andrew Hinck, Greg Delgoffe. *University of Pittsburgh, Pittsburgh, PA, USA*

Background Checkpoint blockade often fails due to a lack of pre-existing immune response. Oncolytic viruses (OVs) induce inflammation and generate a tumor specific immune response which is critical for patients with immune desert or excluded tumors. Further, OVs can be engineered to deliver therapeutic cargo in the tumor microenvironment. However, mechanisms of resistance to OVs are not well understood. To study OV resistance, we developed derivatives of the head and neck cancer line MEER: one sensitive to oncolytic vaccinia virus (VV, $MEER^{vvS}$), and one resistant to VV ($MEER^{vvR}$). Using these, we determined mechanisms which suppressed the anti-tumor immune response and engineered a new VV to target them.

Methods A $MEER^{vvS}$ tumor that grew out post-treatment was passaged in mice with a single intratumoral dose of VV given at each passage. This was repeated until a VV-resistant line was generated. For flow-cytometric tumor infiltrating lymphocyte analysis, $MEER^{vvR}$ and $MEER^{vvS}$ tumors were implanted in mice, treated with a single dose of VV^{ctrl}, $VV^{TGF\beta i}$, or PBS, and harvested 7-days post-treatment.

Results After VV treatment, we found increased T cell infiltration in both tumor types; however, $MEER^{vvS}$ infiltrate had significantly increased function, suggesting local suppressive mechanisms may define VV resistance. Indeed, in mice bearing both $MEER^{vvR}$ and $MEER^{vvS}$ we found the regulatory T (Treg) cells in the sensitive tumors had lower Nrp1 expression and higher STAT1 signaling, suggesting they may be primed for fragility. Resistant tumors were characterized by high intratumoral TGFβ, a driver of resistance to VV. We found TGFβ increased Nrp1 on Treg cell surface and led to maintained Treg suppression in the presence of IFNγ. We then generated a VV expressing a TGFβ inhibitor ($VV^{TGF\beta i}$), which outcompetes TGFβ for receptor binding, preventing receptor signaling. When $MEER^{vvR}$ were treated with $VV^{TGF\beta i}$ there was a significant increase in tumor clearances and survival compared to VV^{ctrl} (figure 1). Response to $VV^{TGF\beta i}$ was linked to a fragile Treg cell phenotype. Further, $VV^{TGF\beta i}$ synergized with PD1-blockade in a melanoma model resistant to either therapy alone.

Conclusions Our data suggest that a TGFβ-rich microenvironment is a main driver of VV resistance, due in part to stabilization of Treg cells. Targeting TGFβ using an inhibitor-armed virus can overcome this resistance. Importantly, virally-encoded TGFβ inhibition is local, carrying no toxicity associated with systemic routes. Taken together, our findings confirm TGFβ as a major player in immunotherapeutic resistance and that OVs are an attractive means to deliver TGFβ inhibition to synergize with other immunotherapies.



Abstract 1133 Figure 1 Growth Curve and Survival
Tumor growth (left) and survival (right) of MEERvvR-bearing C57BL/6 mice treated with an intratumoral injection of PBS, VV-ctrl or VV-TGFβi (black arrow) at 2.5x106 PFU/mouse.CR = complete response. 1134 DYNAMIC ANALYSES OF TUMOR MICROENVIRONMENT MODULATION BY CAN-2409 TREATMENT USING KAEDE PHOTOCONVERTIBLE TRANSGENIC MICE

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1134

[1]David Withers*, [2]Anne Diers, [1]Zhi Li, [1]Suaad Idris, [1]Claire Willis, [2]Paul Peter Tak, [2]Francesca Barone. *[1]University of Birmingham, Birmingham, UK; [2]Candel Therapeutics, Needham, MA, USA*

Background CAN-2409 is a replication-defective adenovirus that delivers the HSV-thymidine kinase gene. Intratumoral administration of CAN-2409 followed by prodrug results in the formation of a toxic metabolite able to induce immunogenic cell death, exposure of tumor-associated antigens, and activation of local and systemic immune responses. Use of state-of-the-art preclinical tools for dynamic assessment of the lymphocyte response in vivo will enable assessment of the evolution of the anti-tumor immune response induced by CAN-2409 and provide the immunological rationale for potential therapeutic combinatory approaches.

Methods We utilized a dynamic labeling model[1] where MC38 tumor cells were implanted subcutaneously into photoconvertible Kaede mice; violet light was used to simultaneously label the entire tumor microenvironment (TME), enabling the discrimination of cells retained within the tumor (Kaede Red+) versus newly entering cells (Kaede Green+) and the ability to assess real-time changes occurring in the immune compartment of the TME. CAN-2409 was administered intratumorally on day 10 after tumor inoculation followed by prodrug (ganciclovir, 50mg/kg IP QD on days 11 to 14). Photoconversion occurred on day 12, and analysis was performed 48h later. Dynamic of MC38-tumor specific T cell clones was evaluated by flow cytometry. We also explored the effect of CAN-2409 in combination with immune checkpoint inhibition (ICI).

Results Administration of CAN-2409 led to control of tumor growth and a significantly increased effector CD8 T cell response. Photolabeling of the TME revealed that rather than enhancing recruitment of T cells to the tumor, CAN-2409 altered the TME such that newly entering, but also retained CD8 T cell were significantly more proliferative. Amongst the retained population, terminally exhausted neoantigen-specific CD8 T cells showed evidence of reinvigoration, adopting a CX3CR1+ GZMB+ phenotype. There was also enhanced proliferation within the PD-1+ stem-like compartment of newly recruited cells and we observed expansion of a population of non-activated, likely less suppressive, Tregs. The combination of CAN-2409 and anti-CTLA-4 (clone 9H10) treatment further improved control of tumor growth and remodeled the Treg compartment to further skew the Treg: CD8 ratio in favor of the effector response.

Conclusions CAN-2409 alters the TME such that newly entering CD8 T cells expand and retain key effector functions while the exhausted CD8 compartment is reinvigorated, likely reducing Treg-mediated suppression. Collectively, these data suggest at least two temporally distinct pathways underpinning CAN-2409 action that overcome cell exhaustion and decreased immune suppression, supporting the rationale for the use of CAN-2409 either as monotherapy or in combination.

1135 SINGLE CELL RESOLUTION OF IMMUNE RESPONSES TO ONCOLYTIC HERPES SIMPLEX VIRUS C134 IN PRECLINICAL MEDULLOBLASTOMA MODELS

[1]Jack Hedberg*, [1]Adam Studebaker, [2]Luke Smith, [1]Chun-Yu Chen, [1]Jesse Westfall, [1]Maren Cam, [1]Amy Gross, [1]Ryan Roberts, [1]Timothy Cripe, [1]Elaine Mardis, [1]Kevin Cassady, [1]Jeffrey Leonard, [1]Katherine Miller. [1]*Nationwide Children's Hospital, Columbus, OH, USA*; [2]*Ohio State University, Columbus, OH, USA*

Background Medulloblastoma is the most common malignant brain tumor in children.[1] Despite recent advances in our understanding of its tumor biology, one-third of affected children do not survive this disease. Even amongst survivors of medulloblastoma, there are significant issues with treatment-related health sequelae, and thus more effective and safer therapies are urgently needed. Oncolytic herpes simplex viruses (oHSV), which exploit the dysregulated cellular programs in malignant cells as a replicative advantage, also evoke innate immune responses. As such, they provide an increasingly appealing option for treating many malignancies, including brain cancers.

Methods Here, we studied the effects of the oHSV C134 in two syngeneic medulloblastoma mouse models, one that aligns with the sonic hedgehog (SHH) subtype (MYCN) and another that aligns with group 3 subtype tumors (CMYC).[2,3] We treated intracranial tumors with C134 or vehicle to evaluate changes in overall survival, then applied single cell RNA-sequencing (scRNA-seq) and flow cytometry to study tumor samples across multiple post-treatment timepoints and characterize the immune responses evoked by C134 treatment.

Results Treatment with C134 increased survival in C57BL/6 mice bearing tumors for the CMYC model (C134 median = 38.5 days, range = 24-75 days, n = 10 vs. vehicle median = 19 days, range = 17-24 days, n = 10, $p<0.0001$) as well as the MYCN model (C134 median = 17.5 days, range = 14-23 days, n = 10 vs. vehicle median = 13 days, range = 10-14 days, n = 10, $p<0.0001$). Flow cytometry demonstrated similarities in immunophenotypic response to C134 between the two models including increased M1-like macrophages, CD4+ T cells, CD8+ T cells, NKT cells, and myeloid-derived suppressor cells. Collectively these data provided evidence for a complex immune response. scRNA-seq data analysis allowed higher resolution immune response characterization, indicating over twenty cell types (figure 1). Here, we identified statistically significant (FDR < 0.05) increases in proportions of macrophages, monocytes, lymphocytes, and dendritic cells after C134 treatment. Differential gene expression revealed that cytokines, MHC class I, Ib, and II genes, and interferon-response genes exhibited marked expression changes in lymphocytes, macrophages, microglia, and dendritic cells in response to C134.

Conclusions Our findings suggest a multifaceted immune response contributes to the efficacy of C134 oHSV treatment to prolong survival in two mouse models of medulloblastoma. A wide array of gene expression changes occurs in response to C134 treatment across immune cell types, time points, and medulloblastoma models, illuminating potential mechanisms involved in C134's antitumor effects.

1136 INDUCTION OF TERTIARY LYMPHOID STRUCTURES IN NON-SMALL CELL LUNG CANCER IMPROVES B AND T CELL ANTI-TUMOR IMMUNITY

[1]Hye Mi Kim*, [2]Dongyan Liu, [1]Ayana Ruffin, [2]Alexandra McDonough, [2]Caleb Lampenfeld, [2]Sheryl Kunning, [2]Ashwin Somasundaram, [2]Laura Stabile, [2]Tullia Bruno. *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA, USA; [2]UPMC Hillman Cancer Center, Pittsburgh, USA*

Background Tertiary lymphoid structures (TLS) are lymphoid aggregates that often form locally in tissues with chronic infection, autoimmune disease, and cancer. As such, TLS correlate with favorable prognosis in patients with solid tumors, including non-small-cell lung cancer (NSCLC). Further, TLS have recently been associated with superior response to immune checkpoint blockade (ICB).[1, 2, 3] B cells are predominantly located within TLS and correlate with improved survival and ICB response.[4] Despite the therapeutic promise of B cells and TLS, they have not been investigated as immunotherapeutic targets. Moreover, a mechanistic understanding of TLS formation and function in cancer is lacking.

Methods Our studies aim to interrogate unique factors that promote or inhibit TLS formation. First, we studied TLS in human lung adenocarcinoma using multispectral imaging and spatial transcriptomics (Nanostring Digital Spatial Profiler) to uncover known and unknown pathways that could improve TLS formation and subsequently B and T cell function. We paired these studies with murine models of lung adenocarcinoma. Specifically, we utilized a physiologically relevant, carcinogen (4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone; NNK) induced murine model of lung cancer that spontaneously forms TLS. A syngeneic tumor line derived from this model that can be orthotopically injected into the murine lung also forms high B cell infiltrate and TLS. We utilized these models to test if TLS induction and maturation were increased with an oncolytic virus that targets known TLS-initiating factors.

Results According to spatial transcriptomics, tumor-associated TLS have decreased TLS-initiating and maturation factors such as CXCL13, IL-21, CD40, and LTbeta/LIGHT in comparison to normal lymphoid tissues. Further, as TLS proximity to the tumor increases, there is an increased immune regulation surrounding TLS formation. Thus, using an oncolytic virus that targets CXCL13, IL-21, CD40 and LTbeta ligation or LIGHT, we observed increased TLS induction and tumor reduction.

Conclusions These studies will increase our understanding of TLS formation for improved immunotherapies in NSCLC patients and will potentially provide therapeutic interventions that could be administered prior to cancer development.

1137 SUPERNOVA1 (SNV1), A NOVEL ONCOLYTIC-CELL BASED PLATFORM FOR CANCER THERAPY

[1]Duong Nguyen*, [2]Mohamed Hammad, [2]Rachael Mooney, [1]Forrest Neuharth, [1]Ashley Alamillo, [1]Ivelina Minev, [1]Israel Romero, [1]Stephanie Songco, [1]Emma Kedl, [1]Yunyi Kang, [2]Hoi Ngai, [2]Marisa McDonald, [2]Linda Flores, [2]Dae Kim, [2]Jacqueline Lara, [3]Thomas Herrmann, [3]Barbara Härtl, [3]Laura Edith, [3]Daniela Kleinholz, [1]Boris Minev, [2]Karen Aboody, [1]Antonio Santidrian. *[1]Calidi Therapeutics, San Diego, CA, USA; [2]City of Hope, Duarte, CA, USA; [3]StemVAC, Bernried, Germany*

Background The therapeutic potential of the oncolytic virotherapy is severely restricted by multiple innate and adaptive immune barriers. To overcome this obstacle, we utilized adipose-derived stem cells (AD-MSC) loaded with tumor selective CAL1 oncolytic vaccinia virus to generate a new therapeutic agent called SNV1 (SuperNova-1). Intratumoral injection of SNV1 inhibited drastically tumor growth of multiple human cancer xenograft models at significant low virus titers. In syngeneic immunocompetent models, SNV1 showed a robust tumor growth inhibition and immune cell recruitment of both the local injected tumors and distant non-injected tumors.

Methods SNV1 was tested for its ability to resist humoral immunity-mediated virus inactivation in cell culture. In tumor-bearing mouse models, tumor growth inhibition of multiple human xenografts and murine syngeneic was examined by using either single or three dose regimens. Additionally, in bilateral tumor-bearing mouse models, immune profiles at different time courses of both treated and untreated tumors as well as lymph nodes were analyzed by flow cytometry. Antiviral and anti-tumor immunity was analyzed by ELISPOT.

Results Data showed that SNV1 was more resistant to rapid inactivation by humoral immune system as compared to naked CAL1 virus leading to a significant and robust improvement of oncolytic virus therapeutic efficacy in human melanoma (MeWo), head and neck (Fadu) and triple negative breast (MDA-MB-231) cancer cells. Furthermore, SNV1 significantly inhibited the growth of the tumors even at the very low dose of $1.5x10^3$ cells containing $1.6x10^4$ PFU. In a bilateral colon cancer tumor-bearing immunocompetent mouse model CT26, data showed both one (1) and three (3) administrations of SNV1 significantly inhibit tumor growth of injected tumors in comparison with the naked CAL1 virus or controls. However, significant systemic therapeutic efficacy was only achieved by three (3) but not one (1) intratumoral administrations of SNV1 suggesting multiple intratumoral administrations of SNV1 were required to induce robust systemic activation of the immune system. Furthermore, tumor infiltrating lymphocytes (TILs) from both treated and untreated tumors showed increased CD4 and CD8 T-cell infiltrations while suppressing frequency of Tregs. Early recruitment of innate populations was observed in tested models.

Conclusions The SNV1 stem cell-based platform protects and potentiates oncolytic vaccinia virus by circumventing humoral innate and adaptive immune barriers, resulting in enhanced anti-cancer effects in tumor-bearing mouse models. SNV1 provided instantly active viral particles for immediate infection in the injected tumors which help transforming tumor environment from “cold” to “hot” locally and systemically.

1138 ENGINEERED ONCOLYTIC VIRUSES EXPRESSING IMMUNOMODULATORY GENES ENHANCED ANTI-TUMOR IMMUNE RESPONSES *IN VITRO*

Zhongbao Song*, Limin Tian, Guangxu Ding, Ka Fung Noi, Jie Xu, Qingyang Gu. *WXi ApTec, Nantong, China*

Background While chemo- and radio-therapies were considered the first-line treatment for most cancers, their serious side effects have led to continuous innovation and discovery of new cancer therapies. Oncolytic viruses (OVs), either naturally occurred or genetically engineered to selectively target and lyse cancer cells without harming normal tissues, have emerged as the next remarkable wave in cancer immunotherapy. OVs possess a magnitude of mechanisms to elicit anti-tumor immune response, including the infection in cancer cells causing the viral replication and cell lysis. In addition to OVs innate cytotoxicity, further anti-tumor enhancement can be achieved *via* inserting tumor-associated antigen (TAA)/immunomodulatory genes by genetic engineering technology, leading to the release of inflammatory and immunoregulatory cytokines. This in effect, causes the tumor to become "hot" and detectable by other immune cells, which are subsequently stimulated to eradicate tumor. Our recent study assessed the effect of modified OVs (mOVs) engineered with immunomodulatory genes in the *in vitro* assays with various immune cells including T, natural killer (NK) and monocyte-derived dendritic cells (moDC).

Methods
- The expression of exogenous immunomodulatory genes, in different tumor cells infected with mock or mOV, was detected by flow-cytometry and ELISA.
- Cytotoxicity of mOV on different tumor cell lines were evaluated by CCK-8 and plaque assays.
- The apoptosis induced by mOV in different tumor cells was analyzed by flow-cytometry.
- The activation of T cells in co-culture with mOV-infected tumor cells was evaluated by the ELISA detection of IFN-γ.
- T or NK cells were treated with supernatants from the culture of mOV-infected tumor cells. Released IFN-γ was detected by ELISA.
- $CD8^+$ T cells were co-cultured with mOV-treated moDC cells, and the T cell activation was evaluated by flow-cytometry and ELISA.

Results A susceptible cell line was identified for mOV infection, which had high expression efficiency of exogenous immunomodulatory genes.

mOV induced a cytotoxicity on the susceptible cells through apoptosis effect.

mOV-infected tumor cells and the harvested surpernatants significantly promoted the activation of T or NK cells.

mOV treatment promoted the maturation of moDCs and the secretion of IFN-γ by CD8+ T cells.

Conclusions Modified OV significantly induced cytotoxicity on the susceptible tumor cells, and promoted the activation of T, NK and moDC immune cells with increased inflammatory cytokine secretion. Our study suggested an effective approach for the development and validtion of the next generation of oncolytic viruses being more potent in both the direct tumor killing and immune activation.

1139 VIROTHERAPY WITH CODALYTIC™, A CODON-MODIFIED INFLUENZA VIRUS, INDUCES AN ANTI-TUMOR IMMUNE MICROENVIRONMENT ACROSS PRECLINICAL MODELS WITH DIFFERENT IMMUNE CONTEXTURES

Marcin Stawowczyk, Yiwen Zhao, Katie Pfeffer, Juliana Tafrova, Nusrat Jahan, James Rodriguez, Chen Yang, Sybil Tasker, Steffen Mueller, J Robert Coleman, Johanna Kaufmann*. *Codagenix Inc., Farmingdale, NY, USA*

Background Multiple oncolytic viruses have been shown to induce beneficial changes in the tumor microenvironment (TME) by increasing immune cell infiltration and activating stimulatory immune responses, which ultimately support induction of anti-tumor immunity and efficacy. We have previously demonstrated that CodaLytic™, a codon-modified influenza virus, can activate the cancer immunity cycle at various steps in EMT6, a murine triple-negative breast cancer model with moderate responsiveness to immunotherapies, leading to 67% complete tumor regressions. Here, we are confirming the mechanisms of action of the virus alone and in combination with immune checkpoint inhibition in several murine models and human tumor explants with different baseline immune contexture.

Methods Efficacy after intratumoral injection of 10^8 PFU CodaLytic 3x/week for up to 12 doses as a monotherapy and/or in combination with systemic anti-PD-1 checkpoint blockade was determined in EMT6 breast cancer, CT26 colon cancer and B16F10 melanoma mouse models. Pharmacodynamic changes in the TME after treatment were characterized using flow cytometry. Anti-tumor immune memory was assessed by interferon-γ ELISpot in splenocytes of long-term survivors. Human breast cancer tumoroids maintaining the orignal patient TME were incubated *ex vivo* with 10^8 PFU CodaLytic, 10 μg/ml pembrolizumab or both. Tumor cell killing (TCK) was detected by high-content imaging at 72h and the TME was characterized by flow cytometry, cytokine release and RNA sequencing at 24h and 48h.

Results CodaLytic monotherapy led to significant tumor growth inhibition (TGI) across tumor models, including 76% in EMT6 with moderate, immunologically active infiltration [1] and 69% TGI in poorly infiltrated B16F10 melanoma resistant to PD-1 blockade. In this model, efficacy further improved to 86% with addition of anti-PD-1. In all models, CodaLytic treatment increased infiltration of CD45+ leukocytes, CD8+ T cells and cross-presenting dendritic cells. *Ex vivo* recall responses to tumor cell lysate (EMT6) or AH1 peptide (CT26) were observed in long-term survivors, confirming generation of an anti-tumor T cell response. Efficacy of the CodaLytic/anti-PD-1 combination was confirmed in well-infiltrated human breast cancer tumoroids (51% TCK vs 24% with pembrolizumab alone, 6% with CodaLytic alone, and 2% in poorly-infiltrated tumoroids), a system in which priming and immune cell recruitment from a systemic reservoir are absent.

Conclusions CodaLytic treatment induced favorable changes in multiple murine tumor models independently of their intrinsic immune contexture and sensitized B16F10 melanomas to PD-1 blockade. Ongoing work investigates correlates of TCK in human tumoroid cultures beyond baseline immune infiltration to support future development of CodaLytic for immunovirotherapy.

1140 CANCER STEM CELLS AND PD-L1-EXPRESING EXOSOMES SUPPRESS ANTI-TUMOR EFFECTOR B CELLS

Ying Xin*, You Qin, Max Wicha, Alfred Chang, Qiao Li. *University of Michigan, Ann Arbor, USA*

Background We have identified anti-tumor effector B cells in adaptive immunotherapy. We also reported that cancer stem cell (CSC) vaccination induces CSC-specific T and B cell responses associated with the therapeutic efficacy which can be enhanced by anti-PD-L1 administration. Tumor cells were reported to suppress T cell function *via* secretion of exosomes that express PD-L1. However, the role of exosomal PD-L1 in CSC-B cell interaction is unknown.

Methods 4T1 and CT26 tumor-bearing mice were administered with anti-CD20 mAb to deplete B cells prior to anti-PD-L1 mAb administration. We isolated exosomes from D5 tumor cell culture media. To investigate if exosomal PD-L1 contributes to immunosuppression of B cells, we generated Rab27a^{ko} D5 cells to delete exosomes and PD-L1^{ko} D5 cells by CRISPR/Cas9 gene editing system.

Results *In vivo* B cell depletion significantly abrogated the efficacy of anti-PD-L1 with more aggressive tumor growth, indicating the anti-tumor effect of anti-PD-L1 involves host B cells. We detected upregulated expression of PD-1 on activated B cells, and higher PD-L1 expression on ALDH^{high} CSCs than on ALDH^{low} non-CSCs. ALDH^{high} CSCs directly suppressed IgG production by purified normal spleen B cells in culture and the suppression could be blocked by anti-PD-L1 in a dose-dependent manner. Anti-PD-L1 also rescued CSC suppression on the IgG production by B cells isolated from the spleen of tumor-bearing mice. Administration of anti-PD-L1 partially recovered the humoral immune response, confirming the PD-L1/PD-1 pathway involvement in B cell suppression by CSCs. D5-derived exosomes suppressed B cell proliferation and IgG production *in vitro*, and administration of these exosomes promoted tumor growth and reduced animal survival, indicating the role of tumor-derived exosomes in B cell immunosuppression. Tumor-derived exosomes expressed PD-L1, but PD-L1 was absent in the exosomes isolated from the PD-L1^{ko} tumor cells as evident by western blot and flow cytometry. Deletion of Rab27a or PD-L1 did not affect the proliferation of the tumor cells *in vitro*. However, Rab27a^{ko} or PD-L1^{ko} resulted in significantly enhanced host anti-tumor immunity evident by reduced 4T1 tumor growth *in vivo* compared with the WT tumor. Furthermore, anti-PD-L1 therapy significantly reduced Rab27a^{ko} or PD-L1^{ko}4T1 tumor growth and prolonged animal survival *vs.* the WT tumor control.

Conclusions PD-L1-expresing CSCs and exosomes suppress B cells *via* the PD-L1/PD-1 axis. Isolation of Rab27a^{ko} ALDH^{high} CSCs will help further characterize the suppression of CSC-derived exosomes on host B cells as well as T cells.

1141 DKN-01 DEMONSTRATES IMMUNE MODULATORY ACTIVITY AND ROBUST EFFICACY IN COLORECTAL CANCER MODELS

[1]Michael Haas*, [1]Michael Kagey, [1]Walter Newman, [2]James Rottman, [3]Milad Moloudizargari, [3]Ajay Goel, [1]Cynthia Sirard, [1]Jason Baum. *[1]Leap Therapeutics, Cambridge, MA, USA; [2]Athenaeum Pathology Consulting, LLC, Sudbury, MA, USA; [3]Beckman Research Institute, Duarte, CA, USA*

Background Colorectal cancer (CRC) is the third most prevalent cancer and the second leading cause of cancer-related death worldwide. CRC has elevated Wnt signaling activity in which DKK1 plays a regulatory role. DKN-01 is an IgG4 clinical stage antibody that specifically neutralizes DKK1. Fluorouracil (5FU)-based therapies are the standard backbone treatment for CRC and have demonstrated clinical activity in combination with DKN-01 in gastroesophageal adenocarcinoma (GEA). DKK1 expression has been shown to correlate with 5FU resistance in CRC tumors and cell lines. We evaluated the efficacy of DKN-01 alone and in combination with 5FU in parental and 5FU-resistant HCT116 and SW480 xenograft models. Further, given the established role of DKK1 on TME modulation, we also explored treatment with DKN-01 as a monotherapy and in combination with anti-PD-1 in a CT26 syngeneic CRC model.

Methods For the xenograft models, athymic nude mice were inoculated subcutaneously (SC) with either parental or 5FU-resistant colon carcinoma cell lines. Once tumors reached 50mm^3, dosing was initiated with either isotype control, DKN-01, 5FU, or the combination. For the CT26 syngeneic model, BALB/c mice were inoculated SC with CT26 mouse colon carcinoma cells. Once tumors reached 50mm^3, dosing initiated with either isotype control, a murinized version of DKN-01 (mDKN-01), anti-PD-1, or the combination.

Results In the parental HCT116 model, 30%, 39%, and 55% tumor growth inhibition (TGI) were observed in the DKN-01, 5FU, and combination treatment groups compared to isotype controls. Strikingly, in the HCT116 5FU-resistant model, 5FU had a negligible effect on TGI compared to DKN-01 monotherapy; and combination treatment groups in both 5FU-resistant models experienced 100% tumor regression. In the CT26 syngeneic model, mDKN-01 monotherapy resulted in 71% TGI with 47% of the group experiencing tumor regression at study termination unlike the anti-PD-1 monotherapy which had negligible TGI. The effect of mDKN-01 was further enhanced by the combination resulting in an additional 58% TGI with 73% of the group experiencing tumor regression. Notably, a robust inflammatory infiltrate was observed in the tumors of mDKN-01 monotherapy and combination groups, correlating with the level of necrosis. In addition, a significant increase in PD-L1 staining occurred with mDKN-01 monotherapy.

Conclusions In multiple models of CRC, DKN-01 showed strong anti-tumor effects. This included tumor regression in a 5FU-resistant setting reflective of second line CRC, as well as significant monotherapy efficacy and synergy with anti-PD-1.

1142 HYPOXIA REDUCTION IN COMBINATION WITH ANTI-ANGIOGENIC THERAPY REMODELS THE PDAC MICROENVIRONMENT

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1142

Arthur Liu*, Michael Curran. *UT MD Anderson Cancer Center, Houston, TX, USA*

Background Pancreatic cancer patients remain largely unresponsive to single agent immune checkpoint blockade (ICB) therapy. This refractory state originates from PDAC's unique immunosuppressive microenvironment that is densely populated by suppressive myeloid cells, exhibits poor vascularity, and is highly hypoxic. We previously showed that the hypoxia-activated prodrug TH-302 (Evofosfamide) reduces intratumoral hypoxia through a tissue remodeling process, initiates tumor vasculature reorganization, and sensitizes aggressive, spontaneous murine models of prostate cancer to ICB.[1] In a clinical trial testing the combination of TH-302 with cytotoxic T-lymphocyte-associated protein (CTLA-4) blockade (NCT03098160) a subset of metastatic, immune checkpoint blockade refractory patients showed prolonged progression free survival.[2] While these studies highlight hypoxia as therapeutically tractable, we lack complete understanding of the contribution of the tumor vasculature to hypoxia reduction therapy, as well as the downstream consequences of hypoxia reduction on the cellular composition of the tumor microenvironment and the associated sensitivity, or lack thereof, to immunotherapy. We hypothesized that anti-angiogenic therapy and Evofosfamide could cooperate to normalize tumor vasculature and diminish hypoxia.

Methods TH-302 and a vascular endothelial growth factor receptor-2 (VEGFR-2) blocking antibody were used to treat several syngeneic murine models, including orthotopic pancreatic cancer and a transplantable model of prostate cancer. Immunofluorescence and flow cytometry were used to assess intratumoral hypoxia, vessel normalization, and tumor immune infiltrate. RNA-sequencing analysis of bulk tumor samples was done to determine changes in gene signatures.

Results We find that Evofosfamide with anti-VEGFR-2 (DC101) significantly extends mouse survival. Combination therapy reduces intratumoral hypoxia, improves vessel integrity, and increases intratumoral DNA damage. In response to the improved metabolic microenvironment, CD8 T cells gain enhanced effector function and lose expression of exhaustion-associated features. Like other anti-angiogenic regimens, combination DC101 and TH-302 leads to an increased frequency of PD-L1 expressing cells within the tumor, however blockade of PD-1 failed to prolong survival. Bulk-tumor RNA sequencing and tumor infiltrating lymphocyte analysis implicates immature myeloid cells as mediators of therapy resistance.

Conclusions Evofosfamide and DC101 utilize unique yet complementary mechanisms to improve the survival of mice challenged with pancreatic or prostate tumors. This combination relieves hypoxic stress and simultaneously reinvigorates T cell function, but may facilitate de novo MDSC infiltration. Future work will determine the underlying factors that shape the tumor immune microenvironment and influence immunotherapy responses.

1143 5T4-CD40 BISPECIFIC ANTIBODIES ACTIVATE IMMUNE RESPONSES IN A 5T4-DEPENDENT MANNER

Fang Liu*, Wenci Gong, Yuanyuan Yang, Zhijian Cai, Feifei Cui, Lei Fang, Wenqing Jiang.
Concept To Medicine Biotech Co.,Ltd, Shanghai, China

Background CD40 is a key costimulatory molecule expressed on professional antigen presenting cells (APCs) and functions to bridge innate and adaptive immunity. CD40 primes dendritic cells (DCs) to upregulate the expression of other costimulatory molecules such as CD80 and CD86 that further activates CD8+T cells. CD40 activation on B cells increases their activation and proliferation that further promotes antitumor effects. Agonistic CD40 monoclonal antibodies displayed clinical response, however, the further development was hampered by dose-limiting toxicities possibly due to the systemic activation. To overcome this issue, we have developed a conditional CD40 bispecific antibody which was only activated in 5T4-expressing tumor cells. 5T4 is a oncofetal protein rarely expressed in normal adult tissues, however, the expression is upregulated in multiple cancers. Therefore, we hypothesized that CD40 crosslinking by engagement of 5T4 on the cancer cells could boost the immune response in the tumor microenvironment while minimizing the risk of peripheral toxicity.

Methods To achieve maximal agonistic effect, we have generated a panel of 5T4 x CD40 bispecific antibodies in different formats. 5T4 x CD40 bispecific antibodies were evaluated in CD40 reporter cells and cocultured with target cells expressing 5T4. The potency was further confirmed by measuring IL12 production from primary DCs and CD80 and CD86 expression on the DC and B cells. The anti-tumor efficacy was determined in CD40-humanized C57BL/6 mice bearing MC38-hu5T4 tumor.

Results 5T4 x CD40 bispecific antibodies activated CD40 signaling in a 5T4-dependent manner. Similarly, DCs and B cells were activated only when cocultured with 5T4-expressing cells. Interestingly, we have identified an optimal format that showing superiority to other formats in inducing more potent CD40 agonism while remained silent in 5T4-negative cells. Treatment of 5T4 x CD40 displayed a more potent antitumor efficacy, compared to an equivalent dose of clinical benchmark CD40 monospecific antibody. Furthermore, tumor-free mice were resistant to tumor rechallenge, indicating an established long-lasting memory response. The *ex vivo* analysis suggested a focused immune activation in the tumor and no peripheral activation.

Conclusions We have generated bispecific antibodies specific to both CD40 and 5T4 that could achieve APC activation only in 5T4-expressing tumor microenvironment and demonstrate anti-tumor efficacy without inducing systemic toxicity. The preclinical data warrant further development of 5T4 x CD40 bispecific antibody as a potential therapeutic option for solid tumor.

1144 IL17-PRODUCING γδ T CELLS PROMOTE RESISTANCE TO CDK4/6 INHIBITORS IN HR$^+$HER2$^-$ BREAST CANCER

[1]Giulia Petroni, [2]Kenneth Gouin, [1]Claudia Galassi, [1]Aitziber Buqué, [1]Norma Bloy, [1]Takahiro Yamazaki, [1]Ai Sato, [1]Carlos Jiménez-Cortegana, [3]Alexander Kirchmair, [4]Chiara Massa, [5]Carlos Eduardo De Andrea, [5]Belén Navarro, [5]Irantzu Serrano, [6]Esther Navarro Manzano, [3]Francesca Finotello, [1]Xi Zhou, [6]Elena García-Martínez, [7]María Rodríguez-Ruiz, [4]Barbara Seliger, [8]Víctor Sánchez-Margalet, [8]Luis de la Cruz-Merino, [2]Heather McArthur, [1]Silvia Formenti, [2]Simon Knott, [1]Lorenzo Galluzzi*. *[1]Weill Cornell Medicine, New York, NY, USA; [2]Cedars-Sinai Medical Center, Los Angeles, CA, USA; [3]Medical University of Innsbruck, Innsbruck, Austria; [4]Martin Luther University Halle-Wittenber, Halle, Germany; [5]Clínica Universidad de Navarra, Pamplona, Spain; [6]Hospital Universitario Morales Meseguer, Murcia, Spain; [7]CIMA Universidad de Navarra, Pamplona, Spain; [8]Universidad de Sevilla, Sevilla, Spain*

Background CDK4/6 inhibitors are approved in combination with hormonotherapy as a first-line intervention against advanced/metastatic hormone receptor (HR)$^+$ HER2$^-$ breast cancer, reflecting their ability to extend progression-free survival (PFS) and overall survival (OS) in this patient population.[1-3] Nonetheless, >50% of women with HR$^+$ breast cancer receiving CDK4/6 inhibitors ultimately progress and succumb to their disease, owing to hitherto poorly characterized mechanisms of acquired resistance.[1-3] While CDK4/6 inhibitors have been conceived to inhibit the proliferation of cancer cells, accumulating preclinical and clinical evidence indicates that they also mediate numerous immunostimulatory effects that may contribute to efficacy.[4,5] These observations suggest that hitherto unidentified immunological mechanisms may promote resistance to CDK4/6 inhibitors in patients with HR$^+$HER2$^-$ breast cancer.

Methods We harnessed a unique immunocompetent mouse model that closely recapitulates the immunobiology of human HR$^+$HER2$^-$ breast cancer – including a cold tumor microenvironment (TME) coupled to poor sensitivity to PD-1 blockers[6] – along with scRNAseq, functional assays and blocking/neutralization experiments to dissect the immunological mechanisms underlying resistance to CDK4/6 inhibitors. The Cancer Genome Atlas (TCGA) was interrogated by *in silico* analysis. Moreover, immunohistochemistry, multispectral immunofluorescence, and circulating immunophenotyping were performed on samples from 3 independent cohorts of patients with HR$^+$HER2$^-$ breast cancer (including longitudinal samples obtained before, during and after CDK4/6 inhibition).

Results Interleukin 17 (IL17)-producing γδ T cells are recruited to mouse HR$^+$HER2$^-$ mammary tumors upon CDK4/6 inhibition through a CCL2-dependent mechanism. In this model, circulating IL17 levels correlate with poor OS, and blocking the γδ TCR, neutralizing IL17 or CCL2 equally improve the therapeutic activity of CDK4/6 inhibitors. Patients from the TCGA with a signature of IL17 signaling have poor OS and signs of immunosuppression in the TME. In diagnostic biopsies from patients with HR$^+$HER2$^-$ breast cancer, γδ T cell infiltration correlate with tumor grade, and γδ T cells reside in the proximity of PD-L1$^+$ tumor cells and macrophages. Patients with high activated γδ T cells in the circulation have reduced PFS on CDK4/6 inhibitors as compared to their low counterparts. Circulating CCL2 levels augment during CDK4/6 therapy in progressing patients. Finally, tumor-infiltrating γδ T cells increase as compared to baseline in patients relapsing on CDK4/6 inhibitors.

Conclusions Our findings prompt the initiation of clinical trials comparing standard-of-care CDK4/6 inhibition plus letrozole vs CDK4/6 inhibition plus letrozole and an IL17 blocker (at least three of which are currently approved for psoriasis treatment) in patients with HR$^+$HER2$^-$ breast cancer.

1146 NKG2D CO-STIMULATION VIA ANTI-SMIC/MIC TARGETING ANTIBODY ENHANCES CD8 T CELL FUNCTIONAL HETEROGENEITY AND MEMORY DEVELOPMENT IN MOUSE PROSTATE TUMORS

[1]Tyler Smith*, [1]Sizhe Liu, [2]Lisha Zhu, [1]Jennifer Wu. [1]*Northwestern University Feinberg, Chicago, IL, USA*; [2]*University of Chicago, Chicago, IL, USA*

Background Effective co-stimulation of CD8 T cells is critical for anti-tumor effector responses and maintenance of antigen-specific TCF-1$^+$ memory CD8 T cells necessary for long-term tumor control. NKG2D co-stimulation of CD8 T cells via binding of stress ligands such as membrane-bound MIC enhances CD8 T cell effector functions and is important for promoting memory development. Cancer cells often shed MIC into a soluble form (sMIC) that inhibits CD8 T cell activation. Humanized TRAMP/MICB prostate tumor mice treated with anti-sMIC/MIC targeting antibody develop potent anti-tumor responses by CD8 T cells by 1) sequestering sMIC and 2) inducing NKG2D pathway signaling, thereby re-invigorating CD8 T cell immunity. However, the mechanistic underpinnings of CD8 T cell reprogramming by NKG2D co-stimulation in the tumor microenvironment are poorly understood. In this preliminary study, we used scRNA-seq of CD8 TILs from TRAMP/MICB mice treated or untreated with the anti-sMIC/MIC targeting antibody B10G5 to investigate the hypothesis that B10G5 differentially reprograms CD8 T cells at the transcriptional and epigenetic level via sustained NKG2D pathway co-stimulation, thereby optimizing TCR-dependent effector and memory responses.

Methods Adult TRAMP/MICB mice were treated with 200μg B10G5 intraperitoneally twice per week for 4 weeks. Prostate tumors from B10G5-treated mice, untreated mice with well-differentiated tumors, and untreated mice with poorly differentiated tumors were collected, and their CD45$^+$ cells isolated via FACS for scRNA-seq. Subclusters specific to CD8 T cells were the focus of subsequent transcriptomic analyses.

Results Prostate tumors from mice treated with anti-sMIC/MIC antibody B10G5 revealed enhanced functional heterogeneity of CD8 T cell subtypes compared to tumors from untreated mice. In contrast to tumors from untreated mice that were populated with primarily effector CD8 T cells expressing CD226^{hi}, CXCR3^{hi}, GZMB^{hi} and/or NKG7, tumors from B10G5-treated mice were enriched in TCF7^{hi} IL7R$^+$ EOMES^{hi} stem-like memory CD8 T cells and EOMES$^+$ CD27^{hi} PD-1$^+$ effector memory CD8 T cells. These memory populations upregulated epigenetic modifiers (KMT2A/E) and transcription factors (NR4A1/2/3) important in metabolic reprogramming and memory CD8 T cell differentiation.

Conclusions These results establish a groundwork for identifying targets for epigenetic and metabolic alteration of CD8 T cells via NKG2D co-stimulation within the tumor microenvironment.

Ethics Approval All animal studies were approved by the Institutional Animal Care and Use Committee (IACUC) committee of Northwestern University.

1147 DIFFERENCES IN CO-EXPRESSION OF T CELL CO-INHIBITORY AND CO-STIMULATORY MOLECULES WITH PD1 ACROSS DIFFERENT HUMAN CANCERS

[1]Ahmad Tarhini*, [2]Dale Hedges, [1]Aik Choon Tan, [1]Paulo Rodriguez, [3]Vineeth Sukrithan, [4]Aakrosh Ratan, [5]Martin McCarter, [6]John Carpten, [7]Howard Colman, [8]Alexandra Ikeguchi, [9]Igor Puzanov, [10]Susanne Arnold, [2]Michelle Churchman, [1]Patrick Hwu, [1]Jose Conejo-Garcia, [2]William (Bill) Dalton, [11]George Weiner. *[1]Moffitt Cancer Center and Research Inst., Tampa, FL, USA; [2]M2GEN, ORIEN, Tampa, FL, USA; [3]The Ohio State University, Bronx, OH, USA; [4]University of Virginia, Charlottesville, VA, USA; [5]University of Colorado Cancer Center, Aurora, CO, USA; [6]USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA; [7]Huntsman Cancer Institute, Salt Lake City, UT, USA; [8]Stephenson Cancer Center, Oklahoma City, OK, USA; [9]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [10]Markey Cancer Center, Lexington, KY, USA; [11]University of Iowa Holden Cancer Center, Iowa City, IA, USA*

Background PD1 immune checkpoint inhibitors (ICIs) have resulted in significant improvements in the care of patients with advanced malignancies. PD1 based combinations including with CTLA4 and LAG3 represent the future of ICI immunotherapy and there is a need to better understand the rationale for investigating combinations involving other immune modulator therapeutic candidates across cancer types.

Methods We utilized real-world clinical and transcriptomic data collected under the Total Cancer Care Protocol (NCT03977402) and Avatar® project within the Oncology Research Information Exchange Network (ORIEN) of 18 cancer centers to which all included subjects provided an IRB-approved written informed consent at their participating institutions. Using RSEM we analyzed mRNA co-expression levels of PD-1 with 12 immune checkpoints including the co-inhibitory receptors LAG3, CTLA4, TIGIT, TIM3 (HAVCR2), VISTA (VSIR), BTLA and the positive co-signaling molecules CD28, OX40 (TNFRSF4), GITR (TNFRSF18), CD137 (TNFRSF9), CD27, HVEM (TNFRSF14) as well as PD-L1 (CD274). Pearson's R coefficients and associated *P* values were calculated using SciPy 1.7.0. We defined Pearson's coefficient > 0.5 and p < 10E-10 as significant correlation.

Results Co-expression of PD1 along with the 12 immune checkpoints and PD-L1 across select malignancies included in our analysis is shown in (table 1), including Pearson's correlation and the associated *P* values, sorted by the level of correlation. In cutaneous melanoma, in terms of co-inhibitory receptors that suppress T cell activation, the expression of PD1 was significantly correlated with four molecules: LAG3, TIM3, TIGIT and VISTA; and only significantly correlated with one costimulatory molecule CD137. For urothelial carcinoma, there were 4 co-inhibitory (TIGIT, CTLA4, LAG3 and VISTA) and 4 co-stimulatory (OX40, CD27, CD137 and HVEM) molecules statistically correlated with PD1 expression. For pancreatic adenocarcinoma, only CD28 was deemed to be correlated with PD1 expression. No immune checkpoints were deemed significantly correlated with PD1 expression in the ovarian cancer cohort. Overall, in melanoma and to a certain extent in urothelial carcinoma, the co-expression of co-inhibitory molecules with PD1 was more dominant reflecting late exhausted T cells, as compared to co-stimulatory molecules likely more dominant in ovarian and pancreatic carcinomas reflecting less differentiated T cells.

Conclusions With PD1 blockade as a backbone for immune checkpoint targeting combinations, our interrogations of pan-cancer transcriptomic data provide support for multiple potential combination strategies in the tested malignancies that warrant further investigation. Melanoma and urothelial carcinoma as more immunogenic tumors reflected a PD1+immunoinhibitory dominant phenotype, while less immunogenic ovarian and pancreatic carcinomas reflected a trend toward a PD1+immunostimulatory phenotype.

1148 SIGNAL-REGULATORY PROTEIN ALPHA (SIRPα) CONFERS TUMOR CELL RESISTANCE TO ANTI-TUMOR IMMUNITY

[1]Chien-Huan Weng*, [1]Linda Hamadene, [2]Shabnam Eghbali, [1]Divya Venkatesh, [1]Sébastien Monette, [1]Levi Mangarin, [1]Fadi Samaan, [1]Cailian Liu, [3]Pamela Holland, [4]Jedd Wolchok, [4]Taha Merghoub. *[1]Memorial Sloan-Kettering Cancer Center, New York, NY, USA; [2]Weill Cornell Medical College, New York, NY, USA; [3]Alpine Immunescience, Seattle, WA, USA; [4]MSKCC and Cornell University, New York, NY, USA*

Background The expression and function of signal-regulatory protein alpha (SIRPα; also known as PTPNS1, SHPS-1, CD172a, and P84) is well characterized in myeloid effector cells (e.g.: monocytes, macrophages, neutrophils, dendritic cells and microglia),[1-3] where it contributes to tissue homeostasis and regulation of erythrocyte, platelet, and hematopoietic stem cells (HSC). In addition, it regulates synaptic pruning during neuronal development.[4-7] Another important feature of SIRPα is that, upon engagement by cluster of differentiation 47 (CD47), a trans-membrane protein ubiquitously expressed on all cells and overexpressed on tumor cells,[4] it activates ITIM and ITSM domains to recruit the SH2-domain-containing protein tyrosine phosphatases SHP-1 and SHP-2, thereby inhibiting phagocytosis of tumor cells by myeloid effector cells.[8, 9] Based on its anti-phagocytic property, CD47 is well recognized as a "don't eat me" signal,[10] together with other anti-phagocytic surface proteins, including programmed cell death ligand 1 (PD-L1),[11] beta2 micro-globulin subunit of the major histocompatibility class I complex (B2M)[12] and CD24.[13] Therapeutic blockade of the CD47 – SIRPα pathway has therefore become a promising strategy to enhance innate immune clearance of tumor cells and subsequent invigoration of anti-tumor immunity.

Methods

Experimental Procedures Our analysis using publicly available datasets published in Human Protein Atlas[14] and the Cancer Cell Line Encyclopedia[15] confirmed that SIRPα is expressed in human melanoma and renal cell carcinoma.[16] To explore the role of tumor SIRPα, we designed gRNAs to CRISPR out the SIRPα region that interacts with CD47. Our study using SIRPα-knockout (hereinafter, SIRPα-KO) B16 melanoma cells show that SIRPα-KO B16 cells proliferate comparably to the control SIRPα-wild type (WT) B16 cells in vitro; however, upon implantation in immune-competent (C57BL/6j; B6) mice, but not immune-deficient (i.e., RAGnull) mice, SIRPα-KO B16 tumors grow significantly slower than the control SIRPα-WT B16 tumors. Intriguingly, SIRPα-KO B16 tumors exhibit significantly more activated infiltrating lymphocytes (e.g., CD8+ T cells and macrophages) than SIRPα-WT B16 tumors as evidenced by flow cytometry analysis, immunohistochemistry (IHC) and our single cell RNA-sequencing (scRNA-seq) data analysis. Analysis of our bulk RNA-seq of unstimulated, cultured SIRPα-WT and SIRPα-KO B16 cells allows us to identify Cxcl10, Ccl5 and several other genes and pathways that potentially contribute to the observed growth inhibition of SIRPα-KO B16 tumors in immune competent mice.

Results Our recent work characterized a novel role of tumor SIRPα in suppressing the anti-tumor adaptive immunity.

Conclusions SIRPα expression on tumor cells confer resistance to anti-tumor immunity.

1149 TARGETING REGULATORY T CELLS WITH CTM033, A NOVEL ANTI-CCR8 ANTIBODY, INHIBITED TUMOR GROWTH

Yuanyuan Yang*, Yuehua Chen, Feifei Cui, Wenqing Jiang, Lei Fang. *Concept To Medicine Biotech Co.,Ltd, Shanghai, China*

Background Regulatory T cells (Tregs) are potent suppressors of immune activation in the periphery and tumor microenvironment and high density of Tregs are associated with poor response to immune oncology (IO) therapies. CCR8 was selectively expressed on tumor infiltrating Tregs across multiple cancer types, but its expression on peripheral Tregs or other proinflammatory effector T cells was negligible. Moreover, CCR8+ Tregs were identified as a highly suppressive cell population within tumors which hampered the efficacy of immunotherapy. Recent studies also showed the CCR8 and its ligand CCL1 potentiated Tregs via an autocrine loop, implying CCL1-CCR8 axis may play a pivotal role in restraining antitumor immunity.

Methods The binding activity and specificity of anti-CCR8 antibody CTM033 was determined by a panel of flow cytometry based assays. Antagonistic activity of CTM033 against CCL1-CCR8 signaling was assessed by β-arrestin, calcium flux and migration assay. Antibody-dependent cell-mediated cytotoxicity (ADCC) function was evaluated by reporter assays and primary cells mediated killing against tumor infiltrating Tregs. The anti-tumor efficacy of CTM033 was evaluated in a MC38 syngeneic mouse model where the murine CCR8 gene was replaced by its human counterpart. Finally, Biacore and ADCC assay was performed to determine the ADCC-enhancing strategies.

Results CTM033 specifically bound to human CCR8 with subnanomolar activity and did not bind to closely related chemokine receptors and other unrelated proteins. CTM033 also potently inhibited CCL1-mediated β-arrestin recruitment, calcium flux, and migration of hCCR8+ cells. Furthermore, to maximize ADCC effect, different strategies were screened to determine the best approach for efficient Treg depletion. In vivo efficacy study suggested CTM033 monotherapy showed significant inhibition of tumor growth with evidence of intratumoral Treg depletion while sparing peripheral Treg subset.

Conclusions CTM033 is a humanized antibody against CCR8 with high affinity. CTM033 efficiently blocked CCL1-CCR8 pathway and induced ADCC function to deplete Tregs in the tumor microenvironment. Targeting CCR8+ Treg by CTM033 showed single agent activity in a preclinical model. Therefore, current data support anti-CCR8 is a promising approach for the cancer treatment that warrants further development.

1150 ATG-101, A TETRAVALENT PD-L1×4–1BB BSAB, DEMONSTRATES POTENT *IN VIVO* ANTI-TUMOR EFFICACY IN ICI-RESISTANT OR REFECTORY MOUSE TUMOR MODELS

[1]Hui Yuwen, [1]Tengteng Li, [1]Yijing Ren, [2]Jay Mei, [2]Bo Shan, [2]Bing Hou*. *[1]Antengene Corporation Limited, Shanghai, China; [2]Antengene Corporation Limited, Shaoxing, China*

Background Immune checkpoint inhibitors (ICIs), has revolutionized the treatment landscape or malignancies. However, many patients present with or develop resistance to them. Tumors with little anti-tumor immune cell infiltration or lack of pre-existing antitumor immune responses are defined as immunologically "cold" tumor. Patients with these tumors have a poor prognosis following PD-(L)1 blocking therapy.[1] On the other hand, malignancies that initially respond well to ICIs may develop acquired drug resistance, in part as a result of a condition known as T cell exhaustion.[2] ATG-101 is a tetravalent PD-L1×4-1BB bispecific antibody (BsAb), which activates 4-1BB signaling upon PD-L1 crosslinking. In this study, we evaluated the potential of ATG-101 in treating ICI-resistant or refectory diseases using mouse syngeneic tumor models.

Methods To assess the efficacy of ATG-101 on exhausted T cells, human T cells were isolated, and the cell exhaustion was induced through consistent strong activation with anti-CD3/CD28 beads for up to 6 days. The in vivo efficacy of ATG-101 was tested in 4-1BB humanized mouse bearing syngeneic B16F10 (Melanoma), EL4 (Lymphoma) or Pan02 (Pancreatic) tumors, all of which have been suggested to be ICI-resistant. To evaluate ATG-101 efficacy in tumors progressing after anti-PD(L)1 treatment, mice bearing MC38 colorectal tumors were treated with anti-PD-L1 initially to achieve tumor growth inhibition, and half of the mice switched to ATG-101 upon disease progression. TIL was analyzed using flow cytometry or multiplex IHC.

Results In the presence of PD-L1 positive cells, ATG-101 enhanced the IL2 and INF-γ production by the terminally exhausted T cells and progenitor exhausted T cells. In Pan02 murine pancreatic model, Aterzolizumab (anti-PD-L1) did not show anti-tumor efficacy at 7.5mg/kg. While ATG-101 at molar-equivalent 10 mg/kg was well tolerated and significantly inhibited tumor growth, with a TGI value of 78.48% (figure 1). ATG-101 also demonstrated significant tumor growth inhibition in EL4 and B16F10 model compared with control. Furthermore, ATG-101 induced growth inhibition or regression in MC38 tumors that had progressed on Atezolizumab, revealing a significant survival advantage over Atezolizumab or the control group. TIL analysis suggested that ATG-101 increases the infiltration, proliferation and activation of CD8+ T cells, the infiltration of natural killer T cells and the CD8+/Treg ratio in TILs (figure 2).

Conclusions ATG-101 activates exhausted T cells upon PD-L1 crosslinking and exhibits effectiveness against ICI-resistant diseases, a significant unmet medical need. A phase I, multicenter, dose-escalating clinical trial evaluating ATG-101 in patients with solid tumors and hematologic malignancies is ongoing.

1151 REVEALING NOVEL THERAPEUTIC INDICATIONS THROUGH PROFILING OF IMMUNE MODULATORY PROPERTIES BY ULILEDLIMAB

Yanni Zhang*, Zhen Sheng, Xinyun Zhu, Yanling Niu, Yuan Meng, Zhengyi Wang, Andrew Zhu. *I-MAB Biopharma, Shanghai, China*

Background The adenosine pathway is associated with immunosuppressive tumor microenvironment, and CD73 is a rate-limiting enzyme for adenosine production. Ulileldlimab is a differentiated CD73 antibody that binds to a unique epitope to achieve complete inhibition of CD73 and its anti-tumor activity is currently being evaluated in clinical studies in combination with checkpoint inhibitors. Here we investigated the immune modulatory mechanism of ulileldlimab in different cell subsets and pathways to explore new therapeutic combinations of ulileldlimab for cancer treatment.

Methods Gene expression of anti-CD3 stimulated human PBMCs in the presence of AMP with or without ulileldlimab was measured using NanoString platform. Association of CD73 and immune signature pathways regulated by ulileldlimab was analyzed in multiple cancer types in TCGA database. In vitro cytolysis by T cells or NK cells or phagocytosis by macrophages in the presence of ulileldlimab alone and in combination with PD-1 antibody were evaluated by co-culture of $CD73^+$ tumor cells and PBMCs or purified macrophages. Anti-tumor activity of ulileldlimab combination was examined subsequently in xenograft tumor models.

Results Expression of cell lineage markers in immuno-suppressive cell subsets was up-regulated in human PBMCs cultured with AMP. Notably, the expression of various co-inhibitory checkpoint receptors was induced in T cells, including PD-L1 and CTLA-4, myeloid cells, including LILRB and SIGLEC1, and NK cells, including KIR and KLRD1. Signature genes involved in the recruitment of immuno-suppressive cells and angiogenesis were also up-regulated. The induction of these genes was inhibited by ulileldlimab. Similar to PD-L1, a panel of angiogenesis signature genes regulated by ulileldlimab were found to positively correlate with CD73 expression in multiple solid tumors ($p<0.05$), and concurrent high expression of CD73 and VEGFA was associated with poor prognosis ($p<0.05$). Ulileldlimab treatment led to increased cytotoxic activity of T cells and NK cells and phagocytic activity of macrophage in tumor killing. When combined with a PD-1 antagonist, ulileldlimab elicited enhanced anti-tumor activity in vitro and in vivo through the regulation of infiltrating immune cells in tumor.

Conclusions Our study has delineated the immune regulatory properties of ulileldlimab as evident by its down-regulation of immuno-suppressive pathways and restored activity of cytolysis and phagocytosis of various effector cells. In addition to the current combination therapy of ulileldlimab with PD-L1 inhibitor, identification of selected pathways regulated by ulileldlimab and their co-expression with CD73 that serves as a negative prognosis factor provides much needed scientific rationale to explore new combination therapies of ulileldlimab in cancers.

1152 IN VITRO ANTICANCER AND IMMUNOMODULATORY ACTIVITIES OF A NOVEL MOLECULAR GLUE COMPOUND NBT-018

[1]Sophia Zhang, [2]Magdalena Dragan, [2]Nicole Potter, [2]Everett Henry, [2]Harris Zhang*. *[1]Mountain Lakes High School, Mountain Lakes, NJ, USA; [2]PicoImmune Co., Whippany, NJ, USA*

Background Targeted protein degradation is a rapidly exploding drug discovery strategy which uses small molecules to recruit disease-causing proteins for rapid destruction via the ubiquitin-proteasome pathway. It shows great potential for treating diseases such as cancer, autoimmune, infectious, inflammatory, and other diseases, especially for those with "undruggable" pathogenic protein targets. Here we report one 'molecular glue' type of protein degrader NBT-018, which binds cereblon (CBRN) and has selective anti-cancer and immunomodulatory activities.

Methods NBT-018 was screened out from our chemical library. Its biological activity was examined using cancer cell survival assays and immunological assays with various types of human cells including various cancer cell lines, PBMCs and enriched immune cells including NK, CD4+ T cells and CD14+ derived macrophages, as well as dg T cells. Luminex-based immunoassay was used to measure cytokine release from immune cells. Automatic western blot was used to quantify degradation of targeted proteins in sensitive cells.

Results NBT-018 selectively Inhibited proliferation of leukemia and myeloma cells such as H292, HL-60, Jurkat cells in *in vitro* experiments (IC50 7.3, 0.12, 1.2 μM respectively); while it had little inhibitory effects on other cancer cells tested including lymphoma, breast cancer, colorectal carcinoma and glioblastoma cells (RIVA, Granta-529, RL, Farage, HCT116, U87, T98G, A172, MCF-7, IC50 > 100 μM). NBT-018 also enhanced production of T cell cytokines (such as IL-2, IFN-g, etc) from anti-CD3/CD28 stimulated normal human PBMC or from mixed culture of allotypic PBMCs. At 100 nM NBT-018 significantly enhanced SLP76 (Ser376) phosphorylation in Jurkat cells stimulated with anti-CD3/CD28 for 15 min; or in the coculture of Jurkat and HCT116 cells in the presence or absence of a bispeci?c T-cell engager. In addition, NBT-018 modulated production of inflammatory cytokines from PBMC stimulated with toll-like receptor agonists including LPS (TLR4), resiquimod (TLR7 and TLR8) and Poly (I:C) (TLR3). Furthermore, NBT-018 enhanced killing activities of human NK and dg T cells against K562 cells. However, NBT-018 had no appreciable effect on phagocytosis of CD14-derived macrophages, THP-1 monocytic cells and immortalized microglial cells (IMG). Finally, NBT-018 was found to bind CRBN and cause the degradation of IKZF1/2/3 in several lines of leukemia cells.

Conclusions Our data showed that NBT-018, a novel 'molecular glue', had anticancer and immunomodulatory activities such as modulation of expression of cytokines in immune cells and induction of cancer cell-killing activities of NK and dg T cells. NBT-018 could be a promising cancer immunotherapeutic agent targeting both cancer cells and immune cells.

1153 PRECLINICAL ACTIVITY OF C-C CHEMOKINE RECEPTOR 2 (CCR2)-TARGETED IMMUNE STIMULATING ANTIBODY CONJUGATE (ISAC), MOTIVATING CLINICAL TESTING OF TAK-500

Vicky Appleman*, Atsushi Matsuda, Michelle Ganno, Angel Maldonado Lopez, Emily Rosentrater, Camilla Christensen, Samantha Merrigan, Hong Myung Lee, Min Young Lee, Linlin Dong, Jian Huang, Natasha Iartchouk, Dong Mei Zhang, Jianing Wang, He Xu, Tomoki Yoneyama, Konstantin Piatkov, Carole Harbison, Adnan Abu-Yousif*. *Takeda Development Center Americas, Inc. (TDCA), Lexington, MA, USA*

Background Increasing evidence suggests that myeloid populations are among the most sensitive to STimulator of InterferoN Genes (STING) agonism and downstream interferon (IFN) production and could augment activity of α-PD-1, radiation, and other therapies. We present preclinical data with a murine surrogate ISAC, mTAK-500, designed to selectively deliver the STING agonist, TAK-676, to CCR2+ cells. This approach enables systemic delivery and is designed to achieve enhanced activity through prolonged exposure and selective targeting of CCR2+ cells.

Methods mTAK-500 was evaluated in preclinical *in vitro* and *in vivo* systems to characterize potency, exposure, mechanism, and antitumor activity alone and in combination with radiation or α-PD-1 treatment.

Results CCR2-mediated delivery of TAK-676 triggered dose-dependent activation of the STING signaling pathway and STING induced gene expression, as well as robust activation of innate and adaptive immune activity both *in vitro* and *in vivo*. Following systemic administration of mTAK-500 in preclinical studies, plasma exposure of total antibody and conjugated TAK-676 was observed beyond 24 hours. Characterization of exposure in the tumor revealed that systemic administration resulted in accumulation of mTAK-500 and liberation of TAK-676 in the tumor microenvironment (TME), however, TAK-676 was below limit of detection in plasma. Collectively, these observations demonstrate that CCR2-targeted delivery of TAK-676 prolongs exposure in the TME. In syngeneic mouse models, a transient decrease in peripheral monocytes along with dose-dependent activation of dendritic cells in the TME, lymph node, and periphery was observed. Further, mTAK-500 treatment caused increases in frequency, proliferation, and activation of peripheral CD8 T cells, ultimately resulting in accumulation and activation of CD8 T cells in the TME resulting in antitumor activity. The combination of 8 Gy radiation and mTAK-500 also resulted in increased frequency of CD8 tetramer specific T cells accompanied by an increase in antitumor activity observed in CT26 tumor bearing mice. In MC38 tumor bearing mice, treatment with a single dose of mTAK-500 treatment alone achieved strong antitumor activity, including a durable complete response (CR). Single agent α-PD-1 treatment also resulted in a 12.5% CR rate, however, when combined, mTAK-500 and α-PD-1 treatment achieved enhanced anti-tumor response with a 37.5% CR rate.

Conclusions Nonclinical antitumor activity and mechanistic insight have motivated design and clinical testing of TAK-500, a CCR2-targeted STING ISAC comprising the clinical stage STING agonist TAK-676 and a high-affinity antibody targeting human CCR2, as a single agent and in combination with pembrolizumab in adults with select locally advanced or metastatic solid tumors (NCT05070247).

1154 HIGH-POTENCY SYNTHETIC STING AGONISTS REWIRE MYELOID SUBSETS IN THE TUMOUR MICROENVIRONMENT TO DISMANTLE IMMUNOSUPPRESSIVE STROMA IN REFRACTORY PANCREATIC DUCTAL ADENOCARCINOMA

[1]Akash Boda*, [2]Casey Ager, [3]Kimal Rajapakshe, [1]Krithikaa Rajkumar Bhanu, [1]Spencer Lea, [1]Michael Curran. *[1]UT MD Anderson Cancer Center, Houston, TX, USA; [2]Columbia University, New York, NY, USA; [3]Baylor College of Medicine, Houston, TX, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) is clinically unresponsive to immune checkpoint blockade (ICB) immunotherapy.[1,2] Dense immunosuppressive myeloid stroma (MS) and consequent T cell exclusion from the tumour microenvironment renders PDAC resistant to immune-based therapies[3–7] Innate immune activation of the MS via cyclic dinucleotide (CDN) agonists of the STING (Stimulator of Interferon Genes) pathway can trigger T cell infiltration into cold tumours leading to robust anti-tumour immunity.[8–11] Despite proven therapeutic efficacy in preclinical models, the cellular and molecular mechanisms of how CDNs reprogram the suppressive MS to sensitise tumours to ICB is poorly understood.

Methods Using flow cytometry, multi-omic profiling followed by pathway analyses of MDSCs and M2 Macrophages of human and murine origin, we compared the ability of synthetic STING agonist, IACS-8803, with natural CDN, 2'3'-cGAMP to rewire these populations from immunosuppressive to immune-permissive phenotypes. To that end we investigated targets and pathways associated with c-Myc signaling, energy metabolism, and cell cycle. Furthermore, we describe the effects of IACS-8803 on apoptosis and Myc-dependent cell proliferation in these cells. We utilised Seahorse assays and CYTO-ID autophagy assays to characterise the metabolic reprogramming of myeloid cells upon treatment with IACS-8803 and CDN agonists.

Results Flow cytometry, RNA-Seq and protein array data on MDSCs and M2 Macrophages of human and murine origin show that IACS-8803 rewire these populations from immunosuppressive to immune-permissive phenotypes in part through inhibition of c-Myc signaling, energy metabolic modulation, and antagonism of cell cycle. IACS-8803 but not 2'3' cGAMP significantly reduces c-Myc gene expression in M2c macrophages and MDSCs. Further, these cells undergo reduced proliferation and enhanced apoptosis in response to IACS-8803 treatment. Metabolically, IACS-8803 rewires M2 Macrophages and MDSCs to a hypometabolic state marked by diminished ATP levels. Seahorse MitoStress analyses on these cells further showed reduced OCR and Spare Respiratory Capacity. Concomitantly, we observe elevated autophagic induction in the MS following IACS-8803 treatment, likely as a salvage pathway to maintain energy and survival.

Conclusions This study uncovers molecular and cellular mechanisms by which STING agonists drive proinflammatory conversion of tumour myeloid stroma. We are the first to report that synthetic CDN STING agonists affect MDSC and M2 macrophage repolarization through downregulation of c-Myc signalling and alterations in energy metabolism. Thus, high potency synthetic STING agonists remodels the MS in an aggressive orthotopic tumour model of PDAC through proinflammatory repolarization of myeloid cells, limiting their proliferation in the TME and forcing them into a hypometabolic state.

1155 ONM-501, A POLYVALENT STING AGONIST, EXHIBITS ANTI-TUMOR EFFICACY WITH INCREASED TUMOR T-CELL INFILTRATION IN MICE AND IS WELL TOLERATED IN RATS AND NON-HUMAN PRIMATES

[1]Zirong Chen*, [1]Jason Miller, [2]Wei Li, [2]Katy Torres, [1]Qingtai Su, [2]Gang Huang, [1]Yasser Saud O Albaroodi, [1]Rachel Morsch, [1]Teresa McElvaney, [1]Fiona Stavros, [1]Don Kruppa, [1]Tian Zhao, [2]Jinming Gao, [1]Ruolan Han, [1]Zirong Chen. *[1]Onconano Medicine, Southlake, TX, USA; [2]University of Texas Southwestern Medical, Dallas, TX, USA*

Background The **St**imulator of **In**terferon **G**enes (STING) plays a crucial role in the innate immune response.[1] Several small molecule STING agonists have demonstrated effectiveness against cancer in preclinical models. In clinical trials, however, they showed limited therapeutic efficacy. We developed ONM-501, a dual-activating STING agonist that employs PC7A, a synthetic polymer that induces polyvalent STING condensation and prolongs innate immune activation.[2,3] ONM-501 encapsulates the endogenous STING agonist 2',3'-cGAMP with the PC7A micelles offering dual 'burst' and 'sustained' STING activation. The mechanism and effectiveness of ONM-501 as an immunotherapy against solid tumors has been demonstrated in multiple preclinical models.[3,4] Here we report in vivo efficacy and pharmacodynamic (PD) analysis of ONM-501 as a monotherapy and in combination with anti-PD1 in multiple murine tumor models and the safety evaluation in rats and primates.

Methods Anti-tumor efficacy of ONM-501 was evaluated by tumor growth inhibition and survival in tumor-bearing mice as a monotherapy or combined with anti-PD1. Immune activation and tumor microenvironment changes were evaluated by FACS analysis in tumors and draining lymph nodes and cytokine analysis in peripheral blood. STING activation was evaluated by expression of IFNB1, IRF7 and CXCL10 in tumors and draining lymph nodes using qPCR. Safety and tolerability were evaluated in rats and primates by single- and multiple-dose subcutaneous injections in naïve animals up to the highest feasible dose.

Results ONM-501 demonstrated broad anti-tumor efficacy both as monotherapy and combined with anti-PD1 in multiple models including A20, CT26, MC38 and B16F10. FACS analysis showed significantly increased tumor-infiltrating T-cells after ONM-501 mono- and combo- therapies in the B16F10 tumors. ONM-501 upregulated PD-L1 expression in tumor tissue. STING activation was confirmed by the increased IRF7 and CXCL10 mRNA levels in tumor and draining lymph nodes after monotherapy and anti-PD-1 combination. In the single- and multiple-dose toxicology studies, Sprague-Dawley rats and cynomolgus monkeys were well tolerated without severe or irreversible systemic toxicities up to the maximum feasible dose (30mg/kg). Dose-dependent increases in lymphocytes and cytokines, consistent with STING activation, were also observed.

Conclusions ONM-501 demonstrated marked anti-tumor efficacy as a monotherapy and in combination with anti-PD1 in murine syngeneic tumor models. The in vivo PD analysis confirmed STING activation, enhanced tumor T-cell infiltration and PD-L1 upregulation by ONM-501. Toxicology studies in rats and primates demonstrated a strong safety profile and large therapeutic window. The novel dual STING agonist ONM-501 is a promising therapeutic candidate for clinical evaluation in solid tumors.

1156 STING ACTIVATION IN SARCOMA: ASSESSING TRANSLATIONAL THERAPEUTIC STRATEGIES

Karys Hildebrand*, Kurt Hildebrand, Kayla Marritt, Carolina Salazar Arcila, Michael Monument. *University of Calgary, Calgary, Canada*

Background Undifferentiated pleomorphic sarcoma (UPS) is a highly aggressive and metastatic soft tissue sarcoma that is resistant to most conventional systemic therapies and immunotherapies.[1–5] Activation of the STimulator of INterferon Genes (STING) pathway is an emerging immunotherapeutic strategy that can be used to recruit effector lymphocytes into the TME to induce tumour eradication.[6–9] In a murine model of UPS, we have demonstrated that intra-tumoural (i.t.) administrations of a murine-specific STING agonist, DMXAA, results in profound immune mediated tumour clearance.[10] The objective of this study is to evaluate the anti-tumour potential of three STING agonists that can activate both murine and human STING receptors as monotherapies and in combination with immune checkpoint blockade (ICB) therapy in a murine model of UPS to assess translational feasibility.

Methods Immune competent mice were orthotopically engrafted with a syngeneic murine UPS cell line in the hindlimb muscle. UPS bearing mice in the monotherapy groups were treated with a single i.t. dose of 1) CDN, 2) MSA-2, 3) E7766 or 4) DMXAA. Mice treated in combination with ICB therapy received monoclonal anti-PD1 in addition to a single dose of CDN, MSA-2, or DMXAA. Tumour volume measurements and bioluminescence were measured over time. Surviving mice were re-challenged with UPS in the contralateral limb. Flow cytometry and transcriptomics were completed 24hrs, 72hrs, and 1-week after STING monotherapy treatment.

Results Unlike DMXAA, monotherapy with CDN or MSA-2 failed to eradicate UPS tumours. Survival studies with E7766 have shown UPS clearance in 18-40% of E7766 treated mice. 100% of the surviving E7766 and DMXAA treated mice completely rejected the re-challenge inoculation of UPS cells. Immune profiling of CDN, MSA-2, and DMXAA treated tumours at multiple timepoints post-treatment showed similar inflammatory changes and increased lymphocytic infiltration. STING+ICB therapy significantly improved survival outcomes in CDN+ICB treated tumours, as 14% of CDN+ICB treated mice eradicated their UPS tumours. In DMXAA monotherapy and DMXAA+ICB combination therapy, there were no significant differences in survival. Unfortunately, there were no survivors in the MSA-2+ICB group, but survival was significantly extended compared to MSA-2 monotherapy.

Conclusions STING activation is a promising immunotherapeutic strategy for UPS. We have demonstrated that the human and murine compatible STING agonist, E7766, can be used to elicit immune mediated UPS clearance and adaptive immune protection against UPS re-challenge. Ultimately, this study demonstrates the potential opportunity for clinical translation of STING as an immunotherapy for UPS which could significantly improve outcomes for this patient demographic.

1157 DISCOVERY OF A NOVEL, POTENT SMALL MOLECULE INHIBITORS OF ENPP1 ENHANCES ANTI-TUMOR EFFICACY IN COMBINATION WITH IMMUNE CHECK INHBITORS

Juhyeon Kim, Pyoung Oh Yoon, A-Ram Lee, Eunji Son, Young Cheol Lee, Eunmi Jung, HyoungRae Kim, YeonHee Lee, SoEun Park, Dae-Yon Lee, Chul-Woong Chung, Pyoung Oh Yoon*. *LegochembiScience, Daejeon, Korea, Republic of*

Background The cGAS-STING (**c**yclic **G**MP-**A**MP **s**ynthase-**s**timulator of **in**terferon **g**enes) signaling pathway has led to significant innate immune responses in cancer immunotherapy. 2'3'-cGAMP, the second messenger in the cGAS-STING signaling pathway, binds to STING and promotes the production of various pro-inflammatory cytokines such as type I interferon (IFN). Therefore, activated STING pathway has been considered an important target for cancer immunotherapy. however, STING agonists excessively activate the STING pathway, causing side effect due to hyper-accumulation of cytokines. Here we show that targeting ENPP1 is emerging as a promising target of STING regulation in immunotherapy, because it indirectly activates the STING pathway. Ecto-nucleotide pyrophosphatase/phosphodiesterases 1 (ENPP1), highly expressed membrane-bound enzyme in cancer cells, modulates cGAMP levels by hydrolyzing 2',3'-cGAMP to alter the inflammatory mileu. In this study, we present our potent ENPP1 inhibitors, which show highly improved enzymatic activities, immune cell related immune responses in vitro and CT-26 syngeneic mouse model.

Methods We discovered potent ENPP1 inhibitors with highly potent activities in various cell-based assay systems. The in vivo antitumor efficacy was assessed as monotherapy and in combination with Anti-PD-L1 (immune checkpoint inhibitor) by monitoring tumor growth for 15 days, in a CT-26 syngeneic mouse model.

Results Our two candidates showed excellent inhibitory activity of nanomolar level in a non-cell-based in vitro ENPP1 inhibition assay using pNP-TMP (artificial substrate) and cGAMP as substrates, respectively. In vitro THP-1 dual reporter assay demonstrated the potency and efficacy of the compounds that induce STING-mediated type I IFN release. In addition, one of the two candidates exhibited good PDE and kinase panel selectivity as well as good in vivo pharmacokinetic properties.

Finally, both candidates exhibited good anticancer efficacy in the CT-26 colorectal cancer syngeneic mouse model. IV administration of one candidate at 25 mg/kg demonstrated a TGI of 53% as monotherapy and a TGI of 81% in combination with anti-PD-L1 treatment. In contrast, another candidate, when administered orally at 25 mg/kg, provided a TGI of 39% as monotherapy and a TGI of 86% in combination with anti-PD-L1 antibody treatment. Therefore, our candidates demonstrated a much better efficacy profile in combination with Anti-PD-L1 antibody.

Conclusions Taken together, our study demonstrates that a novel and potent small molecule inhibitor that inhibits extracellular ENPP1 has been designed. Our candidates with desirable drug properties, were evaluated for activity in the syngeneic mouse tumor model CT-26. As a result, these candidates were well tolerated and demonstrated significant antitumor activity when combined with anti-PD-L1 antibody.

1158 HIGH POTENCY STING AGONISTS INDUCE ADAPTIVE-IMMUNITY DEPENDENT CURATIVE RESPONSES IN CHECKPOINT-REFRACTORY GLIOBLASTOMA MODELS

Spencer Lea*, Michael Curran, Chao-Hsien Chen. *University of Texas MD Anderson Cancer Center, Houston, TX, USA*

Background Glioblastoma (GBM) is the most common and aggressive adult primary brain malignancy, with a median overall survival of 15 months post-diagnosis. Clinically, GBM is refractory to T cell immune checkpoint blockade (ICB), which may be attributable to its immunosuppressive tumor microenvironment enriched in glioma-associated myeloid cells (GAM) and lacking in effector T cells.[1,2] This phenotype is reflected in the Qki$^{-/-}$ Pten$^{-/-}$ P53$^{-/-}$ (QPP8) tumor model,[3] which we show is ICB-refractory but sensitive to agonists of the Stimulator of Interferon Genes (STING) innate immune sensing pathway. While we have shown that STING agonists potently repolarize *in vitro* generated suppressive myeloid cells towards more T cell supportive phenotypes,[4,5] their function in the context of the GBM myeloid compartment remains poorly understood.

Methods Using the synthetic cyclic di-nucleotide STING agonist IACS-8803 we treated orthotopic QPP8 tumors intratumorally. We then analyzed survival and performed high parameter flow cytometry profiling of the tumor immune microenvironment following STING agonist treatment. To assess the contribution of adaptive immunity to STING agonist therapeutic efficacy, we treated orthotopic QPP8 tumors implanted in RAG1 KO mice and monitored survival.

Results We found that STING agonist therapy cured murine orthotopic QPP8 tumors, in contrast to ICB that showed no survival benefit. In RAG1$^{-/-}$ mice bearing QPP8 tumors STING agonist therapy extended survival, however, the curative effect observed in wild-type mice was lost in the absence of adaptive immunity. STING agonist-treated QPP8 tumors displayed increased counts of CD8 T cells and NK cells, and decreased CD8 T cell PD1 expression. Infiltration of STING-treated gliomas by Ly6C+ F4/80+ Mono-MDSC substantially increased; however, these cells expressed reduced CD206 and CD163 and increased CD86, suggestive of a more proinflammatory state. Finally, in the cervical lymph node of QPP8-treated mice the frequency and CD86 expression of cDC1 cells increased.

Conclusions We found that STING agonists induce adaptive immunity-dependent curative responses in ICB-refractory murine QPP8 GBM tumors. Increased frequencies of cDC1 dendritic cells in the draining lymph node, as well as augmented CD8 T cell densities within treated tumors likely help drive regression of these established gliomas. While STING agonist therapy also increased the frequency of cells classically defined as monocytic MDSC, their suppressive capacity may have been reduced, similar to previous publications on expanded Ly6C+ F4/80+ populations in other STING-treated tumors.[6] Together these results indicate that STING activation induces proinflammatory repolarization of the murine GBM myeloid stroma that drives rejection of established, ICB-refractory tumors.

1159 USE OF SMALL MOLECULE STING AGONIST IMMUNOTHERAPY FOR CANINE SOFT TISSUE SARCOMA: A CROSS-SPECIES ANALYSIS

[1]Ye-Jean Park*, [2]Joseph Kendal, [1]Carolina Salazar Arcila, [1]Karys Hildebrand, [1]Max Labrecque, [1]Michael Monument. *[1]University of Calgary, Calgary, Canada*; *[2]University of California Los Angeles, Los Angeles, CA, USA*

Background Soft tissue sarcomas are rare connective tissue malignancies that are highly resistant to traditional systemic therapies.[1] Sarcomas are relatively common in dogs, yet few studies have previously investigated anti-sarcoma immunotherapies in this species.[2,3] In this study, we sought to investigate several small molecule STING (STimulator of INterferon Genes) agonists' dose toxicities and pathway inductions via canonical cytokine responses in canine macrophage and sarcoma lines, as compared to murine and human macrophage and sarcoma lines. We further aimed to assess the efficacy of a selected small molecule STING agonist without species specificity (ADU-S100) as an intra-tumourally administered drug in two canine patients with soft tissue sarcoma.

Methods To assess the cytotoxicity of STING agonists DMXAA, ADU-S100, and MSA-2, an in-vitro MTT cell viability assay was used. Murine, canine, and human macrophages and sarcoma cells were exposed to the following conditions: media, vehicle control, or 0.1, 1, 10, and 100μg/mL of treatment (up to 200μg/mL of treatment for ADU-S100). 6, 12, and 24-hours post-exposure to the conditions, cell viability was assessed via formazan absorbance values. STING-pathway induced interferon-dependent cytokine production (IFN-β, TNF-?, CXCL-10) in cells was assessed via the Luminex cytokine assay. All cells were treated with 177nmol/L of the STING agonists, and cytokine release 2- and 6-hours post-exposure were quantified. Clinical efficacy of ADU-S100 was further evaluated in vivo for two canine STS patients (1 hindlimb, 1 forelimb). Serial intra-tumoural doses further ranged from 200μg to 2.0mg of ADU-S100. Tumour volumes were calculated from caliper measurements of tumour length, width, and depth.

Results DMXAA and ADU-S100 were not cytotoxic below 100 and 200μg/mL, respectively, and MSA-2 was cytotoxic above 10μg/mL. All STING agonists effectively stimulated the interferon-dependent STING pathway in murine macrophage cells. In addition, ADU-S100, MSA-2, and E7766 stimulated the canine and human interferon-dependent STING pathways. Our subsequent in vivo pilot study demonstrated that the intra-tumoural administration of ADU-S100 led to a 3.5-fold and 2.3-fold reduction of canine patients' tumour volumes over the course of 6-weeks, respectively (from 594cm^3 to 172cm^3 for patient 1, and from 420cm^3 to 180cm^3 for patient 2).

Conclusions Overall, our findings suggest that STING agonists – in particular, ADU-S100 – possess potential as a novel and effective therapeutic approach for canine STS. As sarcomas are highly metastatic and commonly fatal in dogs, further evaluating STING agonist therapy in canines may provide therapeutic insights into similar challenges for treating human disease using a comparative biology approach.

1160 STING SIGNALING COMPENSATES FOR MUTATION BURDEN-LOW TUMORS TO STIMULATE THE IMMUNE RESPONSE

Jiayi Tan*, Colt Egelston, Weihua Guo, Peter Lee. *City of Hope, Duarte, CA, USA*

Background Tumor mutation burden (TMB) is known to predict the immune response, especially tumor-infiltrating lymphocytes (TILs) in various tumor types. Besides, it's also one of the most well-accepted biomarkers to select responsive patients for immunotherapy. However, increasing evidence indicates the complex association between TMB and immune infiltration, and the overall response rate to immunotherapy selected based on TMB in clinical trials was not satisfied.

Methods Bulk RNA-seq and somatic mutation datasets from The Cancer Genome Atlas (TCGA) of 10 major cancer types were downloaded to investigate the role of TMB and other derterminants in immune response. Unsupervised patient clustering analysis with UMAP using major immune components and TMB was performed to further identify different types of tumor microenvironment (TME).

Results Mutatoin burden was found poorly correlated with active immune response in various cancer types. The unsupervised clustering analysis revealed the tumor group with low mutation burden but inflamed TME as well as the group with high mutation burden but poor immune response. Notably, the stimulator of interferon genes (STING) signaling was upregulated in that low TMB group to enhance the immune response. In contrast, the tumors harboring high mutation burden with robust proliferation and DNA damage repair machinery failed to stimulate STING signaling leading to poor immune acitvation, which may result from minimal cell death and apoptosis to release tumor DNA.

Conclusions This study demonstrates the non-linear relationship between TMB and inflamed TME. High mutation burden in tumors is not always necessary for the active immune response which instead may lead to non-inflamed TME. Moreover, this study emphasizes the initial step of tumor apoptosis to stimulate either antigen-presenting cells (APCs) to uptake tumor antigens or STING signaling for further immune activation. Together these data suggest the application of STING agonist in high mutation burden tumors with non-inflamed TME to interrupt the aggressive replication cycle and enhance the immune response.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1160

1161 SYNTHETIC CD206 TARGETED CONSTRUCTS CARRYING PACLETAXEL OR NOVEL BISPHOSPHONATE PAYLOADS ALTER MACROPHAGES TOWARDS PRO-INFLAMMATORY PHENOTYPES; THE PACLITAXEL CONSTRUCT IMPROVES THE EFFICACY OF ANTI-CTLA4 IN CT26 TUMORS

David Ralph*, Jeffrey Arnold, Michael Rosol. *Navidea Biopharmaceuticals, Dublin, OH, USA*

Background Tumor associated macrophages (TAMs) promote an immunosuppressive and protumor immune microenvironment reducing the efficacies of cancer immunotherapies. Altering TAM phenotypes from immunosuppressive to proinflammatory should stimulate TAMs directly and lymphocytes indirectly to attack cancer cells and potentially increase the efficacies of check point inhibitor therapies, like anti-CTLA4. Mannosylated Amine Dextrans (MADs) are synthetic ligands for CD206 that can carry small molecule payloads on degradable linkers to CD206 expressing cells, i.e. TAMs. Three MAD constructs were made carrying payloads of paclitaxel or one of two novel bisphosphonates and were evaluated in human GM-CSF macrophages for their abilities to durably alter macrophage phenotypes towards pro-inflammatory. The paclitaxel MAD was tested in the CT26 tumor model with or without anti-CTLA4.

Methods >Human monocytes from 3 donors were differentiated to CD206+ macrophages in GM-CSF supplemented RPMI1640 with 10% FBS (fresh medium) for 5 days.

>Medium was replaced with fresh media with varying concentrations of MAD + drug constructs or molar equivalents of free drugs or zoledronate and incubated for 24 hours.

>Saline or MAD without payload were controls.

>Drug containing media were replaced with fresh medium and incubated for 3 days (for durable responses)

>Cells were assessed by flow cytometry (MFI) for viability, CD206, CD163, CD80, CD86, MHC1, MHC2, SIRPalpha, and PD1.

>CT26 tumors implanted in Balb/c mice, treatment began when tumors were 100mm2.

>Mice treated with MAN-Paclitaxel (127 micrograms/dose), free paclitaxel, saline, or MAD no payload twice/week for 5 doses. Tumor volumes measured with calipers were the output.

Results Cell/FlowAssays

>None of the constructs reduced macrophage viability significantly.

>All three MAD-Drug constructs reduced expression of CD206 and CD163 (immunosuppression markers) and increased expression of CD80 and CD86 (pro-inflammatory markers).

>PD1 expression increased.

>MHC1 and MHC2 expression was not significantly changed.

>Both MAD-bisphosphonates – but not free drugs or MAD-paclitaxel – significantly reduced expression of SIRPalpha ($p<.0001$).

CT26 Studies

>MAD-Paclitaxel and free paclitaxel were equally effective at tumor growth reduction.

>MAD-Paclitaxel plus anti-CTLA4 reduced tumor growth by 76%. Anti-CTLA4 alone by 52%.

Conclusions > All 3 MAD-drug constructs shifted macrophage phenotypes towards pro-inflammatory and more effectively the free drugs.

> Both MAD-Bisphosphonated constructs significantly reduced expression of SIRPalpha (checkpoint)

>MAD-paclitaxel and free paclitaxel increased the efficacy of anti-CTLA4, but

>CD206 targeted delivery can avoid off target toxicities of paclitaxel.

Shifting TAM phenotypes towards a pro-inflammatory state in a targeted fashion has the potential to increase the efficacies of other immunotherapies to reduce tumor burdens.

Acknowledgements Macrophage cell culture assays were performed at Discovery Life Sciences (Huntsville, AL). CT26/Balb/c studies were performed by Charles River Laboratories (North Carolina).

Ethics Approval All studies performed at Charles River Laboratories were reviewed and approved by an institutional IACUC committee.

1162 A NECTIN-4 TARGETED TLR9 AGONIST ANTIBODY CONJUGATE INDUCES ROBUST IMMUNE CELL ACTIVATION AND ANTI-TUMOR RESPONSES

Amy Chen*, Min Li, Maja Bonacorsi, Emma Sangalang, Danielle Fontaine, Ons Harrabi, Mingrui An, Tiffany Chou, Laura Doyle, Janet Sim, Bora Han, Hong Wan, Tracy Kuo, Maria Jose Costa, Pavel Strop. *Tallac Therapeutics Inc, Burlingame, CA, USA*

Background Novel therapies that engage both innate and adaptive immune responses may engender durable anti-tumor immunity. Activation of Toll-Like Receptor 9 (TLR9) by unmethylated CpG oligonucleotides promotes innate inflammatory responses and the induction of adaptive immunity. Several CpG-based TLR9 agonists have demonstrated clinical activity in melanoma by inducing a pro-inflammatory tumor microenvironment (TME), when administered intratumorally.[1] However, intratumoral delivery has various development challenges that need to be addressed, including limited tumor indications, injection site variability and poor pharmacokinetics. A systemically delivered TLR9 agonist with favorable safety profile has potential to provide innate and adaptive anti-tumor immunity across multiple tumor types. We developed a Toll-like Receptor Agonist Antibody Conjugate (TRAAC) comprised of a CpG oligodeoxynucleotide conjugated to a novel Nectin-4-targeting antibody for systemic administration and TME delivery of a potent TLR9 agonist. Nectin-4 is a cancer associated antigen over-expressed in many solid tumor types with limited expression in normal tissues. Additionally, Nectin-4 overexpression correlates with poor prognosis.[2] Activation of myeloid cells via TLR9 signaling within the TME may promote pro-inflammatory signals countering immunosuppressive pathways, thereby resulting in initiation and enhancement of anti-tumor responses.[3] Here we present preclinical data demonstrating that Nectin-4 TRAAC triggers TLR9 signaling, induces myeloid and dendritic cell activation, phagocytosis, cytokine production and lymphocyte activation, resulting in potent anti-tumor efficacy.

Methods *In vitro* activity of Nectin-4 TRAAC was evaluated using human peripheral blood mononuclear cells (PBMCs) co-cultured in presence of Nectin-4 expressing cancer cells. The anti-tumor efficacy of Nectin-4 TRAAC as a monotherapy was evaluated using syngeneic models.

Results Nectin-4 TRAAC induced both innate and adaptive anti-tumor immune mechanisms in human PBMC co-cultured with Nectin-4-expressing cancer cell lines. Nectin-4 TRAAC potently activated myeloid cells, leading to enhanced phagocytosis, increased expression of co-stimulatory molecules, secretion of pro-inflammatory cytokines and B, T and NK cell activation. In both immunogenic and checkpoint inhibitor (CPI) refractory syngeneic tumor models, single agent Nectin-4 TRAAC treatment led to durable tumor regression and eradication across a range of Nectin-4 expression levels. Animals in which Nectin-4 TRAAC treatment led to tumor clearance were protected from tumor growth upon rechallenge, demonstrating that Nectin-4 TRAAC induces potent anti-tumor immunological memory.

Conclusions The preclinical data shown here provide a strong rationale for pursuing Nectin-4 TRAAC for the treatment of Nectin-4-expressing solid tumors, including those that are refractory to CPI therapy.

1163 A UNIQUE DENDRITIC CELL ACTIVATION STATE UTILIZES INFLAMMASOMES TO STIMULATE MEMORY T CELL RESPONSES IN HUMANS

Jon Chow*, Veronica Komoroski, Emily Gosselin, Andrew Cornforth. *Corner Therapeutics, Watertown, MA, USA*

Background Dendritic cells (DCs) represent the primary drivers of new T cell responses that defend against cancer and infection. In order to execute this task, DCs must be stimulated in a manner that induces several T cell stimulatory activities. These activities include the ability of DCs to 1) present tumor or microbial antigens, 2) express T cell co-stimulatory molecules, 3) express cytokines that induce effector T cell differentiation, 4) migrate in high numbers to lymph nodes and 5) produce the memory T cell inducing cytokine IL-1β. Diverse approaches have been undertaken to stimulate these DC activities in a clinical or pre-clinical setting, with common strategies targeting Toll-like Receptors, STING or inflammasomes. These approaches are based on the general concept—permeating the literature for over 30 years—that infection-like signals are sufficient to stimulate DC-mediated instruction of adaptive immunity. However, the therapeutic success of these strategies remains elusive.

Methods Herein, we demonstrate that the aforementioned approaches are unable to elicit all 5 of the aforementioned activities in human DCs. This observation may explain the ineffectiveness of these approaches in generating protective immunity to cancer. We report a distinct means of stimulating DCs, using molecular signals that mimic infection and tissue injury, that elicit all DC activities needed to stimulate adaptive immunity. We devised proprietary chemical mimics of infection and tissue injury that induce a new DC activation state termed hyperactive.

Results Primary human DCs that have been stimulated with hyperactivators far exceed the capacity of other DCs to stimulate Th1-biased memory T cell activities, by a process dependent on inflammasomes and the cytokine IL-1β.

Conclusions These studies reveal a unique DC activation state, and chemical agonists that elicit this state, as key determinants of T cell mediated immunity. DC hyperactivating chemicals represent a means to expand the opportunities in immunotherapy, and may enable durable T cell immunity to be elicited in a clinical setting.

1164 SYSTEMIC ADMINISTRATION OF AXA-042, A NOVEL TLR2/6 AGONIST, RESHAPES THE TUMOR MICROENVIRONMENT, AS REVEALED BY SINGLE CELL SEQUENCING ANALYSIS

[1]Bedrich Eckhardt, [1]Kellie Mouchemore, [1]Yang Liao, [1]Wei Shi, [2]Francesca Mercuri, [3]Phil Kearney, [1]Robin Anderson, [3]Anna Galkin*. *[1]Olivia Newton-John Cancer Research Institute, Heidelberg, Australia*; *[2]ENA Respiratory, Melbourne, Australia*; *[3]Axelia Oncology, Melbourne, Australia*

Background Treatment approaches that engage both the innate and adaptive immune response have the potential to transform anti-cancer therapy, especially in settings of checkpoint inhibitor insensitivity. Toll-like receptors (TLRs) mediate the initial cellular response to external pathogens or endogenous alarmins, activating downstream pro-inflammatory cascades associated with innate cell activation and recruitment. AXA-042 is a novel synthetic TLR2/6 agonist designed for systemic delivery to re-engage the innate immune response to help overcome tumor immune escape. Once-a-week treatment with AXA-042 led to 87% growth inhibition of syngeneic EMT6 tumors. Single cell sequencing analysis was completed to characterize the immediate impact of systemic TLR2/6 activation on the tumor microenvironment.

Methods Female Balb/c mice bearing orthotopic EMT6.5 mammary tumors received a single intravenous treatment of saline or AXA-042 (10 μg/mouse). Equal numbers of viable cells were recovered by flow cytometry from collagenase-digested tumors (n=3/group) 24 hours after treatment and pooled prior to loading onto a Chromium Single Cell Chip. 10x Genomics single-cell transcriptome libraries were prepared from each sample and sequenced with Illumina NextSeq 550 sequencing platform. Cell type annotation based on the ImmGen database was determined using the SingleR package. Differential gene expression analyses were completed to identify AXA-042 responsive gene signatures in cell subsets that included at least 10 cells. The identified genes were required to be expressed in at least 3 cells.

Results AXA-042 treatment decreased the total number of tumor-associated macrophages, monocytes, fibroblasts, endothelial, epithelial and stromal cells within 24 hours of treatment. A parallel increase in neutrophils, B cells, NKT and activated CD4 and CD8 T cells was observed. Re-clustering of myeloid populations revealed AXA-042-induced shifts in the macrophage, monocyte and neutrophil clusters. Differential expression analysis within the TLR2 positive myeloid cells demonstrated AXA-042-mediated engagement of pathways associated with antigen processing and presentation, Fc receptor signaling and immune hypersensitivity in monocytes; granulocyte chemotaxis, lipid metabolism and iron sequestration in neutrophils; and cellular response to bacterial lipopeptide, stress response to metal ions and arginine metabolism in macrophages

Conclusions Systemic AXA-042 treatment led to a reorganization of the tumor microenvironment within 24 hours of treatment. AXA-042 altered the myeloid cell subset profiles, promoted the influx of activated T cells and reduced tumor cell viability. AXA-042 has completed GLP toxicology studies and is currently undergoing evaluation in a Phase 1 clinical trial (ACTRN12622000993796) in advanced solid tumors.

Trial Registration ACTRN12622000993796

Ethics Approval The study was approved by the Austin Health Animal Ethics Committee, approval number 05640.

1165 IMPACT OF SD-101, A TOLL-LIKE RECEPTOR 9 CLASS C (TLR9C), AGONIST ON MYELOID DERIVED SUPPRESSOR CELLS

Chandra Ghosh*, Steven Katz, Chandra Ghosh. *Trisalus Life Sciences, Westminster, CO, USA*

Background Specific immunosuppressive pathways, including unique programming of myeloid derived suppressor cells (MDSC), may limit the success of immunotherapy in the liver. SD-101, a TLR9C agonist delivered via intravascular Pressure Enabled Drug Delivery^{TM} (PEDD^{TM}), is currently under study in combination with systemic checkpoint inhibition across multiple intrahepatic tumor indications (NCT04935229, NCT05220722). There are multiple classes of TLR9 agonists, with differential effects on plasmacytoid DC (pDC) IFNα production, B and NK cell activation, and other immune cell populations. TLR9C agonists have relatively broad immunologic effects, but the impact on MDSC is less clear. We investigated the impact on myeloid cells by various TLR agonists (TLR4, TLR7, TLR9B and TLR9C) to expand our understanding of their differential effects on MDSC and potential to immunomodulate liver tumor microenvironments (TME)

Methods Peripheral Blood Mononuclear Cells (PBMCs) obtained from healthy donors were cultured in IL6+GMCSF (20ng/ml) to induce MDSCs and treated with various TLR agonists. Flow cytometry was performed to evaluate MDSCs ($CD33^+CD11b^+HLADR^-$), subtypes of MDSCs (monocytic/granulocytic $CD14^+/CD15^+$MDSCs), M1 macrophages ($CD14^+CD86^+$), and monocytic dendritic cells ($CD14^+CD11C^+CD123^-$). Nanostring analysis (n=3) was performed on total RNA isolated from day 2 samples, verified by qRT-PCR. Bone marrow (BM) murine MDSCs ($CD11b^+GR\text{-}1^+$) were treated for 72h with GMCSF and effects on MDSC were evaluated by flow cytometry.

Results SD-101, a TLR9C agonist, significantly inhibited MDSC expansion compared to vehicle (Veh), TLR9B, TLR4 and TLR7 agonists on day 2 ($p<0.01$; n=11). Similar results were obtained with murine BM derived MDSCs ($p<0.001$; n=5). SD101 significantly reduced the human M/G MDSC ratio as compared to Veh, TLR4, TLR7 and TLR9B agonists ($p<0.05$; n=11). In addition, SD101 shifted DC towards a myeloid program compared to Veh, TLR4 and TLR7 agonists ($p<0.05$; n=6). Nanostring gene expression analysis revealed that SD101 induced higher adaptive immunity, innate immunity, immunometabolism scores compared with Veh and TLR9B agonist ($p<0.05$; n=3). There was greater induction of TLR, Th1, NFκB and lymphocyte activation signatures in SD101 as compared to Veh and TLR9B agonist ($p<0.05$; n=3). SD101 induced more PD-L1, IFNγ and IP10 gene expression compared to Veh and TLR9B ($p<0.05$; n=6), in addition to B and NK cell expansion compared to Veh ($p<0.05$; n=6).

Conclusions SD101 inhibited MDSC expansion and enhanced polarization towards M1 macrophages. The favorable impact on MDSC, in addition to broad immune activating effects, suggests that TLR9C agonists, if delivered effectively, have the potential to enable better performance of other immunotherapy agents within hostile liver TMEs.

1166 PROFILING THE EFFECTS OF TARGETED TLR9 STIMULATION WITHIN SPONTANEOUSLY ARISING BREAST TUMORS

Caitlyn Miller*, Idit Sagiv-Barfi, Patrick Neuhoefer, Debra Czerwinski, Carolyn Bertozzi, Jennifer Cochran, Ronald Levy. *Stanford University, Mountain View, CA, USA*

Background Tumor-localized delivery of immune-stimulants, such as Toll-like receptor (TLR) agonists, is a promising strategy to treat various cancer types, including immunologically "cold" tumors that lack T cell infiltration. Immunostimulants can elicit anti-tumor immunity by promoting immune activation in the tumor microenvironment (TME), thereby counteracting tumor immunosuppression and driving adaptive responses against tumor antigens available at the tumor site. However, the majority of preclinical studies investigating these therapies are performed in implanted murine tumor models, which do not fully recapitulate the TMEs of naturally-arising tumors. In this work, we performed comprehensive immune profiling studies to understand how tumor-localized TLR9 stimulation remodels the TME of spontaneously-arising tumors during an effective anti-tumor immune response.

Methods Serving as an immunologically "cold" spontaneous cancer model, we utilized female MMTV-PyMT transgenic mice, which spontaneously develop multiple breast tumors throughout their lives. To enable immunostimulant delivery to every tumor site, we employed a systemically-administered tumor-targeting immunostimulant (PIP-CpG), which is comprised of a tumor-targeting peptide (PIP) conjugated to an immune-stimulating TLR9 agonist (CpG).[1] This fully synthetic PIP-CpG conjugate is cross-reactive between mouse and human receptors and enables targeting to most types of solid tumors. To investigate how PIP-CpG therapy modulates the TME, we evaluated cytokine/chemokine profiles in the tumors via Luminex analysis (48-plex) and performed spectral flow cytometry (24-color) to characterize various tumor-infiltrating immune populations and their activation status.

Results We demonstrate tumor-localized TLR9 stimulation via PIP-CpG therapy elicited a systemic anti-tumor immune response that effectively inhibited tumor growth and prolonged survival in an aggressive autochthonous breast cancer model. Immune profiling studies revealed that systemic PIP-CpG treatment dramatically amplified chemokine and cytokine production in the TME and promoted recruitment and expansion of many innate and adaptive immune cells. In addition to transforming the cellular landscape of the TME, PIP-CpG therapy also elicited diverse immune phenotypes that indicate changes in immune activation, cellular maturation, antigen presentation capacity, and inhibitory checkpoint expression. These immune-modulating effects ultimately enabled a T cell-mediated immune response against shared tumor antigens, which promoted regression of existing tumors and also delayed growth of independent newly-arising tumors.

Conclusions Intravenous delivery of a tumor-targeted TLR9 agonist transforms the immune microenvironment of spontaneously-arising malignancies to enable effective T cell-mediated immunity.

1167 APR003, AN ORAL LIVER- AND GI-TARGETED TLR7 AGONIST, ELICITS A ROBUST TYPE I INTERFERON RESPONSE IN ADVANCED COLORECTAL CANCER PATIENTS

[1]Andrew Miller*, [2]Trinh Le, [3]Jaymes Holland, [3]Ron Weitzman, [1]Tom Wu. *[1]Apros Therapeutics, San Diego, CA, USA; [2]Collaborative Clinical Research Consult., Carlsbad, CA, USA; [3]Weitzman Consulting Group, Los Altos Hills, CA, USA*

Background The potential of toll-like receptor (TLR) agonists to induce anti-tumor immunity has been limited by toxicities associated with systemic administration. Recently, intratumoral TLR agonists (CMP-001, SD-101) have shown promising responses in melanoma as single agents and in combination with checkpoint blockade. Building on the concept of localized innate activation to induce systemic anti-tumor immunity and increased safety window, APR003 is a small molecule TLR7 agonist designed to concentrate in the GI/liver upon oral administration for treatment of metastatic GI malignancies. Studies in mice and monkeys demonstrated robust Type-1 Interferon pathway activation with good tolerability compared to benchmark TLR7 agonists. APR003 is also efficacious in several models of liver and colon cancer, both as single agent and in combination with anti-PDL1.[1] APR003 is currently being evaluated in an ongoing Phase 1 dose escalation trial (NCT04645797) in relapsed/refractory colorectal cancer (CRC) patients with hepatic metastasis.

Methods APR003 was administered to patients orally once weekly either at 25 mg or 50 mg in 21-day cycles. Peripheral blood was collected at various time points post-dose on Cycle 1/Day 1 (C1D1), Cycle 1/Day 15 (C1D15), and Cycle 2/Day 1 (C2D1). Plasma was analyzed for pharmacokinetics. Plasma cytokines, including IFNa, IP-10, IL-6, and TNFa, were quantified by SIMOA® technology.

Results Between the 25 mg (n=6) and 50 mg (n=4) dose cohorts, APR003 plasma levels were low, with no dose-dependent increase in exposure. APR003 induced a transient yet robust cytokine response peaking around 6-8 hours post-dose and declining by 24 hours. After a week of recovery, all cytokines returned to baseline before the subsequent weekly dose. Cytokine induction in plasma also revealed no dose-dependency. The dose cohort combined geometric mean maximum fold induction over pre-dose of IFNa, IP-10, IL-6, and TNFa were 41-, 21-, 5-, and 2-fold on C1D1 and 107-, 28-, 6-, and 3-fold on C1D15, respectively. Comparing the cytokine levels at 6 hours on the plasma sampling days indicated slightly diminished response on C2D1 compared to C1D1; no APR003 plasma exposure accumulation or reduction was observed on C2D1.

Conclusions In an ongoing Phase 1 dose escalation trial, oral administration of APR003 elicited a strong type I interferon response (IFNa and IP-10) over the pro-inflammatory response (IL-6 and TNFa) at well tolerated doses. The results suggest our tissue-targeted oral TLR7 agonist may have an increased safety window compared to prior (non-targeted) agents of the same class, thereby achieving Proof-of-Drug Design and warrants further investigation.

Trial Registration This study is registered on Clinicaltrials.gov: NCT04645797

1168 A NOVEL IMMUNOSTIMULATORY TLR7/8 AGONIST IS CURATIVE AS A MONOTHERAPY IN LEWIS LUNG CARCINOMA AND SYNERGIZES WITH ANTI-PD-1 IN B16F10 AND MC38 TUMOR MODELS

Shannon Miller*, Caleb Beyer, Danielle Talbot, Konner Jackson, Margaret Whitacre, Janine Ward, Roman Schoener, Helene Bazin, David Burkhart. *Inimmune Corp, Missoula, MT, USA*

Background Over the past 130 years, the field of immunotherapy has progressed to the use of cytokines and of immune checkpoint inhibitors, namely anti-PD-1 and anti-CTLA4. Despite these advances, response rates remain stubbornly low. New immunotherapies that stimulate the immune system in different ways and can synergize with and expand the population of patients who respond to existing immunotherapies are urgently needed. Inimmune has developed and evaluated a novel TLR7/8 agonist as an immunotherapy for cancer.

Methods To test the activity of our novel TLR7/8 agonist, fresh human peripheral blood mononuclear cells (hPBMCs) were collected from healthy adult donors and stimulated with TLR7/8 agonist for 24 hours. Supernatants were then analyzed for cytokine production by ELISA. For pre-clinical murine studies to determine the efficacy of our novel TLR7/8 agonist as a cancer immunotherapy, LLC, B16F10, or MC38 tumor cells were implanted in the flank of C57BL/6 mice. Our novel TLR7/8 agonist was injected IV, SC, IP, or IT on days 5 and 12 post-implantation. For experiments where anti-PD-1 was used, anti-PD-1 was administered via IP injection on days 3, 6, and 9 post-implantation. To investigate changes in immune cell populations in the TME post-treatment, B16F10 tumors were treated with TLR7/8 agonist on days 5 and 12 post-implantation, or anti-PD-1 on days 3, 6, and 9 post-implantation, or both, and were harvested on day 12 post-implantation. Untreated tumors were harvested on day 12 post-implantation as controls. Tumors were disaggregated to single cell suspensions, stained with phenotyping antibodies, and analyzed by flow cytometry.

Results The lead formulation of our novel TLR7/8 agonist was able to eliminate Lewis Lung Carcinoma (LLC) flank tumors in 80% of mice after just two treatments. Further, as a monotherapy, our novel TLR7/8 agonist slowed growth of MC38 and B16F10 flank tumors and synergized with anti-PD-1 therapy, leading to a 100% rejection rate in MC38 flank tumors and a 75-100% rejection rate in B16F10 tumors when both treatments were used in combination depending on the route of administration and dose schedule. Mechanistically, the combination of our TLR7/8 agonist plus anti-PD-1 lead to increases in monocytes, B cells, and CD8 T cell populations in the TME of B16F10 flank tumors when compared to treatment with TLR7/8 agonist or anti-PD-1 alone.

Conclusions As we advance our novel synthetic TLR7/8 agonist to Phase I clinical trials, these data suggest potential efficacy as a monotherapy or in combination with checkpoint inhibitors in patients with solid tumors.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1168

1169 SYSTEMIC ADMINISTRATION OF TLR7/8 AGONIST MICELLES TRIGGERS A POTENT ANTI-TUMOR RESPONSE MEDIATED BY NEUTROPHILS AS PRIMARY EFFECTOR CELLS FOLLOWED BY ESTABLISHMENT OF AN IMMUNE MEMORY RESPONSE

[1]Simon Jensen*, [2]Esben Christensen, [1]Morten Just Petersen, [2]Anders Hansen, [2]Martin Bak, [2]Camilla Stavnsbjerg, [1]Svetlana Panina, [2]Thomas Andersen. *[1]MonTa Biosciences, Lyngby, Denmark; [2]Danish Technical University, Lyngby, Denmark*

Background Clinical use of TLR7/8 agonists is currently restricted to topical application of Imiquimod for treatment of superficial basal cell carcinoma since systemic administration is a challenge due to dose-limiting toxicity. Here, we present data to overcome this challenge using a novel micelle-based drug delivery technology containing a lipid-anchored TLR7/8 agonist for intravenous administration. The MBS8 formulation shows good efficacy in mouse cancer models, is well tolerated in rodents and non-human primates and is currently being tested in clinical studies (NCT04855435).

Methods MBS8 was tested in 12 syngeneic mouse cancer models as monotherapy or in combination anti-PD-1 and anti-PD-L1 antibodies. MBS8 was administered IV as slow bolus on up to 5 occasions with different time schedules. Tumors and spleens were analysed using histology, immunohistochemistry, ELISPOT and flow cytometry. Phenotyping of tumor immune microenvironment was done using flow cytometry and Nanostring analyses. Safety and tolerability were tested in mice, rats and cynomolgus monkeys.

Results In several syngeneic mouse tumor models, MBS8 led to complete eradication of established tumors. The complete responders showed tumor rejection upon re-challenge. In these mice, a $CD8^+$-dependent tumor-specific immune memory response was evident. Tumors demonstrated a massive tissue necrosis (>80%) within 24-48h after the first drug administration and showed massive neutrophil infiltration 6h after dosing. Antigen specific $CD8^+$ T-cells were detected in tumors 24 hours after treatment with increased $CD8^+$:T_{reg} cell ratio and enhanced antigen presentation in tdLN.

MBS8 showed both additive and synergistic effect when combined with anti-PD-1 or anti-PD-L1 antibody treatment. Moreover, in tumors being resistant to anti-PD-1 treatment, co-administration of MBS8 reverted sensitivity to anti-PD-1 treatment in a synergistic manner.

Conclusions MBS8 showed significant anti-cancer activity in multiple *in vivo* solid tumor models when administered either as monotherapy or in combination with ICIs.

MBS8 demonstrated a novel mode of action with neutrophils playing a central role as primary effector cells causing a rapid killing of tumor cells. Further, an adaptive immune response was initiated including generation of tumor antigen-specific $CD8^+$ cells and establishment of immune memory response.

MBS8 was well tolerated in rodents and cynomolgus monkeys at dose levels above therapeutic effective doses identified in mice, thus providing a good therapeutic window.

1170 EGFR-TA:RNA: MULTIMODAL MECHANISM OF ACTION POTENTIATES IMMUNE CHECKPOINT INHIBITOR ACTIVITY

[1]Babette Schade, [1]Derrick Broka, [1]Caroline De Feyter, [2]Shoshana Klein, [2]Alexei Shir, [2]Alexander Levitzki, [1]Davor Bajic, [1]Lucia D'Amico, [1]David Colecchia, [1]Eric Kitas, [1]Anita Jarzebinska, [1]Esteban Pombo-Villar, [1]Maya Zigler*. [1]*TargImmune Therapeutics AG, Basel, Switzerland*; [2]*The Hebrew University of Jerusalem, Jerusalem, Israel*

Background The discovery and development of immune checkpoint inhibitors (ICIs) revolutionized cancer treatment and cancer immunotherapy. However, the majority of patients with metastatic disease do not achieve durable response following treatment with ICIs, highlighting the unmet need for effective cancer therapeutics. TargImmune`s novel platform technology, Ta:RNAs, consists of targeted nanoparticle drugs, in which polyinosinic polycytidylic acid (pIC), a Pattern Recognition Receptor (PRR) agonist, is formulated with a non-viral vector. The non-viral vector comprises linear polyethyleneimine (LPEI) and polyethylene glycol (PEG), linked to the tumor-targeting moiety EGF. Unlike other PRR inducers under development, which are delivered intratumorally or intramuscularly, the Ta:RNA polyplex is designed for systemic administration: the nanoparticles are targeted to tumors that overexpress EGFR, and the pIC enters the cancer cells by receptor-mediated internalization. Furthermore, while other PRR agonists act as adjuvants, the Ta:RNA polyplex has strong cytotoxic and immunomodulatory effects, displaying a multimodal mode of action that harnesses the body`s antiviral defenses to fight cancer.

Methods The anti-tumor efficacy and complex mode of action of EGFR-targeted Ta:RNA polyplex (EGFR-Ta:RNA) were extensively studied *in vitro* and *in vivo*. *In vitro*, EGFR-Ta:RNA potency and specificity was established by comparing the responses of high-EGFR-expressing cancer cells versus low-EGFR-expressing control cells using a cytotoxicity assay. The effects of EGFR-Ta:RNA alone or in combination with Nivolumab on human PBMC activation were also measured. *In vivo* efficacy was studied in an aggressive syngeneic experimental lung metastasis mouse model overexpressing human EGFR, in which EGFR-Ta:RNA alone was compared to the combination of EGFR-Ta:RNA with anti-PD-1 antibody treatment.

Results

Our EGFR-TA RNA nanoparticles induced cytotoxicity and proinflammatory cytokine (RANTES/CCL5, IP-10) secretion selectively in EGFR-overexpressing cancer cells, *in vitro*. Supernatant from EGFR-overexpressing cancer cells treated with EGFR-Ta:RNA enhanced the activation of human PBMCs, and this was further potentiated by combination treatment with anti-PD-1 antibody Nivolumab, demonstrated by increased INFγ secretion. Systemic administration of EGFR-Ta:RNA in the experimental lung metastasis mouse model led to potent anti-tumor activity, while anti-PD-1 antibody as a single therapy did not have any effect on mouse survival. In contrast, the combination of EGFR-Ta:RNA with an anti-PD-1 antibody exerted a profound effect and further increased the survival of the mice in comparison to EGFR-Ta:RNA alone.

Conclusions

EGFR-Ta RNA nanoparticles provide a multimodal anti-tumor approach by inducing targeted tumor cytotoxicity and anti-tumor immunity. This approach has been shown to potentiate anti-PD-1 antibodies in an experimental lung metastasis mouse model.

1171 CAN1012: A SELECTIVE AND POTENT TLR7 AGONIST WITH STRONG ANTITUMORAL PROPERTIES MEDIATED BY LOCALIZED INNATE IMMUNE ACTIVATION

[1]Henry Yu, [2]Hong-Ming Hu*, [1]Rongliang Lou, [1]Wanping Geng, [1]Sanlong Wang, [3]William Redmond, [3]Yoshinobu Koguchi, [1]Baotian Qin, [4]John Mao, [5]Shaoshan Wang. *[1]Canwell Pharma Inc, Newton, MA, USA; [2]UbiVac, Portland, OR, USA; [3]Providence Cancer Institute, Portland, OR, USA; [4]JWM Pharma, San Francisco, CA, USA; [5]CanWell Pharma In, Newton, MA, USA*

Background Toll-like receptors (TLRs) are commonly expressed on innate immune cells such as macrophages and dendritic cells (DC), and they play crucial roles in 1) mediating the first-line innate immune response against a wide variety of pathogens and 2) promoting adaptive immunity involving T and B cells. The TLR family consists of 10 subtypes (TLR1-TLR10) in humans and 12 (TLR1-TLR9, TLR11-TLR13) in mice. CAN1012 was developed as a selective TLR7 agonist uniquely designed for intratumoral (IT) administration.

Methods CAN1012 was evaluted by *in vitro* cell-based assays and *in vivo* animal models. Its DMPK, safety and toxicitology properties were also studied.

Results Based on the receptor screening study, CAN1012 has been proved to have a significant stimulatory effect (NF-κB activation) via human and mouse TLR7. In addition, CAN1012 stimulated significant IFN-α release from human PBMC at low concentrations (nM), whereas TNF-α secretion required a relatively high concentration.

Most importantly, CAN1012 induced a robust production of IFN-α exclusively by plasmacytoid DCs in human PBMC. When given intratumorally, CAN1012 exposure in tumor tissues was over 1,000-fold higher than in blood, resulting in much less systemic toxicity. The antitumoral effects of IT-administered CAN1012 monotherapy or combined with other therapeutical agents were investigated in mouse SCC7, CT26, and MC38 syngeneic tumor models. The results showed that CAN1012 possessed significant anti-tumor growth effects in a dose-dependent and schedule-dependent manner, and antitumoral effects could be augmented when combined with other agents. Pharmacodynamic studies revealed that IT administration of CAN1012 increased CD4+ and CD8+ T cell infiltration but decreased the number of myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs) in the tumor microenvironment (TME). CAN1012 has a favorable ADME/PK profile when administered subcutaneously in mice, rats and monkeys, and its pharmaceutical properties have also been optimized for IT administration.

Conclusions In conclusion, CAN1012 is a potent, safe, and selective TLR7 agonist and could be a best-in-class agent for cancer immunotherapy. A first-in-human Phase I clinical study in advanced cancer patients is ongoing in the US (NCT04987112).

1172 A UNIQUE DENDRITIC CELL ACTIVATION STATES UTILIZES INFLAMMASOMES TO STIMULATE ANTI-TUMOR IMMUNITY IN MICE

Dania Zhivaki*, Kelsy Finn, Emily Gosselin, Holly Concepcion, Dania Zhivaki, Andrew Cornforth, Caitlin Sullivan. *Corner Therapeutics, Watertown, MA, USA*

Background Dendritic cells (DCs) represent the primary drivers of new T cell responses that defend against cancer and infection. In order to execute this task, DCs must be stimulated in a manner that induces several T cell stimulatory activities. These activities include the ability of DCs to 1) present tumor or microbial antigens, 2) express T cell co-stimulatory molecules, 3) express cytokines that induce effector T cell differentiation, 4) migrate in high numbers to lymph nodes and 5) produce the memory T cell inducing cytokine IL-1β. Diverse approaches have been undertaken to stimulate these DC activities in a clinical or pre-clinical setting, with common strategies targeting Toll-like Receptors, STING or inflammasomes. These approaches are based on the general concept—permeating the literature for over 30 years—that infection-like signals are sufficient to stimulate DC-mediated instruction of adaptive immunity. However, the therapeutic success of these strategies remains elusive.

Methods Herein, we demonstrate that the aforementioned approaches are unable to elicit all 5 of the aforementioned activities in murine DCs. This observation may explain the ineffectiveness of these approaches in generating protective immunity to cancer. We report a distinct means of stimulating DCs, using molecular signals that mimic infection and tissue injury, that elicit all DC activities needed to stimulate adaptive immunity. We devised proprietary chemical mimics of infection and tissue injury that induce a new DC activation state termed hyperactive.

Results Primary murine DCs that have been stimulated with hyperactivators far exceed the capacity of other DCs to migrate to skin draining lymph node and stimulate antigen specific T cell activities in mice. When combined with a tumor-derived antigen source, we find that DC hyperactivators induce T cell responses that prevent the growth of tumors that are otherwise resistant to checkpoint inhibitor therapies.

Conclusions These studies reveal a unique DC activation state, and chemical agonists that elicit this state, as key determinants of T cell mediated anti-tumor immunity. DC hyperactivating chemicals represent a means to expand the opportunities in immunotherapy, and may enable durable T cell immunity to be elicited in a clinical setting.

1173 ST101, A PEPTIDE ANTAGONIST OF NOVEL I/O TARGET CEBPβ, REPROGRAMS MDSC POLARIZATION AND DECREASES TUMOR-ASSOCIATED TREGS, SUGGESTING AN IMMUNE COMPONENT TO OBSERVED CLINICAL RESPONSES

[1]Claudio Scuoppo, [2]Gerald Falchook, [2]Elisa Fontana, [2]Anja Williams, [3]Nehal Lakhani, [4]Jeff Evans, [5]Fabio Iwamoto, [2]Meredith McKean, [6]Stefan Symeonides, [4]Alistair McLaren, [2]Jason Henry, [1]Gina Capiaux, [7]Robert Michel, [7]Stephen Kaesshaefer, [1]Alice Bexon, [1]Jim Rotolo*. *[1]Sapience Therapeutics, Harrison, NY, USA; [2]Sarah Cannon Research Institute, Denver, CO, USA; [3]START MIdwest, Grand Rapids, MI, USA; [4]University of Glasgow, Glasgow, UK; [5]Columbia University, New York, NY, USA; [6]University of Edinburgh, Edinburgh, UK; [7]Bexon Clinical Consulting, LLC, Montclair, NJ, USA*

Background CCAAT/Enhancer Binding Protein β (C/EBPβ) is a basic leucine zipper (bZIP) transcription factor that causes aberrant gene activation in many cancers. Upregulated or over-activated C/EBPβ drives oncogenesis by promoting tumor survival and proliferation[1] and is a critical regulator of the immunosuppressive environment.[2] Specifically, C/EBPβ regulates macrophage differentiation, promoting the expression of M2 myeloid-derived suppressor cells (MDSCs) that contribute to suppression of antitumor immunity and correlate with poor prognosis.[3] Reprogramming tumor-associated macrophages (TAMs) from M2 to M1 phenotype represents a potential strategy to enhance antitumor immunity. ST101 is a novel peptide antagonist that prevents C/EBPβ dimerization and inhibits C/EBPβ-dependent gene expression. Confirmed responses in melanoma and other tumors prompted evaluation of ST101 impact on macrophage differentiation.

Methods Primary human macrophages were cultured from peripheral blood mononuclear cells (hPBMCs) and activated toward the M1 or M2 phenotype by LPS and IFNγ (M1) or IL-4 (M2), respectively, in the presence of ST101. Macrophage M1 (CD80, CD86) and M2 (CD163, CD206) expression were analyzed by flow cytometry and rtPCR. Paired biopsy tissue from the ST101 Phase 1-2 clinical study in patients with advanced unresectable and metastatic solid tumors were collected during screening (prior to ST101 exposure) and within 24 hrs of ST101 administration during cycle 2 of therapy. Nanostring gene expression analysis was peformed to determine differential gene expression and the impact of ST101 on the tumor microenvironment.

Results Treatment with pharmacologically relevant concentrations of ST101 (2.5, 5 or 10 μM) resulted in dose-dependent reduction in M2+ macrophage and corresponding induction of M1+ macrophage. At the highest ST101 concentration, a 12-fold reduction in the M2 to M1 ratio was observed without substantial impact on cell viability. Paired patient biopsy tissue from the ST101 Phase 1-2 clinical study indicates a decrease in C/EBPβ target gene IL-6 signaling, an important driver of the M2 macrophage phenotype. Decreased IL-6 signaling resulted in an increase in the tumor-infiltrating macrophage vs. tumor-infiltrating lymphocyte (TIL) ratio, and a decrease in the regulatory T cell (Treg) vs. TIL ratio in tumor samples of treated patients.

Conclusions Overall, these results validate the potential of ST101 in reprogramming M2 macrophages to M1, support a novel, macrophage-driven mechanism of action for ST101 as an anticancer agent and support future exploration of ST101 in immune-oncology therapeutic strategies.

1174 MULTI-EPITOPE DNA VACCINE TARGETING CANCER NEOANTIGENS ENHANCES EFFICACY OF ANTI-PD1 THERAPY

[1]Pratik Bhojnagarwala*, [2]Alfredo Perales-Puchalt, [1]Ebony Gary, [2]Niranjan Sardesai, [1]David Weiner. *[1]Wistar Institute, Philadelphia, PA, USA; [2]Geneos Therapeutics, Philadelphia, PA, USA*

Background Immune checkpoint inhibition (ICI) has revolutionized cancer therapy and significantly improved survival of patients across several cancer types. However, ICI is only effective in some patients and most patients don't respond to ICI.[1] [2] Neoantigens are tumor specific antigens derived from either point mutations or gene/RNA fusions in cancer cells, and can be recognized by the host immune system as foreign antigens. Several studies have shown that the success of ICI is linked to the number of neoantigens in the patient's tumor[3] [4]. Here, we demonstrate that DNA immunogens designed to target 40 neoantigens derived from MC38 mouse model of colon cancer synergizes with anti-PD1 antibody and improves the efficacy of anti-PD1 therapy.

Methods We performed whole exome sequencing on MC38 tumors to identify neoantigens. Through the sequencing data, we identified 40 neoantigens based on predicted affinity to class I MHC binding. All 40 neoantigens were encoded into a single plasmid vector, we designed each neoantigen separated by a furin cleavage site. Immune responses were measured in C57/Bl6 mice via IFN-γ ELISPOT assay and flow cytometry. Finally, we tested immunization with MC38vax to impact tumors *in vivo* and whether co-treatment with anti-PD1 antibody treatment further impacted tumor control.

Results In ELISPOT data, we observed that 11/40 neoantigens generated immune responses in mice. We also studied immune response to WT peptides and observed that the immune response was specifically induced against mutated peptides. Using flow cytometry, we observed that the vaccine induced predominantly CD8+ T cell responses, although CD4+ T cell responses were also observed. In a therapeutic tumor challenge, both anti-PD1 antibody and MC38vax as single treatment partially controlled the growth of MC38 tumors. However, co-treatment with both therapies was synergistic, demonstrating a 100% tumor control rate and improved animal survival.

Conclusions Large collections of neoantigens in a DNA immunization platform drive CD8+ T cell immunity against a diverse set of tumor antigens resulting in significant impact on tumor growth and improving survival. In combination with anti-PD1 these vaccines allow for tumor clearance and 100% survival from challenge, significantly improving the outcome of anti-PD1 therapy alone. These studies establish the importance and feasibility of improving patient specific T cell immunity, providing new tools for improving immunotherapy of, in this case colon adenocarcinoma, that is worth considering in other cold tumors that respond poorly to ICI.

1175 MEMORY T CELLS ELICITED BY MICROORGANISMS CROSS-REACT WITH TUMOR-ASSOCIATED ANTIGENS

Luigi Buonaguro, Maria Tagliamonte*, Beatrice Cavalluzzo. *National Cancer Institute 'Pascale', Naples, Italy*

Background Individuals are exposed to intracellular pathogens (i.e. viruses and intracellular bacteria) and intestinal microbiota, collectively microorganisms (MOs), which enter the body during the host's lifetime. Altogether, MOs are a natural source of non-self antigens (MoAs) expressed by host's cells in the context of the HLA class I molecules, inducing a wide pool of specific memory $CD8^+$ T cell clones. Such MoAs may share sequence and structural homology with cellular self-antigens (molecular mimicry), possibly inducing autoimmune reactions leading to autoimmune diseases (ADs). We have recently shown that a molecular mimicry may be found also to self-antigens presented by cancer cells (i.e. tumor-associated antigens, TAAs). Consequently, memory $CD8^+$ T cell clones specific for the MoAs may turn out to be a natural "anti-cancer vaccination" if a nascent tumor lesion should express TAAs similar or identical to MoAs.

Methods In the present study we looked for homology between published TAAs and non-self MoAs. Blast search for sequence homology was combined with extensive bioinformatics analyses. Ex vivo immunological validations have been performed by screening with DNA barcode labeled pMHCs strategy and confirmation by tetramer and dextramer staining procedure.

Results Several TAAs and MoAs show sequence and structural similarities as well as comparable patterns of contact with HLA and TCR α and β chains (figure 1 and 2). The predicted average affinity to HLA molecules ofMoAs is very high (<100nM). The structural conformation of MoAs is, in general, highly similar to the corresponding TAA. In some cases, it is identical and contact areas with both HLA and TCR chains are indistinguishable. Moreover, the spatial conformation of TCR-facing residues can be identical in paired TAA and microbiota-derived epitopes, with exactly the same values of planar as well as dihedral angles. Importantly, CD8+ lymphocytes are able to cross-react against paired TAAs and MoAs supporting the concept that the same T cell can recognise similar peptides.[1,2]

Conclusions Here we report for the first time 1) the molecular mimicry between TAAs and MoAs; and 2) cross-reacting $CD8^+$ T cell responses. Therefore, the T cell memory elicited by MoAs may turn out to be an anti-cancer T cell memory, able to control the growth of cancer developed during the lifetime if the expressed TAA is similar to MoAs. This may ultimately represent a relevant selective advantage for cancer patients and lead to novel preventive

1176 OPTIMIZING IMMUNIZATION SCHEDULES FOR THERAPEUTIC VACCINATION

Yushe Dang*, Denise Cecil, Lauren Corulli, Erin Rodmaker, Mary Disis. *University of Washington, Seattle, WA, USA*

Background Most cancer vaccines will not generate high levels of T-cell immunity with only one immunization. Even vaccines against foreign antigens, such as COVID, may require three or four immunizations spaced some months apart to achieve protective levels of immunity in cancer patients. The use of cancer vaccines in the therapeutic setting, as single agents or as part of a combination regimen to treat established cancers, would require high levels of T-cells to be generated quickly. We evaluated immunization schedules with a 5-antigen, multiepitope plasmid DNA vaccine, STEMVAC, targeting cancer stem cell associated proteins. The vaccine is immunogenic in patients with advanced breast cancer (NCT02157051) and the majority of patients can develop high levels of STEMVAC specific type I T-cells after 3 priming and 2 booster immunizations. Using a murine model, we questioned whether we could more rapidly achieve high levels of antigen specific Type I T-cells with STEMVAC immunization.

Methods Six-week-old FVB mice were used for experiments. A dose of 300ug of STEMVAC plasmid with 5ug of rm-GM-CSF as an adjuvant was given in 4 immunizations using three different schedules; (1) every 3-4 days, (2) once a week, and (3) every 2 weeks (standard). Immunogenicity was evaluated two weeks after the last vaccine using IFN-gamma ELISPOT quantitating responses to each of the 5 antigens in the vaccine. Parameters studied included magnitude, incidence, and breadth of the T-cell response. Ten mice were included/group with empty plasmid and PBS as controls.

Results All three immunization schedules could generate a significant IFN-gamma response to at least one of the antigens encoded in STEMVAC as compared to controls. Vaccines given every two weeks elicited the greatest magnitude immune response among the three schedules (vs. 3-4 days, $p=0.001$; vs. 1 week, $p=0.01$). Of note, although the total magnitude of immune response elicited was lower, the weekly immunization schedule resulted in a significantly greater number of mice responding to vaccination as well as a greater breadth of response with all mice responding to at least 2 antigens and 50% to 3-5 antigens.

Conclusions Varying the time between immunizations can significantly impact the quality of the T-cell response to a mulit-antigen plasmid-based vaccine. Further studies are ongoing to correlate these differences to anti-tumor activity.

1177 IDENTIFICATION OF AND VACCINATION WITH ANTIGEN SPECIFIC TH1 SELECTIVE EPITOPES IN BLADDER CANCER: A STEP TOWARDS A MULTI-ANTIGEN VACCINE FOR BLADDER CANCER PREVENTION

[1]Yushe Dang*, [1]Lauren Corulli, [1]Erin Rodmaker, [1]Denise Cecil, [1]Yi Yang, [1]Carissa Walsh, [1]Will Gwin, Jonathan Wright, [1], [1]Jennifer Childs, [2]Shizuko Sei, [1]Mary Disis, [1]Yushe Dang. *[1]University of Washington, Seattle, WA, USA; [2]National Cancer Institute, Bethesda, MD, USA*

Background Bladder cancer is a frequently diagnosed malignancy. Half of patients responding to standard therapy develop recurrence within 5 years. Vaccination for secondary prevention of bladder cancer could reduce recurrence. We developed an epitope identification approach for vaccine construction from non-mutated tumor associated proteins combining in silico prediction of Class II epitopes with functional screening to edit out sequences inducing regulatory responses. The method allows the identification of Th1 selective epitopes which elicit an antigen specific IFN-gamma response without IL-10 secretion. We aimed to identify bladder cancer antigens and determine Class II binding peptides for use in a multi-antigen Th1 selective vaccine.

Methods Seven datasets (GEO); 38 normal bladder, 229 NMIBC and 86 muscle invasive non-metastatic bladder cancers were studied. Genes with at least 2-fold upregulation in cancer compared to normal with a corrected p-value < 0.1 and found in >50% of cancer samples were identified (n=159). We prioritized those upregulated in >75% of cancers (n=15). Nine genes encoded proteins with known overexpression in human bladder cancer; CDC20, TOP2A, CCNB2, MAPK13, CDK1, AURKA, CEP55, PRC1, and MELK. We evaluated expression by IHC in OH-BBN induced mouse bladder tumors. Eight proteins were expressed in tumors and the murine MB49 bladder cancer cell line. Using a multi-algorithm approach, we selected 24 putative class II epitopes, associated with high binding affinity across multiple MHC class II alleles, derived from these proteins. All epitopes had >88% homology between species.

Results We screened PBMC (12 donors/9 bladder cancer patients) by IFN-g/IL-10 ELISPOT. Th1 selective epitopes were identified for 5 antigens, CDC20, TOPO2A, CCNB2, CDK1, and CEP55. We evaluated immunogenicity of single-antigen vaccines in C57BL6 mice to identify any epitopes inducing selective Th1 immunity. Five peptides generated significant antigen-specific Th1 with no evidence of Th2. To evaluate anti-tumor activity, single-antigen vaccines were given four times, two weeks apart, with CFA/IFA. Two weeks after vaccination, mice were implanted with MB49. All vaccines could significantly inhibit tumor growth as compared to PBS control; CDC20 ($p=0.0001$), TOPO2A ($p<0.0001$), CCNB2 ($p<0.0001$), CDK1 ($p<0.0001$), and CEP55 ($p<0.0001$). We admixed epitopes into a single vaccine, BLADVAC, immunizing mice to discern epitope competition. Significantly elevated levels of antigen-specific IFN-g secreting T-cells were detected for all epitopes except CDK1 ($p<0.001$ compared to HIV control).

Conclusions We identified bladder cancer antigens covering the majority of tumors with clinically effective Th1 selective vaccines constructed. Prevention trials in the OH-BBN model are ongoing.

1178 DELIVERY OF DNA ORIGAMI CANCER VACCINE USING ALGINATE MICROPARTICLES

Amani Djouadi*, Niksa Roki, Carlos Castro. *The Ohio State University, Powell, OH, USA*

Background Deploying the immune system to seek out and destroy cancer cells is a rapidly developing strategy for cancer treatment and prevention. This is accomplished via vaccination against tumor antigens to elicit an antigen-specific anti-cancer immune response. DNA origami nanodevices (DO) have shown enhanced antigen and adjuvant delivery to antigen-presenting cells (APCs) and stimulation of antigen-specific $CD8^+$ T cells. This enhancement is due to DO's unique properties, including size, shape, modular nature, and programable payload capacity.[1] Despite these features, free DO-based vaccine (DO-VAC) faces a harsh physiological environment within the lymphatic system and the periphery that compromises its integrity and longevity once injected subcutaneously. Previous work demonstrated that alginate-mediated release of vaccines is advantageous to traditional vaccines due to prolonged release of antigen, payload protection, and promoting adequate delivery of payload to lymph nodes.[2] Therefore, it is believed that DO-VAC delivery can be further enhanced by encapsulation in alginate microparticles. . Encapsulation could address the rapid clearance of DO-VAC, produce a strong persistent immune response, and remove the need for booster shots in clinical settings.

Methods We have constructed a rod-shaped DO (92 x 12 x 15nm) using M13 scaffold DNA devoid of endotoxin with standard DO construction methods. To construct the DO-VAC, DO was hybridized to 65 CpG adjuvant molecules and K10-OVA peptides. Alginate particles were manufactured using 2% endotoxin-free alginate and cross-linked in 2% calcium chloride solution using a syringe pump and pressurized nitrogen gas to create microparticles (10 uM – 100 uM). Alginate encapsulated DO was incubated for 28 days at 37°C in PBS in sink conditions and at 4°C in storage conditions. TEM image samples were prepared with standard methods. Agarose gel electrophoresis was used to characterize DO.

Results Agarose gel and TEM imaging demonstrate that DO retains structural stability once released from alginate particles. Based on release studies, alginate encapsulated DO exhibits sustained release properties in release conditions and stability in storage conditions.

Conclusions The sustained release property of encapsulated DO and stability of released DO indicate encapsulation in alginate microparticles is a promising strategy for future vaccine delivery. This delivery platform could be used to promote vaccine payload stability and protection while promoting a robust tumor-specific immune response.

1179 EFFICACY STUDY OF STC-1010 ANTITUMOR VACCINE ASSOCIATED WITH STANDARD CHEMOTHERAPIES ON MC 38 SYNGENEIC COLON CANCER TUMOR MODEL

[1]Corinne Tortorelli, [2]Celine Gongora*, [3]Doriane Mathe, [1]Benoit Pinteur, [1]Lionel Chalus, [1]Paul Bravetti, [4]Nicolas Gadot, [4]Sylvie Lantuejoul, [5]Charles Dumontet, [6]François Ghiringhelli.
[1]Brenus Pharma, Issoire, France; [2]Brain and Spine Institute (ICM), Paris, France; [3]Antinéo, Lyon, France; [4]Centre de Lutte Contre le Cancer Lyon, Lyon, France; [5]Inserm, Lyon, France; [6]Centre Georges François Leclerc Dijon, Dijon, France

Background Metastatic colorectal cancer(mCRC) is a major cause of death. Unmet medical need in immunotherapy is high for MSS patients and still present for MSI-H/dMMR patients. STC-1010 (Brenus Pharma) therapeutic vaccine is developed by tumor cells stimulation to induce overexpression of tumor associated antigens and neoantigens to mimic mCRC resistant cancer cells. The aim is to educate the immune system to target patient's tumor cells harboring the same resistance factors. We report efficacy results of three (3 CL-S) cell lines S=stimulated by irradiation and heat shock versus three cell lines (6 CL-S) physically and chemically stimulated (irradiation, heat shock and chemotherapies), both haptenized (H) and administrated with immunostimulant (IS=cyclophosphamide and mGM-CSF) associated w/o to standard chemotherapy FOLFOX or FOLFIRI.

Methods Female C57BL6 mice were subcutaneously grafted with 1.10^6 MC38 tumor cells. 7 groups (15 mice/group) were allocated to: Control, FOLFOX, FOLFIRI (intra-peritoneal injection to D5, D8 and D11 post-tumour injection), 3 CL-SH, 6 CL-SH, 6 CL-SH + FOLFOX and 6 CL-SH + FOLFIRI groups. Subcutaneous vaccine injections (3CL-SH or 6 CL-SH) were associated to IS once a week for 3 weeks. Overall survival (OS) and tumor growth (TG) were recorded until 1600 mm^3 or tumor necrosis. We conducted automated immunohistochemical analysis (HALO IndicaLabs software) on 5 tumor groups (n=35) to evaluate the correlation between response and immune population (number of cells/mm^2) including: CD3, CD4, CD8, FOXP3 T cells and M1/M2 macrophages.

Results At Day16, all groups treated by 6CL-SH had a significant reduction of the mean tumor volume compared to the control group (p=0,0011), as well as for 6CL-SH+ FOLFIRI versus FOLFIRI alone (p=0,0024).

The necrotic tumors in the 3CL-SH, 6CL-SH and 6CL-SH +FOLFIRI groups are denser (weight/volume) than the control group. Tumors treated by 6CL-SH+FOLFIRI were also denser than the FOLFIRI ones (p=0,0052).

Grafted mice treated by FOLFOX alone had dramatic weight loss and some had to be sacrificed.

HALO analysis showed that adding 6CL-SH to FOLFOX increase CD8 infiltration in comparison with FOLFOX alone (> 200 cells/mm^3) and a recruitment of immune cells within the tumor. Among treated groups, M1/M2 ratio >7 was main criteria correlated with a long survival.

Conclusions This third preclinical study confirms efficacy and safety of Brenus STC vaccine stimulated and haptenized alone or with standard chemotherapies associated to immunostimulant. This significant anticancer effect in mice could be explained by mobilization of CD3, CD8, CD4 T cells within the tumors and oriented M1 macrophage immune responses.

1180 LISTERIA-BASED IMMUNOTHERAPY SCULPTS CD8$^+$ T CELL RESPONSE IN THE TUMOR MICROENVIRONMENT TO CONTROL RENAL CELL CARCINOMA

Mariam Oladejo*, Laurence Wood. *Texas Tech University Health Sciences Center, Abilene, TX, USA*

Background Agents that modulate the tumor microenvironment (TME) to promote anti-tumor effects are desirable for the therapy of solid tumors. Recombinant Listeria-monocytogenes vaccine consisting of the fusion protein of truncated Listeriolysin O and tumor-associated antigen (TAA) is an established strategy to improve antigen-specific T cell response for cancer immunotherapy. CD105 is a co-receptor for the TGF-beta signaling cascade. Due to its elevated expression in many cancer types, including renal cell carcinoma (RCC), CD105 is characterized as a TAA of therapeutic potential. Here we evaluated the efficacy and immunomodulatory effects of a Listeria-based vaccine encoding CD105 (Lm-LLO-CD105A) for the therapy of renal cell carcinoma (RCC) in a murine model.

Methods Murine RCC cell line (Renca) cells were implanted subcutaneously or orthotopically into male Balb/c mice. Subsequently, mice were vaccinated with PBS, Lm-LLO-CD105A, or Control Lm weekly for three weeks, and tumor progression was routinely monitored. Splenocytes and subcutaneous and orthotopic tumor tissues were immunophenotyped by flow cytometry. Lymphocyte depletion experiments were carried out in subcutaneous and orthotopic models to evaluate the immune subset responsible for the anti-tumoral effect of the recombinant Listeria-based vaccine.

Results In both models, vaccination with Lm-LLO-CD105A led to significant control of tumor growth compared to placebo and Control Lm (figure 1). This antigen-specific vaccine promoted tumor control by significantly improving the infiltration of effector CD8$^+$ T and CD4$^+$T cells into the TME. The CD8$^+$ T cells are polyfunctional and characterized by profound production of inflammatory cytokines, including IFN-g, IL-2, and TNF-a, but the functionality of the CD4$^+$ T cells was not as robust. Similarly, the systemic cytotoxic response demarcated by IFN-g $^+$IL-2 $^+$ TNF -a $^+$ producing splenic CD8$^+$ T cells was highly potent upon Lm-LLO-CD105A vaccination. Further, in both subcutaneous and orthotopic models, the TME was polarized from an immunosuppressive phenotype to an inflamed phenotype characterized by a reduction in the CD4$^+$ Foxp3$^+$Treg population and a reduced population of MDSCs (CD11b$^+$Gr1$^+$) in the kidney TME. Not surprisingly, the antitumor effect was completely abrogated when Lm-LLO-CD105A was utilized in the presence of a CD8$^+$ T cell-depleting antibody (figure 2)

Conclusions Lm-LLO-CD105A effectively controlled subcutaneous and orthotopic kidney tumors. This efficacy depended on the profound infiltration of cytokine-producing CD8$^+$ T cells and the reduction of suppressive immune subsets in the TME. Altogether our data suggest that tumor targeting with a Listeria-based approach is an effective strategy to modulate the TME for effective control of renal cell carcinoma.

1181 THERAPEUTIC VACCINES CONSISTING OF CANCER GERMLINE ANTIGEN-BASED SYNTHETIC LONG PEPTIDES ARE IMMUNOGENIC IN HUMAN HEPATOCELLULAR CARCINOMA PATIENTS

[1]Yannick Rakké*, [2]Marij Schoenmaekers-Welters, [1]Lisanne Noordam, [2]Sanne Boekestijn, [1]Luc Magre, [1]Robbie Luijten, [1]Rachelle van Gemerden, [1]Monique de Beijer, [1]Michael Doukas, [1]Jeroen Demmers, [3]Anna-Sophia Wiekmeijer, [3]Willem-Jan Krebber, [3]Cornelis Melief, [1]Jan IJzermans, [1]Jaap Kwekkeboom, [2]Sjoerd van der Burg, [1]Sonja Buschow, [1]Dave Sprengers. *[1]Erasmus MC University Medical Center, Rotterdam, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands; [3]ISA Pharmaceuticals B.V., Oegstgeest, Netherlands*

Background In melanoma, cancer germline antigen (CGA)-directed vaccination has shown to induce objective clinical responses accompanied by strong anti-tumor immune responses.[1] As CGAs are immunogenic and highly expressed by hepatocellular carcinoma (HCC) tumor cells, these have demonstrated to be attractive targets to be implemented in therapeutic anti-liver cancer vaccination as well.[2]Synthetic long peptide (SLP) vaccination has proven to elicit efficient anti-tumor $CD4^+$ and $CD8^+$ T cell responses and to have promising clinical effects.[3] We aimed to develop an SLP vaccine targeting HCC-restricted CGA-epitopes covering at least five different HLA super types that are highly prevalent globally.

Methods We applied an integrative pre-clinical approach of *in silico* epitope prediction, immunopeptidomics, and *in vitro* tools to select GSAs and validate CGA-SLPs in HCC patient-derived tumor infiltrating lymphocytes (TILs) and peripheral blood mononuclear cells (PBMCs).

Results Out of a set of 13 CGAs, previously shown to be expressed in primary human HCC tissues, two CGAs (i.e., CGA-A and -B) demonstrated no healthy tissue expression and covered >75% of HCC patients collectively (N = 55). Immunopeptidome analysis of human HCC-derived hepatocytes (N = 12), together with *in silico* CGA-related epitope predictions according to epitope immunogenicity, enabled identification of 196 and 220 potential epitopes for CGA-A and -B, respectively. HLA-A*02:01 binding of these epitopes was validated *in vitro* using a HLA-A2 stabilization assay and ranked accordingly. Six SLPs were designed incorporating 54 HLA-A*02:01, 25 HLA-A*01:01, 24 HLA-A*03:01, 27 HLA-A*24:01, and 15 HLA-B*07:02 predicted and/or validated CGA-A- and -B-related epitopes. Top three-ranked epitopes were selected to validate ex vivo intra-tumor immune reactivity using corresponding peptide-HLA-A*02:01 dextramers in human HCC-derived TILs. Tumors of 8/11 patients contained CGA-A- and CGA-B-specific TILs that were characterized by a tumor reactive phenotype. Upon *in vitro* enrichment, SLP immunogenicity was demonstrated through Interferon gamma ELISPOT in 2/3 of human HCC-derived PBMCs using an *in vitro* co-culture system with autologous antigen presenting cells.

Conclusions Here, we describe the intelligent design of a set of immunogenic SLPs comprising CGA-related epitopes for the global population that can be further exploited for the development of an off-the shelf anti-cancer vaccine to treat HCC.

1182 MODULATING THE TUMOR MICROENVIRONMENT BY A TARGETING TGFB1 WITH VACCINE-INDUCED IMMUNE RESPONSES

Brian Weinert*, Tine Hannibal, Preeyam Patel, Evelina Martinenaite, Marion Chapellier, Marco Carretta, Alireza Alavi, Ayako Pedersen, Muhammad Al-Hajj. *IO Biotech, Copenhagen, Denmark*

Background Recent clinical results[1] provide a rationale for cancer immunotherapy based on activation of "anti-regulatory" T cells. Anti-regulatory T cells recognize antigens expressed by immunosuppressive cells and thereby target pro-inflammatory signals to the tumor microenvironment.[2] TGFB1 promotes immune suppression in diverse cancers. We hypothesize that activating T cells against TGFB1 may allow targeting of pro-inflammatory immune response to TGFB1-expressing tumors while avoiding the toxicities associated with TGFB1 pan-inhibition. TGFB1-specific T cells are frequently detected in humans.[3] Vaccination with a TGFB1 peptide ameliorates fibrosis in a model of chronic colitis [4] and enhances the anti-tumor activity of an HPV16 E7-specific vaccine[5], indicating a therapeutic potential of a TGFB1 vaccine. Here we sought to enhance the specificity anti-TGFB1 immune responses and identify peptides with high TGFB1 selectivity (vs TGFB2/3), thereby mitigating potential off-target toxicities. To understand the TGFB1 landscape in human tumors we performed a multiplexed IHC analysis of TGFB1 expression on tumor cells and the multiplicity of cells in the tumor microenvironment.

Methods PBMCs were assayed by ELISPOT to measure responses to peptides from TGFB1, TGFB2, and TGFB3. TGFB1 expression was examined by multiplex immunofluorescence in a tissue microarray panel of tumor indications with hyperplexed visualization of markers on a single section. Vaccination is evaluated in mouse models expressing TGFb1. Tumor growth monitored, organs and tumor samples collected. Histopathological examination is performed on multiple tissues. Vaccine activity is determined and immune infiltrate analysis conducted by FACS and RNAseq.

Results Healthy human donors exhibited robust immune responses to TGFB1 peptides selected for improved TGFB1-specificity. Stimulation of PBMCs with TGFB1 peptides did not result in cross-reactivity to homologous TGFB2 or TGFB3 peptides. Analysis of TGFB1 expression showed widespread TGFB1 expression in cancers and provides a rationale for targeting TGFB1 in selected indications. Anti-TGFB1 T cell clones functional activity and TGFB1-specificity were confirmed. Therapeutic activity of TGFb1 vaccine in mouse models and in addition to the cellular and molecular analysis of the tumors in the various cohorts will be presented.

Conclusions A TGFb1 vaccine is an attractive new approach for cancer immune therapy. Optimal synthetic long peptides able to elicit robust and highly selective TGFB1-immune responses were developed. These peptides showed ability to change an immune suppressive TME to a pro-inflammatory state and drive efficacy in mouse models. These data support the preclinical development of an TGFb1 vaccine for the treatment of multiple solid tumors.

Immuno-Conjugates and Chimeric Molecules

1183 ASKG915 – AN ANTI-PD-1 ANTIBODY-IL-15 PRODRUG FUSION MOLECULE WITH ENHANCED THERAPEUTIC POTENTIALS

[1]Kurt Shanebeck*, [1]Chunxiao Yu, [1]Shiguang Yu, [2]Jieye Sun, [2]Dongfang Wang, [1]Jeanine Luiz, [1]Ming Li, [1]Ray Chuang, [1]Jing Chen, [1]Samantha Luiz, [1]Lynwel Cunanan, [1]Stone Shi, [1]Matt Hsu, [2]Yong Wen, [1]Jeff Lu, [1]Yuefeng Lu. *[1]AskGene Pharma Inc., Camarillo, CA, USA; [2]Aosaikang Biotherapeutics Co Ltd, Nanjing, China*

Background AskGene has established a proprietary cytokine prodrug platform (Smartkine®) to achieve its overarching objective of modulating immune reactions at a disease site in a selective and controlled manner. Cytokines are potent molecules, yet their broad application as therapeutics has been hampered due to short PK, severe systemic toxicity, and narrow therapeutic window. To improve the therapeutic potential of cytokines, AskGene has developed several antibody-cytokine prodrug fusion molecules using its proprietary SmartKine® platform.

Methods The in vitro activities of ASKG915 were evaluated using reporter cell line and PBMC-based assays. Peripheral immune activation was evaluated in a GvHD model with human PBMC-engrafted NSG mice. Anti-tumor activities were tested in a human PBMC-engrafted tumor xenograft model and a syngeneic tumor model. The PK/PD properties and safety profiles of ASKG915 were assessed in non-human primates (NHPs) following three IV injections every two weeks.

Results ASKG915 showed minimal activity prior to protease-dependent activation and significantly enhanced activity after protease-dependent activation in vitro. Specifically, it has significantly higher activities stimulating PD-1^+ immune cells, presumably through"cis activation". In in vivo efficacy studies, it showed similar potency as a reference anti-PD-1-IL-15 fusion molecule (not masked) while having a better safety profile. In addition, in a GvHD study, ASKG915 at 10 mg/kg i.p. induced lower interferon gamma levels in the periphery at Day 4 compared to the reference molecule at 1 mg/kg i.p. These results showed that, compared to the reference molecule, ASKG915 had comparable immune stimulation in the tumor while having significantly reduced immune stimulation in the periphery. In NHPs, ASKG915 demonstrated prolonged and antibody-like PK profiles. More importantly ASKG915 was well tolerated at the highest dosage tested in NHP, with no cytokine release syndrome (CRS) and minimal immune reaction at injection sites.

Conclusions Activated ASKG915 showed selective stimulation for PD-1^+ immune cells in in vitro assays with human PBMC. ASKG915 in vivo showed tumor-selective activation compared to a reference molecule. In addition, it had extended antibody-like PK in NHPs and was well tolerated at the highest dosage tested in the GLP PK/PD study. It also showed a significantly expanded therapeutic window. An IND filing is planned in the second half of 2022. To our knowledge, ASKG915 is the first anti-PD-1 antibody-IL-15 prodrug fusion molecule moving into clinical development.

Ethics Approval The use of the animals in the studies have been approved by the ethics committees of the research contract organizations (CRO).

1184 SYN101, A FIRST IN CLASS, IMMUNE CELL TARGETED TGF-BETA INHIBITOR THERAPY, SELECTIVELY BLOCKS IMMUNE SUPPRESSION AND DRIVES TUMOR CLEARANCE IN VITRO AND IN VIVO

Dori Thomas-Karyat*, Robert Lutz, Douglas Burtrum. *Synthis Therapeutics, New York, NY, USA*

Background TGF-b is both a validated pro-tumorigenic pathway and a fundemental immunosuppressive cytokine that is overexpressed in virtually all solid tumors. In cancer patients, elevated TGF-b levels limit T cell activation and drive resistance to immune checkpoint inhibitors.[1] Preclinically, mice with a genetic blockade of TGF-b signaling only in T cells reject multiple tumors, including melanoma, lymphoma and colorectal cancers.[2] However, because TGF-b is also essential in maintaining host tissue homeostasis, systemic TGF-b therapies, such as the TGF-b receptor I/ALK5 inhibitors, cause significant host toxicity and have fallen far short in clinical efficacy.[3] Novel, targeted TGF-b therapies are required to improve safety and increase patient response rates.

Methods To improve immune function, efficacy and safety relative to systemic TGF-b therapies, Synthis has developed a first in class, immune cell targeted TGF-b therapy, SYN101, for cancer patients. Utilizing proprietary antibody drug conjugate (ADC) components, SYN101 is comprised of an immune cell specific antibody linked to a potent ALK5 inhibitor payload to selectively block TGF-b signaling in immune cells.

Results As a monotherapy, SYN101 reversed TGF-b mediated immune suppression in primary human T cells and increased expression by 3-4 fold of critical T cell functions required for tumor clearance, such as Granzyme B in cytotoxic killer CD8 + T cells and IFNg levels and fully restored T cell proliferation. In combination studies, SYN101 plus antiPD1 increased IFNg expression by 4-fold, compared to only 2-fold with monotherapy treatment. In the EMT6 breast tumor model, SYN101 + antiPD1 combination led to >93% tumor regression in vivo, with 3/5 complete and 1/5 partial responders ($p=0.0003$, versus antiPD1 alone). Mice with complete responses to SYN101 combination therapy were resistant to subsequent tumor rechallenge, demonstrating immunological memory. In circulating immune cells, combination therapy significantly increased pharmacodynamic markers, CD69 and Ki67+ (CD4+ and CD8+ T cell activation and expansion, respectively), relative to antiPD1 alone ($p<0.05$), correlating with tumor clearance. Similar in vivo efficacy and PD markers were observed with colorectal tumor models, CT26 and MC38.

Conclusions Synthis is the only company developing a non-cytotoxic ADC therapeutic that inhibits TGF-b induced immune suppression and drives tumor clearance in vivo. Current studies will expand in vivo efficacy studies and demonstrating improved safety. Safer, more effective TGF-b therapies, like SYN101, will provide novel monotherapy options for cancer patients. Additionally, because TGF-b sets the overall threshold for T cell activation, SYN101 could improve the efficacy of a variety of therapies, including checkpoint inhibition, radiation and NK/CAR-T therapies.

1185 OPTIMIZATION OF PURINE-BASED TLR7 AGONISTS AS PAYLOADS FOR IMMUNE-STIMULATING ANTIBODY CONJUGATES (ISACS)

[1]Graham Garnett*, [1]Katina Mak, [1]Renee Duan, [1]Truman Hirkala-Schaefer, [1]Manuel Lasalle, [1]Nichole Escalante, [1]Joy Guedia, [2]Kara Moyes, [1]Sam Lawn, [1]Raffaele Colombo, [1]Jamie Rich, [1]Stuart Barnscher. [1]*Zymeworks, Vancouver, Canada*; [2]*Nuvation, Vancouver, Canada*

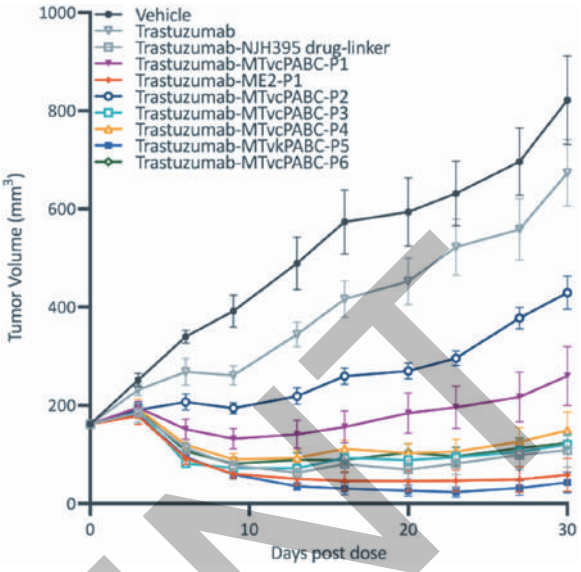
Background Immune-stimulating antibody conjugates (ISACs) consist of antibodies conjugated to immune stimulants and are designed to induce antitumor immune response. Despite promising preclinical results, ISAC clinical development has been hampered by systemic toxicities or lack of efficacy. Substituted purines have previously been identified as a privileged scaffold to elicit TLR7 activation. Here, we demonstrate newly designed purine-based TLR7 agonists conjugated to trastuzumab which show significant tumor volume reduction in a HER2-high gastric cancer xenograft model without associated body weight loss (BWL) in healthy mice.

Methods A library of TLR7 agonists was generated by varying substituents at C2- and N9-positions of a common 6-amino-8-hydroxy-purine scaffold, and the structure-activity relationship was studied *in vitro* using human and mouse TLR7 reporter gene assays (RGAs) as well as measuring cytokine secretion from human peripheral blood mononuclear cells (PBMCs) and mouse splenocytes. Lead TLR7 agonists were conjugated to trastuzumab, and the resulting ISACs were evaluated *in vitro* for their abilities to induce the production of interleukin-6 (IL-6) from human PBMCs or mouse splenocytes co-cultured with NCI-N87 tumor cells. Selected ISACs were tested for efficacy (single iv injection at 2.5 mg/kg) in mice bearing NCI-N87 tumors (figure 1) and for tolerability (single iv injection at 3, 15, and 45 mg/kg) in healthy mice (figure 2).

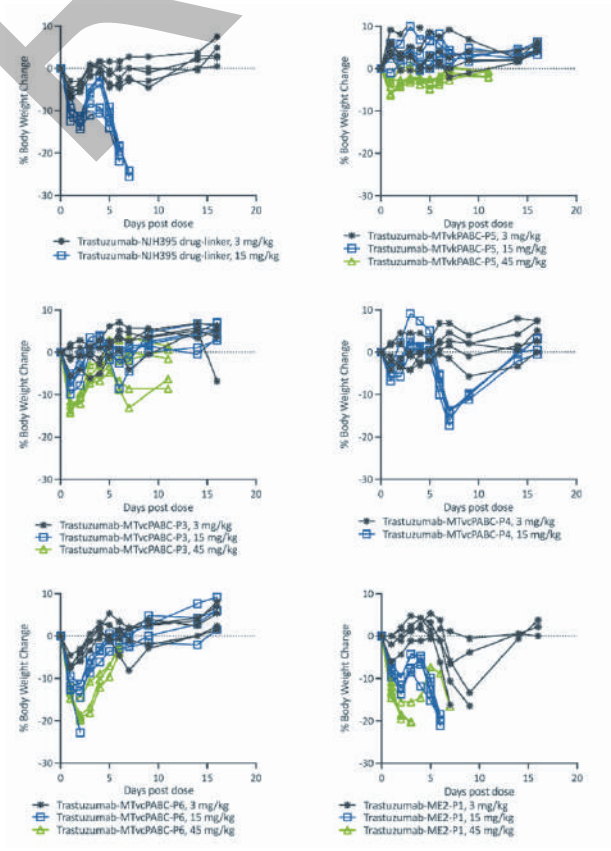
Results We prepared ~220 new TLR7 agonists with different substituents at C2- and N9-positions of the purine scaffold. Compounds with IC50 <100 nM in both human and mouse TLR7 RGAs were further screened for their abilities to induce production of cytokines in PBMCs and mouse splenocytes. Certain substituents were found to be highly immunostimulatory in both human and murine settings. Lead TLR7 agonists were conjugated to trastuzumab with a drug-to-antibody ratio of ~4 using cleavable or non-cleavable linkers. ISACs capable of inducing IL-6 production from PBMCs or splenocytes co-cultured with tumor cells were further tested in an NCI-N87 xenograft model in comparison to unconjugated trastuzumab and trastuzumab conjugated with the same linker-payload as NJH395, a clinical benchmark ISAC. Selected ISACs were tested for tolerability in healthy mice with a lead ISAC (Trastuzumab-MTvkPABC-P5) identified, capable of inducing tumor regression without causing BWL.

Conclusions We demonstrated the potential of using novel purine-based TLR7 agonists as payloads for ISACs. In contrast to other TLR7-agonist conjugates, our lead ISAC appears to have a sufficiently wide therapeutic window displaying efficacy in an NCI-N87 xenograft model at 2.5 mg/kg without causing BWL in healthy mice at 45 mg/kg.

Ethics Approval All animal studies were performed in accordance with Institutional Animal Care and Use Committee (IACUC)-approved protocols.



Abstract 1185 Figure 1 Antitumor activity of selected purine-based TLR7 agonist conjugated to trastuzumab (DAR = 4) in a NCI-N87 tumor cell-line derived xenograft model, following single intravenous administration of 2.5 mg/kg of the respective ISACs or control articles



Abstract 1185 Figure 2 Body weight change over time of healthy mice following single intravenous administration of 3, 15, or 45 mg/kg of the respective ISACs or control articles

1186 SGN-B6A INDUCES IMMUNOGENIC CELL DEATH AS A SECONDARY MECHANISM OF ACTION

Robert Lyon*, Vivian Trang, John Gosink, Michelle Ulrich, Allana Ubben, Sean Allred, Li-Ya Huang, Kelly Hensley, Piper Treuting, Kerry Klussman, Shaylin Higgins, Patrick Younan, Roma Yumul, Natalya Nazarenko. *Seagen, Bothell, WA, USA*

Background SGN-B6A is a novel investigational antibody-drug conjugate (ADC) directed to integrin beta-6 and uses the clinically validated vedotin drug-linker platform that delivers the microtubule disrupting agent, monomethyl auristatin E (MMAE).1 SGN-B6A is designed to bind and internalize the integrin beta-6/ADC complex from the surface of malignant cells and release the cytotoxic payload MMAE. We have previously demonstrated the antitumor activity of SGN-B6A in cell line-derived xenograft models originating from multiple carcinomas as well as patient-derived xenograft models of non-small cell lung cancer (NSCLC).[2] Other ADCs delivering the MMAE payload (including vedotin ADCs using the antibodies brentuximab, enfortumab, ladiratuzumab, and tisotumab) have been shown to induce immunogenic cell death (ICD) in preclinical models[3-7] and have demonstrated promising clinical activity in combination with immunotherapy.[8-10] Since the induction of ICD appeared to be a consequence of the activity of MMAE, and is independent of the antibody that delivers it, we hypothesized that this mechanism of action may also apply to SGN-B6A.

Methods In vitro and in vivo assessment of ICD was performed in cell lines derived from pancreatic carcinoma. Induction of ICD markers were assessed using plate-based assays, flow cytometry, and immunoblotting. ICD was also assessed in vivo using RNA sequencing and immunohistochemistry (IHC) on cell line-derived xenografts.

Results Consistent with this hypothesis we observed that tumor cells treated with SGN-B6A in vitro showed key hallmarks of immunogenic cell death, including markers of endoplasmic reticulum (ER) stress, exposure of calreticulin, and release of ATP and high mobility group protein B1 (HMGB1). Further, in vivo studies demonstrated that treatment with SGN-B6A led to immune activation and recruitment of immune cells to the tumor environment.

Conclusions Preclinical models suggest that, like other vedotin ADCs, SGN-B6A induces immunogenic cell death which then promotes activation and recruitment of immune cells to the tumor. These data provide a strong rationale for the combination of SGN-B6A with immunotherapies, which may further lead to enhanced antitumor activity and can be utilized as a potential treatment for integrin-beta-6-expressing tumors including NSCLC, head and neck squamous cell carcinoma, and esophageal carcinoma. Altogether, our preclinical results support the current evaluation of SGN-B6A in an ongoing phase 1 study (NCT04389632).

1187 ENFORTUMAB VEDOTIN INDUCES IMMUNOGENIC CELL DEATH, ELICITS ANTITUMOR IMMUNE MEMORY, AND SHOWS ENHANCED PRECLINICAL ACTIVITY IN COMBINATION WITH IMMUNE CHECKPOINT INHIBITORS

[1]Devra Olson, [1]Patrick Younan, [1]Bernard Liu, [1]Gabriele Blahnik-Fagan, [1]John Gosink, [1]Katie Snead, [1]Elena Tenn, [1]Kelly Hensley, [1]Disha Sahetya, [1]Albina Nesterova, [1]Margo Zaval, [1]Anthony Cao, [1]Christine O'Day, [1]Ryan Heiser, [1]Timothy Lewis, [1]Shyra Gardai, [2]Taisuke Nakazawa, [3]Masashi Shimazaki, [1]Christopher Carosino, [1]Sharsti Sandall*. *[1]Seagen, Inc., Bothell, WA, USA; [2]Astellas Pharma Inc., Tsukuba, Ibaraki, Japan; [3]Astellas Research Institute of America, Northbrook, IL, USA*

Background Enfortumab vedotin (EV) is a first-in-class Nectin-4-directed antibody-drug conjugate (ADC) with demonstrated improved overall survival in patients with previously treated advanced-stage urothelial carcinoma.[1] EV is comprised of a fully human Nectin-4-directed monoclonal antibody conjugated to the microtubule-disrupting agent monomethyl auristatin E (MMAE) by a protease cleavable maleimidocaproyl-valine-citrulline linker. EV has a multifaceted mechanism of action. Previously, we demonstrated that EV induces antitumor activity in vitro via direct cytotoxicity on Nectin-4-expressing malignant cells and indirect bystander activity on neighboring Nectin-4 negative cells, both of which are mediated by MMAE release within target cells. Here, we expand upon the mechanism of action and show EV induces tumor cell killing in a manner leading to immunogenic cell death (ICD) and improves antitumor responses when combined with checkpoint inhibitors.

Methods The ability of EV to induce hallmarks of ICD was evaluated in vitro in Nectin-4-expressing human urothelial carcinoma cell lines. Immune activation associated with ICD was assessed in vitro in monocytes co-cultured with EV-treated tumor cells and in vivo by immunohistochemistry, RNA-seq, flow cytometry, and immune cytokine profiling. The effects of EV plus anti-PD-1 on tumor growth inhibition, the tumor microenvironment, and immune memory were evaluated in syngeneic mouse models engineered to express human Nectin-4. Antitumor immune memory was also assessed in mice vaccinated with EV-treated cells.

Results In vitro, EV induced ICD via MMAE-mediated microtubule disruption and concomitant endoplasmic reticulum (ER) stress, as evidenced by increased phosphorylation of JNK, extracellular release of inflammatory mediators ATP and HMGB1, and cell surface exposure of calreticulin. Xenograft tumors treated with EV demonstrated upregulation of MHC genes as well as genes involved in ER stress, autophagy, and type I interferon response. Additionally, there were noted increases in both macrophages and dendritic cells along with cytokines involved in chemoattraction and T-cell stimulation. Consistent with ICD induction, vaccination with EV-treated Nectin-4-expressing tumor cells promoted antitumor immunity and provided protection against tumor rechallenge. Lastly, the combination of EV with PD-1 inhibition improved antitumor activity and durable immunity in vivo, consistent with complementary modes of action of these two anticancer agents.

Conclusions These data provide insight into the clinical activity observed with EV and bolster the scientific rationale to combine EV with checkpoint inhibitors, which is currently an area of active clinical investigation across multiple studies.[2-6]

1188 ANTIBODY SUBSTRATE OLIGONUCLEOTIDE CONJUGATES (ASOCS): A NEW CLASS OF IMMUNOTHERAPEUTIC AGENTS TO INHIBIT METASTASIS OF TUMOR CELLS AND BLOCK CHECKPOINT INHIBITION

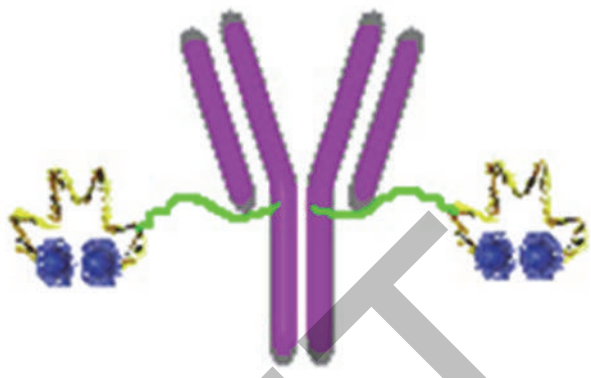
[1]Beverly Packard*, [2]Akira Komoriya. [1]*OncoArrestin, LLC, Gaithersburg, MD, USA*; [2]*OncoImmunin, Inc., Gaithersburg, MD, USA*

Background Armed monoclonal antibody (mAb)-based therapeutics, e.g., antibody-drug conjugates (ADCs) or antibody-oligonucleotide conjugates (AOCs), can be highly effective for patients with gene-amplified or protein-overexpressing tumors. However, many tumor cells do not overexpress surface antigens recognized by mAbs and, for these patients, armed mAb therapies are often poorly effective. Additionally, expression of checkpoint molecules on tumor infiltrating lymphocytes (TILS) can vary with disease progression. ASOCs are a new class of modified mAb that enable delivery of oligonucleotides into targeted cells without requiring overexpression of the antigen or internalization of the mAb (figure 1).

Methods We have covalently modified mAbs such that they are linked to protease substrates specific for proteases that enable metastasis; the latter are also covalently linked to oligonucleotides bearing H-type excitonic dimers. The substrates can be cleaved by proteolytic enzymes on a tumor cell surface essential for metastasis, e.g., matrix metalloproteases (MMPs). Cleavage of the protease substrates results in localization of oligonucleotides at a targeted cell surface. Oligonucleotides (both single strand DNA and double strand RNA) are then able to diffuse into the tumor cell or lymphocyte and inhibit translation of targeted mRNAs.

Results Oligonucleotides cleaved from ASOCs by cell surface proteases enter cells *via* the delivery mechanism we have previously used to block HIV proliferation in $CD4^+$ T cells.[1] Thus, ASOCs differ from the current armed mAb-based therapies, e.g., antibody-drug conjugates (ADCs) or antibody-oligonucleotide conjugates (AOCs), in that delivery of the oligonucleotides into the cytoplasm does not require internalization of the mAb or endosomal processing; additionally, off-target toxicity will be reduced by release at the cell surface of the payload (the oligonucleotide). With this approach, using an MHC-Class I mAb (KE-2) or the antiCD20 mAb Rituxan we have delivered antisense oligonucleotides targeting β-Actin and *KRAS* into the following tumor cell lines: Raji (Burkitt's lymphoma), A549 (NSCLC), COLO205 (colon), MB-MDA231 (breast), and Caki (kidney). Additionally, anti-PD-1 and anti-PD-L1 mAbs can be derivatized to block checkpoint inhibition. Proof of delivery of oligonucleotides into cells was confirmed by confocal imaging after binding of mAbs to the cell surface with quantitation by flow cytometry.

Conclusions ASOCs represent a unique immunotherapeutic structural class that overcomes the previous requirements of: (1) internalization of the mAb and (2) delivery of the payload (oligonucleotides) through intracellular degradative organelles, e.g., lysosomes. Additionally, off-target toxicity is minimized.



Abstract 1188 Figure 1 Structure of ASOCs: mAbs (purple) are covalently linked to protease substrates (green) specific for proteases that enable metastasis; the latter are also covalently linked to oligonucleotides (yellow) bearing H-type excitonic dimers (blue)

1189 A GPC2 ANTIBODY-DRUG CONJUGATE REPROGRAMS THE NEUROBLASTOMA IMMUNE MILIEU TO ENHANCE MACROPHAGE-DRIVEN THERAPIES

[1]Guillem Pascual-Pasto*, [1]Brendan McIntyre, [1]Rawan Shraim, [1]Samantha Buongervino, [2]Amy Erbe, [3]Dontcho Jelev, [1]Anna Giudice, [1]Daniel Martinez, [4]Laura Garcia-Gerique, [3]Dimiter Dimitrov, [2]Paul Sondel, [1]Kristopher Bosse. *[1]The Children's Hospital of Philadelphia, Philadelphia, PA, USA; [2]University of Wisconsin, Madison, WI, USA; [3]University of Pittsburgh, Pittsburgh, PA, USA; [4]Wistar Institute, Philadelphia, PA, USA*

Background Antibody-drug conjugates (ADCs) have emerged as an effective and safe anticancer therapy. ADCs may induce immunogenic cell death (ICD) that promotes additional endogenous antitumor immune responses. We have identified GPC2 as a target in neuroblastoma and developed an anti-GPC2 pyrrolobenzodiazepine (PBD) dimer-bearing ADC (D3-GPC2-PBD). Here, we explored whether the D3-GPC2-PBD ADC induces ICD, reprograms the neuroblastoma tumor immune microenvironment (TIME) and synergizes with other immunotherapies.

Methods Mouse neuroblastoma cell lines NXS2 and 9464D were engineered to express GPC2 to study D3-GPC2-PBD immunoregulatory properties. Induction of ICD was evaluated *in vitro* by quantifying calreticulin and HSP70/90 membrane translocation and HMGB1 and ATP release, and *in vivo* performing vaccination/re-challenge experiments. ADC modulation of the neuroblastoma TIME was studied using RNA-seq, cytokine profiling, CyTOF, and flow cytometry. ADC efficacy was tested alone and in combination with anti-CD40 agonists and anti-CD47 antagonists. We also studied ADC-mediated ICD in human neuroblastoma cells *in vitro* and elucidated synergy with macrophages and CD47 blockade *in vitro* and *in vivo* in a neuroblastoma patient-derived xenograft (PDX).

Results In GPC2-expressing murine neuroblastoma cells, the GPC2 ADC induced markers of ICD (mean ICD marker fold-change of 5.3 vs vehicle-treated controls). *In vivo*, subcutaneous vaccination with ADC-treated NXS2-GPC2 cells prevented tumor growth in 72% and 70% of mice re-challenged with naïve GPC2 isogenic and empty-vector NXS2 cells, respectively. Transcriptomic and immunophenotypic analyses of ADC-treated NXS2-GPC2 allografts revealed reprogramming of the TIME to a pro-inflammatory state. By RNA-seq, ADC-treated tumors showed upregulation of genes related to immune cell recruitment and activation (*e.g.*, *Ccl2*, *Cd40*, *Cd80*, or *Cd69*) and cytokine arrays showed upregulation of CXCL16, CD40 and CCL12. By CyTOF and flow cytometry, ADC increased intratumor infiltration of activated $CD40^+$, $MHCII^+$ macrophages and $CD69^+$, $CD8^+$ T-cells. In this model, inhibition of antitumor macrophages and T-cells impaired ADC efficacy, whereas combination of GPC2 ADC plus CD40 agonist antibodies induced 100% of complete responses. In human neuroblastoma cells, ADC treatment induced phagocytosis of NB-EbC1 ($P=0.0004$) but not SMS-SAN cell lines, which correlated with higher calreticulin translocation in NB-EbC1 cells. The addition of CD47 blockade increased ADC-mediated phagocytosis of SMS-SAN cells ($P=0.0001$). Finally, we observed that low doses of the D3-GPC2-PBD ADC combined with CD47 antagonist antibodies significantly increased survival of mice bearing neuroblastoma PDXs compared to ADC treatment alone ($P=0.012$).

Conclusions We elucidated the immunoregulatory properties of GPC2-targeted ADCs and showed robust efficacy of this ADC in combination with rationally selected antibodies that modify host macrophage anti-tumor immunity.

Acknowledgements We thank the DNA sequencing, Human Immunology, and CyTOF core facilities at the University of Pennsylvania for their work on plasmid verification, human monocyte isolation, and mass spectrometry analysis, respectively. We also would like to thank the Pathology and Small Animal Imaging facility cores at The Children's Hospital of Philadelphia. Additionally, we appreciate the Cancer Genomics Laboratory at Sidney Kimmel Cancer Center (Thomas Jefferson University) for their work on RNA-sequencing. Finally, we thank Drs. 1190 SGN-B7H4V INDUCES IMMUNOMODULATORY CHANGES TO THE TUMOR MICROENVIRONMENT AND PAIRS WELL WITH AN ANTI-PD1 AGENT IN A PRECLINICAL MODEL

Michelle Ulrich, Angela Epp, Kelly Hensley, Julie Hahn, Sean Allred, John Gosink, Piper Treuting, John Hernandez Villanueva, Sarah Anderson, Alyson Smith, Jason Schrum, Natalya Nazarenko, Shyra Gardai*, Elizabeth Gray. *Seagen, Bothell, WA, USA*

Background SGN-B7H4V is an investigational vedotin antibody-drug conjugate (ADC) directed to B7-H4, an immune checkpoint ligand with elevated expression on multiple solid tumor types, including breast, ovarian, and endometrial tumors.[1] SGN-B7H4V is composed of an anti-B7-H4 human monoclonal antibody conjugated to the microtubule disrupting agent monomethyl auristatin E (MMAE) via a protease-cleavable peptide linker. This vedotin drug linker system has been clinically validated in multiple ADC programs, including brentuximab vedotin, enfortumab vedotin, and tisotumab vedotin. SGN-B7H4V is designed to bind the immune checkpoint ligand B7-H4, internalize the ligand/ADC complex from the surface of B7-H4-expressing tumor cells and release the cytotoxic payload, MMAE, within the cell. SGN-B7H4V demonstrates strong antitumor activity in preclinical models through multiple potential mechanisms including direct MMAE-mediated cytotoxicity as well as antibody-mediated functions including antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis (ADCP) in vitro.[1] Vedotin ADCs can elicit MMAE-mediated immunomodulatory changes to the tumor microenvironment (TME) via induction of immunogenic cell death [2–4] which may position vedotin ADCs to uniquely synergize with checkpoint inhibitors. This is supported by clinically meaningful responses observed when vedotin ADCs are paired with anti-PD1 agents.[5,6] Here, we use an immunocompetent mouse model to characterize SGN-B7H4V-mediated immunomodulatory activity along with antitumor activity and induction of immune memory in combination with an anti-PD1 agent.

Methods Immunomodulatory changes in SGN-B7H4V-treated tumors were characterized by RNAseq and immunohistochemistry. The antitumor activity of SGN-B7H4V as a monotherapy and in combination with an anti-PD1 agent was evaluated using a murine B7-H4-expressing Renca syngeneic tumor model. Finally, tumor rechallenge experiments were performed to evaluate immune memory.

Results Treatment of B7-H4-expressing syngeneic tumors with SGN-B7H4V led to immunomodulatory changes in the TME, including recruitment of multiple immune cell types and upregulation of immune-related genes that have been previously associated with response to anti-PD(L)1 agents. Moreover, SGN-B7H4V drove robust antitumor activity as well as durable immune memory as a monotherapy and in combination with an anti-PD1 agent.

Conclusions In preclinical models, SGN-B7H4V demonstrates robust antitumor activity accompanied by immunomodulatory changes in the TME. Moreover, SGN-B7H4V in combination with an anti-PD1 agent led to improved antitumor activity and elicited durable immune memory. Altogether, these nonclinical data further support the evaluation of SGN-B7H4V as a monotherapy in the ongoing Phase 1 Study of SGN-B7H4V in Advanced Solid Tumors (NCT05194072) and potential future clinical combinations with immunotherapies.

1191 STRO-003 IS A NOVEL ROR1-TARGETED ADC FOR BREAST AND LUNG CANCER

[1]Alice Yam*, [1]Jeff Hanson, [1]Krishna Bajjuri, [1]Sihong Zhou, [1]Dayson Moreira, [1]Jennifer Smith, [2]Cristina Abrahams, [3]Xiaofan Li, [1]Grace Lee, [1]Stephanie Armstrong, [1]Amandeep Gakhal, [1]Daniel Calarese, [1]Young Park, [1]Miao Wen, [1]Gang Yin, [4]Simon Chivers, [1]Faye Hsieh, [1]Guifen Xu, [1]Werner Rubas, [1]Andreas Maderna, [1]Kristin Bedard, [1]Trevor Hallam. *[1]Sutro Biopharma, South San Francisco, CA, USA; [2]Seagen, South San Francisco, CA, USA; [3]Sutro Biopharma, Inc., South San Francisco, CA, USA; [4]ibiologix, Basel, Switzerland*

Background Receptor tyrosine kinase-like orphan receptor 1 (ROR1) is a cell-surface, oncofetal protein whose expression is correlated with oncogenic properties such as enhanced proliferation, survival, and chemoresistance. Despite its prevalence across many cancer indications, ROR1 has restricted expression in adult tissues, making it an ideal target for targeted therapies.

Methods We have designed a novel ROR1-targeted ADC, STRO-003, which is composed of an anti-ROR1 human IgG1 antibody (SP11285) conjugated to an exatecan warhead via a stable, β-glucuronide linker (SC3417) with a drug-to-antibody ratio (DAR) of 8. SP11285 was discovered using Fab ribosome display as a selective and high affinity ROR1 antibody that exhibits favorable internalization activity upon cell binding, consistent with an ADC mechanism of action. The exatecan payload is a potent topoisomerase I inhibitor of the camptothecin class and has anti-proliferative activity against a variety of cancer cell lines *in vitro*. The SC3417 linker-payload releases exatecan upon glucuronidase linker cleavage and is site-specifically conjugated using strain promoted alkyne-azide cycloaddition (SPAAC) to form a stable, homogeneous ADC.

Results The anti-Ror1 antibody SP11285 binds with high affinity to the ROR1 immunoglobulin domain and is cross-reactive to both rodent and monkey ROR1. Unlike other camptothecin analogs, exatecan is resistant to overexpression of Pgp, and therefore has reduced risk of multi-drug resistance. Exatecan also induces immunogenic cell death, thereby providing an avenue for engaging the immune system and enriching the anti-tumor response. STRO-003 has exhibited potent and specific activity in xenograft models for TNBC and lung cancer, and importantly, elicited significant anti-tumor suppression in a panel of NSCLC PDx models, including those with low ROR1 expression. In nonclinical safety studies conducted in cynomolgus monkeys, STRO-003 was tolerated up to 45 mg/kg without signs of hematological toxicity or tissue-specific lesions. By comparison, a similar exatecan-ADC with a cathepsin-sensitive linker was more poorly tolerated and elicited signs of inflammation in the lung.

Conclusions Our data suggests that STRO-003 is a promising clinical candidate for solid tumor indications and we have initiated IND-enabling studies.

Ethics Approval All in vivo procedures were conducted in compliance with the guidelines of the Institutional Animal Care and Use Committee (IACUC) at Sutro Biopharma or commissioned contract research organization (CRO).

1192 IDENTIFICATION OF ONCOGENE-INDUCED SURFACE PROTEIN IL1RAP AS AN IMMUNOTHERAPY TARGET IN MULTIPLE CANCERS

[1]Hai-Feng Zhang*, [2]Wei Li, [3]Christopher Hughes, [4]Rajesh Kumar, [1]Alberto Delaidelli, [3]Yue Zhou Huang, [3]Michael Lizardo, [4]Rimas Orentas, [2]Dimiter Dimitrov, [1]Poul Sorensen. *[1]University of British Columbia, Vancouver, Canada; [2]University of Pittsburgh, Pittsburgh, PA, USA; [3]BC Cancer Research Centre, Vancouver, Canada; [4]Seattle Children's Research Institute, Seattle, WA, USA*

Background Adoptive and antibody-based immunotherapies are highly successful in the clinic for the treatment of certain malignancies. However, effective immunotherapy targets remain elusive for various cancers, in particular metastatic diseases. Certain existing targets often encounter antigen loss, leading to tumor relapse. Thus, it is crucial to discover novel cell surface targets that are essential for tumor sustenance and metastasis, and thus less prone to immunotherapeutic escape.

Methods To uncover crucial cell surface proteins that drive anoikis-resistance and metastasis, we performed an integrated analysis of the global proteome and acute translatome in distinct oncogene-transformed and non-transformed cells in 3D cultures. Anoikis-resistance *in vitro* and metastasis *in vivo* were measured by 3D spheroid cultures and a murine renal subcapsular implantation metastasis model, respectively. Candidate surface targets from the screens were evaluated by immunohistochemistry using tissue microarrays (TMAs) of multiple human cancers, and TMAs consisting various adult and pediatric normal tissues. Phage-display biopanning was performed to identify single-domain VH binders, based on which CAR-T cells and a panel of humanized IgG1 antibody-drug conjugates (ADCs) were engineered. The CAR-T cells and ADCs were tested both *in vitro* and *in vivo* using murine tumor xenograft models.

Results The screens identified that distinct oncoproteins such as mutant $KRas^{G12V}$, $KRas^{G13D}$, ETV6-NTRK3, and EWS-FLI1 each upregulate IL1RAP (IL-1 receptor accessory protein) to suppress tumor cell anoikis. IL1RAP is highly expressed on cell surface in multiple malignancies, including Ewing sarcoma (EwS), melanoma, pancreatic ductal adenocarcinoma, high-grade astrocytoma, glioblastoma, and ALK+ anaplastic large cell lymphoma. Genetic *IL1RAP* inactivation in EwS triggers anoikis and ferroptosis *in vitro* and impedes metastasis *in vivo*. Importantly, IL1RAP is minimally expressed in pediatric and adult normal tissues and blood cells, nominating IL1RAP as a promising surface target for immunotherapy. We identified a panel of novel and highly specific IL1RAP binders via phage-display biopanning, and engineered IL1RAP CAR-T cells and anti-IL1RAP ADCs conjugated to cytotoxic payloads such as pyrrolobenzodiazepine (PBD) dimer and Duocarmycin SA. IL1RAP CAR-T cells and anti-IL1RAP ADCs induced massive cell killing in a panel of EwS cells *in vitro*. Although the efficacy of IL1RAP CAR-T cells in murine EwS xenografts was limited by an immune suppressive tumor microenvironment, the anti-IL1RAP ADCs effectively limited EwS tumor progression at low doses such as 0.1mg/kg.

Conclusions Therefore, we have defined surface IL1RAP as an immunotherapy target in EwS and potentially other human malignancies, and our pre-clinical studies suggest anti-IL1RAP ADCs as a highly promising immunotherapy strategy.

1193 INDUCING IMMUNOGENIC CELL DEATH AND ANTITUMOR ACTIVITY IN RESPONSE TO RADIOIMMUNOTHERAPY

Denis Beckford*, Jason Li, Caroline Jennings, Megan McCloskey, Le-Cun Xu, Debbie Lewis, Patrik Brodin, Amanda Chin, Monideepa Roy, Mary Chen, Helen Kotanides. *Actinium Pharmaceuticals, Inc, New York, NY, USA*

Background Conventional cancer therapies, such as chemotherapy and external beam radiation therapy, are known to induce the release of damage-associated molecular patterns (DAMPs) that stimulate an antitumor immune response. Radioimmunotherapy (RIT) offers a unique opportunity by delivering cytotoxic energy specifically to target-expressing cancer cells. However, the immunomodulatory properties of RIT are not well characterized. Hence, we hypothesized that tumor cell cytotoxicity induced by radiolabeled antibodies (ARCs) can activate an immune response by releasing DAMPs. Herein we investigated the effects of alpha or beta emitting ARCs (^{225}Ac and ^{177}Lu) on DAMP induction and engagement of the innate immune response in vitro. Furthermore, we evaluated the antitumor effects of ^{225}Ac and ^{177}Lu ARCs in vivo.

Methods ^{225}Ac or ^{177}Lu ARCs (CD33, HER2 and HER3) were prepared using p-Bn-SCN-DOTA. ARCs were evaluated for target-binding using human recombinant proteins and receptor positive tumor cell lines. The cytotoxic effect of ARCs was determined by XTT, flow cytometry and clonogenic assays. DAMP induction was investigated in cells treated with ^{225}Ac or ^{177}Lu ARCs and levels of CRT, HSP70, and HMGB1 were measured by flow cytometry and ATP concentrations determined by ELISA. The influence of ARC treatment on the innate immune response was evaluated by flow cytometry. The antitumor effects of ^{225}Ac or ^{177}Lu ARCs was examined in mice bearing human NCI-H1975 NSCLC xenograft tumors.

Results The ^{225}Ac and ^{177}Lu ARCs showed cytotoxicity and inhibited colony formation in target expressing cancer cells in vitro. DAMP levels in ^{225}Ac ARC treated cells was induced, including CRT translocation to cell surface, increased ATP release and HSP70 upregulation. Furthermore, an enhanced innate immune response was observed following ^{225}Ac ARC treatment. Contrastingly, treatment with ^{177}Lu ARCs did not show significant DAMP induction compared to untreated cells in the dose ranges studied. However, the efficacy study testing ^{225}Ac and ^{177}Lu ARCs in mouse xenograft model of NSCLC revealed that both ARCs had similar antitumor efficacy in vivo.

Conclusions The observations from this study suggest that ^{225}Ac radionuclide-based ARCs as part of their mechanism of action can induce immunogenic cell death by the release of DAMPs whereas beta radionucleotides such as ^{177}Lu may utilize different damage response pathways. These findings could be explained by DNA double stranded breaks caused by alpha radiation. Importantly, both ^{225}Ac and ^{177}Lu ARCs showed in vivo antitumor activity that warrants their further evaluation as warheads for RIT.

1194 DISCOVERY AND PRE-CLINICAL DEVELOPMENT OF A NOVEL AND DIFFERENTIATED EPHA2-TARGETED ANTIBODY IN MULTIPLE BISPECIFIC FORMATS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1194

Maryam Bhatti, Michael Weiss, Amanda Haltom, Jessica Finn, Annie Gai, Anne Ye, Danhui Zhang, Cathrin Czupalla, Andreea Stuparu, Yvonne Leung, Erin Wechsler, Iraz Aydin, Daniel Emerling, Amy Manning-Bog, Nikhil Vad, Alexander Scholz, Philippe Marguet, Shaun Lippow*. *Atreca, Inc., San Carlos, CA, USA*

Background Eph proteins are the largest family of receptor tyrosine kinases in humans and are normally involved in cell-to-cell communication, plasticity, and patterning. EphA2 represents an attractive therapeutic target due to its overexpression in many cancers. Unfortunately, to date, clinical efforts to target EphA2 have demonstrated limited efficacy or significant toxicity.

Methods We sequenced the antibody chains expressed by single plasmablast B cells from patients with cancer and identified antibodies selectively binding to non-autologous human tumor tissues. The target and epitope of an antibody of interest were identified by FACS, yeast display, and crystallography methods. Lead optimization used sequence- and structure-based rational mutations, combined with selections from high-throughput yeast display screening. Optimized leads were engineered into several weaponized formats and tested for safety and anti-tumor activity.

Results An anti-EphA2 antibody was identified from plasmablasts of a patient with lung cancer after treatment with nivolumab. This antibody binds to the surface of tumor cell lines and selectively to human tumors compared with normal tissue. The antibody binds a novel conformational epitope on the most membrane-proximal fibronectin type-II domain, and this epitope is conserved across relevant model species. The epitope targeted is non-overlapping with biologics previously or currently in clinical development exhibiting neither agonist nor antagonist activity.

Antibody engineering yielded leads with significantly improved potency and developability, exhibiting single-digit picomolar activity in cell-based assays. Optimized leads demonstrated tumor-selective binding across multiple tumor types and labeling of plasma membranes and cytoplasmic puncta.

Antibody weaponization in multiple formats delivered potent anti-tumor activity in vivo without safety signals. A novel 4-1BB bispecific significantly enhanced therapeutic index compared with untargeted 4-1BB agonist antibodies. A weak 4-1BB agonist paired with tumor targeting drove cross-linking and activation at the tumor and dose-dependently inhibited tumor growth while avoiding the alanine transaminase increases observed with a urelumab surrogate. In addition, a CD3-bispecific T-cell engager was generated that exhibited sub-picomolar potency in vitro and robust tumor reduction in vivo. Separately, an antibody–drug conjugate version, ATRC-301, is entering IND-enabling studies and is described elsewhere.

Conclusions Our EphA2 program leverages a patient-derived antibody and a novel epitope to deliver differentiated biologics for this potentially high-value target. Optimized leads with high potency and developability exhibit anti-tumor activity in multiple formats, including a 4-1BB bispecific. These data demonstrate the power of our antibody discovery platform to uncover unique antibodies and their epitopes.

1195 GENERATION OF A HIGHLY POTENT, CIS-SIGNALING PD1-IL2 IMMUNOCYTOKINE USING A NOVEL CHEMICAL SYNTHESIS AND CONJUGATION PLATFORM

Jean Carralot*, Matilde Arévalo Ruiz, Rubén Alvarez Sanchez, Robert Tam, Lilian Gremlich, Andrew Chi, Vijaya Pattabiraman Bertolt Kreft. *Bright Peak Therapeutics, Basel, Switzerland*

Background Immunocytokines (IC) provide the opportunity to simultaneously address distinct and complementary mechanisms of action and to deliver cytokine payloads to specific immune cells ("cis-signaling") resulting in enhanced antitumor activity. To generate ICs, we developed an entirely different approach based on the site-specific, chemical conjugation of cytokines to existing antibodies (Ab) taken "off-the-shelf". Using an anti PD-1 Ab that is in advanced stages of clinical development, we generated a PD1-IL2 IC to target an "alpha-dead" IL-2 to tumor resident PD-1^{high} effector T cells while simultaneously releasing PD-1-mediated immune suppression.

Methods Our novel protein engineering platform allows the generation of enhanced and conjugatable cytokines that can be used as "payloads" to create ICs. Enhanced cytokine payloads can be chemically conjugated to existing Abs in a site-specific manner without prior Ab engineering yielding ICs with a defined drug-Ab ratio. Using various IL-2 variants that lack IL-2Ra binding ("alpha-dead"), we created PD1-IL2 ICs with different payload potencies. PD1-IL2 ICs were characterized *in vitro* and subsequently *in vivo* determining PK/PD profiles and antitumor efficacy in tumor-bearing transgenic mice expressing human PD-1.

Results Chemical conjugation was found to have no impact on the potency and selectivity of the cytokine payload nor to alter Ab properties such as antigen recognition or binding to either Fc gamma receptors or the neonatal Fc receptor. PD1-IL2 IC shows superior potency *in vitro* due to *cis*-signaling on PD-1^{high} CD8+ T cells and, compared to a non-PD1 targeted control IL-2 IC, it exhibits increased tumor over plasma exposure levels. This translates into strong immune stimulation resulting in superior antitumor efficacy compared to the naked PD-1 Ab, the non-PD1 targeted IL-2 IC, and to the combination of both agents.

Conclusions Bright Peak has developed a unique, chemical conjugation process that enables the generation of ICs via rapid conjugation of synthetically engineered cytokines to the Fc domain of existing human Abs. We generated a PD1-IL2 IC with significantly enhanced potency in PD-1^{high}versus PD-1^{low} T cells. In mice, PD-1-targeting and *cis*-signaling results in high tumor exposure, potent immune stimulation, and strong antitumor efficacy. These results demonstrate the ability of our cytokine engineering platform to generate potent, multi-modal IC therapeutics that synergize complementary mechanisms of action.

1196 STREAMLINING T CELL ENGAGER DEVELOPMENT WITH A DIVERSE PANEL OF FULLY HUMAN CD3-BINDING ANTIBODIES, BISPECIFIC ENGINEERING TECHNOLOGY, AND AN INTEGRATED DISCOVERY ENGINE

Lindsay DeVorkin, Juntao (Matt) Mai, Kate Caldwell, Tim Jacobs, Raffi Tonikian, Karine Herve, Yuri Hwang, Cristina Faralla, Wei Wei, Emma Lathouwers, Rhys Chappell, Stefan Hannie, Katherine Lam, Harveer Dhupar, Tran Tran, Melissa Cid, Lena Bolten, Tova Pinsky, Ping Xiang, Courtenay Lai, Ahn Lee, Patrick Chan, Jasmine Chin, Aaron Yamniuk, Kush Dalal, Bryan Barnhart*. *AbCellera, Vancouver, Canada*

Background CD3 T cell engagers have the potential to be a cornerstone of immuno-oncology. However, a limited pool of CD3-binding antibodies and technological challenges in engineering bispecifics have hindered development. Discovering effective T cell engagers requires two target-binding arms — a CD3 arm that fine-tunes T cell activation and a tumor arm with high specificity for cancer cells — optimized as a whole to work in concert with each other. Beginning with diverse panels of antibodies increases the probability of finding appropriately potent and developable T cell engagers and reduces the need for downstream engineering.

Methods We used microfluidic technology to screen more than 3.5 million single cells from humanized mice and identified >200 CD3-specific antibodies. Using high-throughput assays, we determined affinity for CD3$\epsilon\delta$ and CD3$\epsilon\gamma$, cross-reactivity to human and cyno primary T cells, CD3 binding kinetics, and epitope bins. We assessed T cell activation by measuring CD25 and CD69 expression by flow cytometry. We then used our bispecific engineering platform, OrthoMab^{TM}, to generate a proof-of-concept panel of CD3 x EGFR bispecific antibodies. Developability properties were assessed, including hydrophobicity (aHIC), self-association (AC-SINS), polyspecificity (BVP-ELISA), stability (nanoDSF), and aggregation (aSEC). CD3 T cell engager potencies were measured using an NFAT reporter T cell activation assay and an xCELLigence tumor cell killing assay, and cytokine release was assessed by FLEXMAP CD.

Results We identified hundreds of fully human CD3-specific antibodies that are diverse, developable, and validated. The antibodies displayed a wide range of CD3 binding affinities (K_D ~1 nM to 1 μM), binding kinetics, and T cell activation potencies (EC_{50} ~6 to 190 nM). Data on this novel panel includes epitope binning, which revealed human and cyno CD3-binders that are distinct from previously described cross-reactive antibodies. The antibodies were assessed using a range of biophysical assays and have favorable developability properties. In an expanded proof-of-concept study, we used OrthoMab^{TM} to generate a panel of CD3 x EGFR bispecific antibodies. The resulting bispecifics had favorable developability properties, and displayed a wide range of antigen-dependent T cell activation (EC_{50} ~2 pM to 2 nM) and tumor cell killing potencies (EC_{50} ~0.01 to 1 nM). From this panel, we identified potent T cell engagers that achieved >90% tumor cell killing with low levels of cytokine release.

Conclusions By integrating our panel of CD3-binding antibodies with our bispecific engineering and high-throughput antibody assessment capabilities, we identified developable CD3 T cell engagers with potent tumor cell-killing activity and minimal cytokine release.

1197 OPTIMIZING A T CELL-ENGAGING BISPECIFIC ANTIBODY TARGETING THE HIGHLY RECURRENT P53 R175H NEOANTIGEN VIA AFFINITY MATURATION

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1197

Sarah DiNapoli*, Emily Hsiue Wright,, Brian Mog, Sandra Gabelli, Kenneth Kinzler, Bert Vogelstein, Shibin Zhou. *Johns Hopkins Univ. School of Medicine, Baltimore, MD, USA*

Background Targeting mutation-associated neoantigens (MANAs) is a highly-cancer specific strategy to selectively eliminate cells harboring common driver mutations in genes encoding intracellular proteins such as Ras and p53.[1, 2] T cell-engaging bispecific antibodies targeting MANAs redirect T cells to kill cancer cells presenting mutant peptides on human leukocyte antigens (pHLA). However, T cell-redirecting therapies' efficacy can be limited by the low antigen density of these MANAs on the cell surface. Here, we investigate whether increasing the affinity of a T cell-engaging bispecific antibody (clone H2) targeting the p53 R175H MANA (HMTEVVR**H**C) presented on HLA-A*02:01 (R175H/A2) improves its efficacy *in vitro* and *in vivo*.

Methods To identify higher affinity variants, we screened a phage display library consisting of 1159 single-amino acid variants at 61 sites in the six complementarity determining regions of the H2 single chain variable fragment targeting R175H/A2. Variants retaining R175H/A2 specificity were selected over multiple rounds of panning followed by affinity enrichment via thiocyanate elution. Selected variants were compared to the original H2 bispecific antibody in co-cultures with primary human T cells and cancer cell lines expressing endogenous levels of HLA-A*02:01 and the mutant p53-R175H protein or isogenic control cell lines. For in vivo comparison, NSG mice inoculated with KMS26 or Nalm6 cells and human T cells were treated with a continuous infusion of bispecific antibody for 14 days.

Results Three variant bispecific antibodies were identified with higher affinity and retained specificity for R175H/A2 (KD of 12.9 nM, 6.8 nM, 3.3 nM vs. the original KD of 29.5 nM). The highest affinity variant was a double mutant incorporating two top single variants. Each higher affinity variant elicited greater T cell activation as measured by interferon gamma release and cytotoxicity in co-cultures with cell lines expressing endogenous levels of the R175H/A2 pHLA. *In vivo* testing demonstrated that the higher affinity bispecific antibodies had improved tumor control in xenograft models compared to the lower affinity bispecific, particularly at a lower treatment dose (0.075 mg/kg/d).

Conclusions Increasing affinity for the p53 R175H/A2 pHLA to the low nanomolar range yields increased T-cell activation and cancer cell killing without sacrificing specificity for the R175H mutation.

1198 A DUAL TARGETING CD33/CD123 NANOBODY® T-CELL ENGAGER WITH POTENT ANTI-AML ACTIVITY AND A MANAGEABLE SAFETY PROFILE

[1]Melissa Dullaers*, [1]Geert Deschamps, [2]Helene Bonnevaux, [2]Stephane Guerif, [1]Veronique De Brabandere, [2]Celine Amara, [1]Ann Brige, [1]Eline Dejonckheere, [2]Angela Virone-Oddos, [2]Marielle Chiron, [1]Annelies Roobrouck. [1]*Sanofi Ghent, Zwijnaarde, Belgium*; [2]*Sanofi RandD, Vitry, France*

Background Novel therapies are needed for effective treatment of Acute Myeloid Leukemia (AML). Relapse is common and salvage treatment with cytotoxic chemotherapy is rarely curative. CD123 and CD33, two clinically validated targets in AML, are jointly expressed on blasts and leukemic stem cells in >95% of AML patients. However, their expression is heterogenous between subclones and between patients which may impact the efficacy of single-targeting agents in some patient populations. We present here a dual targeting CD33/CD123 NANOBODY® T-cell engager (TCE) that was designed to decrease the risk of relapse from single antigen-negative clones and to increase coverage within and across patients.

Methods TCE-driven redirected T cell killing was evaluated *in vitro* against cells lines with different expression levels of both tumor antigens: MOLM-13, U-937 and KG1a. *In vivo* efficacy was addressed in a MOLM-13 disseminated CDX mouse model. PK, PD and safety were studied in an exploratory single-dose study in cynomolgous monkeys. Cytokine release was measured in an *in vitro* autologous PBMC setup.

Results The CD33/CD123 TCE killed AML tumor cells expressing one or both antigens *in vitro*. Compared to single-targeting control compounds, the CD33/CD123 TCE conferred equal or better *ex vivo* killing of AML blasts in most primary AML samples tested, suggesting a higher patient coverage. In a disseminated CDX mouse model of AML, the multispecific CD33/CD123 TCE cleared cancer cells in long bones as well as in soft tissues. As cytokine release syndrome is a well-documented adverse effect of TCE, the compound was tested in a cytokine release assay and shown to induce less cytokines compared to CD123 single-targeting control.

In an exploratory single-dose non-human primate study, the CD33/CD123 TCE revealed a favorable PK profile. Depletion of CD123 and CD33 expressing cells was observed at 0.04µg/kg, without associated cytokine release syndrome nor signs of clinical toxicity.

Conclusions Taken together, the CD33/CD123 dual-targeting NANOBODY® TCE exhibits potent and safe anti-AML activity and promises a broad patient coverage.

Ethics Approval All in vivo experiments were approved by the Sanofi Ethical Committee and conducted in accordance with local and institutional Laws, Ethics and guidance in AAALAC accredited facilities.

1199 COMPARISON OF FOUR IN VITRO CYTOTOXICITY ASSAYS FOR ASSESSING THE POTENCY OF CD3-BISPECIFIC ANTIBODIES REDIRECTING T CELLS TO KILL TUMOR TARGET CELLS

[1]Jun Guan*, [1]Charlie Kang, [1]Alejandro Amador Arjona, [1]Ricardo Macarron, [1]Patrick Mayes, [2]Yao-Bin Liu. *[1]Incyte Research Institute, Wilmington, DE, USA; [2]Incyte Corporation, Wilmington, DE, USA*

Background Evaluation of cytotoxicity is a critical step in the selection of CD3-bispecific antibodies (BsAbs) for cancer immunotherapy. The objective of this study was to compare sensitivities, strengths, and limitations of four commonly used in vitro cytotoxicity assays to determine potency of CD3 BsAbs in a co-culture system composed of tumor target cells and human $CD3^+$ T cells.

Methods

Lactate dehydrogenase (LDH) Release Assay 786-O renal cancer cells were co-cultured with human $CD3^+$ T cells in the presence of tool CD3 BsAbs or control antibodies. LDH release from membrane-damaged cells was measured using a fluorometric method (Promega). IncuCyte-based Assay: Co-culture plates as prepared for the LDH release assay were scanned by IncuCyte S3 system with 5 images captured per well; phase object confluence was measured. Killing Immune-Lysis Reaction (KILR) Assay: 786-O KILR cell pool generated by transduction of KILR retroparticles into the parental 786-O cells was co-cultured with human T cells. The release of tagged KILR reporter proteins from dying cells was detected by a luminescence method (Eurofins). Flow Cytometry–based Assay: U266 myeloma target cells were co-cultured with effector T cells. CD3 BsAbs–induced T-cell cytotoxicity, proliferation, and activation marker expression were evaluated using Intellicyte iQue flow cytometer. Cytokine secretion from activated T cells in the co-culture systems was measured using Meso Scale Discovery assays.

Results All 4 in vitro cytotoxicity assays consistently demonstrated that tool CD3 BsAbs induced T cell–mediated tumor cytotoxicity in a dose-dependent and time-dependent manner. This was in agreement with other T-cell activation parameters in terms of INF-γ secretion, surface expression of CD25 and CD69, and T cell proliferation. The KILR assay was the most sensitive and specific assay. The fluorescence produced in LDH release assay was mainly contributed by the dead 786-O target cells with minimum contribution from the dead T cells. Automated imaging and phase object confluence analysis by IncuCyte selectively quantified tumor cell death in real-time without labeling the target cells. The flow cytometry–based assay was relatively time consuming, but allowed for measurement of multiple T-cell activation biomarkers simultaneously.

Conclusions All 4 in vitro cytotoxicity assays evaluated are suitable to assess the efficacy of CD3 BsAbs redirecting T-cell cytotoxicity against tumor cells. The LDH release assay, IncuCyte-based assay, and KILR assay may be more robust for screening of CD3 BsAbs, while flow cytometry–based assay is beneficial for confirmation of the lead clones.

1200 A CLINICALLY VALIDATED PH-SENSITIVE NANOMEDICINE PLATFORM FOR ENCAPSULATING THERAPEUTIC BISPECIFIC T CELL ENGAGERS FOR TUMOR SPECIFIC DELIVERY AND ACTIVATION

Stephen Gutowski*, Qingtai Su, Austin Burcham, Irina Kalashnikova, Ashley Campbell, Zirong Chen, Bhargavi Allu, Jason Miller, Tian Zhao. *OncNano Medicine, Inc., Southlake, TX, USA*

Background Bispecific antibodies (BsAbs) are an important class of therapeutics for immune-oncology applications. T cell engagers (TCEs) target tumor-associated antigens and cytotoxic T cells to eradicate antigen-expressing tumor cells. Blinatumomab (CD19 X CD3 bispecific) is approved for CD19-positive B cell acute lymphoblastic leukemia,[1] but its toxicity may be limiting, with one-third of patients in the pivotal Phase 3 study requiring treatment interruption for adverse events.[2] TCEs for solid tumors have likewise demonstrated encouraging clinical efficacy but shown dose-limiting toxicities due to on-target/off-tumor effects[3,4] For instance, patients receiving solitomab (EpCAM X CD3 bispecific) experienced severe gastrointestinal toxicity which precluded its further development.[5] To minimize the off-tumor effects, we have developed ON-BOARD, an ultra-pH sensitive nanoparticle platform, has shown utility in cytokine and monoclonal antibody encapsulation and targeted delivery to the acidic tumor microenvironment.[6,7] The clinical safety and feasibility of ON-BOARD has been demonstrated by effective delivery of fluorophores to solid tumors for imaging of multiple tumor types in Phase I and II clinical trials with pegsitacianine.[8] Herein we expand the utility of ON-BOARD platform for the encapsulation and pH-specific activation of bispecific antibodies with potential for anticancer therapy.

Methods A panel of BsAbs (including biosimilar equivalents of blinatumomab, solitomab, and others) was used to demonstrate encapsulation by the ON-BOARD platform and pH-dependent activation. Formulations of ON-BOARD with BsAbs were purified by size exclusion chromatography and the encapsulation efficiencies were quantified by HPLC. Particle size and uniformity were studied by dynamic light scattering. ON-BOARD/BsAb formulations were assessed *in vitro* under neutral pH or acid-activated conditions to determine target engagement by ELISA, bio-layer interferometry. The target-specific bioactivity and therapeutic window was determined by TDCC assays in multiple models.

Results ON-BOARD nanoparticles successfully encapsulated bispecific antibodies across a wide range of tumor-associated antigens (TAAs), including HER2, EpCAM, CEACAM5, CD19, and CD20, and structural configurations (tandem scFv and Fc-fusion). ON-BOARD formulations were stable nanoparticles with narrow size distribution (<70 nm), good encapsulation efficiency (up to 98%) and drug loading (up to 8%). Acid-mediated release and target engagement of both TAA-targeting and CD3-targeting arms was demonstrated using *in vitro* binding assays with >100-fold activation window. Further pH-specific cell killing was confirmed by TDCC assays in multiple *in vitro* models including Burkitt lymphoma, breast cancer, colorectal cancer, and lung cancer.

Conclusions The ON-BOARD pH-sensitive nanoparticle platform demonstrated potential as an effective and universal tool for solid tumor specific activation and delivery of bispecific antibody therapeutics, potentially minimizing systemic side effects.

1201 SGN-BB228 IS A FIRST-IN-CLASS CD228-TARGETED COSTIMULATORY ANTIBODY ANTICALIN® BISPECIFIC DELIVERING POTENT AND CONDITIONAL 4–1BB COSTIMULATION TO TUMOR-SPECIFIC T CELLS

Ryan Heiser*. *Seagen Inc., Bothell, WA, USA*

Background Agonist antibodies targeting 4-1BB (CD137) effectively costimulate cytotoxic T cells and are active in preclinical models of cancer. However, clinical development of these agents has been hampered by limited efficacy and/or poor tolerability at active doses.[1,2] To overcome the efficacy and safety limitations of this approach, SGN-BB228, a first-in-class, investigational CD228/4-1BB Antibody Anticalin® bispecific was created. SGN-BB228 targets CD228 (melanotransferrin, p97), a glycosylphosphatidylinositol-anchored membrane protein with limited normal tissue expression, but high and prevalent expression in melanoma, mesothelioma, lung cancer and other tumor types.[3,4] SGN-BB228 is designed to provide a potent costimulatory bridge between tumor-specific T cells and tumor cells, improving and constraining T cell mediated cytotoxicity to tumors, potentially expanding the therapeutic window for 4-1BB agonism.

Methods Here we describe the expression profile of CD228 in cancer and normal tissues and preclinical activity of SGN-BB228 across reporter cell and primary T cell-based assays.

Results SGN-BB228 is comprised of a hinge-stabilized (S228P), Fc-null (FALA) fully human IgG4 antibody specific for CD228 connected to 4-1BB-targeting Anticalin® proteins[5] via C-terminal heavy-chain fusions. The proposed mechanism of action (MOA) for SGN-BB228 is CD228-conditional clustering of 4-1BB on antigen experienced tumor-specific T cells, resulting in enhanced activation and cellular cytotoxicity. Expression analysis across cancer and normal tissues demonstrates CD228 is a tumor associated antigen prevalent in melanoma, mesothelioma, lung cancer and other tumor types with minimal normal tissue expression. Preclinical testing of SGN-BB228 in vitro shows potent CD228-conditional 4-1BB stimulation and cytotoxic T cell activation across a range of assay systems. In the presence of CD228-expressing tumor cells, but not CD228-negative tumor cells, SGN-BB228 drove dose-dependent amplification of NFkB signaling using a 4-1BB reporter cell system. SGN-BB228 also consistently drove potent CD228-conditional costimulatory activity in assays using primary T cells or whole peripheral blood mononuclear cells (PBMCs) receiving different forms of T cell receptor stimulation. The CD228-conditional activity of SGN-BB228 consistently outperformed a clinical benchmark antibody, even in the presence of antibody-clustering FcgRs expressed by PBMC.

Conclusions Together these data introduce SGN-BB228, a first-in-class, investigational CD228/4-1BB costimulatory Antibody Anticalin® bispecific with potent and CD228-conditional 4-1BB costimulatory activity with therapeutic potential in multiple solid tumor types. These data support future clinical study of SGN-BB228 in a first-in-human Phase 1 trial.

1202 TRI-SPECIFIC KILLER ENGAGERS TARGET NATURAL KILLER CELLS TOWARDS MESOTHELIOMA

[1]Philippa (Pippa) Kennedy, [1]Quinlan Kile, [1]Blake Jacobson, [1]Brianna Ettestad, [1]Nicholas Zorko, [1]Caroline Hallstrom, [1]Behiye Kodal, [1]Deborah Todhunter, [1]Daniel Vallera, [2]Gregory Berk, [1]Jeffrey Miller, [1]Manish Patel, [1]Martin Felices*. [1]*University of Minnesota, Minneapolis, MN, USA*; [2]*GT Biopharma, Dover, MA, USA*

Background Mesothelioma is a rare but deadly malignancy of cells lining internal organs. It is most commonly found in the pleura (cells lining the lung), but also in the peritoneum. Between 2015 and 2019, half of all mesotheliomas diagnosed were at a distant site, where five-year survival was as low as 9%. Immunotherapy is emerging as a viable systemic therapy both as a first-line and second-line treatment, but there is still room for improvement. We hypothesized that natural killer (NK) cells could be mobilized to contribute to immune control. We set out to test our Tri-specific Killer Engager (TriKE®) platform in the context of mesothelioma. TriKEs consist of a single chain variable fragment (scFv) or camelid nanobody targeting a tumor antigen and camelid nanobody targeting Fc receptor CD16 on NK cells, linked by an IL-15 moiety. We tested two different TriKEs, one targeting mesothelin (cam1615SS1), commonly found on epithelioid mesothelioma, and a second TriKE targeting B7H3 (GTB-5550), a common tumor antigen.

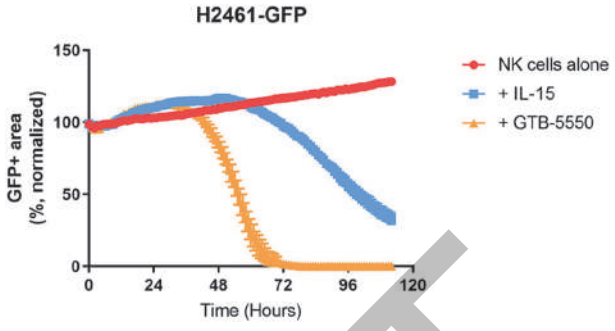
Methods Three pleural mesothelioma lines, H2373, H2596 (both sarcomatoid) and H2461 (epithelioid), and four peritoneal mesothelioma lines, ROB, YOU, HAY and ORT (all epithelioid), were assessed for mesothelin and B7H3 surface expression by flow cytometry. NK cells were isolated from human blood and challenged with these lines in the presence of TriKE or IL-15 as a control. NK cell degranulation and cytokine production were assessed by flow cytometry and tumor cell control was assessed by live cell imaging in three dimensional spheroid cultures.

Results The peritoneal mesothelioma lines had detectable mesothelin and cam1615SS1 induced NK cell degranulation and cytokine responses against these cells. The pleural mesothelioma lines had low levels of surface mesothelin, so although cam1615SS1 triggered NK cell degranulation, it failed to control the tumor in three dimension cultures. B7H3 was expressed on all mesothelioma lines, regardless of subtype, and GTB-5550 induced robust degranulation and cytokine responses in NK cells. Levels of B7H3 and mesothelin did not change with overnight interferon gamma treatment to mimic an inflammatory tumor environment. In long-term spheroid assays, GTB-5550 induced NK cell destruction of tumor spheroids more rapidly than IL-15 treatment (figure 1).

Conclusions GTB-5550 drove NK cell responses towards all mesothelioma subtypes, while cam1615SS1 successfully targeted epithelial peritoneal mesothelioma. In future studies we aim to combine TriKE with immune checkpoint inhibitors to test their potential to drive innate immune responses in the context of currently approved therapies.

Acknowledgements Ira Pastan (NIH) kindly provided the sequence for the anti-mesothelin scFv, SS1. Raffit Hassan (NIH) kindly provided the peritoneal mesothelioma lines. This project was supported in large part by the Meso Foundation and also by the Department of Defense (CA200922) and National Institutes of Health (R35 CA197292, P01 CA111412).

Ethics Approval This study was deemed not to constitute human research as determined by the University of Minnesota Institutional Review Board.



Abstract 1202 Figure 1 NK cells with GTB-5550 decrease the survival time of H2461 spheroids. Live imaging tracks the survival of three-dimensional spheroids made from GFP+ mesothelioma cells over 5 days. The relative two-dimensional area observed in widefield microscopy images is plotted against time for one donor, representative of four.

1203 ANTIGEN TARGETED BUTYROPHILIN HETERODIMER-BASED BISPECIFIC ENGAGERS INDUCE Vγ9δ2$^+$ T CELL-MEDIATED ANTI-TUMOR ACTIVITY

Derek Franklin*, Anne Lai, Faraha Brewer, Arpita Patel, Kinsley Evans, Mahmud Hussain, Louis Gonzalez, Keith Wilson, George Fromm, Taylor Schreiber, Suresh De Silva. *Shattuck Labs, Durham, NC, USA*

Background Decreased antigen expression and antigen presentation via major histocompatibility complexes (MHCs) evades αβ T cell recognition. γδ T cells recognize stressed cells in an MHC-independent manner, and consequently, may be exploited to overcome immunotherapy resistance. The butyrophilin (BTN) 2A1/3A1 heterodimer specifically activates Vγ9δ2$^+$ T cells, the predominant subtype in peripheral blood. BTN2A1 directly binds to the Vγ9 chain of the γδ T cell receptor (TCR), but only activates the γδ T cell if phosphoantigen-sensing BTN3A1 forms a heterodimer complex with BTN2A1. To mimic BTN-mediated activation of γδ T cells, we generated bispecific γδ T-cell engagers (GADLEN) containing heterodimeric BTN2A1 and BTN3A1 extracellular domains fused via inert Fc linkers to scFv domains targeting a tumor antigen. We previously reported that in the presence of costimulatory signals from either a cytotoxicity receptor (NKG2D) or T-cell co-stimulatory receptor (CD28), GADLEN compounds activated Vγ9δ2$^+$ T cells to facilitate antigen-dependent tumor cell killing. The specificity of γδ TCR/BTN interactions and dependence upon a secondary co-stimulatory signal suggests that GADLENs could be used to redirect Vγ9δ2$^+$ T cells against hematologic and solid tumors, with a lower risk of off-target activation common with other bispecific engagers. Here, we report the functional characterization of CD20- and B7H3-targeting GADLEN compounds for targeting heme malignancies and solid tumors, respectively.

Methods Specificity of CD20- and B7H3-targeting GADLENs were evaluated using ELISA and cell-based assays by flow cytometry. The functionality of the compounds to activate Vγ9δ2$^+$ T cells and mediate killing of tumor cells was assessed *in vitro* in tumor co-cultures using flow cytometry and live cell imaging, as well as *in vivo* in murine xenograft models.

Results CD20- and B7H3-targeting GADLENs bound to human cells expressing CD20 or B7H3 and to Vg9d2$^+$ T cells with low nanomolar affinity. GADLEN compounds activated Vγ9δ2$^+$ T cells in *in vitro* co-culture assays resulting in degranulation and apoptosis of CD20+ or B7H3+ tumor cells, respectively. Importantly, GADLEN treatments induced the secretion of pro-inflammatory cytokines suggesting the potential of both direct and indirect tumor killing mechanisms via additional immune cell subset activation and recruitment. Introduction of CD20-GADLEN into NSG-hIL15 mice engrafted with human PBMCs efficiently depleted human CD20+ B cells in the blood and spleen. Similarly, coadministration of GADLEN with Vγ9δ2$^+$ T cells reduced tumor growth in tumor xenografts.

Conclusions These results provide proof of concept for *in vivo* manipulation of γδ T cells using antigen targeted GADLENs for the treatment of hematologic and solid tumor malignancies.

1204 ENHANCING NK CELL FUNCTION IN THE 'COLD' TUMOR MICROENVIRONMENT OF PROSTATE CANCER WITH A NOVEL TRI-SPECIFIC KILLER ENGAGER AGAINST PROSTATE-SPECIFIC MEMBRANE ANTIGEN (PSMA)

Shee Kwan Phung*, Yvette Soignier, Nicholas Zorko, Trygve Nelson, Joshua Walker, Philippa (Pippa) Kennedy, Jeffrey Miller, Martin Felices. *University of Minnesota, Minneapolis, MN, United States*

Background Natural killer (NK) cell effector function is suppressed in the tumor microenvironment (TME) of metastatic castration-resistant prostate cancer (mCRPC), the lethal form of prostate cancer. This is largely due to the inherently 'cold' nature of the TME of mCRPC that is immunosuppressive, hypoxic and lacks cytolytic lymphocyte infiltration. To improve NK cell anti-tumor responses against mCRPC in the TME, we designed a novel tri-specific killer engager (TriKE®) molecule that consists of three parts: an arm that engages with CD16, an activating receptor of NK cells, an arm that binds to prostate-specific membrane antigen (PSMA) that is highly and specifically expressed on mCRPC, and an interleukin (IL)-15 moiety that is essential for NK cell survival, proliferation, priming and motility (figure 1).

Methods Flow cytometry-based functional and dye dilution proliferation assays were used to compare activation and proliferation of NK cells treated with PSMA TriKE or IL-15. NK cell cytolytic capacity against C4-2, a PSMA-expressing prostate cancer cell line, was measured using IncuCyte live cell imaging. In various assays, hypoxic (1% oxygen) culture condition and cytokine-induced myeloid-derived suppressor cells (MDSC) were incorporated to better examine PSMA TriKE function in the physiological setting of mCRPC.

Results PSMA TriKE significantly enhanced expansion of peripheral blood NK cells derived from healthy donors up to 10 folds (N=9). This effect was specific to NK cells and not T cells. Additionally, PSMA TriKE induced NK cell degranulation (up to 60%) and intracellular IFNγ and TNFα buildup (up to 50%) when compared to IL-15 and no treatment groups after incubation with C4-2 (N=6). This result was not observed when PSMA knockout C4-2 were used as target cells. NK cell incubation in hypoxia for 7 days severely impacts cytotoxicity, some of which can be improved with IL-15. However, PSMA TriKE treatment markedly improved NK cell cytolytic capacity against C4-2 in hypoxia (N=5) (figure 2). Similarly, MDSCs suppressed NK cell degranulation in the presence of IL-15 alone but not with PSMA-TriKE treatment (N=4) (figure 3).

Conclusions PSMA-TriKE induces specific NK cell proliferation and activation against PSMA+ tumor cells. Efficient delivery of IL-15 to NK cells by PSMA-TriKE robustly relieves NK cells from suppression induced by hypoxia and MDSCs. These results demonstrate promising potential of PSMA TriKE in overcoming suppression of NK cells in the TME of mCRPC.

1205 SELECTIVE BLOCKADE OF CD47-SIRP ALPHA "DON'T EAT ME" SIGNALING WITH A HER2-CD47 BISPECIFIC ANTIBODY-DERIVATIVE

Yuzhu Qi*, Harm Lourens, Gerwin Huls, Edwin Bremer. *University Medical Center Groningen, Groningen, Netherlands*

Background Human epidermal growth factor receptor 2–positive (HER2+) breast cancer accounts for ~25% of breast cancer cases. Trastuzumab improves clinical outcomes by targeting HER2, but recurrences still occur. Targeting the CD47-SIRPα interaction alone or in combination with therapeutic antibodies such as Trastuzumab contributes to cancer cell elimination, but ubiquitous CD47 blocking associates with toxicity. Here, we designed a bispecific antibody fragment aimed to selectively block CD47 on HER2-positive breast cancer cells (BC) in order to reduce off-tumor binding and limit toxicity towards normal CD47-positive cells, while increasing efficacy against cancer cells.

Methods A novel HER2-CD47 bispecific single chain fragment (HER2-CD47 bs-scFv) antibody with HA tag was produced in HEK293 cells and purified using Anti-HA affinity purification. The HER2-CD47 bs-scFv comprised a CD47-targeting scFv and a Her2-targeting trastuzumab-derived scFv fragment. For binding experiments, BC cells were incubated with HER2-CD47 bsAb in the presence (or absence) of either trastuzumab or anti-CD47 or both, whereupon binding was detected using anti-HA staining. Her-2 restricted blocking activity of the HER2-CD47 bs-scFv was assessed using recombinant human SIRP-α-Fc. For phagocytosis experiments, cancer cells were labelled with CSFE and then incubated with differentiated macrophages (derived from peripheral blood mononuclear cells). Phagocytosis was measured by flow cytometry.

Results The HER2-CD47 bispecific selectively bound to CD47+/Her2+ cells, but only marginally to single CD47 positive cancer cells. Binding of the HER2-CD47 bs-scFvwas partially reduced by trastuzumab or epitope-competing CD47 antibody. Furthermore, incubation with HER2-CD47 blocked the binding of recombinant human SIRPalpha-Fc only on CD47+/Her2+ cells, demonstrating that functional blocking of SIRP-alpha/CD47 interaction is restricted to HER2+ cells. Importantly, HER2-CD47 selectively enhanced macrophage-mediated phagocytic removal of CD47+/Her2+ BC cells cancer cells by up to 30%. In contrast, similar treatment did not significantly increase phagocytosis of CD47+/Her2- BC cells.

Conclusions The HER2-CD47 bs-scFv blocked CD47 "don't eat me" signaling in a HER2-restricted manner with essentially only activity towards Her2 and CD47 double-positive cancer cells. This HER2-CD47 bs-scFv may provide a new strategy for the treatment of Her2+ breast cancers.

1206 DISCOVERY AND PRECLINICAL PHARMACOLOGY OF BISPECIFIC ANTIBODIES TARGETING AN HLA-A2 RESTRICTED TUMOR-ASSOCIATED ANTIGEN

[1]Alejandro Ramirez, [2]Nora Guidotti, [1]John Leonard*, [1]Olivier Dalmas, [1]Jake Kleiner, [1]Joshua Goldsmith, [1]Greg Tuffy, [1]Jason Romero, [1]Bindu Hegde, [1]Tina Giese, [1]Lisa Kirkemo, [2]Rafaela Truffer, [2]Oralea Buchi, [2]Nadine Uebersax, [2]Philipp Wild, [2]Rohan Eapen, [1]Joanna Dreux, [1]Alaina Cagalingan, [1]Lena Flood, [1]Kyle Pelot, [1]Nathan Katz, [1]Marvin Gee, [1]Venita De Almeida, [2]Johannes Schilling, [2]Patrik Forrer, [1]Leah Sibener, [1]John Leonard. *[1]3T Biosciences, South San Francisco, CA, USA; [2]Athebio, Zurich-Schlieren, Switzerland*

Background T cell engagers (TCEs) are bi-functional biologics that bind a target on tumor cells and the CD3 of the TCR-complex on T cells to induce immune-mediated killing of tumors expressing the epitope of interest. While most TCEs on the market and in development target cell surface antigens with tumor- or lineage-specific expression, this approach cannot exploit the tumor-specific expression of intracellular proteins, which make up the majority of the human proteome. However, peptides derived from virtually all intracellular proteins are presented on the cell surface by Human Leukocyte Antigen (HLA) and can be targeted therapeutically to exploit the tumor-specific expression of intracellular proteins. A key safety concern for therapeutics targeting peptide-HLA complexes is cross-reactivity, as unintended binding of peptides expressed on healthy tissues can lead to lethal off-target toxicity.

Methods Here, we utilize Athebody® DARPins (Designed Ankyrin Repeat Proteins), engineered proteins based on an ankyrin repeat scaffold, to generate highly specific binders against an epitope from the cancer-germline antigen MAGE-A4 bound to HLA-A2. Using our proprietary 3T-TRACE™ platform, we perform a global cross-reactivity assessment to identify potential off-target liabilities, many of which are sequence-dissimilar to the intended MAGE-A4 epitope and would therefore be undetectable by traditional methods. The interplay of this cross-reactivity risk evaluation, informing tailored binder selection, allowed us to identify leads of unparalleled efficiency and safety profiles. TCEs armed with these Athebody® DARPins induce high potency killing of MAGE-A4-expressing cancer cell lines with no detectable killing of antigen-negative cells. We further tune the format of these molecules to retain high killing activity while minimizing cytokine release, a key determinant of dose-limiting toxicity in the clinic.

Conclusions These optimized TCEs express at high titers and display a favorable developability profile. The work presented here demonstrates a novel approach to develop TCEs with excellent potency and specificity against tumor-restricted intracellular targets.

1207 NKP46 ENGAGING BICYCLE® NK-TICA™ DRIVES TARGETED TUMOR CYTOTOXICITY

Alexandra Rezvaya*, Fay Dufort, Christopher Leitheiser, Hannah Gardner, Tucker Ezell, Liuhong Chen, Peter Brown, Philip Brandish, Michael Skynner, Kevin McDonnell, Nicholas Keen. *Bicycle Therapeutics, Lexington, MA, USA*

Background Natural killer (NK) cells are immune cells that can detect and eliminate tumor cells and bridge innate to adaptive immune responses. Bicycles are small (ca. 1.5 kDa), chemically synthetic, structurally constrained peptides discovered via phage display and optimized using structure-driven design and medicinal chemistry approaches. We have now applied this technology to identify Bicycles that bind specifically to a key activating receptor, NKp46. We term this new class of fully synthetic molecules Natural Killer tumor-targeted immune cell agonists (NK-TICA™) and herein we will describe their in vitro evaluation.

Methods Using our unique phage display screening platform, we have identified high affinity, selective binders to NKp46. By conjugating the Bicycle® NK cell-engaging binders to model tumor antigen EphA2-binding Bicycle®, we have developed a bifunctional Bicycle® NK-TICA™ molecule. In in vitro functional assays, we evaluated the ability of the Bicycle® NK-TICA™ to induce NK cell activation and proliferation as well as cell-mediated cytotoxicity and cytokine production in NK-tumor co-culture assays. We similarly evaluated changes in EphA2 tumor binding affinity of the Bicycle® NK-TICAs in their ability to enhance NK immune response.

Results We have developed novel modular compounds with high affinity and selectivity to NK cell receptors with specific tumor targeting capability. We demonstrate potent, selective binding of our Bicycles to receptor-expressing cells and the capability of the bifunctional molecule to induce NK cell function. With Bicycle's novel NK-TICA™ compounds, we demonstrate engagement of NK cells, specific activation and function of NK cells, and enhanced tumor cytotoxicity across multiple tumor antigens, in a dose dependent manner. With changes in tumor binding affinity, we found changes in the activation of the NK cells in vitro.

Conclusions We have shown that when chemically coupled to a tumor antigen binding Bicycle®, the result is a bifunctional molecule (NK-TICA™) capable of directing potent and specific NK cell activation and kill in vitro.

1208 DUOBODY®-PD-L1X4–1BB (GEN1046) REVERSES T-CELL EXHAUSTION *IN VITRO*

[1]Jordan Blum*, [1]Vanessa Spires, [1]Gregg Masters, [1]Christina Yu, [2]Saskia Burm, [2]Matt Hancock, [1]Omar Jabado, [1]Brandon Higgs, [3]Alexander Muik, [3]Kristina Nuermberger, [3]Friederike Gieseke, [1]Tahamtan Ahmadi, [1]Kate Sasser, [3]Ozlem Tureci, [1]Maria Jure-Kunkel, [3]Ugur Sahin, [1]Mark Fereshteh, [2]Nora Pencheva. *[1]Genmab US, Princeton, NJ, USA*; *[2]Genmab BV, Utrecht, Netherlands*; *[3]BioNTech SE, Mainz, Germany*

Background DuoBody®-PD-L1x4-1BB (GEN1046) is an investigational, potential first-in-class bispecific immunomodulatory antibody designed to elicit an anti-tumor immune response by simultaneous and complementary blockade of PD-L1 on tumor or immune cells and conditional 4-1BB stimulation on T cells and NK cells. Here we utilized a multi-omics approach to evaluate whether DuoBody-PD-L1x4-1BB could reverse T-cell exhaustion in vitro.

Methods An *in vitro* mixed lymphocyte reaction (MLR) assay was developed, optimized, and validated, where healthy donor T cells were exhausted by repeated stimulation with anti-CD3/CD28 beads prior to co-culturing with allogeneic LPS-matured dendritic cells. Publicly available single cell RNA sequencing (scRNAseq) datasets were harmonized across multiple solid-tumor indications (including treatment-naïve and anti-PD-1 and/or anti-CTLA-4 pretreated samples) and analyzed for co-expression of PD-1 and 4-1BB on various immune-cell subsets based on their transcriptome signatures.

Results In the T-cell exhaustion MLR assay, T cells showed increased expression of inhibitory receptors (e.g., TIM-3, LAG-3) and exhibited hyporesponsiveness for both proliferation and cytokine secretion upon restimulation with anti-CD3/CD28 beads, which was partially reversed by PD-1 blockade. DuoBody-PD-L1x4-1BB reinvigorated the exhausted T-cell response *in vitro*, as shown by restored IFNγ secretion. The effect of DuoBody-PD-L1x4-1BB in this assay was roughly two-fold higher to that of PD-1 blockade. When combined, DuoBody-PD-L1x4-1BB showed the potential to synergize with anti-PD-1 antibody treatment as cytokine secretion was further potentiated compared to each agent alone. More extensive molecular profiling from the T-cell exhaustion MLR assay will be presented. Using solid tumor public scRNAseq datasets, we demonstrated co-expression of 4-1BB and PD-1 on exhausted CD8+ T cells in the tumor microenvironment. Furthermore, in patients treated with agents that block the PD-1 pathway, an increase in exhausted CD8+ T cells expressing PD-1 was observed.

Conclusions PD-1 and 4-1BB are co-expressed on exhausted CD8+ T cells within the tumor microenvironment in solid tumors and T cell dysfunction may represent a potential resistance mechanism to checkpoint inhibitors (CPI). DuoBody-PD-L1x4-1BB restored IFNγ secretion by exhausted T cells in vitro more potently than PD-1 blockade, which could be further potentiated by the combination with an anti-PD-1 antibody. Together, these results support evaluation of DuoBody-PD-L1x4-1BB in the post-CPI setting and the combination of tumor-targeted 4-1BB co-stimulation with PD-1 checkpoint blockade for the treatment of solid tumors. DuoBody-PD-L1x4-1BB is currently being investigated in an ongoing phase 2 clinical trial in NSCLC patients who have progressed on prior CPI therapy (NCT05117242).

1209 ANTIBODY-LECTIN BISPECIFICS FOR GLYCO-IMMUNE CHECKPOINT BLOCKADE

[1]Jessica Stark*, [1]Melissa Gray, [1]Simon Wisnovsky, [2]Itziar Ibarlucea-Benitez, [1]Nicholas Riley, [1]Mikaela Ribi, [2]Jeffrey Ravetch, [1]Carolyn Bertozzi. [1]*Stanford University, Stanford, CA, USA*; [2]*The Rockefeller University, New York, NY, USA*

Background Cancer immunotherapies, including checkpoint blockade antibodies, represent a breakthrough in cancer treatment with long-term remission observed in select patients. Unfortunately, many tumors remain unresponsive to existing immunotherapies, creating an urgent need to therapeutically target additional immune checkpoints that drive cancer progression. Glyco-immune checkpoints – in which cell-surface biopolymers decorated with sugars, or glycans, engage glycan-binding receptors on immune cells – have emerged as immune modulatory pathways that are misregulated in the context of cancer. In particular, recent evidence suggests that upregulation of the sialic acid monosaccharide on cancer cell surfaces allows tumors to resist treatment by engaging inhibitory receptors called Siglecs on immune cells. However, the lack of glycan-binding reagents with high affinity and selectivity has historically prevented targeting of tumor-associated glycans for cancer immunotherapy.

Methods To address this need, we have developed a new class of antibody-lectin bispecifics (AbLecs) targeting tumor-associated glycans for checkpoint blockade (figure 1). In this approach, glycan-binding domains from immune receptors (e.g., Siglec receptors) are coupled to high-affinity binding domains from FDA-approved antibodies targeting common tumor-associated antigens (e.g., trastuzumab, rituximab, cetuximab) via knobs-into-holes heterodimerization technology.

Results Western blot and mass spectrometry results indicated correct heterodimeric assembly of eight AbLec candidates, demonstrating the feasibility of the AbLec approach. We found that AbLecs bind cancer cell lines at nanomolar concentrations and block cognate Siglec receptor binding via flow cytometry. Finally, we showed that AbLecs enhance antibody-dependent phagocytosis and cytotoxicity of diverse human tumor cell lines by primary immune cells *in vitro* compared to their FDA-approved parent antibodies. Enhancement of *in vitro* tumor cell killing with AbLecs was dependent on the targeted Siglec and was more potent than the combination of the parent monoclonal antibody and a Siglec-blocking antibody.

Conclusions These studies provide proof-of-principle for AbLecs as a first-in-class, modular platform technology enabling blockade of glyco-immune checkpoints for cancer immunotherapy.

1210 A HUMAN BISPECIFIC ANTIBODY TARGETING LAG-3 AND PD-1 (INCA32459) POTENTLY ACTIVATES EXHAUSTED T CELLS

[1]Shaun Stewart, [2]Floris Fransen, [1]Shane Harvey*, [2]Franziska Mortensen, [2]Anita Stam, [1]Rahel Awdew, [1]Arpita Mondal, [1]Christina Stevens, [2]Eric Rovers, [2]Steef Engels, [2]Melissa Rentrop-Boeijen, [2]Linda Hendriks, [2]Brenda van Dieren, [1]Rebecca Buonpane, [2]Therese Visser, [2]Pepijn Schellen, [1]Ashwini Kulkarni, [1]Jonathan Rios-Doria, [1]Jing Zhou, [2]Paul Tacken, [1]Lu Lu, [2]Vanessa Zondag-van der Zande, [1]Cheng-Yen Huang, [2]Renate den Blanken-Smit, [2]John de Kruif, [2]Rinse Klooster, [2]Simon Plyte, [1]Horacio Nastri, [1]Patrick Mayes. *[1]Incyte Research Institute, Wilmington, DE, USA; [2]Merus N.V, Utrecht, Netherlands*

Background Exhausted T cells are characterized by the expression of negative immune regulatory receptors, including programmed death protein-1 (PD-1) and lymphocyte-activation gene 3 (LAG-3), which inhibit the proliferation and function of T cells and limit antitumor immunity. We describe the generation and characterization of INCA32459, a human IgG1 Fc-silenced bispecific antibody that simultaneously binds to PD-1 and LAG-3 and reverts their inhibitory function.

Methods INCA32459 was generated using the Merus common light chain Biclonics® platform. LAG-3 and PD-1 Fab panels were generated through immunization of Merus MeMo® mice, and large panels of Biclonics® libraries were screened before optimizing lead candidate molecules.

Results INCA32459 binds with high affinity to both human (K_D=0.39 nM) and cynomolgus monkey (K_D=0.44 nM) PD-1, and human (K_D=1.15 nM) and cynomolgus monkey (K_D=0.20 nM) LAG-3, as measured by surface plasmon resonance. The monovalent PD-1 arm of INCA32459 blocks PD-1 with similar potency as a bivalent PD-1 antibody (nivolumab analog) in a PD-1/PD-L1 reporter assay. In a loss-of-function reporter assay where luciferase expression increases upon blockade of both LAG-3 and PD-1, INCA32459 significantly induced luciferase expression to a greater extent than either PD-1 (nivolumab analog) or LAG-3 (relatlimab analog) single agent antibody controls, and greater than PD-1 (nivolumab) and LAG-3 (relatlimab) analog antibodies combined. In 2 human primary immune cell assays, a T-cell exhaustion model using chronically SEB-stimulated peripheral blood mononuclear cells (PBMCs), and an antigen recall assay using CEFT MHCII peptide pool-stimulated PBMCs, INCA32459 treatment resulted in higher interleukin-2 and interferon-γ induction, respectively, compared with PD-1 (nivolumab analog) and LAG-3 (relatlimab analog) antibodies combined. In a human MDA-MB-231 breast tumor model in $CD34^+$ humanized NSG mice, INCA32459 treatment decreased tumor growth compared with a combination of PD-1 (pembrolizumab) and LAG-3 (relatlimab analog) antibodies. Pharmacodynamic analysis in mice demonstrated a dose-dependent increase in receptor occupancy at 1 and 10 mg/kg. Pharmacokinetic characterization of INCA32459 in cynomolgus monkeys after a single IV infusion at 3 and 30 mg/kg demonstrated an average clearance, steady-state volume of distribution, and mean residence time of 0.515 mL/h/kg, 74.1 mL/kg, and 144 h, respectively.

Conclusions We have developed INCA32459, a potent dual inhibitor of PD-1 and LAG-3 in preclinical models, which induces activation of exhausted T cells to a greater extent than a combination of bivalent monospecific antibodies targeting PD-1 (nivolumab analog) and LAG-3 (relatlimab analog). These data support the clinical evaluation of INCA32459, and a phase 1 study in cancer patients is underway.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1210

1211 DUAL TARGETING OF INNATE AND ADAPTIVE IMMUNE CHECKPOINTS WITH A PD-L1/SIRPα BISPECIFIC MACROPHAGE ENGAGER TO PROMOTE ANTI-TUMOR ACTIVITY

Dawei Sun*, Hongtao Lu, Haixia Jiang, Yanan Geng, Jiahui Hu, Ziqiao Ding, Jinfeng Zhao, Xiang Xu, Wenqiang Lu, Xiaofeng Niu, Rui Gao, Zhihao Wu, Quan Qiu, Zheng Song, Yangsheng Qiu. *Elpiscience Biopharma, Shanghai, China*

Background Tumor-associated macrophages are major component of immune cells in the tumor micro-environment that express an array of effector molecules leading to the inhibition of anti-tumor immune responses. Signal regulatory protein α (SIRPα) is a myeloid-lineage inhibitory receptor that restricts phagocytosis through engagement of its ligand CD47 expressed on tumors and normal tissues. Compared to anti-CD47 therapeutics, targeting myeloid-restricted SIRPα may provide a differential pharmacokinetic, safety, and efficacy profile. Here, we report the construction of a SIRPα antagonist-based bispecific macrophage engager (BiME) called ES019, which uses PD-L1 antibody as a tumor associated antigen (TAA) targeting arm and also as a tool to relieve the inhibition of T cell. The PD-L1/SIRPα bispecific macrophage engager aims to promote macrophage phagocytosis against PDL1 expressing tumor cells, and to activate T cell adaptive immunity resulting in further tumor cell killing.

Methods Through Elpiscience proprietary BiME platform, we have generated a panel of single domain antibody (sdAb) based anti-PDL1/SIRPα bispecific antibodies, including different orientations, ratios, and IgG isotypes of anti-PDL1 arm and anti-SIRPα arm. These bispecific antibodies were evaluated for PDL1, SIRP family homologue binding, PD1-PDL1 and CD47-SIRPα blocking properties by ELISA and FACS. *In vitro* function activity was determined by phagocytosis assay using human monocyte derived macrophage and mouse bone marrow derived macrophage. *In vivo* anti-tumor efficacy was tested in a syngeneic tumor model with hSIRPα knock-in mice. The pharmacokinetic (PK) and safety profile were assessed in hSIRPα knock-in mice or cynomolgus monkeys.

Results In this study, we demonstrated that anti-PDL1/SIRPα bispecific antibodies bound to PD-L1 expressing tumor cell and macrophage simultaneously, effectively inhibited CD47-SIRPα signal and triggered strong macrophage phagocytosis. ES019 showed potent *in vitro* macrophage and T cell tumor killing activity in the presence of peripheral blood mononuclear cells, but without nonspecific killing in PDL1 negative cells. Remarkably, ES019 showed almost 100% tumor growth inhibition in *in vivo* SIRPα knock-in syngeneic models. On the other hand, ES019 did not induce phagocytosis of normal immune cells like activated T cells. In summary, we demonstrated that ES019 exhibited super anti-cancer effects, evidenced by potent phagocytosis *in vitro* and almost complete tumor regression *in vivo*.

Conclusions Using our bispecific macrophage engager (BiME) platform, we have developed a PD-L1/SIRPα bispecific antibody that is capable of activating both macrophages and T cells to kill cancer cells with the potential to overcome the limitations of traditional anti-PD1 therapies.

1212 AFVT-2101, AN INNATE IMMUNE-CELL ENGAGER THAT SELECTIVELY TARGETS FOLR1 EXPRESSING TUMOR CELLS TO SAFELY HARNESS POTENT ANTI-CANCER RESPONSES

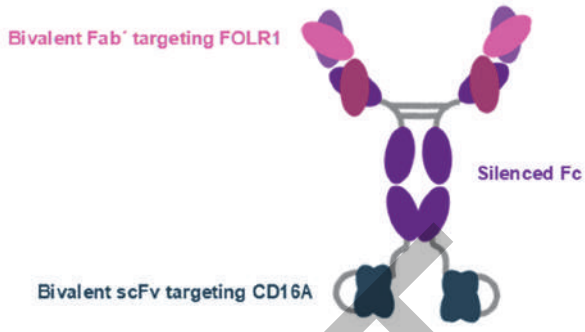
[1]Ahmad Trad, [1]Michael Tomaszowski, [1]Josef Caslavsky, [2]Robert Freitag, [2]Keith Haan, [2]Markus Rohrwild, [3]Daniel O'Shannessy, [4]Jana Siegler, [2]Sudhir Penugonda, [2]Peter Sandy, [2]Eric Gaukel, [4]Daniela Penston, [5]Zoë Johnson*. *[1]Abcheck, Plzen, Czech Republic; [2]Roivant Sciences, New York, NY, USA; [3]TMDx Consulting LLC, Philadelphia, PA, USA; [4]Affimed, Heidelberg, Germany; [5]Affivant Sciences GmbH, Basel, Switzerland*

Background Innate Cell Engager (ICE®) molecules are designed to bivalently bind CD16A+ natural killer (NK) cells and macrophages and a tumor cell-surface antigen, inducing potent, tumor-directed cytotoxicity via antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP). AFVT-2101 (figure 1) is a tetravalent, bispecific ICE® that bridges folate receptor alpha (FOLR1) on tumor cells with innate immune cells, to induce potent and selective targeted tumor cell killing. Herein we describe the structure, mechanism of action and preliminary safety data of AFVT-2101.

Methods Binding of AFVT-2101 to CD16A and human FOLR1 was assessed by ELISA. Binding of AFVT-2101 to NK cells was assessed by flow cytometry in the presence of physiological levels of IgG (10 mg/mL). ADCC was assessed using a 4h- calcein release assay with purified NK cells from healthy donors against a panel of tumor cell lines with different expression levels of FOLR1. ADCP was assessed using a flow cytometry-based method with macrophages derived from healthy donor monocytes and target cell lines with different levels of FORL1 expression. Quantification of secreted cytokines by healthy donor PBMC cultures in the presence of AFVT-2101 and target cells was assessed after a 24 h incubation using multiplex cytokine quantification.

Results AFVT-2101 binds to CD16A (both 158V and 158F variants) with an apparent avidity of 0.1 nM and to hFOLR1 with an apparent avidity of 0.5 nM. Physiological levels of competing IgG do not alter binding efficacy. AFVT-2101 induces potent and selective ADCC, even on FOLR1^{low} cells. AFVT-2101 is also shown to induce efficient ADCP *in vitro*. Further, AFVT-2101 is demonstrated to be more efficacious and potent in both ADCC and ADCP assays than farletuzumab, an Fc competent monoclonal antibody targeting FOLR1 which shares the same VH/VL sequence as AFVT-2101. Co-culture of PBMCs, tumor cells and AFVT-2101 showed concentration-dependent release of pro-inflammatory cytokines (IFNγ, IP-10, TNFα) and minimal off-target cytokine release.

Conclusions We demonstrate that AFVT-2101 selectively and potently kills tumor cells with a range of expression levels of FOLR1 by two complimentary mechanisms: ADCC and ADCP. The high avidity for CD16A imparts increased potency and efficacy compared to an Fc competent, FOLR1-targeting antibody with the same VH/VL sequence. As AFVT-2101 binds selectively to CD16A outside the IgG binding epitope, physiological levels of IgG do not compete for binding. We show that AFVT-2101 induces moderate concentration-dependent pro-inflammatory cytokine release in a target-restricted manner, confirming a potent but safe *in vitro* profile of AFVT-2101.



Abstract 1212 Figure 1 Structure of AFVT-2101

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1212

1213 HYDROPHOBIC INTERACTIONS UNDERLIE RECOGNITION OF A KRAS G12V NEOANTIGEN BY A TCR-MIMIC ANTIBODY

[1]Katharine Wright*, [1]Sarah DiNapoli, [2]Michele Miller, [1]Sandra Gabelli, [1]P Aitana Azumendi, [1]Jacqueline Douglass, [1]Kenneth Kinzler, [1]Bert Vogelstein, [1]Shibin Zhou, [3]Xiaowei Zhao, [3]Zhiheng Yu. *[1]Johns Hopkins School of Medicine, Baltimore, MD, USA*; *[2]Johns Hopkins University, Baltimore, MD, USA*; *[3]Janeila, Ashburn, VA, USA*

Background Antibodies' exquisite specificity enables the development of new targeted immunotherapies for treatment in the fight against cancer. Antibodies can be engineered to target peptides derived from oncogenic proteins that are presented on the cell surface by human leukocyte antigens (pHLA).[1, 2] Here, we describe the structural basis of recognition of a T cell receptor (TCR)-mimic antibody, termed V2, against the HLA-A*03:01-restricted $KRAS^{G12V}$ epitope (VVVGAVGVGK), highlighting its specificity.

Methods For structural studies, the $KRAS^{G12V}$-specific full-length antibody (V2-IgG) was expressed in mammalian cells to generate an optimal protein fold. Structure determination of the V2-IgG in complex with $KRAS^{G12V}$/HLA-A*03:01 was performed by single particle cryo-electron microscopy (cryoEM). Two-dimensional and three-dimensional classifications were performed to produce a final refined map at 3.1 Å resolution. To fully understand determinants of the specificity of the V2 antibody, we determined the X-ray crystal structure of the $KRAS^{WT}$/HLA-A*03:01 monomer (resolution 2.6 Å). Biophysical characterization included carrying out differential scanning fluorimetry (DSF) and binding kinetics experiments using surface plasmon resonance (SPR). Furthermore, we screened a single variant library of the V2 TCRm antibody to identify key residues for peptide specificity and affinity enhancement.

Results The cryoEM complex structure revealed the V2 TCRm antibody sits on top of the $KRAS^{G12V}$-HLA-A*03:01 binding groove, making multiple contacts and leaning heavily towards the C-terminus of the $KRAS^{G12V}$ peptide. All contacts made between the V2 TCRm antibody and $KRAS^{G12V}$ peptide were aliphatic and hydrophobic in nature, with no hydrogen bonds made directly with the peptide. Three complementarity determining regions (CDRs) of the V2 TCRm antibody formed a loose cage-like configuration around the G12V neoantigen. Structural alignment of the V2 bound $KRAS^{G12V}$-HLA-A*03:01 and unbound $KRAS^{WT}$-HLA-A*03:01 structures revealed the $KRAS^{G12V}$ peptide underwent a conformational change upon antibody binding. This observation is in congruence with the SPR data that showed a two-state binding model. Moreover, the affinity matured process yielded V2 variant antibodies with comparable or enhanced affinity, but none retained both specificity and increased T-cell activation.

Conclusions This complex structure is the first cryoEM structure of an antibody fragment binding a neoantigen-HLA target and the first structures of the $KRAS^{WT/G12V}$ peptides presented by HLA-A*03:01 with or without an antibody in complex. Characterizing how the V2 TCRm antibody recognizes $KRAS^{G12V}$-HLA-A*03:01 and differences in $KRAS^{WT}$ and $KRAS^{G12V}$ peptide binding to HLA-A*03:01 offers insight into how highly hydrophobic peptide neoantigens can be targeted with antibody-based therapies.

1214 A NOVEL ANTI-MSLN X 4–1BB BISPECIFIC ANTIBODY WITH FC EFFECT FUNCTION AUGMENTS THE ANTITUMOR EFFICACY

Liansheng Cheng, Dayan Zhang*, Dayan Zhang, Lingling Wu, Weiming Zhou, Xiaoli Zeng, Xuejing Dai, Wenting Liu, Qun Zhao. *Hefei Hankemab Biotechnology CO., LTD, Hefei, Anhui, China*

Background Mesothelin (MSLN) is a ~71kDa cell surface glycoprotein that is rarely expressed in normal tissues but overexpressed in a variety of cancers.[1] 4-1BB is not only expressed on the surface of activated T cells and NK cells but also a marker for Treg.[2] Moreover, 4-1BB shows high selectivity for human tumor-derived Tregs and is associated with worse survival outcomes in patients with multiple tumor types, such as bladder cancer, glioblastoma, prostate cancer, or renal clear cell cancer.[3] Here, we developed a IgG1-based bi-specific antibody, HK013-1, targeting both MSLN and 4-1BB to achieve better antitumor therapeutic efficacy.

Methods We tested the binding ability of HK013-1 to tumor cells with different expression levels of MSLN, and tested the killing ability of HK013-1-mediated NK cells against these tumor cells in vitro. Moreover, the 4-1BB agonist activity of HK013-1 was detected using CD8+T cells co-cultured with MSLN+ or MSLN- cells. To confirm the safety of HK013-1, non-specific activation of 4-1BB signal mediated by Fc receptor and killing potency to CD8+T cells and Tregs induced by HK013-1 was evaluated. In vivo, we verified the ability to inhibit tumor growth of HK013-1 and examined the effects of HK013-1 on spleen and tumor CD8+T cells and Tregs.

Results HK013-1 could bind to various tumor cells that differentially expressed MSLN and induce NK cells to kill these cells. In co-cultured assay, HK013-1 increased IFN-γ production only in the presence of MSLN+ cells. Compared with anti-4-1BB parent antibody and urelumab, HK013 induced weaker FcγR-mediated 4-1BB activation. Furthermore, HK013-1 engaged NK cells to kill Treg but not CD8+T cells. In 4-1BB humanized transgenic mice, HK013-1 was revealed to reduce the proportion of Treg cells in tumor but had no effect on CD8+T cells, and CD8+T and Treg cells in the spleen. Compared with IgG4-based bi-specific antibody,IgG1-based HK013-1 showed a more significant anti-tumor effect in MC38/MSLN tumor model.

Conclusions IgG1-based HK013-1 prevents tumor development by directly killing tumor cells and depleting Treg to relieve immunosuppression. Preclinical studies have shown that IgG1-based HK013-1 has good antitumor activity and safety, which may further develop its clinical potential.

1215 IGM-7354, AN ANTI-PD-L1/IL-15 IGM IMMUNOCYTOKINE, ACTIVATES AND EXPANDS NK CELLS AND EFFECTOR MEMORY CD8+ T CELLS IN VIVO

Mélanie Desbois*, Thierry Giffon, Poonam Yakkundi, Sivani Pandey, Rodnie Rosete, Daniel Machado, Marigold Manlusoc, Susan Calhoun, Tasnim Kothambawala, Jey Ananta, Kristina Koyama, Yuan Cao, Dean Ng, Tomas Miranda-Katz, Avneesh Saini, Abhinav Jain, Hongjun Yue, Yang Cai, Miho Oyasu, Liz Bogaert, Roel Funke, Genevive Hernandez, Denise Nagata, Maya Leabman, Eric Humke, Stephen Carroll, Beatrice Wang, Bruce Keyt, Angus Sinclair, Maya Kotturi. *IGM Biosciences, Inc., Mountain View, CA, USA*

Background IGM-7354 is an engineered, humanized high affinity, high avidity anti-PD-L1 pentameric IgM antibody with an IL-15Rα chain and IL-15 fused to the joining (J) chain. IGM-7354 was designed to deliver IL-15-mediated stimulation of NK and CD8+ T cells to PD-L1 expressing tumors and antigen-presenting cells, to enhance anti-tumor immune responses.

Methods IGM-7354 has 10 binding sites for human PD-L1 that cross-react with cynomolgus monkey (cyno) PD-L1, but not with rodent PD-L1. The IL-15 component of IGM-7354 binds to human and cyno β chain of the trimeric IL-15 receptor with similar affinities but has weaker affinity to rodent IL-15Rβ. In vitro activity of IGM-7354 on NK or CD8+ T cells was assessed using PBMCs from healthy donors. In vivo pharmacodynamic studies were conducted in cynos and humanized mice engrafted with human CD34+ cells from cord blood in the absence of tumor (BRGSF-HIS mice) or with human PBMC in MDA-MB-231 human tumor-bearing animals (MHC-/- NSG mice). Immune profiling was done by flow cytometry. Serum cytokines and chemokines were analyzed by ELISA or Luminex assays.

Results Using in vitro assays with human and cyno PBMCs, IGM-7354 dose-dependently enhanced the proliferation of NK and CD8+ T cells. These immune subsets were further phenotypically characterized in vivo in the humanized BRGSF mouse model. Increases in NKp30, Granzyme B, and the proliferation marker Ki67 in NK cells were observed in animals treated with IGM-7354 as low as 1 mg/kg. IGM-7354 also enhanced the proliferation of CD8+ T cells with an increase of serum soluble CD25, suggestive of T cell activation. In MDA-MB-231 tumor-bearing mice engrafted with human PBMCs, the frequencies of proliferating CD8+ T cells, effector memory and CD39+ TCF-1- CD8+ T cells were increased following IGM-7354 treatment. In cynos, intravenous infusion of IGM-7354 was well tolerated at dose levels up to 10 mg/kg, with increased proliferating NK and effector memory CD8+ T cells in blood and lymphoid tissues. Soluble CD25 was also elevated in the serum of treated monkeys.

Conclusions IGM-7354 administration in humanized mouse models and cynomolgus monkeys demonstrated potent activation and expansion of NK cells, effector memory CD8+ T cells, and increased levels of soluble CD25 in the serum. This approach may enhance targeted delivery of the immunostimulatory cytokine IL-15 through high affinity and high avidity binding to PD-L1 potentially improving anti-tumor responses and minimizing toxicity.

Ethics Approval The animal studies were approved by the Testing Facilities' IACUC.

1216 THE CHIMERIC AD5/AD34 FIBER OF ICVB-1042 ONCOLYTIC VIRUS REQUIRES THE CD46 CELL SURFACE RECEPTOR FOR EFFICIENT TUMOR ENTRY

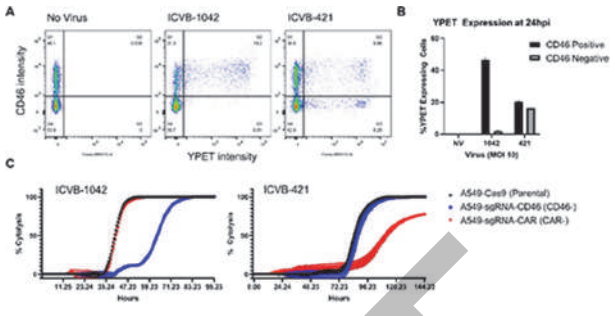
Michael Pokrass*, Peter Rosenthal, Joshua Messinger, Nathaniel Rice, Heba Nowyhed. *IcoOVir Bio, San Diego, CA, USA*

Background Viral entry into target cells through cell surface receptor-viral protein interactions is a crucial step in oncolytic virotherapy. The broad tropism and high transduction efficiency of adenoviruses (Ads) have contributed to their extensive employment in gene therapy and as oncolytic viruses (OVs). The commonly used Ad type-5 (Ad5) utilizes the coxsackie adenovirus receptor (CAR) for cell entry. However, CAR downregulation during cancer progression[1,2] limits the therapeutic efficacy of OVs reliant on this surface protein. Group B Ads use CD46 (a ubiquitously expressed receptor frequently overexpressed in cancer)[3,4] for cell entry, thereby presenting an opportunity to equip OVs with chimeric fibers to enhance tropism to malignant cells. We engineered ICVB-1042, a potent, selective, and systemically available OV, with an Ad5/Ad34 chimeric fiber to enable viral entry via CD46 instead of CAR proteins. Here, we demonstrate the cell entry requirements for ICVB-1042 compared to ICVB-421, an Ad5-derived virus with wild-type fiber and capsid.

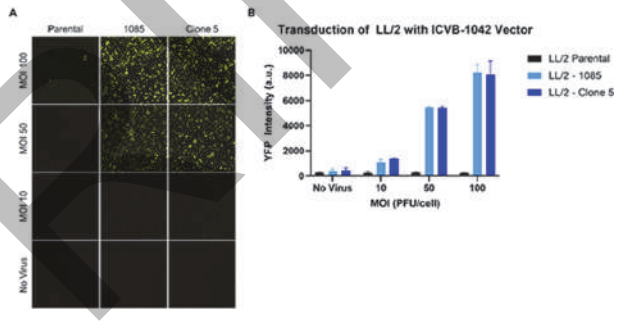
Methods CD46 and CAR knockout (CD46- and CAR-) A549 human lung carcinoma cell lines were generated using CRISPR editing. The cell lines were exposed to ICVB-1042 or ICVB-421, and the yellow fluorescent reporter protein (YPET) expression was analyzed in viable CD46+ and CD46- cells. Viral cytotoxicity was measured using cell index, a cell viability surrogate, in CD46-, CAR-, and CD46+ cells. The percentage of cytolysis was quantified relative to controls (no virus). Mouse LL/2 cells expressing transgenic human CD46 were exposed to a replication-independent YPET-expressing vector with the capsid of ICVB-1042 to determine viral entry.

Results A dramatic increase in YPET expression in CD46+ cells was observed post-infection with ICVB-1042, suggesting that CD46 expression is a requisite for ICVB-1042 cell entry (figure 1A-B). ICVB-421 infection was not strongly associated with CD46 expression, indicating that the absence of CD46 did not impair ICVB-421 tumor cell entry. ICVB-1042 infection induced 100% cytolysis in all cell lines faster than ICVB-421 but with a lower rate in CD46- cells (figure 1C), demonstrating that CD46 deficiency induces resistance to ICVB-1042-induced tumor killing. High YPET fluorescence intensity in mouse LL/2 cells harboring human CD46 transgenes was observed, denoting that human CD46 expression by LL/2 cells enabled transduction by a vector version of ICVB-1042 (figure 2A-B).

Conclusions These results demonstrate that replacing wild-type fiber with the chimeric Ad5/Ad34 fiber of ICVB-1042 results in a potent OV that relies on CD46 expression for tumor entry.



Abstract 1216 Figure 1 (A) Flow cytometry analysis of YPET expression in CD46 knockout cell lines; the A549 parental cell line with endogenous CD46 expression (CD46+) was used as a positive control. (B) Plots showing percentage of YPET-expressing CD46+ and CD46- cells (46.5% in CD46+ versus 1.9% in CD46- cells; p=0.0005, t-test). (C) Cell viability was measured at baseline and every 30 minutes for 144 hours following ICVB-1042 or ICVB-421infection. MOI: multiplicity of infection; 24hpi: 24 hours post infection.



Abstract 1216 Figure 2 (A) Representative images showing YPET fluorescence in mouse lung carcinoma LL/2 cells (generated via piggyBac transposition) following infection of a replication-independent YPET-expressing vector of ICVB-1042. (B) Plots showing average YPET fluorescence signal intensity (with background fluorescence subtracted). MOI: multiplicity of infection; 1085 and Clone 5 are constructs expressing CD46 isoforms in parental LL/2 cell lines.

1217 EFFICACY AND ADDITIONAL MECHANISM OF ACTION OF SACITUZUMAB GOVITECAN, A TROP-2 DIRECTED ANTIBODY-DRUG CONJUGATE, IN PRECLINICAL MODELS OF NON-MUSCLE INVASIVE BLADDER CANCER

Chih-Chien Chou, Dmytro Kornyeyev, Becky Yang, Jessica Orf, Hai-Ling Sun, Rutwij Dave, Yurong Lai, Giuseppe Papalia, Thomas Cardillo, Nathalie Scholler*. *Gilead Sciences Inc., Foster City, CA, USA*

Background Sacituzumab govitecan (SG, Trodelvy®) is a TROP–2-directed antibody (hRS7) drug conjugate (ADC) coupled to an active form of irinotecan (SN–38) via novel hydrolysable linker (CL2A). SG was approved for adult patients with locally advanced or metastatic urothelial cancers after 2 lines of therapy. TROP-2 is also highly expressed by non-muscle invasive bladder cancers (NMIBC) and treatment options remain limited for BCG-unresponsive NMIBC. We developed model systems to address SG biology and efficacy during short cell exposure and to evaluate SG intravesicular instillations as a treatment option for high-risk NMIBC patients.

Methods Binding affinity of SG and its naked antibody moiety hRS7, was determined by Surface Plasmon Resonance. SN38 release from SG was measured in buffers (pH 6-8) and human urine. SG internalization was visualized by confocal microscopy and Incucyte. SG cytotoxicity after continuous vs. pulse exposure of NMIBC cells was assayed by proliferation assays and DNA damage quantification (γH2Ax staining). SG efficacy was measured by *in vivo* imaging in sub-cutaneous vs. orthotopic NMIBC xenografts (UM-UC3-hTROP-2^{+}-luc^{+}) after intraperitoneal injections vs. intravesicular instillations, respectively.

Results hRS7 and SG bound mammalian-expressed human TROP-2 protein with similar affinity (K_D=0.33 and 0.36 nM, respectively). Free SN-38 conversion from SG was below 3.5% after 2 hours in buffer pH 6 to 8 and in human urine at 37°C. Loss of cell viability and enhanced DNA damage were demonstrated in TROP-2^{high} NMIBC cells after both continuous and short exposures to SG. In TROP-2^{high} cells, SG 2-fold more potent than control ADC after 2h-pulsed exposure (EC_{50}, p = 0.0223) and SG mediated more DNA damage than control ADC after 30 min-pulsed exposure (p < 0.0001). Moreover, SG rapidly internalizes in TROP2-positive cells (Incucyte) and, after 1-hr incubation at 37°C of RT112, 5637, and TROP-2-transduced UM-UC-3 NMIBC cells, confocal analysis demonstrated diminishing SG signal at the cell surface and appearance of SG-positive lysosomes (LAMP1^{+}) along with vesicles positive for both TROP2 and SG. Finally, SG produced antitumor effects in both subcutaneous and orthotopic xenografts models (vehicle vs. SG p <0.0001).

Conclusions SG colocalization with intracellular TROP-2 and LAMP1 is consistent with prompt SG internalization and SN-38 intracellular release and suggests an additional mechanism of action of SG via TROP-2-dependent endocytosis. Altogether, our results support the hypothesis that intravesicularly-delivered SG can release SN-38 payload in bladder tumor before voiding and indicate that SG instillations in bladder may offer a therapeutic option to high-risk NMIBC patients.

Ethics Approval All animal experiments were approved by the Institutional Animal Care and Use Committee of Gilead Sciences Inc. and carried out by certified staff in an Association for Assessment and Accreditation of Laboratory Animal Care International (AAALACi) accredited facility, in compliance with the institution's Guide for the Care and Use of Laboratory Animals and applicable laws (including the Animal Welfare Act of 1966 and, if applicable, the California Laboratory Animal Use Approval Program).

1218 MSLN-TARGETED IMMUNOTOXIN LMB-100 INDUCES DEVELOPMENT OF TERTIARY LYMPHOID STRUCTURES AND TUMOR REGRESSIONS OF ORTHOTOPIC MESOTHELIOMA

Wenlong Liu*, Chin-Hsien Tai, Xiu-fen Liu, Ira Pastan. *National Institutes of Health, Bethesda, MD, MD, USA*

Background Recombinant immunotoxins (RITs) are chimeric proteins composed of an Fv linked to a toxin and kill cells by arresting protein synthesis. LMB-100 is an RIT that kills mesothelin (hMLSN) expressing cells. Mesothelin is expressed in mesothelioma and many other cancers. Clinically, we observed some patients had delayed responses to LMB-100, suggesting the induction of antitumor immunity. The present study has developed a transgenic mouse model to investigate if LMB-100 monotherapy eradicates orthotopic mesothelioma and induces anti-tumor immunity in mice, and to study the mechanism of this immunity.

Methods To study the immune response induced by LMB-100, we established an immunocompetent transgenic mice model that expresses hMLSN only in the thyroid gland, so that hMSLN-expressed cells won't be rejected. AB1-L9 mouse mesothelioma cells expressing hMSLN were injected into the peritoneal cavity. Mice were treated with LMB-100 (i.p.) and mice with complete responses (CRs) were rechallenged with tumor cells (s.c.) to determine if anti-tumor immunity has developed. Tumors were analyzed by Nanostring and protein arrays, and the distribution of various immune cells was assessed by immunohistochemistry.

Results LMB-100 treatment alone induced CRs in 19/35 mice. Importantly, the CR mice were protected from re-challenge with AB1-L9 cells (17/19 mice), indicating LMB-100 induces anti-tumor immunity in mice. Both non-targeted immunotoxin (LMB-34) and inactive immunotoxin (LMB-255) had no anti-tumor activity, indicating both cell targeting and killing are necessary. The CRs were blocked by antibodies that deplete $CD8^+$ T cells, $CD4^+$ T cells as well as B cells. We further analyzed regressing tumors and found that pathogen response pathways are activated as early as 12 hours, followed by upregulation of a cascade of immune-related pathways associated with chemotactic-related activities (cytokine & receptors), antigen presentation (DC function), and TIL-based cell killing activities (T cell functions). We observed tertiary lymphoid structures (TLS) with aggregations of B cells developed in the tumor. Genes encoding proteins that are responsible for chemotaxis signals, such as CCL20, CXCL13, and CCL21, were specifically increased in tumors stroma, but not in tumor cells treated *in vitro*.

Conclusions We show RIT monotherapy gives complete regressions of tumors and reprograms the tumor immune microenvironment to trigger anti-tumor immunity. The regression of the primary tumor requires $CD8^+$ T cells, $CD4^+$ T cells as well as B cells. LMB-100 mediated tumor cell death induces the development of TLS in the solid tumor, probably by upregulating chemotaxis chemokines and cytokines that are associated with TLS formation.

1219 NONCLINICAL SAFETY EVALUATION OF SACITUZUMAB GOVITECAN, A TROP-2-DIRECTED ANTIBODY DRUG CONJUGATE (ADC), FOR NON-MUSCLE INVASIVE BLADDER CANCER

Carrie McMahon*, Lauri Diehl, Laurie Tatalick, Jennifer Boggs, Sunish Mohanan, In Kyoung Mah, Jordan Kardos, Chih-Chien Chou, Congrong Niu, Rutwij Dave, Nathalie Scholler, Yurong Lai. *Gilead Sciences, Foster City, CA, USA*

Background Trodelvy® (sacituzumab govitecan-hziy, SG) is approved as second-line therapy for patients with locally advanced or metastatic bladder cancers (BC). SG is a TROP-2-directed ADC that delivers an active metabolite of irinotecan (SN-38) to tumors. SG binds to Trophoblast cell-surface antigen 2 (TROP-2), a cell-surface glycoprotein overexpressed in various solid tumors, including non-muscle invasive bladder cancers (NMIBC), and is also expressed in normal epithelial bladder cells. SG cytotoxic payload, SN-38, forms a ternary complex with Topoisomerase 1 (TOP1)-DNA complex. Most BC are diagnosed as NMIBC and treatment options remain limited for BCG-unresponsive patients with high-risk papillary tumors or with carcinoma *in-situ*. We hypothesize that local instillation of SG could offer an alternative to radical cystectomy for the treatment of high-risk NMIBC patients.

Methods Human TROP-2 expression was evaluated in cell lines by flow cytometry and in a bladder cancer tissue panel by IHC and compared to TROP-2 quantification by LC-MS/MS. Normal cynomolgus monkey bladder tissue was similarly analyzed. Human TOP1 RNA expression was quantified and compared across TCGA normal, tumor-adjacent, and tumor tissue panels. SG toxicity for normal epithelial bladder cells and tumor cells was assessed after pulse exposure for apoptosis (annexin V) and DNA damage (p-γH2AX). SN-38 release from SG in human and monkey urine was determined under various pH conditions. Following two (once weekly) bladder instillations of SG to cynomolgus monkeys, urine cytology and histopathology of uroepithelial tissues were assessed, along with urine and plasma SG exposures.

Results TROP-2 protein detection (IHC) and quantification (LC-MS/MS) were consistent across human bladder cell lines, and human and monkey normal bladder tissues. TROP-2 distribution was differentially localized in normal bladder compared to tumor tissues. TOP1 RNA expression was upregulated in various TCGA tumors compared with normal tissues, consistent with increased SG sensitivity of bladder cancer cell lines compared to normal epithelial bladder cells. Minimal increases in free SN-38 levels in human or monkey urine following 1-hour incubation under physiological conditions with SG were noted. SG was well-tolerated in monkeys with no in-life or histopathological changes following two weekly instillations of 1 hour each, and SG and SN-38 plasma exposures were minimal.

Conclusions Overall, in vitro and in vivo data suggest that SG intravesicular instillation may provide a favorable safety risk benefit for high-risk NMIBC patients. SG instillation in naïve monkey bladder showed no toxicity at a localized exposure margin of approximately 2.5-fold higher than the projected efficacious dose for NMIBC patients.

Ethics Approval All animal experiments were approved by the Institutional Animal Care and Use Committee of Gilead Sciences Inc. and carried out by certified staff in an Association for Assessment and Accreditation of Laboratory Animal Care International (AAALACi) accredited facility, in compliance with the institution's Guide for the Care and Use of Laboratory Animals and applicable laws (including the Animal Welfare Act of 1966 and, if applicable, the California Laboratory Animal Use Approval Program).

Immuno-Engineering

1220 DEVELOPMENT OF B CELL MATURATION ANTIGEN (BCMA)-SPECIFIC CD8$^+$ CYTOTOXIC T LYMPHOCYTES USING INDUCED PLURIPOTENT STEM CELL TECHNOLOGY FOR MULTIPLE MYELOMA

[1]Jooeun Bae*, [1]Shuichi Kitayama, [1]Zach Herbert, [2]Laurence Daheron, [1]Nikhil Munshi, [1]Jerome Ritz, [3]Shin Kaneko, [1]Kenneth Anderson. *[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]Harvard University, Cambridge, MA, USA; [3]Kyoto Univ., Kyoto, MA, USA*

Background A strategy for reversal of T cell exhaustion is reprograming of antigen-specific CTL to early lineage memory T cells with selective anti-tumor activities. To accomplish this goal, we epigenetically reprogrammed BCMA-specific CD8$^+$ CTL to a pluripotent state through key defined transcription factors, established "induced Pluripotent Stem Cells (iPSC)" exhibiting transcriptional and epigenetic features, re-differentiated them back into antigen-specific CTL and evaluated their properties and functional activities against multiple myeloma (MM).

Methods Functionally active IFN-g producing HLA-A2 heteroclitic BCMA$_{72\text{-}80}$ (**Y**LMFLLRKI)-specific CD8$^+$ CTL were applied for iPSC via transduction of four reprogramming factors (OCT3/4, SOX2, KLF4, c-MYC). Upon characterization of the BCMA-specific iPSC with high pluripotency potential, embryoid body was formed from the iPSC and further polarized into mesoderm layer development as evidenced by upregulation of transcriptional regulators (ABCA4, BMP10, CDH5, FOXF1, HAND1, PLVAP, SNAI2, TBX3). Next, BCMA-specific embryoid body-derived hematopoietic progenitor cells (HPC; CD34$^+$ CD43$^+$/CD14$^-$ CD235a$^-$) were sorted and induced to undergo T cell differentiation in the presence of Fc-DLL4 signaling and rectonectin.

Results Our RNAseq analyses demonstrated unique transcriptional profiles of HPC from different iPSC clones committing to CD8$^+$ T cells or other cell lineages (monocytes/granulocytes, B lymphocytes/NK cells). Principal component analyses demonstrated a high similarity and low variability of transcription profiles within the replicates of HPC committed to the same cell lineage. In addition, distinct genome-wide shifts and differential gene expression profiles were detected in HPC committed to each specific cell differentiation pathway. Specifically, the HPC commit to CD8$^+$ T cells utilized a diverse repertoire of modulators promoting development of T cell maturation, specific immune response regulation, memory T cells, cytotoxicity and interferon induction, which were significantly higher than shown in HPC that differentiate to other cell lineages. In parallel, specific repression genes were identified in the HPC commit to CD8$^+$ T cells, which develop TGF-β receptor, rearrangement of Ig heavy chain genes and inhibitory receptors. The T cells differentiated were mainly CD45RO$^+$ memory CTL and fully rejuvenated without immune checkpoints expression and regulatory T cells and with high anti-MM activities.

Conclusions These findings identify genetic and epigenetic mechanisms and regulatory elements, which play key roles during lineage specific commitment of HPC developed in iPSC into CD8$^+$ CTL and help to further design a next generation of regenerative medicine that provide the appropriate signals for T cell lineage commitment from progenitor cells.

1221 BP1202-NF2, A NOVEL ADCC-ENHANCING CD39 ANTIBODY, INDUCES DESTRUCTION OF REGULATORY T CELLS AND ENHANCES CYTOTOXIC T LYMPHOCYTESINDUCTION

Toshifumi Obonai*, Haruka Ban, Motoya Mie, Norihiro Nakamura. *BrighPath Biotherapeutics, Kawasaki, Japan*

Background The immune suppression in the tumor microenvironment (TME) was promoted by the adenosine signaling in metabolites downstream of CD39 (ENTPD1). CD39, an extracellular enzyme, is one of the surface markers of regulatory T cells (Tregs). Tregs were suppressive immune cells that induce inhibitory and anti-proliferative effects on effector cells. Therefore, selective reduction of tumor-infiltrating Tregs is expected to re-invigorate anti-tumor immunity. Here, we describe the development of BP1202-NF2, a novel glycosylation-modified monoclonal antibody (mAb) targeting human CD39 that induces Treg depletion through antibody-dependent cellular cytotoxicity (ADCC) followed by antigen specific cytotoxic T lymphocytes (CTLs).

Methods Anti-human CD39 antibodies were screened by sorting B cells of mice immunized with human CD39 protein. The clones that inhibited the enzyme activity of CD39 were humanized on IgG1. A glycosylation modification was then introduced to the antibody during its production. Binding to human CD39 and Treg was evaluated via surface plasmon resonance (SPR) or flow cytometry. Functional assay was performed by Promega CD16 (V/F variants) ADCC signaling assay. Treg depletion and CTL induction were assayed using peripheral blood mononuclear cells (PBMCs) from healthy donors.

Results The humanized anti-CD39 antibody, BP1202 has a high affinity for the recombinant CD39 protein (K_D: 481 pM) and inhibits the enzyme activity on CD39-expressing cells and human Tregs (IC_{50}: 1 nM). BP1202-NF2, a glycosylation-modified version of BP1202, binds to CD39 on activated Treg with a K_D value in the nano-molar range, and demonstrated a robust ADCC activity in a dose-dependent manner. The ADCC activity was conferred by the glycolyration-modification and peaked at 1 μg/mL in PBMCs with either of V and F variants of FcγRIIIa receptor. By using ADCC assay, BP1202-NF2 selectively depleted $CD39^{hi}$ T cell populations and completely $CD39^{hi}$ Tregs in PBMCs from healthy donors. Further stimulation with CMV peptide robustly induced antigen-specific cytotoxic T lymphocytes. Their exhaustion level was lower than the reference antibodies.

Conclusions The humanized anti-CD39 antibody with glycosylation modification, BP1202-NF2 specifically binds to CD39 and targets $CD39^{hi}$ Tregs for depletion via ADCC and subsequently enhances CTL induction. Our results suggest that BP1202-NF2 modulates the TME to promote immune response in human tumors via Treg depletion and inhibition of CD39 enzymatic activity.

Ethics Approval The present study was approved by the Institutional Ethics Committee of BrightPath Biotherapeutics Co., Ltd. (approved number: ERD-01).

1222 *IN SITU* CAR THERAPY USING ORNA™ LIPID NANOPARTICLES REGRESSES TUMORS IN MICE

Robert Mabry*, Amy Becker, Alex Wesselhoeft, Allen Horhata, Akinola Emmanuel, Thomas Lee, David Soto, Akshi Thakkar, Ramya Elangovan, Magnolia Chinn, Sharmistha Kundu, Kevin Kauffman, Kristen Ott, Trent Stevens, Yessica Wiryawan, Ashley Wong, Ian Langer, Rahul Vungutur, Corey Ciullo, Zifiso Nyoni, Nelson Chau, Thomas Barnes. *Orna Therapeutics, Cambridge, MA, USA*

Background LNP-mediated delivery of long coding RNA has been clinically validated for vaccines and gene editing. We have been developing a novel, synthetic, circular coding RNA platform (oRNA technology) which exhibits significant improvements in production, expression and formulation compared to mRNAs. Lacking the cap structure of mRNA, our oRNA technology uses a proprietary sequence-based IRES element to initiate protein translation in target cells. At the same time, *ex vivo* generated chimeric antigen receptor (CAR) T cell therapies have had tremendous success in treating hematologic malignancies, yet manufacturing, safety and efficacy challenges remain. At Orna Therapeutics, we are combining oRNA technology with novel immunotropic LNPs to address these challenges, by creating off-the-shelf "autologous" *in situ* CAR (isCAR™) therapies.

Methods Orna's immunotropic LNPs show preferential biodistribution to the spleen, with oRNA reporter expression detected in multiple immune cell subsets, including T cells, macrophages and NK cells. Delivery to immune cells is preserved across mice, rats and non-human primates. *In vitro*, expanding human T cells expressing an anti-human CD19 CAR oRNA show potent and sustained cytotoxicity and pro-inflammatory cytokine production compared to controls. To maximize protein expression, we developed FoRCE (**F**ormulated **o**RNA **C**ell-based **E**valuation)[AB1] [AW2] : a robust high-throughput platform that enables parallel arrayed synthesis, purification, lipid nanoparticle (LNP) formulation, and cell-based screening of oRNAs. We applied FoRCE to almost 3,000 unique oRNAs containing UTRs extracted from viral genomes and discovered hundreds of IRESs that drive translation from synthetic oRNA in primary human T cells, hepatocytes, and myotubes.

Results Select IRESs from this screen drove high levels of CAR expression in primary human T cells. This elevated CAR expression translated to signficantly improved tumor regression in a human PBMC-engrafted NALM6 tumor-bearing mouse model. Tumor regression was dose-dependent, and the novel imunotropic LNP was well tolerated. oRNA-enabled isCAR therapies promise a re-dosable and scalable immune cell therapy.

Conclusions This off-the-shelf treatment dose not require leukapheresis or lymphodepletion, and the transient expression of isCAR may provide better management of cytokine release syndrome (CRS) and complexities associated with tumor lysis as compared to conventional autologous cell therapy. Future opportunities exist to expand targeting strategies and leverage a payload capacity (up to 12 kb) well beyond the current cell therapy delivery space.

1223 NG-796A: A T-SIGN VECTOR DESIGNED TO REPROGRAM THE TUMOR MICROENVIRONMENT AND DRIVE ANTI-TUMOR IMMUNITY

Manuela Zonca*, Katy West, Carla Cerqueira, Alice Muntzer, Rochelle Lear, Samuel Hardy, Darren Plumb, Maria Stella Sasso, Eva Vainiute, Tae Hyun Jang, Samantha Bucktrout, Brian Champion. *PsOxus Therapeutics Ltd, Abingdon, UK*

Background T-SIGn virus vectors are transgene-modified variants of enadenotucirev (EnAd), an Ad11p/Ad3 chimeric group B adenovirus, which retain all the functional and epithelial tumor-selectivity properties of EnAd, while also mediating the selective expression of transgenes by infected tumor cells. NG-796A is a vector encoding a single chain variant form of the human interleukin (IL)-12, IL-15, a soluble form of the Sushi domain of IL-15 receptor alpha (IL-15Rα), and the chemokine CCL21. Locally produced IL-12 and IL-15 cytokines can synergize to drive T- and NK cell activity within the tumor microenvironment (TME) to promote an effective anti-tumor immunity. Dendritic cells can be recruited by the CCL21 gradient to enhance the uptake and presentation of tumor antigens.

Methods Transgenes were placed under the control of the virus major late promoter (MLP) which is activated following initiation of genome replication in permissive epithelial tumor cells. Tumor cell lines and primary cells derived from surgically-excised patient tumor samples were infected to evaluate the production and activities of the different transgenes. Further functional experiments were run with peripheral blood derived T-cells and NK cells from healthy volunteers. *In vivo* data were obtained in a model of immunodeficient mice bearing human tumor xenografts, and adoptively transferred with tumor antigen specific CAR-T cells.

Results High levels of functionally active IL-12, as well as the other three transgenes, were produced by *in vitro* infected tumor cells. Interestingly, our initial screening of vectors demonstrated that an effective secretion of IL-15 requires co-expression of the Sushi domain of IL-15Rα. In NG-796A-infected tumor cells co-cultured with T-cells and NK cells, as well as in primary human tumor cell cultures, sustained IL-12 and IL-15 transgene production synergized potently to drive IFNg production. In *in vitro* transwell-migration assays, CCL21 produced by NG-796A selectively increased the chemotaxis of dendritic cells. Results obtained using human A549 tumor xenografts in immunodeficient mice, showed that intravenous dosing with NG-796A synergized with adoptively transferred tumor antigen specific CAR-T cells to induce long-term clearance of the tumor mass (an effect not observed in mice dosed with EnAd with or without CAR T-cells). This data is consistent with the encoded transgenes supporting the infiltration and anti-tumor activity of T-cells in this solid tumor setting.

Conclusions Due to its potential to reprogram the TME and support T-cell activity, NG-796A was selected as a candidate for progression into formal preclinical development activities in preparation for clinical evaluation.

1224 CELL-SPECIFIC NANOENGINEERING STRATEGY TO DISRUPT TOLEROGENIC SIGNALING FROM MYELOID-DERIVED SUPPRESSOR CELLS AND INVIGORATE ANTITUMOR IMMUNITY IN PANCREATIC CANCER

Nilesh Deshpande, Anna Bianchi, Iago De Castro Silva, Bapu Surnar, Ifeanyichukwu Ogobuiro, Siddharth Mehra, Samara Singh, Vanessa Garrido, Nipun Merchant, Shanta Dhar, Jashodeep Datta*. *University of Miami Miller School of Medicine, Miami, FL, USA*

Background A defining hallmark of immunosuppression in pancreatic ductal adenocarcinoma (PDAC) is the frequent trafficking of neutrophilic/granulocytic myeloid-derived suppressor cells (gMDSC) which exert their tolerogenic anti-T-cell functions through multiple mechanisms, particularly STAT3-mediated arginase-1 (Arg1) activity. Systemic inhibition of gMDSC trafficking and/or function (e.g., CXCR2, TGF-β, etc.) has been disappointing due to neutropenia, compensatory myelopoietic adaptations, and off-target effects. We sought to design a novel nanoengineering strategy to abrogate tolerogenic signaling in a gMDSC compartment-specific manner.

Methods We chemically modified AZD5069—a small-molecule inhibitor of the gMDSC surface receptor CXCR2—by conjugating it with polyethylene glycol (PEG) to enhance aqueous solubility. This AZD5069-PEG construct was chemically grafted on an amphiphilic polysaccharide derivative to engineer AZD5069-decorated nanoparticles (NP^{CXCR2}). We encapsulated hydrophobic STAT3i Ruxolitinib in NP^{CXCR2} nanoparticles and compared its effect on inhibition of Arg1 activity from gMDSCs and T-cell activation *in-vitro* and *in-vivo*.

Results To confirm CXCR2 as a gMDSC-specific target, we identified exclusive expression of CXCR2 in gMDSCs in human and murine PDAC via single-cell RNA sequencing and flow cytometric analysis in peripheral blood mononuclear cells derived from treatment-naïve PDAC patients (n=57). NP^{CXCR2} loaded with Cy5.5 dye showed dramatically higher uptake in gMDSC-like promyelocytic J774 cells compared with other PDAC-relevant cells *in-vitro*— KPC6694c2 tumor-cells, cancer-associated fibroblasts (CAF), and M0 macrophages RAW274.1. In *in-vivo* orthotopic $K\text{-}ras^{LSL.G12D/+};p53^{R172H/+};Pdx1^{Cre/+}$ (KPC) tumor cell:CAF co-injection models, although Cy5.5 dye-loaded non-AZD5069 decorated NP^{CTL} and NP^{CXCR2} both trafficked to tumor sites equally, NP^{CXCR2} but not NP^{CTL} constructs preferentially concentrated in $F4/80^{-}Ly6G^{+}$ gMDSCs compared with $F4/80^{+}$ macrophages, $F4/80^{-}Ly6C^{+}$ monocytic MDSCs, $EpCAM^{+}$ tumor cells, $PDPN^{+}$ CAFs, $CD3^{+}$ T-cells, and $Cd11c^{+}$ dendritic cells by flow cytometry. Encapsulation of STAT3i Ruxolitinib in NP^{CXCR2} and treatment of endogenous $pSTAT3^{hi}$ J774 cells *in-vitro* showed significantly more durable inhibition of pSTAT3 compared with Ruxolitinib drug treatment alone. Consequently, given that JAK2/STAT3 signaling is the major regulator of Arg1 activity in gMDSCs, Ruxolitinib-NP^{CXCR2} treatment of J774 cells significantly reduced gene expression and enzymatic activity of Arg1 compared with free Ruxolitinib treatment. Co-culture of splenocyte-derived murine $CD8^{+}$ T-cells with J774 treated with Ruxolitinib-NP^{CXCR2} showed significant improvement in T-cell IFN-γ release compared with NP^{CTL} or free Ruxolitinib-treated co-culture conditions. In orthotopic KPC tumor-bearing mice, intravenous delivery of NP^{CXCR2}-encapsulated Ruxolitinib significantly augmented intratumoral trafficking of $IFN\text{-}\gamma^{+}CD107a^{+}$ $CD8^{+}$ T-cells, compared with free Ruxolitinib treatment, without appreciable systemic neutropenia *in-vivo*.

Conclusions Cell-specific delivery of payloads via CXCR2-homing nanoparticles represent a novel immunotherapeutic strategy to target tolerogenic signaling pathways in gMDSCs and invigorate antitumor immunity in PDAC.

Ethics Approval All animal experiments were performed in accordance with the NIH animal use guideline and protocol 21-176 approved by the Institutional Animal Care and Use Committee (IACUC) at the University of Miami.

1225 NCG-SGM3 HUMANIZED MICE – AN IDEAL MODEL FOR HUMAN IMMUNE RECONSTITUTION OF T AND MYELOID CELL LINEAGES

Shiying Guo, Cunxiang Ju, Hongyan Sun, Mingkun Zhang, Liyou Dong, Mengting Wang, Shuai Li, Dong Li, Huiyi Wang, Santi Suryani Chen, Zhiying Li*, Mark Moore, Jing Zhao, Xiang Gao. *GemPharmatech, Nanjing, China*

Background Immunodeficient mice transplanted with human hematopoietic stem cells (HSC) have been extensively used in immuno-oncology studies to evaluate therapeutic agent's efficacy against cancer cells. However, the lack of human cytokines in these mice provides limited growth support for human immune cells beyond human T cells. Increasing evidence show that myeloid cells, such as macrophages and monocytes, provides critical functions in the immune system's anti-tumor effect.

Methods We established a mouse model, NCG-SGM3, that can support T and myeloid cells in such a way that the evaluation of agents that require the interplay between these two critical immune cell populations can be evaluated appropriately. This model was genetically engineered on the severe immunodeficient strain NCG and can produce human granulocyte/macrophage colony stimulating factor 2 (GM-CSF, also named as CSF2), interleukin-3 (IL-3) and stem cell factor (SCF, also known as KITLG).

Results Upon human $CD34^+$ HSC cells transplantation, increased myeloid lineage cells, such as granulocytes, monocytes, neutrophils, macrophages, and dendritic cells, were evident in the NCG-SGM3 cohort compared to NCG. The NCG-SGM3 mouse also supports the development of human T cells, and preliminary data showed increased B cells and NK cells as well.

Conclusions The NCG-SGM3 is an appropriate model for studying therapeutic agents that require human T cells and myeloid cells.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1225

1226 NCG-HIL15 HUMANIZED MICE – AN EXCELLENT MODEL FOR HUMAN IMMUNE RECONSTITUTION OF NK CELLS

Xing Liu, Meirong Wu, Huiyi Wang, Weiwei Yu, Hongyan Sun, Cunxiang Ju, Hongyu Wang, Zhiying Li, Mark Moore, Jing Zhou, Xiang Gao, Santi Suryani Chen*. *GePharmatech, Nanjing, China*

Background IL-15 is a four α-helix bundle cytokine produced by dendritic cells, monocytes, and epithelial cells. IL-15 is necessary for the development, survival, and activation of natural killer (NK) cells.

Methods Human *IL-15* (*hIL-15*) was knocked into NCG mice to create a model (NCG-hIL15) that can assist the reconstitution of human NK cells.

Results Compared with NCG, hIL-15 expression was significantly increased in NCG-hIL15het and NCG-hIL15homo. The development and function of human NK cells were evaluated in the NCG-hIL15 mouse reconstituted with three different types of human cell sources: (1) purified NK from human PBMC, (2) human PBMC, and (3) human CD34+ hematopoietic stem cells (HSC). In PBMC and CD34+ HSC-reconstituted mice, NK cell development was evident, with approximately 20% of hCD45+hCD56+ NK cells detected in the peripheral blood within weeks of engraftment. The level of hCD45+hCD3+ T cells reached 10 to 30% within 12 weeks of HSC reconstitution, while it reached greater than 80% within 2 weeks of PBMC reconstitution. In the purified NK engrafted cohort, the hCD45+hCD56+ NK cell numbers increased by at least two-fold within the first 3 weeks. Human NK cells were detected in multiple tissues and organs of all reconstituted NCG-hIL15 mice regardless of source of engraftment, except the colon, in the hPBMC-reconstituted NCG-IL15 mice. It was also noted that the level of NK cells post-engraftment varied depending on the donor of the PBMC.

To determine whether the reconstituted NK cells remain functional, purified NK cells from CD34+ HSC engrafted NCG-IL15 were isolated. Data showed that the NK cells could exert cell cytotoxicity when tested in vitro with leukemia cells, Raji, and Rituximab. Similarly, in vivo tumor growth inhibition (TGI= 49%) was observed with Raji.

Conclusions Overall, the addition of human IL-15, via genetic engineering in immunodeficient NCG mice provides excellent support for NK cell development. The NCG-hIL15 is a valuable tool for NK cell research and preclinical agent evaluation that requires NK and T cell activity.

1227 ELIMINATING THE IMMUNOTOXICITY OF INTERLEUKIN-12 THROUGH PROTEASE-SENSITIVE MASKING

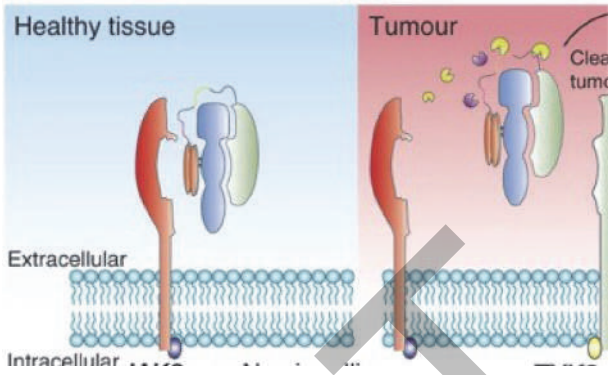
[1]Jun Ishihara*, [2]Aslan Mansurov, [2]Jeffrey Hubbell. [1]*Imperial College London, London, UK*; [2]*University of Chicago, Chicago, USA*

Background Checkpoint inhibitor (CPI) immunotherapy demonstrates modest efficacy against immunologically 'cold' or immune-excluded tumors, therefore needs another approach for majority of patients. Although interleukin-12 (IL-12) is a promising antitumor cytokine that enables activation and recruitment of immune cells into tumors, its widespread use in the clinic has been hindered due to severe immune-related adverse events (irAEs). An ideal IL-12 therapy would restrict the proinflammatory effects of IL-12 to the tumor site, while limiting its exposure in the periphery.

Methods Here, we solved the IL-12 toxicity challenge by exploiting the preferential overexpression of proteases (Matrix Metalloproteinases, Serine Proteases) in the tumor to engineer tumor-selective, masked IL-12. A IL-12RB1 receptor-based masking domain was fused to IL-12 p35 domain via a protease-cleavable linker.[1]

Results Recombinant fusion of masking domain to IL-12 prevented IL-12 from signaling systemically, whereas proteolytic cleavage of the linker domain by tumor-associated enzymes restored the biological activity of IL-12. We demonstrate that intravenously (i.v.) administered, masked IL-12 produces strong therapeutic effects through remodeling the immune-suppressive microenvironment and renders CPI-resistant tumors responsive, while systemic irAEs are eliminated, boosting the therapeutic index of this promising cytokine. In several solid tumour models, the therapeutic effects of masked IL12 were similar to its unmasked wild-type form, yet its toxicity was as low as saline injections. Masked IL-12 synergised with anti-PD-1 antibody for efficacy. We found that addition of human tumour lysates, and not adjacent healthy tissue lysates, cleaved off the mask, induced significant IFNy production and STAT4 phosphorylation, similar to wild-type IL-12. We made fully humanized masked IL-12 molecule already.

Conclusions Masking approach to IL-12 may solve the toxicity issue of IL-12 observed in 1990s clinical trials, while maintaining extremely high anti-tumor effects in immunologically cold tumors (figure 1).



Abstract 1227 Figure 1 Masking IL-12 to restrict its activity only in tumorSchematic of masked IL-12 in healthy tissues (no signalling) and in the tumour, with the mask being cleaved by various tumour-associated proteases.

1228 STRUCTURAL BASIS FOR LAG3 ENGAGEMENT OF IMMUNOMODULATORY LIGANDS AND ANTIBODIES

[1]Qianqian Ming, [1]Daiana Celias, [2]Chao Wu, [2]Aidan Cole, [1]Srishti Singh, [1]Charlotte Mason, [3]Shen Dong, [1]Timothy Tran, [2]Gaya Amarasinghe, [1]Brian Ruffell, [1]Vincent Luca*. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Washington University School of Medicine, St. Louis, MO, USA; [3]UCSF, San Francisco, CA, USA*

Background Lymphocyte activation gene 3 (LAG3) was recently validated as a target for next-generation immune checkpoint inhibitors. However, unlike PD-1 and CTLA-4, we have a poor molecular-level understanding of the LAG3 immunosuppression mechanism. We determined the structure of the LAG3 ectodomain to gain insight into its architecture and assembly on the surface of T cells.[1] Subsequent functional studies identified key interfaces that mediate LAG3 engagement of antagonist antibodies and its cellular ligands Fibrinogen-like 1 (FGL1) and MHC class II.

Methods To facilitate structural studies of unstable LAG3 proteins, we used yeast display to evolve a human LAG3 variant with improved biochemical properties. This variant (named LAG3*) contains a single conservative M171I mutation and had increased expression yield, stability, and ligand-binding affinity compared to WT LAG3. The LAG3* protein was co-crystallized with an antagonist antibody fragment and the structure was determined to 3.7-angstrom resolution. Mutational mapping identified the binding sites of FGL1 and multiple antagonist antibodies on the LAG3 protein. We also used x-ray crystallography to map the LAG3-binding site of the FGL1 protein, and we used confocal microscopy to visualize LAG3-FGL1 complex formation on the surface of Jurkat T cells.

Results The structure of LAG3* revealed an elongated "X-shaped" architecture and a dimer interface formed by domain 2 (D2) of the LAG3 extracellular domain (ECD). A potent neutralizing antibody blocked LAG3 interactions with both FGL1 and MHCII and bound to a flexible "loop 2" region within LAG3 domain 1 (D1). This loop is distinct from the "loop 1" region previously implicated in MHCII binding and suggests that dual-ligand blockade can be achieved by targeting the loop 2 epitope. Structural modeling and microscopy studies revealed that FGL1 binding to LAG3 induces clustering on the cell surface, which may be important for disrupting proper immune synapse formation.

Conclusions Our structural studies enabled us to finally "see" how LAG3 proteins are organized on the surface of T cells. Subsequent structural analyses revealed multiple potential targets for LAG3 antagonist drugs, including a potent neutralizing epitope linked to dual-inhibition of FGL1 and MHCII binding.

1229 IMMUNOTHERAPY IN THREE DIMENSIONS: THE TUMOR MICROENVIRONMENT, IMMUNE CELLS, AND TUMOR INVASION

[1]W Gregory Sawyer*, [1]Duy Nguyen, [2]Ryan Smolchek, [2]Jack Famiglietti, [2]Stephanie Warrington. [1]*University of Florida, Gainesville, FL, USA*; [2]*Aurita Bioscience, Gainesville, FL, USA*

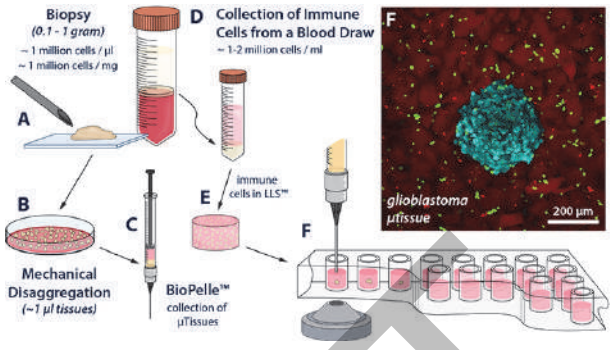
Background Cancer is a complex and heterogeneous disease, an ecosystem architecture that involves far more than just cancer cells. We have developed a 3D ex vivo culture platform that enables the controlled delivery of media and removal of waste metabolites via perfusion in Liquid-Like Solids (LLS) medium that acts as both a 3D support medium and an open porous network mimicking a capillary-bed for fluid transport and cell motility. Using integrated fast scanning laser confocal microscopy we collect in situ spatiotemporal measurements of cytokine concentrations, track immune cells in the tumor microenvironment, and study tumor invasion dynamics in 3D.

Methods Glioblastoma patient derived tumor microexplants (200-400 μm) and PBMCs were co-cultured in 3D LLS. Spatiotemporal cytokine profiles were measured by 3D printing arrays of ELISA beads across the experiment to measure local concentrations of cytokines in situ. Modeling the bead kinetics (cytokine on-rates and off-rates), coupled with measurements of each bead's fluorescence at a specific time and position from the tumor periphery were fit to spatiotemporal reaction-diffusion models quantifying the tumor's production rate, concentrations, and the immuno-regulatory micro-environment (figure 1). 3D imaging of immune and cancer cells created movies that were analyzed frame-by-frame to track 3D positions, motion, proliferation, action, cell death, and elimination as well as quantify tumor evolution-dynamics, and T cell killing. Surface conjugation of the LLS microgels with type 1 collagen (COL1-LLS) enabled cell adhesion to the LLS and cancer invasion studies. Cell tracking used novel AI algorithms from astrophysics data processing (figure 2).

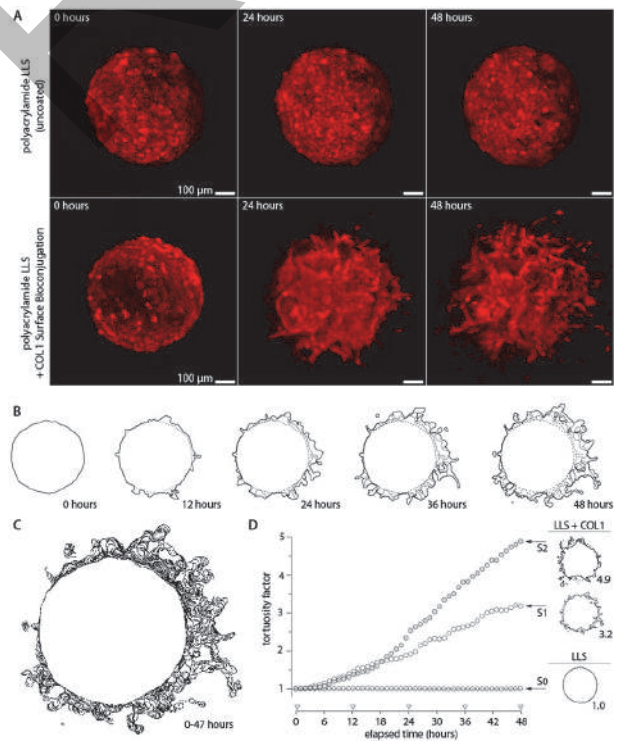
Results Fitting spatiotemporal data of cytokine concentrations revealed production rates of 2 IL8 molecules per cell per second giving tumor margin concentrations of over 2ng/ml after 10 hours (figure 3). Invasive fronts of the micro-tumor protruded into interstitial space and analysis of these invasive paths revealed super-diffusive behavior of these fronts. Off-lattice agent based computational simulations reveal that the interstitial space guided tumor invasion by restricting available paths resulting in super-diffusive behavior. COL1 bioconjugation reveals that glioblastoma cancer cells utilize anchorage-dependent migration to explore their surroundings, and geometrical cues guide 3D tumor invasion along the accessible paths. Tracking revealed both chemotaxis and chemokinetics of CD8+ cells: average migration speed of > 2.8 μm/min, and average killing rates ~3 cancer cells/h decreasing monotonically to ~1 cancer cell/h over 12 hours.

Conclusions The in vitro immuno-oncology platform with in situ fast scanning fluorescence microscopy was able to quantify spatiotemporal concentrations of cytokines, T Cell motions and activity, and tumor invasion dynamics.

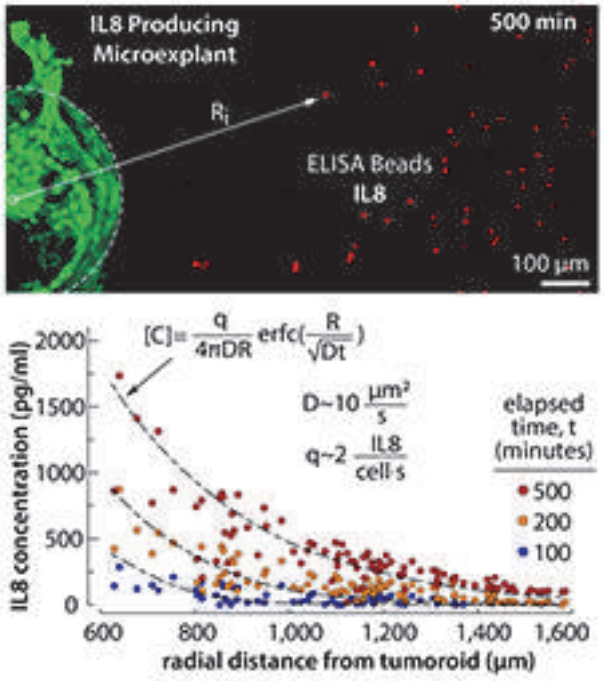
Consent Written informed consent was obtained from the patient for publication of this abstract and any accompanying images. A copy of the written consent is available for review by the Editor of this journal.



Abstract 1229 Figure 1 Schema for in vitro immunotherapy assays (A) Biopsied tissue sample and blood draw from properly consented donor. (B) The tissue sample is mechanically disaggregated into microexplants on the order of 1μl each. (C) Microexplant samples are collected in the BioPelle, a custom micromanipulator mounted on a microscope, for dispensing into sample wells. (D) Immune cells are separated from the blood draw, sorted for CD8+ and CD4+ T cells and stained with CFSE prior to dispersing in LLS and being dispensed into culture wells. (E) Microexplants are placed into a 3D dispersion of immune cells in LLS in each culture well and a liquid cover is added atop the LLS layer. (F) Maximum intensity projection image of glioblastoma microexplant (cyan) in a field of immune cells (green) within the LLS microgel bed (red).



Abstract 1229 Figure 2 Tumor invasion
(A) Glioblastoma microexplant over the course of 48 hours in inert polyacrylamide LLS (top) and Collagen-1 coated polyacrylamide LLS (bottom). Where Collagen-1 context is provided, invasion outward into the surrounding regions is seen while the microexplant without Collagen context remains adherent to self. (B) Outlines of the microexplant cultured in Collagen-1 coated LLS over the course of 48 hours. (C) Microexplant outline progression over duration of the experiment (48 hours). (D) Tortuosity index over time showing monotonic increases in LLS with COL functionalization.



Abstract 1229 Figure 3 Cytokine GradientsSpatiotemporal measurements of cytokine concentrations using distributed arrays of ELISA beads allow for in situ measurements that can be fit to reaction-diffusion equations to give production rates and diffusivity for specific cytokines, such as IL8.

1230 VIVOVEC LENTIVIRAL VECTOR PARTICLES SURFACE-ENGINEERED WITH T CELL ACTIVATING AND CO-STIMULATORY LIGANDS ENHANCE *IN VIVO* CAR T CELL GENERATION AND ANTITUMOR ACTIVITY

Chris Nicolai*, Jim Qin, Way Wu, Mollie McDonnell, Erica Shirazi, Greyson Hamilton, Max Chen, Don Parrilla, Susana Hernandez, Kathryn Michels, Shon Green, Andrew Scharenberg, Laurie Beitz, Ryan Larson, Byoung Ryu, Wai-Hang Leung. *Umoja Biopharma, Seattle, WA, USA*

Background Autologous chimeric antigen receptor (CAR) T cell therapies have revolutionized the treatment of B cell malignancies, leading to long-term remission in 30-40% of certain patient populations. Despite the promising clinical efficacy of CAR T cells in hematologic malignancies, major limitations hinder their widespread application, including challenges for patient access, complex manufacturing, and high cost.

Methods To overcome these challenges, we have developed VivoVec, a surface-engineered lentiviral vector-based platform harboring a CAR transgene that is being developed for off-the-shelf use for the generation of CAR T cells *in vivo*. To achieve specific and efficient *in vivo* T cell transduction, VivoVec particles are pseudotyped with the Cocal fusion glycoprotein and an anti-CD3 single chain variable fragment (scFv), and we have previously shown that these first-generation particles generate CAR T cells *in vivo* that mediate antitumor activity.

Results We have advanced the VivoVec platform through incorporating costimulatory molecules into the particle surface, in addition to the anti-CD3 scFv and Cocal fusion glycoprotein. These second-generation VivoVec particles exhibit enhanced T cell binding and activation, resulting in increased transduction and greater numbers of CAR+ T cells *in vitro*. In addition, CAR T cells generated with second-generation VivoVec particles exhibited a less-differentiated, central memory-like phenotype and enhanced CAR-antigen-specific polyfunctionality, including cytokine production, proliferation, and tumor cell killing. Finally, in a humanized NSG mouse model of B cell malignancy we observed that second-generation VivoVec particles generated greater numbers of CAR T cells in the blood, resulting in enhanced antitumor activity at lower doses compared to first-generation particles. Our results indicate that incorporation of costimulatory molecules onto the surface of VivoVec particles increases both the overall number and functionality of the resulting CAR T cells, greatly augmenting VivoVec mediated CAR T cell generation and antitumor activity *in vivo*.

Conclusions Overall, these data demonstrate that second-generation VivoVec particles efficiently generate large numbers of highly functional CAR T cells able to mediate durable tumor control in a preclinical model of B cell malignancy. VivoVec particles have the potential to overcome many of the limitations associated with the current class of CAR T cell therapies.

1231 VIRUS-FREE, TARGETED INSERTION OF LONG TRANSGENES WITHIN PRIMARY NATURAL KILLER CELLS USING CRISPR-CAS9

Keerthana Shankar*, Isabelle Zingler-Hoslet, Christian Capitini, Krishanu Saha. *University of Wisconsin-Madison, Madison, WI, USA*

Background Natural killer (NK) cells are innate cytotoxic lymphocytes capable of killing virally infected cells and malignant tumors. Unlike T cells, NK cells are human leukocyte antigen (HLA)-agnostic and cause little to no Graft vs. Host Disease in allogenic transfusions, making them excellent candidates for off-the-shelf therapies. However, current techniques to insert a chimeric antigen receptor (CAR) gene into NK cells primarily employ viral vectors. Viral methods can give rise to complications such as insertional mutagenesis, which can lead to gene silencing or oncogene activation.[1] Here we have developed a CRISPR genome editing strategy to modify primary NK cells and report the targeted virus-free CAR integration within peripheral blood NK cells.

Methods In our strategy, the transgene (e.g., CAR) is encoded in a linear double stranded DNA (dsDNA) template and produced by polymerase chain reaction (PCR). The template includes homology to the intended target for insertion that is defined by nuclease mediated double strand break formation by a Cas9-single guide RNA (gRNA) ribonucleoprotein complex (figure 1A).[2]

Results We show efficient (>80%) CRISPR knock-out of the inhibitory NKG2A receptor encoded by the *KLRC1* gene within primary NK cells. Optimization of electroporation timing showed that delivery of 3 mg of donor DNA on day 4 of *ex vivo* expansion results in gene knock-in rates of up to 24% for the transgene (figure 1B). Lastly, we report that the use of K562-mbIL15-41BBL feeder cells improves expansion of CRISPR edited cells by approximately twenty-fold.

Conclusions These data provide a proof-of-principle for on-target integration of long transgenes, including CAR, without viral vectors within primary NK cells via CRISPR-Cas9 genome editing. Overall, this virus-free manufacturing strategy could enable the development of novel genetically-programmed NK immunotherapies.

1232 ENGINEERING A PSEUDOTYPED LENTIVIRAL PLATFORM TO ENABLE LINEAGE-SPECIFIC TRANSDUCTION OF IMMUNE CELLS

[1]Blake Smith*, [1]Stephanie Dougan, [2]Michael Birnbaum. *[1]Harvard Medical School, Boston, MA, USA; [2]MIT, Cambridge, MA, USA*

Background Cell-specific transduction remains one of the next frontiers for virally-delivered gene therapy. Efforts to achieve cell-specific transduction have largely been limited to borrowing of preexisting viral glycoproteins and pseudotyping viral surface envelopes to result in altered tropism. VSVG is derived from vesicular stomatitis virus (VSV) and is one of the most commonly used lentiviral (LV) pseudotype glycoproteins as its cognate receptor (LDLR) is present on nearly all dividing and non-dividing cells, enabling broad tropism of VSVG-pseudotyped LVs.

Methods Our lab recently developed a "receptor-blinded" version of VSVG, in which point mutations (K47Q, R354A) of this glycoprotein results in a mutated VSVG with inability to bind and infect LDLR-expressing cells. This mutant viral glycoprotein, which we call "VSVGmut", thereby loses its broad tropism, but critically retains its fusogen ability, enabling co-display of a new LV pseudotype ligand to drive LV tropism.

Results Initial experiments displaying high-affinity anti-CD19 scFvs alongside VSVGmut on the LV surface demonstrated infection of CD19+, but not CD19- cells. Subsequent work using endogenous ligands (CD80), Fabs (a-CD3e), cytokines (IL-13), viral glycoproteins (SARS-CoV-2 RBD), and peptide MHCs (pMHCs) revealed the modularity of this platform for achieving potent transduction of on-target cells, with minimal infection of bystander cells, across a range of affinities (pM to uM) and at frequencies as low as 1 in 100,000. This technology allowed for library on library screening of 96 viral pMHC-displaying LVs against a repertoire of >450,000 TCRs in pool, which accurately uncovered EBV- and Flu-specific TCRs through scRNA sequencing.

Conclusions The VSVGmut platform has resulted in our lab's ability to pair pMHCs with cognate TCRs and viral surface antigens with cognate BCRs, in addition to achieving lineage-specific transduction of T and B cell subsets, setting the stage for cell-specific gene therapy.

Acknowledgements Connor S. Dobson who initially developed the VSVGmut platform.

1233 REPROGRAMMING PRIMARY MELANOMA CELLS TO DENDRITIC CELL FATE ENHANCES TUMOR IMMUNOGENICITY

[1]Marta Velasco Santiago*, [2]Olga Zimmermannova, [1]Morten Hansen, [3]Fabio Rosa, [3]Cristiana Pires, [1]Özcan Met, [3]Carlos-Filipe Pereira, [1]Inge Marie Svane. *[1]National Center of Cancer Immune Therapy (CCIT-DK), Herlev, Denmark; [2]Molecular Medicine and Gene Therapy, Lund, Sweden; [3]Asgard Therapeutics, Lund, Sweden*

Background Direct cell reprogramming is characterized by the use of defined factors to rewire the transcriptional and epigenetic network of one cell-type into one of a different lineage. We have recently identified the transcription factors PU.1, IRF8, and BAFT3 (PIB) as sufficient to induce a type 1 conventional dendritic cell (cDC1) fate in both somatic and cancer cells.[1,2] cDC1 is a rare dendritic cell subset with unique ability to initiate *de novo* T cell responses after migrating to the tumor site. Several studies have shown that higher levels of cDC1s within the tumor microenvironment strongly correlate with good prognosis and responsiveness to immunotherapy for patients with melanoma.[3] Therefore, we hypothesized that PIB factors could reprogram primary melanoma cells into functional antigen presenting cDC1s capable of presenting tumor antigens and restoring anti-tumor immunity.

Methods Primary melanoma cells from eight patients were reprogrammed into cDC1-like cells through transduction with lentivirus constitutively expressing PIB. Reprogrammed cells were profiled at multiple time-points to characterize reprogramming efficiency, phenotype, and functional properties including cytokine secretion and the capacity to prime T cells.

Results All eight PIB-transduced melanoma cells progressively acquired a cDC1 surface phenotype characterized by the expression of CD45 and HLA-DR, marking the acquisition of hematopoietic and antigen presentation phenotype. The cell reprogramming process was consistent across all cell lines. Induced cDC1s also expressed CD11c, the cDC1-specific markers CLEC9A and CD141 as well as the costimulatory molecules CD40, CD80 and CD86. Functionally, cDC1-like melanoma cells at day 9 secreted the human cDC1-specific cytokines IL12p70 and IL-29 upon stimulation with Poly(I:C). After pulsing with a 9mer MART-1 peptide restricted to HLA-A2, cDC1-like melanoma cells were able to prime allogeneic HLA-A2 matched naïve CD8+ T cells and resulted in expansion of MART-1-specific T-cells after an eight-day co-culture with IL-2 and IL-7. Moreover, autologous tumor-infiltrating lymphocytes (TILs) were more reactive (higher expression of CD107a, CD137, IFN-gamma, and TNF-alpha) and cytotoxic towards cDC1-like melanoma cells compared to the original tumor cells.

Conclusions Here, we demonstrated that melanoma cells from multiple patients can be efficiently reprogrammed into cDC1-like cells and present tumor-associated antigens. These results lay the groundwork for the development of cDC1 reprogramming as an innovative cancer immunotherapy to counteract immune escape and reactivating anti-tumor immunity.

1234 NCG-MHC DKO MICE – AN EXCELLENT MODEL FOR PBMC RECONSTITUTION AND PHARMACODYNAMIC EVALUATION IN THE ABSENCE OF GVHD

Huiyi Wang, Cunxiang Ju, Mark Moore*, Jun Xing, Jialu Fan, Huanhuan Hou, Santi Suryani Chen, Zhiying Li, Jing Zhao, Xiang Gao. *GePharmatech, Nanjing, China*

Background Human immune cell reconstitution (PBMC or $CD34^+$ hematopoietic stem cell; HSC) is commonly done in immunodeficient mouse lines such as NCG, NSG or NOG. The use of PBMC over $CD34^+$ HSC is preferred for multiple reasons, including faster engraftment, lower cost, and the presence of mature immune cell populations. One major limitation of human PBMC reconstituted models is the acute Graft-versus-Host Disease (GvHD) that set in within weeks of PBMC injection, leading to a high mortality rate. While donor-to-donor variations exist and specific donors can be selected, the symptoms of GvHD typically occur within 4 weeks. This significantly limits the study window required for appropriate evaluation of the agents, such as cancer immunotherapies. GvHD is an immune reaction triggered mainly by donor T cells identifying the mouse MHC class I and class II as foreign and attacking the host cells and organs. Removing MHC molecules from the host seems a viable approach to avoiding GvHD.

Methods We used CRISPR-Cas9 to knockout the mouse H2-K1, H2-D1 and H2-Ab1 genes. We first generated two KO strains for H2-K1 and H2-Ab1 respectively. After identifying the correctly engineered strain targeting the H2-K1 gene, we generated H2-K1 and H2-D1 double KO strains by knocking out the H2-D1 gene in the embryos of the H2-K1 KO strain. In the final step, we generated the triple KO strain by cross-breeding the H2-K1 and H2-D1 double KO strain with the H2-Ab1 KO strain.

Results While the deletion of β2M (NCG-β2M-KO) reduces the occurrence of GvHD, this model knocked out not only the MHC class I subunit but also the FcRn subunit, which shortens the half-life of IgG, making it unsuitable for IgG antibody agent evaluation. In addition, deletion of MHC class I or class II alone resulted in low or high CD4/CD8. Compared with the existing NCG-β2M or other β2m null mouse models, the NCG-MHC dKO significantly prolonged survival and reduced GvHD occurrences when reconstituted with PBMC.

Conclusions Based on our preliminary data, the NCG[SSC1] - MHC dKO is a promising model for antibody and cell therapy agent evaluation, determining therapeutic-related cytokine release syndrome, and long-term toxicity evaluation of cell therapies.

1235 TARGETING THE SECRETORY PATHWAY OF T CELLS TO BOOST THE EFFICACY OF CANCER IMMUNOTHERAPY

[1]Anthea Wirges*, [1]Armin Rehm, [1]Mario Bunse, [1]Jara J Joedicke, [2]Eric Blanc, [3]Venugopal Gudipati, [1]Michael Moles, [2]Dieter Beule, [3]Johannes Huppa, [1]Uta Hoepken, [1]Anthea Wirges. *[1]MDC Berlin, Berlin, Germany; [2]BIH Berlin, Berlin, Germany; [3]Medical University Vienna, Vienna, Austria*

Background The efficiency of adoptive immunotherapy correlates with the ability of the transferred T cells to release effector molecules. Furthermore, T cell memory formation is important to ensure a long lasting anti-tumor effect and thus, to prevent tumor relapse. Here, we optimized the efficacy of adoptive immunotherapy by silencing EBAG9, a negative regulator of cytolytic enzyme release from $CD8^+$ T cells.

Methods Using a retroviral vector that includes an intronically located EBAG9-targeting miRNA, we equipped T cells with defined TCR or CAR specificities and, simultaneously, knocked down EBAG9. *In vitro*, cytotoxicity as well as cytokine release assays were employed. Kinetics of tumor cell killing and the sensitivity of CAR activation were determined by microscopy-based methods. Knockout mice, cytotoxicity assays and xeno-transplantation models served as tools to study EBAG9 functionality *in vivo*. Furthermore, T cell memory formation, *in vivo* target cell killing and tumor growth after adoptive transfer of engineered T cells were investigated.

Results EBAG9 knockdown in mouse CTLs resulted in a significant increase of antigen-specific *in vivo* killing activity. Granzyme A release from engineered human TCR and CAR $CD8^+$ T cells was increased after EBAG9 silencing, while cytokine secretion was not altered. Enhanced granzyme release translated into strongly improved killing capability and kinetics without leading to faster exhaustion. Adoptively transferred EBAG9-silenced BCMA CAR T cells exhibited an extended control of multiple myeloma growth, even at low effector cell numbers. Upon leukemia challenge of *Ebag9*$^{-/-}$ mice, the enhanced $CD8^+$-mediated cytotoxicity was associated with increased commitment to the $CD8^+$ T cell memory lineage. Single cell RNA sequencing revealed a preferential expression of the memory-related transcription factors *Zeb1, Id3*, and *Stat3* as well as anti-apoptotic genes like *Traf1* in *Ebag9*$^{-/-}$ $CD8^+$ cells.

Conclusions Targeting EBAG9 has a promising therapeutic potential when applied to adoptive immunotherapy of leukemia and multiple myeloma and represents a platform technology that can be favorably combined with variable CAR or TCR specificities. We suggest a strategy to boost the efficacy of engineered T cells that, concomitantly, facilitates an optimized manufacturing combined with the need for a lower therapeutic dose. From Ebag9-KO mice we infer that an enhanced primary immune response leads to improved memory formation and, thus, lowers the risk for tumor relapse. Gain of cytolytic efficacy by EBAG9 silencing does not come at the expense of adverse effects, such as faster exhaustion or release of inflammatory cytokines.

1236 SELECTIVE DELIVERY OF LOW-AFFINITY IL-2 TO PD-1+ T CELLS REJUVENATES ANTITUMOR IMMUNITY WITH REDUCED TOXICITY

[1]Zhenhua Ren*, [2]Anli Zhang, [2]Yang-Xin Fu. [1]*Changping Laboratory, Beijing, China*; [2]*UT Southwestern Medical Center, Dallas, TX, USA*

Background Increased levels of tumor-infiltrating lymphocytes (TILs) are associated with improved survival in patients with cancer. Anti–PD-1/PD-L1–based cancer immunotherapies have revolutionized the treatment of cancers, and TIL abundance can be used as a prediction marker for immunotherapy responsiveness. Even though PD-1/PD-L1 blockade can release the brake on the T cell response, T cells are not fully functional and are limitedly expanded in the tumor. Most patients either fail to respond or develop adaptive resistance after an initial response. Importantly, the role of T cell–associated cytokines in the tumor microenvironment for anti–PD-1/PD-L1 responsiveness has not been fully studied. It is possible that additional T cell–driven cytokine therapy might overcome PD-1 therapy resistance. IL-2 is an important T cell growth factor for T cell proliferation. How to target IL-2 to tumor-specific T cells remains a challenge in IL-2 cancer immunotherapy.

Methods Here, we designed a fusion protein (IL-2 linked to an anti–PD-1 antibody) to target TILs, as TILs express more PD-1 than other cells. To reduce the binding of IL-2 to Tregs, we selected a lowaffinity IL-2 (laIL-2) that has greatly reduced binding to both IL-2Rα and IL-2Rβ. We linked laIL-2 to an anti–PD-1 antibody (generating PD-1–laIL-2) to increase its avidity to intratumoral CD8+ T cells.

Results We fortuitously observed that anti–PD-1 therapy depends on IL-2 signaling, which raises the possibility that a lack of IL-2 limits anti–PD-1–induced effector T cell expansion. To selectively deliver IL-2 to PD-1+CD8+ tumor-infiltrating lymphocytes (TILs), we engineered a low-affinity IL-2 paired with anti–PD-1 (PD-1–laIL-2), which reduced affinity to peripheral Treg cells but enhanced avidity to PD-1+CD8+ TILs. PD-1–laIL-2 exerted better tumor control and lower toxicity than single or mixed treatments. Mechanistically, PD-1–laIL-2 could effectively expand dysfunctional and tumor-specific CD8+ T cells. Furthermore, we discovered that presumably dysfunctional PD-1+TIM3+ TILs are the dominant tumor-specific T cells responding to PD-1–laIL-2.

Conclusions Collectively, these results highlight that PD-1–laIL-2 can target and reactivate tumor-specific TILs for tumor regression as a unique strategy with stronger efficacy and lower toxicity.

1237 IN VIVO PROGRAMMING OF MYELOID CELLS BY MRNA MEDIATED DELIVERY OF NOVEL FCA FUSION RECEPTOR ACTIVATES ANTI-TUMOR IMMUNITY

Yuxiao Wang*, Hongyun Zhao, Edward Cochran, Michael Gorgievski, Thomas Prod'homme, Bruce McCreedy, Daniel Getts. *Myeloid Therapeutics, Cambridge, MA, USA*

Background Immunotherapy has revolutionized cancer treatment. However, for the majority of patients with advanced solid tumors, sustained clinical benefit has yet to be achieved. Myeloid cells such as monocytes and macrophages readily accumulate in tumors, in some cases contributing up to 75% of the tumor mass. Reprogramming circulating and tumor associated myeloid cells to activate their ability to elicit anti-tumor adaptive immunity by phagocytosis, cytokine secretion and antigen presentation is an attractive approach to harness and orchestrate systemic anti-tumor immunity. It remains challenging to specifically target and activate myeloid cells in vivo. **Methods** To overcome this hurdle, we have developed a novel in vivo myeloid cell engineering platform: Fca Receptor Fusion Constructs. Unlike other chimeric antigen receptors (CARs) the construct was engineered by fusing a tumor recognition scFv with the alpha chain of human Fc receptors. The stable expression and function of these receptors requires endogenously expressed Fc receptor gamma chain, an protein with limited expression to immune cells, mostly myeloid cells. Here, we present that intravenous infusion of lipid-nanoparticle (LNP) encapsulating the Fca Receptor Fusion Construct mRNA results in the uptake and expression of the construct by myeloid cells. In immunodeficient xenograft models of hepatocellular carcinoma and triple negative breast cancer, delivery of LNP mRNA encoding for GPC3 or TROP2 targeted Fca Receptor Fusion Constructs resulted in tumor killing, confirming the ability of this approach to program myeloid cells. Furthermore, in the B16 syngeneicinc melanoms melanoma model, treatment with the melanoma antigen GP75 targeted Fca Receptor Fusion Constructs was also associated with the the initiation intiatation of broad systemic immune responses, characterized by tumoral accumulation of activated CD8+ T cells, reduced tumor associated Tregs and activation of antigen presenting cells in spleen. Together these studies highlight the potential of Fca Receptor Fusion Construct delivered directly in vivo to program myeloid cells to recognize and kill cancer.

1238 SEPARATING THE WHEAT FROM THE CHAFF: ENGINEERING CARTS WITH SUPERIOR METABOLIC ATTRIBUTES AGAINST SOLID TUMORS

Yufan Zhou, Andre Kelly, Andrew Frisch, Decheng Song, Saba Ghassemi, Carl June, John Scholler, Roddy O'Connor*. *University of Pennsylvania, Philadelphia, PA, USA*

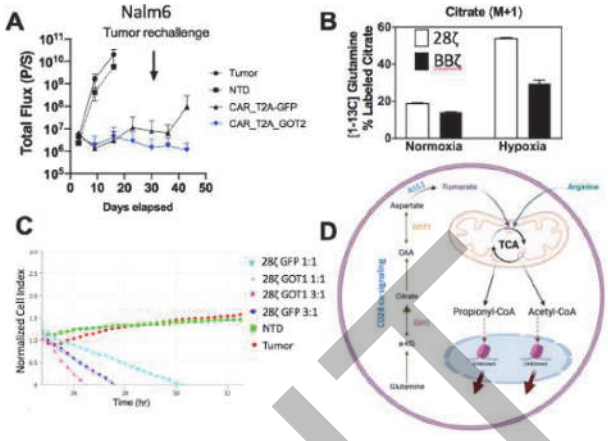
Background For cellular immunotherapies, clinical outcomes depend on the proliferative potency and metabolic fitness of the therapeutic product. For their most successful indications, CAR T cells are effective 'serial killers,' each T cell recognizing and eliminating many target cells. What fuels CAR T cell serial killing is unknown. Two critical events define the efficiency of T cell serial killing: migration and immune synapse formation/cytolysis. Importantly, each event is influenced by the local metabolic milieu.

Methods Using a specialized CAR T cell conditioning regimen, the goal of this research to is determine the relative energy cost of migration versus cytolysis using innovative eSIGHT RTCA technology. Our project will reveal how the spare respiratory capacity (SRC), supports CAR T cell migration and/or cytolysis, founded on the hypothesis that cells that can replenish their SRC in repetitive antigen stimulation models, are more efficient serial killers.

Results Our data sheds light on critical metabolic states that impair CAR T cell cytolytic activity. We also use multi-omic approaches to identify arginosuccinate synthase 1 (ASS1), a gene distinguishable at the metabolic (Seahorse), transcriptional (RNAseq), epigenetic level (ATAC seq), and functional (tumor clearance in vivo) in

CAR T cells. Supporting the premise of our work, we show that ASS1 supports high SRC levels despite frequent antigen encounter in repetitive stimulation models in vitro. In parallel work, we provide data that reductive glutamine metabolism is enhanced in 28zCARTs, suggesting mechanisms for why 28zCARTs outperform BBz CARTs in some hypoxic tumor models (figure1B). We also show that expressing isoforms of the GOT family of amino transaminases enhance CAR T cell anti-tumor function (figure 1A&C). Given the prior link connecting reductive glutamine metabolism and GOT1 in Jurkat cells we hypothesize a fundamental link, involving reductive glutamine metabolism, GOT1-mediated aspartate replenishment, and fumarate production via ASS1, to support mitochondrial function and serial killing in CAR T cells (figure 1D).

Conclusions Our findings reveal unique conditioning and genetic strategies to arm CAR T cells with unique metabolic attributes against solid tumors.



Abstract 1238 Figure 1 A model for enhancing CART metabolic activity(A) Serial quantification of tumor burden in Nalm6 tumor-bearing mice treated with CAR T cells. CARTs with a superior ability to replenish aspartate (GOT2) demonstrate superior tumor control, even after tumor cell re-challenge (day 31). Data are means ± SEM from starting cohorts (n=5 mice per treatment arm), from a single experiment. (B) Lentivirally transduced CAR T cells (SS1-CAR-28ζ vs SS1-CAR-BBζ) were expanded for 9 days until restdown. These cells were restimulated with mesothelin-fc, that was previously conjugated to dynabeads. At 5 of re-stimulation, the cells were treated with [1-13C] glutamine that distinguishes reductive gln metabolism overnight at 20% O2 or 1% O2. Citrate labeling (m+1 isotopologue) is accentuated in 28ζ CARTs. Data are means ± SEM from two independent studies with separate donors. (C) Aspartate replenishment via GOT1 enhances CAR T cell cytolytic potency as assessed by eSIGHT impedance assay. SY5Y-CD19 target cells were adhered to the well. 24 hr later, CARTs were added at various E:T ratios as indicated. Data are means ± SEM from a single experiment. (D) A novel model proposing how 28ζ signaling drives the vectorial flux of glutamine to citrate, which replenishes OAA, is converted to aspartate which supports TCA anaplerosis (fumarate) by ASS1.

1239 OVEREXPRESSION OF THE CHEMOKINE RECEPTOR CCR7 CONFERS ANTI-CXCR5 CAR T CELLS WITH INCREASED HOMING TO LYMPH NODES AND ENHANCED CYTOTOXICITY TOWARD B CELL LYMPHOMA

Maria Zschummel, Jara Joedicke, Anca Margineanu, Susanne Blachut, Eric Lindberg, Norbert Hübner, Armin Rehm, Uta Höpken*. *Max-Delbrück-Center for Molecular Medicine (MDC), Berlin, Germany*

Background The efficacy of CAR T cell therapy correlates with the ability of the transferred therapeutic T cells to traffic to the respective tumor niche. We observed that engineered T cells downregulate the lymphoid homing receptor CCR7 during the manufacturing process. Consequently, *in-vitro* and *in-vivo* migration of CAR T cells toward the corresponding chemokine ligands was severely impaired. To improve nodal CAR T cell trafficking and anti-lymphoma efficacy of B-NHL-targeting anti-CXCR5 CAR T cells, we engineered CAR T cells which co-expressed the homing receptor CCR7.

Methods The anti-human CXCR5 CAR and anti-mouse CXCR5 CAR, encoded within a retroviral MP71 backbone, were generated essentially as described.[1] In case of the human and mouse CXCR5 CAR-CCR7 vectors, hCCR7 or mCCR7 cDNAs without stop codons were introduced upstream of the CXCR5 CAR cassette via P2A linkage. To test the functionality of CCR7-engineered CAR T cells in-vitro, transwell migration, cytotoxicity, and cytokine release assays were employed. CAR T cell killing dynamics were determined by microscopy-based methods. Mouse leukemia and lymphoma models served as tools to study in-vivo CCR7-modulated CAR T cell homing to lymph nodes and target cell killing.

Results CCR7 overexpression on human and mouse anti-CXCR5 CAR T cells restored their migratory capacity and improved lymph node homing. In addition, we observed an enhanced killing capacity of CCR7-equipped CAR T cells in-vitro, which is likely supported by the costimulatory role of CCR7 in the formation of an immunological synapse. We showed that CCR7 accumulated in mature CAR synapses, an observation that is supported by the transcriptional upregulation of genes associated with cytoskeletal rearrangement, relevant for immunological synapse formation and migration in CCR7-engineered CAR T cells.

Conclusions Therapeutically, CCR7-enforced nodal recruitment and enhanced killing kinetics of CAR T cells conferred improved lymphoma eradication in a mouse lymphoma model. Beyond improved anti-tumor responses in nodal hematological malignancies, we envisage that this CCR7-engineering approach might be useful to improve CAR T cell therapies that specifically target solid tumor entities metastasized to lymph nodes.

Immunotherapy Toxicities

1241 IL-1 BLOCKADE PREVENTS CARDIAC TOXICITY AND IMPROVES IMMUNOTHERAPY EFFICACY IN MOUSE MODELS OF PANCREATIC CANCER

[1]Rakesh Jain, [2]Nilesh Talele*, [2]Heena Kumra, [2]Igor Gomes Dos Santos, [2]Sylvie Roberge, [2]William Ho, [2]Patrik Andersson, [2]Sampurna Chatterjee, [2]Marie Siwicki, [2]Dan Duda, [3]Mikael Pittet, [2]Dai Fukumura, [2]Rakesh Jain. *[1]Edwin L. Steele Laboratories, MGH, Boston, MA, USA; [2]Massachusetts General Hospital/Harvard Medical School, Boston, MA, USA; [3]University of Geneva/Geneva University Hospitals, Geneva, Switzerland*

Background Immune checkpoint blockers (ICBs) have revolutionized cancer treatment, but they are often associated with severe immune related adverse events (irAEs). These severe irAEs are more often seen in patients with obesity or concomitantly treated with cytotoxic therapies.

Methods We aimed to understand the mechanisms of ICB-induced irAEs, in the context of obesity [FD1] and ICB/chemotherapy combinations. We used a mouse model of cardiac irAEs, which is the most fatal type of irAE in ICB-treated cancer patients, with clinically relevant features: (i) an ICB-resistant cancer (pancreatic ductal adenocarcinoma or PDAC), (ii) obesity induced with high-fat diets, and (iii) a combination treatment of ICB (α-PD1 + α-CTLA4) and chemotherapy (FOLFIRINOX[FD2]

Results Mice with orthotopic PDAC and obesity developed irAEs after treatment with ICB and chemotherapy as compared to [FD1] chow diet. These irAEs recapitulated those observed in patients with cancer and obesity, including cardiac dysfunction consistent with myocarditis, cardiac fibrosis, and increased circulating levels of interleukin-1 beta (IL-1b). IL-1b blockade prevented myocarditis and reduced cardiac fibrosis after immunotherapy. Importantly, IL-1b blockade also enhanced the anti-tumor effects of ICB + FOLFIRINOX combination therapy, and increased mouse survival.

Conclusions Using a translationally relevant mouse model, we discovered that IL-1b mediates ICB-induced cardiotoxicity, which is the most fatal type of irAE in ICB-treated cancer patients. In addition, we found that IL-1b blockers, which are already used in the clinic for other indications[FD1] , may both reduce adverse events and enhance the antitumor effects triggered by immunotherapy.

1242 ALTERED INTERACTIONS BETWEEN CIRCULATING AND TISSUE-RESIDENT CD8 T CELLS WITH THE COLONIC MUCOSA DEFINE CHECKPOINT INHIBITOR COLITIS

[1]Kamil Slowikowski*, [1]Molly Thomas, [1]Kasidet Manakongtreecheep, [1]Pritha Sen, [1]Jessica Tantivit, [1]Mazen Nasrallah, [1]Leyre Zubiri, [1]Neal Smith, [1]Alice Tirard, [1]Swetha Ramesh, [1]Benjamin Arnold, [1]Linda Nieman, [1]Jonathan Chen, [2]Thomas Eisenhaure, [1]Karin Pelka, [1]Katherine Xu, [1]Vjola Jorgji, [1]Christopher Pinto, [1]Tatyana Sharova, [1]Rachel Glasser, [1]PuiYee Chan, [1]Ryan Sullivan, [1]Hamed Khalili, [1]Dejan Juric, [1]Genevieve Boland, [1]Michael Dougan, [1]Nir Hacohen, [1]Bo Li, [1]Kerry Reynolds, [1]Alexandra-Chloé Villani. *[1]MGH, Boston, MA, USA; [2]Broad Institute, Boston, MA, USA*

Background Antibodies targeting immune checkpoint inhibitors (ICIs) CTLA-4 and PD-1/PD-L1 have revolutionized the treatment of metastatic solid tumors. However, their use is limited by a high incidence of immune-related adverse events. The colon is a frequent target of this immune attack seen in up to 45% of patients on dual PD-1 and CTLA-4 blockade. We leveraged a multi-omics strategy to further our understanding of the cellular and molecular drivers giving rise to ICI-associated colitis and nominate treatment solutions that spare anti-tumor immune response.

Methods We collected paired endoscopic colon mucosal biopsies and blood specimens from 13 irColitis patients, 8 healthy individuals, and 8 controls on ICIs, and analyzed them with single-cell/nuclei RNA sequencing with paired TCR and BCR sequencing, multispectral fluorescence microscopy, and secreted factor analysis.

Results Analyses of over 300,000 single epithelial, mesenchymal, and immune single cells revealed that patients with irColitis showed expanded mucosal Tregs, *ITGAE*^{Hi} CD8 tissue-resident memory T cells expressing *CXCL13* and Th17 gene programs. We also identified two circulating *ITGB2*$^{+}$ CD8 T cell populations associated with irColitis – a *CX3CR1*^{Hi} population predicted to be intravascular and an *EOMES*^{Hi} *KLRG1*^{Hi} population. Comparison of dual anti-PD-1/CTLA-4 versus anti-PD1 monotherapy revealed expansion of those two circulating *ITGB2*^{Hi} CD8 T cell populations, as well as a cytotoxic *GNLY*^{Hi} CD4 T cell subset, and endothelial cells associated with hypoxia gene programs. Cell-cell communication analysis predicted crucial roles for ICAM and CXCR3 ligand-mediated recruitment and retention of these two circulating T cell populations by epithelial, endothelial and myeloid cells during active colitis. In irColitis, we also observed significant epithelial turnover marked by fewer *LGR5*$^{+}$ stem cells, more transit amplifying cells, and upregulation of apoptotic and DNA-sensing programs. Mature epithelial cells with top crypt genes upregulated interferon-stimulated pathways, *CD274* (PD-L1), anti-microbial genes, and MHC-class II genes, and down-regulated aquaporin and solute-carrier gene families, likely contributing to epithelial cell damage and absorptive dysfunction. Transcriptional programs associated with irColitis were distinct from those in the tumor microenvironment, which may have important therapeutic implications. Finally, by examining many drugs in clinical trials for inflammatory bowel disease, we expand the putative therapeutic options for treating irColitis reported to-date.

Conclusions This multi-omics approach nominates novel irColitis therapeutic targets and redefines irColitis as a disease not simply marked by the aberrant expansion of CD8 T cells but rather altered global interactions between immune cells and the colon mucosal epithelial or mesenchymal cells.

Ethics Approval Informed consent was obtained from all patients in accordance with protocols obtained from the Mass General Brigham and/or DANA- Farber/Harvard Cancer Center Institutional Review Boards (DFCI/HCC 11-181 and 13-416, Mass General Brigham 2015P001333).

1243 IMMUNE CHECKPOINT INHIBITOR-INDUCED POLYARTHRITIS: A CASE SERIES

Megan Smith-Uffen*, Konstantinos Tselios. *MMaster University, Hamilton, Canada*

Background Immune checkpoint inhibitors (ICIs) have revolutionized cancer care. However, their mechanism of action also results in the uncontrolled collateral of ICI-related adverse events (ICI-AEs). Polyarthritis is a rare ICI-AE. Here we describe two cases of ICI-induced polyarthritis, induced by nivolumab/ipilimumab and sasanlimab for melanoma and urothelial cancer, respectively.

Results A 64-year-old male received combination immunotherapy with nivolumab and ipilimumab for metastatic melanoma. Within one month of his second cycle of nivolumab alone, he developed polyarthritis of the small joints of the hands bilaterally, as well as the shoulders and knees; active synovitis; and erosive arthropathy on radiographic findings. He was successfully treated with prednisone at 20mg daily, gradually tapered over several months.

A 43-year-old male with high-grade non-invasive urothelial cell carcinoma received two cycles of adjuvant sasanlimab. Within two months of his second treatment, he developed a large-joint polyarthritis involving the bilateral knees, ankles, elbows, and the cervical spine. His symptoms resolved with prednisone, initiated at 50mg daily with a recommended slow taper, however resurfaced five days after he abruptly ceased treatment. He was subsequently started on methotrexate in combination with prednisone.

Both patients had a past medical history of non-rheumatological autoimmune disease, developed symptoms within 8 weeks of ICI, had elevated inflammatory markers and negative autoantibodies. Neither had to discontinue their cancer therapy and indeed both had a good tumour responses to their ICI. Both of our patients were initially well-managed prednisone. However, our second patient relapsed after abrupt cessation of his prednisone and required a combination of methotrexate with prednisone to control his symptoms.

Conclusions These cases add to the literature on ICI-induced polyarthritis, a rare ICI-AE. Clinical manifestations most commonly resemble rheumatoid arthritis, with bilateral inflammation of the small joints. Time to onset tends to be <12 weeks after ICI exposure, and repeated ICI exposure is a risk factor. Most patients have no personal or family history of autoimmune disease, negative autoantibodies, and can be managed well with glucocorticoids. As ICIs become more widely used, rheumatologists and oncologists alike should familiarise themselves with their adverse effects. More research is needed to understand the epidemiology, clinical presentation, and treatment of these adverse events.

Consent Written informed consent was obtained from the patients for publication of this abstract. A copy of the written consent is available for review by the Editor of this journal.

1244 ALLIANCE A151804: ESTABLISHMENT OF A NATIONAL BIOREPOSITORY TO ADVANCE STUDIES OF IMMUNE-RELATED ADVERSE EVENTS

[1]David Kozono*, [2]Tyler Zemla, [3]Elie Dib, [4]Mark Watson, [5]Yujia Wen, [6]Frank Keller, [7]John Kirkwood, [8]Gary Lyman, [9]Jarushka Naidoo, [2]Barb Mulhern, [5]Laura Hoffman, [2]Jennifer Le-Rademacher, [10]Andrew Nixon, [11]Elad Sharon. *[1]Brigham and Women's Hospital, Boston, MA, USA; [2]Mayo Clinic, Rochester, MN, USA; [3]St. Joseph Mercy Ann Arbor, Sioux Falls, SD, USA; [4]Washington University, St. Louis, MO, USA; [5]University of Chicago, Chicago, IL, USA; [6]Children's Healthcare of Atlanta, Atlanta, GA, USA; [7]University of Pittsburgh, Pittsburgh, PA, USA; [8]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [9]Johns Hopkins University, Baltimore, MD, USA; [10]Duke, Durham, NC, USA; [11]National Cancer Institute, Bethesda, MD, USA*

Background Immune-related Adverse Events (irAEs) are rare but serious sequelae of treatment with immuno-oncology (IO) therapeutics. These therapeutics, including monoclonal antibodies targeting programmed cell death protein 1 (PD-1), programmed death-ligand 1 (PD-L1) and cytotoxic T-lymphocyte-associated protein 4 (CTLA-4), have had transformative effects on outcomes for patients with advanced cancers. Although most patients tolerate the therapies well, a few experience irAEs ranging in severity up to life-threatening or fatal. These irAEs involve diverse organs including the heart, kidney, liver and lung, and gastrointestinal, musculoskeletal, central and peripheral nervous systems. Because of the relatively low incidence and wide variety of irAEs due to various immunotherapies for multiple tumor types, establishment of an efficient centralized repository for acquisition and organized distribution of well-annotated biospecimens is vital for translational studies that improve understanding of the molecular pathogenesis and treatment of these significant toxicities.

Methods This multi-institutional study is open at sites across the National Clinical Trial Network. Patients may be pre-registered prior to starting IO therapy, or registered when they experience one or more irAEs. Any patient who has not previously been treated with CTLA-4, PD-1 or PD-L1 inhibitors is eligible for pre-registration. These patients provide blood and stool samples prior to starting IO therapy and again after 1 month. Regardless of whether they were pre-registered, patients who received $\geq$ 1 IO therapeutics (e.g., CTLA-4, PD-1 or PD-L1 inhibitor) and experienced 1) $\geq$ 1 grade 3–5 irAEs, 2) $\geq$ 1 grade 2 dermatologic or rheumatologic irAEs, 3) rare infection, or 4) tumor hyperprogression may be registered to the study. IrAEs of interest include myocarditis, colitis, hepatitis, nephritis, myositis, pneumonitis, meningitis/encephalitis, dermatitis, endocrinopathies, neuropathy, other rheumatological, hematologic cytopenias, and pancreatitis. Patients may be on an NCTN or non-NCTN IO trial or be receiving standard-of-care therapy. Registration must occur $\leq$ 96 hours after confirmation of the irAE. Clinical data are collected at registration, after 1 month after, and for up to 1 year. Biospecimens include archival tumor blocks, biopsies of inflammatory tissues used to establish irAE diagnosis, blood for isolation of plasma and peripheral blood mononuclear cells, and stool samples. Imaging data are collected for patients with hyperprogression, pneumonitis, or other radiographically-diagnosed irAEs. Accrual goal is 2000 pre-registered and 360 registered subjects. As of June 30, 2022, 485 sites have been approved to participate and 88 subjects have been registered. Biospecimens and data will be made available to investigators following future submission and approval of proposals.

1245 SAFETY AND EFFICACY OF IMMUNE CHECKPOINT INHIBITORS (ICIS) IN PATIENTS WITH PRE-EXISTING ORGAN DYSFUNCTION

Meghana Kesireddy*, Apar Ganti, Alissa Marr, Makayla Schissel. *Univ. of Nebraska Medical Center, omaha, NE, USA*

Background ICIs (PD-1 inhibitors, PDL-1 inhibitors, CTLA-4 inhibitors) are increasingly used to treat various malignancies. The percentage of cancer patients in the US who may benefit from ICIs has increased from 1.54% in 2011 to 43.63% in 2018[1]. ICIs cause unique side effects called immune-related adverse events (IrAEs). There is limited to no data regarding the safety/efficacy of ICIs in patients with pre-existing organ dysfunction, as these patients are frequently excluded from clinical trials. Our study aims to evaluate the effects of ICIs in patients with chronic kidney disease (CKD), cirrhosis, COPD (chronic obstructive pulmonary disease), and congestive heart failure (CHF).

Methods Data were obtained retrospectively for patients over 18 with any solid organ malignancy, who received at least 1 dose of ICI between 1/1/2015- 1/1/2021 and had either CKD (n=90), cirrhosis (n=20), COPD (n=142), or CHF (n=82) at our institution. Patients on chronic immunosuppression were excluded. Descriptive statistics (mean/counts/percentages) were used to summarize patient characteristics, treatment characteristics, IrAEs, and outcomes. An independent samples t-test or Wilcoxon Rank Sum test was used to assess differences in continuous variables; Chi-Square or Fisher's Exact test was used to assess differences in categorical variables between patients with IrAEs compared to those without IrAEs. Progression-free survival (PFS) was assessed using Kaplan- Meier curves, and the log-rank test was used to assess differences in PFS. $p < 0.05$ was considered statistically significant.

Results In this analysis, 21/90 CKD patients, 4/20 patients with cirrhosis, 34/142 patients with COPD, and 25/82 patients with CHF had a clinically significant IrAE (table 1). In each of the 4 cohorts, there were no statistically significant differences in the patient characteristics or treatment characteristics, or outcomes among patients with IrAEs compared to those without IrAEs (table 2). In the CKD cohort, those with IrAE were significantly less likely to die than those without IrAE, 52% versus 81%, p=0.009; this difference in survival was not seen in other cohorts. There was no statistically significant difference in the number of heart failure and COPD exacerbations while receiving immunotherapy in the CHF and COPD cohorts, respectively. There was no statistically significant difference in PFS between patients with IrAE and without IrAE in any of the cohorts (figure 1).

Conclusions Our study showed that ICIs are safe in patients with pre-existing organ dysfunction with a trend towards better PFS (though not statistically significant) in those with IrAEs. This is the most extensive study to date assessing ICI in this patient population.

1246 TROPONIN-T LEVELS AND LONG-TERM SURVIVAL IN IMMUNE CHECKPOINT INHIBITOR ASSOCIATED MYOCARDITIS

Nikhil Dubey*, Daniel Zlotoff, Leyre Zubiri, Kerry Reynolds. *Massachusetts General Hospital, Boston, MA, USA*

Background Immune checkpoint inhibitor (ICI) associated myocarditis carries a high rate of morbidity and mortality. Despite the clinical consequences, little is known about the relationship between initial troponin-T (TnT) levels at presentation and prognosis or concurrent immune related adverse events (irAEs).

Methods We conducted a retrospective analysis of 37 patients diagnosed with ICI-associated myocarditis at Massachusetts General Hospital in Boston, MA between March 1, 2016, and March 1, 2022. Clinical data including patient demographics, cancer type, ICI regimen, lab values, cardiac tests, immunosuppressive treatment, diagnostic procedures, and survival were obtained from the electronic medical record. Patients were categorized into three groups based on the first measured TnT during the admission for myocarditis: 1) mild elevation (<five-fold the institutional upper limit of normal [ULN]), 2) moderate elevation (five to 50-fold the ULN), and 3) high elevation (>50-fold the ULN). Statistical analyses were performed using the Fisher-Freeman-Halton exact test and Cochran-Armitage test for trend.

Results This cohort consisted of 29 men and 8 women with a median age of 74.5 years. Cancer types included non-small cell lung cancer (n=11), melanoma (n=9), RCC (n=9), SCC (n=3), and other types of cancer (n=5). The median time of myocarditis onset from the start of ICI was 49.5 days. ICI regimen primarily consisted of pembrolizumab (n=21) and nivolumab (n=12). Concurrent irAEs occurred in 17 patients during their index admission. Of the total cohort, 30% of patients had a mildly elevated TnT, 46% moderately elevated, and 24% highly elevated. 10 patients died within 30 days of myocarditis diagnosis, 8 patients died between 30 and 180 days, and 19 were alive past 180 days. Of those patients that died prior to 30 days from diagnosis, 60% had highly elevated TnT and 40% had moderately elevated TnT; however, of the patients alive past 180 days, 37% had mildly elevated TnT, 47% had moderately elevated TnT, and 16% had highly elevated TnT levels (figure 1; p=0.014 for the association of TnT elevation grade with survival category). Furthermore, while concurrent irAEs were diagnosed in 27% of patients with mildly elevated TnT, they were present in 47% of patients with moderately elevated TnT and 67% of patients with highly elevated TnT (figure 2; p=0.078 for test of trend).

Conclusions Initial TnT values at time of presentation with ICI-related myocarditis associate with patient survival to at least 180 days from time of diagnosis. Initial TnT values may be related to the presence of concurrent non-myocarditis irAEs.

Ethics Approval The study was approved by Mass General Brigham's Ethics Board, approval number 2017P000501.

1247 DISTRIBUTION OF IMMUNE-RELATED ADVERSE EVENTS (IRAES) IN SOLID MALIGNANCIES

Dalia Kaakour*, Matthew Slaught, Armon Azizi, Gianna Kroening, Jennifer Valerin, Nataliya Mar. *UCI, Orange, CA, USA*

Background Checkpoint inhibitors (CPIs) targeting PD-1/PD-L1 and CTLA-4 have dramatically improved outcomes for a range of solid malignancies. irAEs from CPIs affect a wide range of tissues, vary in severity, and are difficult to predict. Multiple studies have reported on incidence of irAEs by immunotherapy type, but few have examined the association of irAEs with tumor histology or with sites of metastasis. This study aims to investigate the association between type and incidence of irAEs with type of solid tumor histology, as well as with sites of cancer metastasis.

Methods We performed a retrospective analysis of all patients with genitourinary (GU), melanoma, gastrointestinal (GI), and lung malignancies treated with CPI monotherapy at the University of California, Irvine using an outpatient oncology pharmacy database. Data was collected from 1/1/2020 to 6/30/2021. Patients were aged 18 years and older. Patients must have received at least one dose of a CPI agent. Patients who received CPI-containing combination therapy with chemotherapy or targeted therapy were excluded.

Results Of 423 patients on unique treatment lines in our data set, 268 patients received CPI monotherapy. irAEs were documented in 133 patients (49.6%). 71 patients (62.8%) required treatment with oral or intravenous steroids, and 42 patients (37.2%) received treatment with other supportive therapy. The incidence of irAEs based on tumor type is listed in table 1. Most common irAEs per tumor type were rash in GU malignancies (26.0%), colitis in melanoma (25.4%), rash in GI malignancies (29.3%), and pneumonitis in lung malignancies (60.0%). In patients with irAEs, 102 (76.7%) had metastatic disease and of those, 18 (17.6%) had an irAE involving a metastatic site ($p<0.0001$). In patients with irAEs involving the primary site of malignancy, 2 patients (4.7%) with renal cell carcinoma had nephritis, 12 patients (37.5%) with melanoma had dermatitis, and 2 patients (50%) with a lung malignancy had pneumonitis.

Conclusions This study examines the differences in type and incidence of irAEs across GU, melanoma, GI, and lung cancers treated with CPI monotherapy. We found differences in the incidence of irAEs as relavant to tumor histology. Further, there was a statistically significant increased incidence of irAEs involving a metastatic site. Additional studies are needed, including those with a larger sample, combination immunotherapy and chemotherapy, as well as with additional tumor histologies.

Ethics Approval Application #16536 for HS #2021-6843 titled, "Primary Cancer Histology and Sites of Metastatic Disease Correlate with Tissues Affected by Immune-Related Adverse Events" obtained approval by the University of California, Irvine Institutional Review Board. A waiver of consent was obtained as this study involved no more than minimal risk as it was a retrospective chart review.

Abstract 1247 Table 1 Solid Tumor Category and irAE type

		Solid Tumor Category*

1248 RISK FACTORS AND A RISK-SCORING MODEL FOR SEVERE CHECKPOINT INHIBITOR-RELATED PNEUMONITIS IN LUNG CANCER PATIENTS

[1]Haiyi Deng, [2]Jiating Deng, [1]Xinqing Lin, [1]Chengzhi Zhou*, [2]Yanbin Zhou. *[1]Guangzhou Institute of Respiratory Health, Guangzhou, China; [2]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

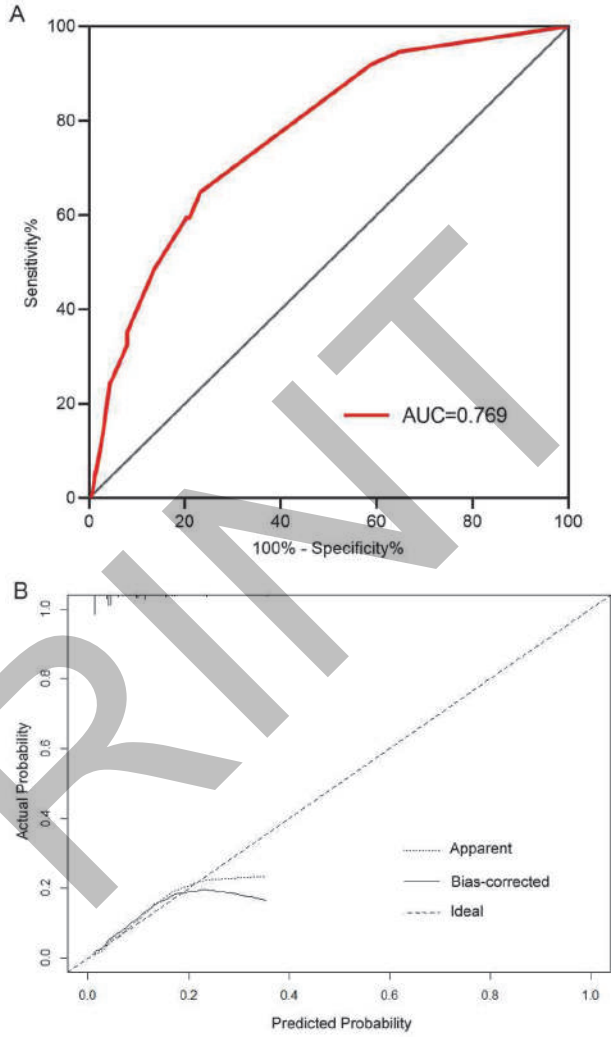
Background Immune checkpoint inhibitors (ICIs) provide enhanced survival benefits for lung cancer patients but can cause potentially fatal adverse events such as checkpoint inhibitor-related pneumonitis (CIP).

Methods This retrospective, case-control study enrolled 666 lung cancer patients receiving ICIs. Patients exhibiting The CIPs were divided into mild (grades 1–2) and severe (grades ≥3). Logistic regression identified risk factors for all grade and severe CIP, and a risk score for severe CIP was constructed. The model was validated in a separate patient cohort of 187 patients.

Results In the evaluation cohort, 95 patients developed CIP, of which 37 were severe cases Multivariate analysis revealed age ≥65 years (OR=1.95), current smoking (OR=3.00), chronic obstructive pulmonary disease (COPD, OR=2.49), squamous cell carcinoma (SCC, OR=1.67), prior thoracic radiotherapy (OR=3.12), and extrathoracic radiotherapy during ICI (OR=2.80) were independently associated with CIP events. Five factors, emphysema (OR=2.87), interstitial lung disease (ILD, OR=4.76), pleural effusion (OR=3.00), history of radiotherapy during ICI (OR=4.30), and single agent immunotherapy (OR=2.44) were independently associated with severe CIP and were incorporated into a risk-score model (score ranging 0–17). The area under the model receiver operating characteristic curve for the model was 0.769 in the evaluation cohort and 0.749 in the validation cohort (figure 1).

Conclusions Advanced age, current smoking, COPD, SCC, previous thoracic radiotherapy and extrathoracic radiotherapy during ICI treatment were independent risk factors for CIP incidence. The risk of severe CIP was observed to be independently associated with emphysema, ILD, pleural effusion, radiotherapy during ICI, and immunotherapy alone. The model has a promising predictive capacity for severe pneumonitis.

Ethics Approval This study was approved by the local Ethics Committee of the First Affiliated Hospital of Guangzhou Medical University (No.2021-38).



Abstract 1248 Figure 1 Internal validation of the the risk-scoring model(A) Receiver operating characteristic (ROC) curve analyses the model predicting the occurrence of severe checkpoint inhibitor-related pneumonitis (CIP); (B) Calibration curve of the model for prediction of severe CIP. A perfect model would fully match the 45 ° ideal line.

1249 TREATMENT INTERRUPTIONS FOR IMMUNE RELATED ADVERSE EVENTS AND OVERALL SURVIVAL IN PATIENTS WITH NON-SMALL CELL LUNG CANCER (NSCLC) TREATED WITH FIRST LINE IMMUNE CHECKPOINT INHIBITORS (ICI)

Evelyn Goodyear*, Songzhu Zhao, Mingjia Li, Yihzen Guo, Gabrielle Lopez, Austin Secor, Parthib Das, Nitya Surya, Marium Husain, Madison Grogan, Daniel Spakowicz, Lai Wei, Kai He, Erin Bertino, Asrar Alahmadi, Regan Memmott, Jacob Kaufman, Carolyn Presley, Peter Shields, David Carbone, Gregory Otterson, Dwight Owen. *The Ohio State University, Columbus, OH, USA*

Background Data from prospective phase 3 trials of anti-PD-1 and anti-CTLA-4 demonstrate durable clinical benefit even in patients who discontinue ICI due to treatment related adverse events. However, outcomes for patients treated with anti-PD-1 therapy alone or with chemotherapy who discontinue treatment due to immune toxicities is unknown.

Methods We retrospectively evaluated patients with stage IV NSCLC treated with first line ICI alone or with platinum-based chemotherapy at a tertiary cancer center between 2017 and 2021. Overall survival (OS) was calculated from the date of ICI treatment initiation to death from any cause or date of last follow-up. Patients still alive were censored at last follow-up. Overall survival was estimated using Kaplan-Meier method.

Results 225 patients were identified and included, mean age 63.5 years, 57% were male, 91% former/current smokers, 17% squamous histology. ICI type was anti-PD-1 alone in 43%, ICI+chemotherapy in 56%, and ICI+ICI in 1%. 42 out of 225 patients had treatment held either temporarily or permanently for irAE (42/225, 19%, table 1). Of these patients, 19 were permanently discontinued from irAE and 22 were resumed on ICI (1 missing due to lost follow up). There was no difference in patient age, race, sex, smoking status, histology, or ICI type among patients with irAE and permanent ICI discontinuation vs not (table 2), however permanent discontinuation was more common in treatment with ICI monotherapy (60% vs 37% in ICI+Chemo vs 0% in ICI+ICI), but not statistically significant (p=0.13). Among all patients with any irAE treatment interruption, the median overall survival (mOS) was 54.1 months (95% CI 26.9, NR). There was no significant difference in mOS among patients who permanently discontinued ICI: 26.9 months (95% CI 3.3, NR) vs 22.8 months (95% CI 16.3, 28.1) for all other patients, p=0.84 (figure 1). Among patients with treatment interruption for irAE, there was no significant difference in mOS among those who resumed treatment vs those who permanently discontinued, though this may have been limited by sample size: 54.1 months (95% CI 26.9, NR) vs 26.9 months (95% CI 3.3, NR) (p=0.07, figure 2).

Conclusions We observed no significant difference in mOS between patients with treatment interruption or discontinuation due to irAE. There appeared to be longer OS in patients who resumed treatment, though this was nonsignificant and likely limited by small sample size. These findings are consistent with continued clinical benefits despite treatment discontinuation in patients treated with first line ICI alone or with chemotherapy.

Ethics Approval The study was approved by the OSU Institutional Ethics Board

Abstract 1249 Table 1 Demographics of all patients and those with treatment held for irAE

1250 A NOVEL IN VIVO PBMC HUMANIZED MOUSE PLATFORM FOR LONG-TERM ANALYSIS OF EFFICACY AND TOXICITY OF T CELL-BASED IMMUNOTHERAPY DRUGS

Guoxiang Yang*, Hongyuan Yang, Li-Chin Yao, Leonard Shultz, Danying Cai, James Keck, Mingshan Cheng. *The Jackson Laboratory, Sacramento, CA, USA*

Background Immune cell-based therapies, such as bispecific T cell engagers (BiTE), have been developed for treatment of malignancies. However, the current overall success rate of anti-tumor drugs during clinical development remains low. One prominent reason is that the existing animal models in preclinical studies often do not accurately predict the clinical outcomes. The differences between human and mouse immune systems hamper the development of new cancer therapeutic approaches. Herein, we developed a novel humanized mouse model with solid tumor that can allow long-term evaluation of the effectiveness and risk of unwanted toxicity for bispecific immune drugs.

Methods We utilized two human cancer cell lines in this study: 1) Breast cancer cell MDA-MB-231 (MDA, expressed EGFR); 2) B cell lymphoma Raji (Raji, expressed CD19). To establish the breast tumor model, MDA cells were implanted in NSG-MHC class I/II double knock-out (DKO) mouse via mammary fat pad (MFP) 2 days before humanized mice with human peripheral blood mononuclear cells (PBMCs). The same MDA cells were then intravenously (IV) implanted 3 days before EGFRxCD3 BiTE administration. Similarly, subcutaneous (SC) solid lymphoma model was established and treated with CD19xCD3 BiTE. Following BiTE dosing tumor burden was quantified by a Xenogen imaging system. To evaluate the toxicity levels in response to BiTE therapy, serum inflammatory cytokine levels were analyzed. Clinical observation, mouse clinical score, and body weight change were also monitored for drug toxicity assessment.

Results PBMC-humanized model with solid tumors were successfully established. Either MFP MDA tumor or SC B cell lymphoma could keep growing for more than one month in the mice. Low dose BiTE treatment did suppress tumor cell growth in the mouse lungs but did not inhibited solid tumor growth. Increased dosage significantly inhibited MFP or SC solid tumor growth. The mice with BiTE treatment exhibited elevated serum levels of human inflammatory cytokines. This cytokine production was dose-dependent and was associated with an increase of toxicity.

Conclusions This model provides a growth environment like that of the patients with solid tumor and can be used for both short-term and long-term data analysis of efficacy, toxicity, and dosing requirements of immunotherapy drugs. We emphasize that the solid tumor model using both IV and SC/MFP co-engraftment is a promising preclinical platform for simultaneously evaluating long-term efficacy and predictive safety of any T cell-based immunotherapies to define optimal approaches for clinical treatment.

1251 IMMUNE CHECKPOINT INHIBITOR-INDUCED TYPE 1 DIABETES MELLITUS IS ASSOCIATED WITH LONG-TERM RESPONSE AND SURVIVAL IN PATIENTS WITH MELANOMA

[1]John Marsiglio*, [2]Magdalena Kovacsovics, [2]Xuechen Wang, [1]Sheetal Hardikar, [2]Arabella Young, [2]Jennifer Doherty, [2]John Hyngstrom, [2]Jordan McPherson, [2]Ben Haaland, [2]Siwen Hu-Lieskovan. *[1]University of Utah, Salt Lake City, UT, USA; [2]Huntsman Cancer Institute, Salt Lake City, UT, USA*

Background Type 1 diabetes mellitus (T1DM) is a rare but serious immune-related adverse event (irAE) of immune checkpoint inhibitors (ICIs).[1] Our goal was to characterize treatment outcomes with ICI-induced T1DM through analysis of clinical and immunological data.

Methods This was a single-center case series of patients with solid tumors at Huntsman Cancer Institute (HCI) who received ICIs and subsequently had a new diagnosis of T1DM. The enterprise data warehouse at the University of Utah used ICD codes (ICD-10-CM E10 and ICD9CM 250.01) to identify patients for chart review to confirm ICI-induced T1DM. Serial blood specimens were studied for proteomic and immunophenotypic changes.

Results Between April 14, 2011 and July 15, 2021, 37 of 2745 patients who received ICIs at HCI had a T1DM diagnosis after the first cycle. 8 were confirmed to have ICI-induced T1DM (0.3%), including 3 with melanoma. An additional 5 cases with melanoma were identified by chart review only (table 1). Average age at onset was 54.5 years. 10 of 13 patients received anti-PD1 monotherapy (6 pembrolizumab, 4 nivolumab), 2 received pembrolizumab plus chemotherapy or enzalutamide, and 1 received ipilimumab plus nivolumab. Only 1 received prior ICI (ipilimumab). Median time to onset was 6.4 months (range 0.7-13.7). 10 patients presented with diabetic ketoacidosis (77%) (table 2). Of 6 patients who had autoantibodies tested at onset, only one had elevated anti-glutamic acid decarboxylase. At median follow-up of 24.3 months (range 13.1-66.4), no melanoma patients had progressed nor died, including 6 who received adjuvant and 2 who received active treatments (1 complete response, 1 partial response). Median progression free survival and overall survival were not reached. The 5 patients with other cancers received active treatments (1 partial response, 2 stable disease and 2 disease progression), and 3 died. All patients became permanently insulin-dependent. Further analysis by Olink and CyTOF of serial blood (baseline, pre-irAE, peak-irAE) from 3 ICI-induced T1DM patients, and baseline blood from 6 patients who received anti-PD1 but did not develop irAE, is ongoing and will be presented. Preliminary data suggest lower IL6 and OSMR (in IL-6 signaling) in baseline samples from patients who developed T1DM, among other changes.

Conclusions Despite ICI-induced T1DM, patients with melanoma displayed excellent clinical response and survival. All cases were treated with anti-PD1 antibodies, highlighting the importance of PD-1 blockade in the pathogenesis of ICI-induced T1DM. Most of these patients had negative autoantibodies, suggesting a distinct mechanism of this irAE.[2]

1252 IMMUNE-CHECKPOINT INHIBITOR INDUCED AUTOIMMUNE DIABETES IS A HETEROGENEOUS DISEASE WITH DISTINCT CLINICAL AND IMMUNE PHENOTYPES

[1]Karina Ruiz-Esteves*, [2]Kaitlyn Shank*, [1]Caitlin Colling, [1]Tianqi Ouyang, [1]Leyre Zubiri, [1]Chloe Villani, [1]Kerry Reynolds, [1]Meghan Sise, [1]Michelle Rengarajan. *[1]Massachusetts General Hospital, Boston, MA, USA; [2]Brigham and Women's Hospital, Boston, MA, USA*

Background Immune checkpoint inhibitors (ICIs) can lead to immune-related adverse events (IrAEs). One such irAE, ICI-induced autoimmune diabetes (ICI-DM), affects approximately 1% of ICI recipients. Most reports suggest resemblance to fulminant type 1 diabetes, with low or absent endogenous insulin production at presentation.[1,2] However, more recent reports have revealed milder cases, suggesting a heterogeneous disease entity.[3] We identified distinct clinical phenotypes of ICI-DM that could allow for better optimization of insulin therapy.

Methods We performed a retrospective chart review of 16,582 patients treated with anti-PD1, anti-PDL1, anti-CTLA4, or combination between 2010 and 2022 at a multi-centered academic hospital system. Criteria for inclusion were new diagnosis of type 1 diabetes or drug-induced diabetes and new prescription for insulin following ICI therapy; cases were confirmed by two board-certified endocrinologists. To phenotype ICI-DM based on endogenous insulin production, we reviewed patients with ICI-DM and a C-peptide level, allowing us to classify 45 cases of ICI-DM based on endogenous insulin production and autoantibody status. We are characterizing ICI-DM in these patients at both initial presentation and up to 30 months of follow-up.

Results We identified three distinct clinical phenotypes of ICI-DM based on initial presentation: patients with preserved endogenous insulin production (insulin+) and patients with decreased or absent endogenous insulin production (insulin -), with the latter divided into autoantibody positive (Ab+) and negative (Ab-) patients. Insulin+ ICI-DM patients have high levels of pre-existing insulin resistance, longer time-to-diagnosis (median 175 days), higher A1c at presentation (median 9.8%) and lower likelihood of presenting in diabetic ketoacidosis (DKA). Insulin-Ab+ patients have lower levels of insulin resistance, the lowest time-to-diagnosis (median 65 days), intermediate A1c at presentation (median 8.2%), high rates of DKA and nearly universal hospitalization at presentation. Insulin-Ab- had no pre-existing insulin resistance, a longer time-to-diagnosis (median 154 days) with a relatively low A1c at presentation (media 7.6%) and moderate rates of DKA and hospitalization. As expected, insulin- patients had higher total daily insulin needs compared to insulin+ patients.

Conclusions Our study examined the largest data set to date of deep clinical phenotyping of patients with ICI-DM. We define at least two distinct subsets of ICI-DM, with antibody-positive, islet negative patients being most similar to cases of ICI-DM initially described. However, patients with a milder form of ICI-DM (islet positive patients) may require simpler insulin regimens that could profoundly improve their quality of life. Our findings may also suggest distinct underlying mechanisms for ICI-DM with implications for other IRAEs.

1253 RETROSPECTIVE ANALYSIS OF IMMUNOTHERAPY TOXICITIES REQUIRING HOSPITALIZATION IN LUNG CANCER PATIENTS

[1]Ayo Falade*, [2]Leyre Zubiri, [2]Kerry Reynolds, [2]Meghan Mooradian. [1]*MGB Salem Hospital, Salem, MA, USA*; [2]*Massachusetts General Hospital, Boston, MA, USA*

Background Immune checkpoint inhibitors (ICI) are associated with a distinct spectrum of toxicities. Data on irAE hospitalization rates and clinical course of patients with thoracic malignancies are lacking.

Methods Patients with advanced thoracic malignancy treated with ICI (2/2016 – 6/2021) were retrospectively identified. Demographic and clinical data of confirmed irAE hospitalizations were extracted from the medical record and a descriptive analysis was performed.

Results From February 2016 to June 2021, 1,312 patients with thoracic malignancy received ICI (monotherapy, combination with 2nd ICI or other agents) with 102 patients (7.7%) hospitalized for irAEs . Treatment intent was first-line therapy with ICI in most patients (N= 50, 49%) and adjuvant ICI in 9% (N =9). 59% (N =60) received ICI alone, 32% (N =33) chemo plus immunotherapy, and 7% (N =7) dual ICI. The average age on admission was 68 years in both genders. The median time between ICI initiation and admission was 64 days (1-935). The most common evidenced irAEs were pneumonitis (N = 38, 37%), hepatitis (N = 20, 20%), myocarditis (N = 14, 14%) and colitis (N = 13, 13%). Nearly half (N = 18, 47%) of patients with pneumonitis were treated with prior thoracic radiation and received first line (N = 22, 58%) ICI. Pneumonitis cases had the highest 60-day readmission rate (37%, N = 14) with a 60-day mortality rate of 53% (N = 20). 60-day re-admission and mortality rates were 19% (N = 17) and 29% (N = 26), respectively, among the rest of the cohort. Multi-organ toxicity occurred in 36% (N = 37) of patients. Myocarditis patients often had a concomitant irAE (79%; 11/14) with 36% (N = 5) presenting overlapping neuromuscular toxicity. Overall, 64% (N = 65) received IV corticosteroids for a median duration of 42.5 days (0-527) and 18% (N = 18) required second line immunosuppression. irAEs solved to grade 1 or less after immunosuppression in 63 patients. Seven patients (7%) experienced a grade 5 event while admitted. ICI rechallenge occurred in 14 patients. Median OS was 360 days; (16 – 2219, table 1).

Conclusions Severe irAE requiring inpatient admission, though infrequent, results in considerable morbidity, mortality, and healthcare utilization. Pneumonitis was the most common irAE requiring inpatient management in our lung cancer population with a significant risk of mortality despite the use of guideline-directed systemic immunosuppression. This study highlights the continued need for prospective research to optimally manage severe toxicities, particularly pneumonitis.

Ethics Approval The study obtained IRB approval.

1254 DISTINGUISHING T-CELL RESPONSES IN PAIRED HEART AND TUMOR SAMPLES FROM PATIENTS WITH IMMUNE CHECKPOINT-RELATED MYOCARDITIS

[1]Steven Blum*, [2]Neal Smith, [2]Daniel Zlotoff, [2]Jaimie Barth, [2]Swetha Ramesh, [2]Isabela Kernin, [2]Leyre Zubiri, [2]John McGuire, [2]Alice Tirard, [2]Dejan Juric, [2]Ryan Sullivan, [2]Genevieve Boland, [2]Mari Mino-Kenudson, [2]James Stone, [2]Molly Thomas, [2]Kerry Reynolds, [2]Thomas Neilan, [2]Chloe Villani. *[1]Massachusetts General Hospital/Dana-Farber Cancer Institute, Boston, MA, USA; [2]Massachusetts General Hospital, Boston, MA, USA*

Background The relationship between severe immune-related adverse events (irAE) and anti-tumor efficacy resulting from the use of immune checkpoint inhibitors (ICI) is poorly understood. ICI-related myocarditis (irMyocarditis) is among the most serious toxicities and is fatal in 25-50% of cases.[1] Reports of shared T-cell clones in irAE and tumor suggest that common antigens or epitopes may couple anti-tumor immunity and irAE biology.[2, 3] To test this hypothesis and account for potential nonspecific "bystander" T cells,[4] we examined the T-cell receptor (TCR) repertoire of matched human heart, tumor, and control tissues to identify T cells enriched in tumor or irMyocarditis.

Methods Five autopsy cases with matched irMyocarditis, tumor, and histologically normal tissue adjacent to tumor ("control") were identified. FFPE slides were stained for H&E, and marked regions of interest were macroscopically dissected in serial unstained slides to isolate gDNA. Bulk TCRβ chain sequencing of the CDR3 region was performed.[5] Expanded TCRs were defined as those comprising >0.5% of the TCRβ repertoire from a given tissue. For each expanded clone, a Fisher's exact test was used to determine if the TCRβ sequence was enriched in irMyocarditis tissue compared to control tissue and in tumor tissue compared to control tissue.

Results Four tumor histologies were captured: melanoma (n=2), renal cell carcinoma, cholangiocarcinoma, and prostate cancer. TCRβ sequencing recovered tumor-enriched clones in four of five samples (range: 0-18 clones) and irMyocarditis-enriched clones in all five samples (range: 2-8). Across all patients, 17% (11/63) of tumor-enriched clones and 29% (11/37) of the irMyocarditis-enriched clones were enriched in both tissues. In two patients, the most abundant TCRβ sequence in irMyocarditis was not enriched in tumor tissue.

Conclusions TCRs enriched in ICI-treated tumors and irMyocarditis heart tissue are often distinct, suggesting that T-cell responses causing severe irAEs and anti-tumor immunity may not be driven by common antigens or epitopes, as has been previously suggested in other settings.[2,3] We are currently analyzing these data together with our unpublished single-cell RNA sequencing and TCR data from peripheral blood and heart, which encompass 25 patients and ~300,000 cells.[6] This effort could identify pathologic T cells that are distinct from tumor-reactive clones or nominate biomarkers for patients with irMyocarditis. Differentiating the T-cells responses driving irMyocarditis and anti-tumor immunity may be the first step towards developing clinical strategies that can maximize ICI efficacy while mitigating irAEs.

1255 IMPACT OF IMMUNE CHECKPOINT INHIBITORS ON BONE TURNOVER IN CANCER PATIENTS: PROSPECTIVE CLINICAL STUDY AND PRECLINICAL CORRELATES

[1]Tamara Gassner*, [1]Sonia Vallet, [1]Christina Chittilappilly, [1]Theo Pirich, [1]Judith Lind, [1]Osman Aksoy, [1]Vincent Sunder-Plassmann, [1]Klaus Hackner, [1]Elisabeth Zwickl-Traxler, [1]Peter Errhalt, [2]Martin Pecherstorfer, [1]Klaus Podar. *[1]Karl Landsteiner University of Health Sciences, Ober-Grafendorf, Austria*; *[2]University Hospital Krems, Krems, Austria*

Background Treatment-induced bone loss is a risk factor for skeletal morbidity in cancer patients. Despite the widespread use of immune checkpoint inhibitors (ICIs) their impact on bone health is still poorly defined. Here, we prospectively analyzed bone turnover markers (BTM) in patients receiving single-agent PD1 or PD-L1 inhibitors and we evaluated direct effects of ICI on bone cell homeostasis in vitro.

Methods Patients with advanced cancer and no evidence of bone metastases assessed per bone scan or PET-CT were enrolled. Serum markers of bone resorption (C-terminal telopeptide (CTX)) and bone formation (osteocalcin (OCN) and procollagen type I N-propeptide (PINP)) were measured before each ICI application, as well as parameters of bone metabolism. Dose-dependent effects of PD1 and PD-L1 inhibitors on osteoclast and osteoblast differentiation in vitro were evaluated by morphological and functional assays.

Results A total of 53 samples were collected from 10 patients receiving PD1 (n=5) and PD-L1 (n=5) inhibitors for a median of 15 weeks (range 7 to 31). 80% of the patients were male, median age was 71 years (range 58-77). Three weeks after the first ICI application we observed a significant decrease in CTX levels (mean CTX 0,51 ng/ml ± 0,42 at baseline to 0,42 ± 0,37 at week 3; p = 0,017), which remained below baseline at 15 weeks (mean 0,36 ng/ml ± 0,25, p= NS). No significant changes in OCN, PINP and parameters of bone metabolism were detected. Interestingly, changes in CTX at 3 weeks correlated with treatment response and a decrease above 20% was associated with a longer progression-free survival (PFS) (median PFS 68,7 months vs 15,8 months, p < 0,003). In vitro studies confirmed inhibition of osteoclast differentiation (OC number decreased to 26% and 18% of control in the presence of 1000 ng/ml PD-L1 and PD1 inhibitors, respectively) as well as function (resorbed area 8% in the control vs < 0,2%) in the presence of ICI. In contrast, no direct effect of ICI was observed on osteoblasts.

Conclusions Despite the small number of patients included, our study demonstrates for the first time that ICIs inhibit bone resorption in cancer patients by directly impairing osteoclastogenesis. Further analyses are ongoing to elucidate the molecular mechanisms responsible for the anti-catabolic effects ICIs.

1256 RELATIONSHIPS BETWEEN IRAES AND CHECKPOINT INHIBITOR RESPONSE IN RADIOHEAD: A LARGE PROSPECTIVE PAN-TUMOR COHORT OF STANDARD-OF-CARE PATIENTS WITH CLINICAL ANNOTATION, MOLECULAR AND IMMUNE PROFILING

[1]Anastasia Lucas*, [1]Samantha Liang, [1]Diane Da Silva, [2]Arabella Young, [3]Zoe Quandt, [4]Silvia Boffo, [4]Lisa Salvador, [1]Lacey Padron, [3]Mark Anderson, [1]Christine Spencer, [1]Marshall Thompson. *[1]Parker Institute for Cancer Immunotherapy, San Francisco, CA, USA; [2]Huntsman Cancer Center at the University of Utah, University of Utah, Salt Lake City, UT, USA; [3]University of California, San Francisco, San Francisco, CA, USA; [4]Bristol Myers Squibb, Princeton, NJ, USA*

Background Checkpoint immunotherapies (CPI) have resulted in long lasting responses in subsets of cancer patients. Despite this, responses come with the risk of immune-related adverse events (irAEs) which can limit the overall benefit of CPI. Associations with response, such as the correlation between development of irAE and better overall survival (OS), are well characterized in clinical trials but less understood in standard of care settings with wide varieties of patient profiles. Thus, real-world evidence cohorts are integral to bridging the gap between clinical trials reports and clinical practice. The RADIOHEAD study is a pan-tumor, prospective cohort study of 1,200 individuals on standard of care first-line CPI treatment regimens aiming to identify drivers of irAEs and clinical response.

Methods To capture a comprehensive profile of each patient, we prospectively collected blood samples and clinical features at pretreatment, early on treatment, and 6 and 12 month timepoints via case report forms and electronic medical records from 52 community oncology clinics across the United States. Patients who experienced irAEs had additional samples and clinical data collected at analogous time intervals from the irAE onset. Clinical data were structured and harmonized and unbiased statistical analysis was performed to identify clinical predictors of OS.

Results A total of 3951 samples and associated clinical data points were collected over the course of participants' treatment. Patients with any irAE (25%) had significantly longer OS in the pan-tumor cohort (n=1061, HR=0.4, 95% CI= [0.3, 0.6]). The association between irAE and survival held in the largest tumor sub cohorts, non-small cell lung cancer (NSCLC) (N = 397) and melanoma (N = 128), when adjusting for age, and in multvariable analysis. Patients who reported already taking steroids at the time of their pretreatment blood draw had significantly shorter survival than those who did not (HR=1.5 [1.2, 2]); this association appeared more pronounced in patients taking systemic steroids. Comparing NSCLC and melanoma to all other tumor types in this standard of care dataset, patients with melanoma had significantly longer (HR=0.4 [0.3,0.6]) OS.

Conclusions Results from this cohort study of standard of care patients support previously identified variables associated with CPI response. In the future, the potential for molecular profiling of samples collected in the RADIOHEAD cohort provides an opportunity to elucidate the potential mechanistic link between irAE and clinical response to CPI, as well as identify clinically actionable mechanisms for immunotherapy resistance via integrated analyses of multi-omic datasets to be generated from longitudinal patient samples.

1257 SINGLE CELL IMMUNOLOGIC DISSECTION OF CHECKPOINT INHIBITOR HEPATITIS AND AUTOIMMUNE HEPATITIS REVEALS INSIGHTS INTO IMMUNE TOLERANCE IN THE HUMAN LIVER

[1]Molly Thomas*, [1]Tos Chan, [1]Neal Smith, [1]Marc Sherman, [1]Swetha Ramesh, [1]Alice Tirard, [1]John McGuire, [1]Mazen Nasrallah, [1]Kasidet Manakongtreecheep, [1]Jessica Tantivit, [1]Leyre Zubiri, [1]Dejan Juric, [1]Ryan Sullivan, [1]Genevieve Boland, [1]Georg Lauer, [2]Nir Hacohen, [1]Kerry Reynolds, [1]Chloe Villani. *[1]MGH, Boston, MA, USA; [2]Broad Institute, Cambridge, MA, USA*

Background The emergence of monoclonal antibodies targeting PD-1 and CTLA-4 to treat solid tumors has revolutionized the field of immuno-oncology. However, immune checkpoint blockade (ICB) is limited by frequent immune-related adverse events. ICB-induced hepatic toxicity (irHepatitis) occurs in approximately 1-17% of patients. While these adverse events are usually mild, they often delay cancer treatment and require initiation of immunosuppressive therapy, which may compromise anti-tumor immune responses. irHepatitis shares clinical and histologic features with autoimmune hepatitis (AIH). As such, the study of irHepatitis is important not only for the care of oncology patients but also for the understanding how immune tolerance is lost across a spectrum of inflammatory liver diseases.

Methods To characterize the cellular and molecular pathways underpinning hepatic injury in irHepatitis, we used single-cell and single-nuclei RNA sequencing (scRNAseq/snRNAseq) with paired T-cell receptor (TCR) and B-cell receptor (BCR) sequencing to characterize ~300,000 cells from the liver and blood of 23 patients – 9 patients with irHepatitis, 4 patients with AIH, 3 controls on ICB, and 7 controls not on ICB. irHepatitis was defined by a hepatocellular or cholestatic rise in LFTs often with centrilobular histiocytic liver injury requiring treatment with steroids. Control patients had drug-induced liver injury, hepatic steatosis, non-alcoholic steatohepatitis, primary biliary cirrhosis, or venous outflow obstruction that did not require immunosuppressive therapy.

Results In irHepatitis we detected liver T cells expressing *CXCL13* and expanded cycling and cytotoxic CD8 T cells spanning effector to exhausted phenotypes. TCR repertoire analysis demonstrated clonal expansion of CD8 T cell subsets specific to irHepatitis. Parallel analysis of tissue immune cells from patients with AIH and irHepatitis enabled the identification of cell types and states both common and unique to each type of immune-mediated liver injury. For all patients, matched blood samples were also analyzed by scRNAseq to determine how cellular and transcriptional signatures in the liver tissue microenvironment were mirrored in circulating immune cells. Lastly, analysis of hepatocytes, cholangiocytes, and mesenchymal cells revealed specific inflammatory signatures in irHepatitis and AIH that suggested significant liver parenchymal dysfunction.

Conclusions In defining the cellular and transcriptional programs that are altered in irHepatitis, we have identified novel pathways that could be therapeutically targeted to treat liver inflammation in this context and have determined how PD-1 and CTLA-4 signaling may contribute to immune tolerance in the liver.

1258 PBMC HUMANIZED MOUSE MODEL WITH CLINICAL RELEVANCE IN ASSESSING THE SAFETY PROFILE OF 4–1BB AGONISTS UTOMILUMAB AND URELUMAB

[1]Destanie Rose*, [2]Wenqian He, [2]Bernard Buetow, [2]Allison Vitsky, [2]Maggie Lui, [1]Jiwon Yang, [1]Guoxiang Yang, [1]James Keck, [2]Bart Jessen. *[1]The Jackson Laboratory, Sacramento, CA, USA; [2]Pfizer, San Diego, CA, USA*

Background Immunotherapy is an important tool that can be used to stimulate a patient's own immune system against cancer. 4-1BB agonists were designed to target costimulatory molecules on a patient's immune cells to activate anti-tumor activity. Two 4-1BB agonists were recently investigated in clinical trials. Urelumab demonstrated clinical efficacy but also induced severe liver toxicity while utomilumab was well tolerated. Preclinical toxicity evaluations were unable to predict the clinical safety profile of urelumab.

Methods We developed a PBMC humanized mouse model to better meet the needs of preclinical toxicity evaluations. This model can be used to test a variety of therapeutics that target human immune cells, including both monoclonal and bispecific antibodies, and induce acute or systemic cytokine release responses which can manifest within hours or days later resulting in tissue damage and lethality of the mice. For this study PBMC humanized mice were dosed with 10 or 1 mg/kg of urelumab or utomilumab. Mice were evaluated on a daily basis for bodyweight loss and clinical evaluation scores. Toxicity was also evaluated by liver histology and terminal serum clinical chemistry.

Results Mice dosed with 10 mg/kg of urelumab experienced body weight loss, met the clinical criteria for early euthanasia, and showed marked liver necrosis compared to utomilumab treated animals and PBS controls. Serum levels of AST, ALT and GLDH were also significantly higher in urelumab treated mice. Cytokine analysis of terminal serum revealed similarities with those found to be increased in urelumab clinical trials, including elevated IFNγ, IP-10, MIG, and MIP-1α and MIP-1β.[1] Toxicity of urleumab could be reduced by lowering the dose to 1 mg/kg, while utomilumab was safe at both 10 mg/kg and 1mg/kg doses.

Conclusions The data generated in PBMC humanized mice were similar to findings from the clinical trials of utomilumab and urelumab and suggest that our model could identify the clinically relevant toxicity profile induced by 4-1BB agonists. The use of PBMC humanized mouse models for preclinical safety assessments could become an important part of novel immunotherapeutic development for both patient safety and reducing drug development costs.

1259 REAL WORLD EXPERIENCE OF IMMUNOTHERAPY IN AN ELDERLY TRIAL-INELIGIBLE COHORT OF PATIENTS WITH ADVANCED CUTANEOUS SQUAMOUS CELL CARCINOMA

Luke Mclean, Annette Lim, Angela Pizzolla, Benjamin Solomon, Danny Rischin. *Peter MaCallum Cancer Centre, Parkville, Australia*

Background Elderly patients are often underrepresented in clinical trials owing to exclusionary comorbidities which are more common with age, frailty and a poorer overall performance status.[1, 2] Chemotherapy is poorly tolerated in elderly comorbid advanced cutaneous squamous-cell carcinoma (CSCC) patients however little is known on the efficacy and tolerability of immunotherapy in this population. To our knowledge this is the largest dedicated report on a cohort of elderly trial-ineligible patients with advanced CSCC treated with immunotherapy to date. The cemiplimab registrational study, which established immunotherapy as the standard of care for advanced CSCC, enrolled patients with a median age of 71 years (73% over 65 years, n=43).[3]

Methods This study was a single-centre retrospective review of elderly patients (aged 70 years or more) with locally advanced (not amenable to curative surgery or radiotherapy) or metastatic CSCC who were deemed ineligible for clinical trials and received immunotherapy via a compassionate access scheme between August 2017 and January 2022. Patient demographics, tumor characteristics, treatment history and toxicity data were collected. Disease control rates (DCR), overall response rates (ORR), median overall survival (OS), disease specific survival (DSS) and median progression-free survival (PFS) were assessed. Response assessments for patients with imaging available post commencement of immunotherapy were performed as per RECIST1.1 and/or PERCIST1.0 criteria as appropriate. Kaplan-Meier analysis was performed and descriptive statistics were used.

Results 53 patients $\geq$ 70 years old receiving immunotherapy were analyzed. Median age was 81 years (range 70-96); 81% were male; 34% immunocompromised; and 34% ECOG 2 or higher. 15% patients had distant metastatic disease (see table 1). All patients were treatment naïve. Average Charlson Comorbidity Index including and excluding solid organ cancer was 9 and 5 respectively. 33% developed an immune-related adverse event (IRAE) but only 2 patients experienced a grade 3 IRAE and 6 patients discontinued due to toxicity with no treatment related deaths. 34 patients were followed with FDG-PET with an ORR of 59% and DCR of 76%. Response assessments are summarised in table 2. With a median follow up of 7.9 months, median OS was 20.5 months (95%CI 11-NA) (Figure 1) and median DSS 25.6 months (95%CI 20.5-NA) (Figure 2).

Conclusions Immunotherapy is effective and well tolerated among elderly trial-ineligible patients with advanced CSCC with no increase in toxicity and a comparable efficacy to what has been demonstrated in current clinical trials.

1260 COMPARATIVE SAFETY AND EFFECTIVENESS OF IL6R INHIBITORS, TNF INHIBITORS AND METHOTREXATE FOR THE TREATMENT OF IMMUNE CHECKPOINT INHIBITOR-ASSOCIATED ARTHRITIS

[1]Anne Bass*, [3]Noha Abdel-Wahab, [4]Jeffrey Sparks, [5]Pankti Reid, [6]Cassandra Calabrese, [2]Deanna Jannat-Khah, [7]Divya Rajesh, [2]Nilasha Ghosh, [6]Komal Mushtak, [8]Farah Al Haj, [4]Lydia Gedmintas, [3]Adewunmi Falohun, [4]Lindsey Macfarlane, [9]Michael Postow, [3]Adi Diab, [10]Ami Shah, [10]Clifton Bingham, [2]Karmela Chan, [10]Laura Cappelli. *[1]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, USA; [2]Hospital for Special Surgery/Weill Corne, New York, NY, USA; [3]MD Anderson Cancer Center, Houston, TX, USA; [4]Brigham and Women's Hospital, Boston, MA, USA; [5]University of Chicago, Chicago, IL, USA; [6]Cleveland Clinic, Cleveland, OH, USA; [7]Hospital for Special Surgery, New York, NY, USA; [8]Detroit Medical Center, Detroit, MI, USA; [9]Memorial Sloan Kettering, New York, NY, USA; [10]Johns Hopkins, Baltimore, MD, USA*

Background Immune checkpoint inhibitor associated arthritis (ICI-A) affects 4% of ICI-treated cancer patients and often persists, even after ICI cessation. Given its long duration, it is important to identify effective treatments that do not interfere with cancer responses. No studies have compared the safety or effectiveness of disease-modifying antirheumatic drugs (DMARDs) for ICI-A.

Methods We performed a retrospective multicenter observational study. Inclusion criteria were 1) diagnosis of ICI-A and 2) treatment with a DMARD, specifically an interleukin 6 receptor inhibitor (IL6Ri), tumor necrosis factor inhibitor (TNFi), or methotrexate (MTX). Patients with preexisting autoimmune diseases, and patients who received an IL6Ri or TNFi in combination with MTX were excluded. The primary outcome was cancer progression. The secondary outcome was arthritis control, defined as grade 1 arthritis (mild pain, not interfering with function) and prednisone 10 mg daily, within the first 90 days of DMARD treatment. Demographic and clinical features were compared between DMARD groups with Fisher's exact test, Chi-square tests, T-Tests, Wilcoxon rank sum tests and ANOVA as appropriate. Cox proportional hazard models were performed to determine hazard ratios for cancer progression and arthritis control by DMARD treatment, adjusted for confounders (age, sex, cancer type and stage, ICI type, and steroid duration).

Results One hundred sixteen patients from 6 institutions were included, mean(SD) age 62(12) years, 63(54%) male. DMARD treatment was IL6Ri in 43(37%), TNFi in 25(22%), and MTX in 48(41%) (table 1). Kaplan-Meier curves showing time from ICI initiation to cancer progression by DMARD treatment and time to arthritis control are shown in figures 1&2. Compared to patients treated with MTX, patients treated with an IL6Ri had a shorter time to cancer progression (HR 3.67, 95%CI 1.13-11.9, p=0.03) but also a shorter time to arthritis control (HR 3.98, 95%CI 1.21-13.1, p=0.02) in adjusted Cox models. Patients treated with TNFi similarly had a shorter time to cancer progression and arthritis control compared to patients treated with MTX, but these differences were not statistically significant: cancer progression (HR 3.17, 95%CI 0.95-10.5, p=0.06); arthritis control (HR 3.33, 95% CI 0.99-11.1, p=0.051).

Conclusions In this retrospective cohort study, ICI-A treatment with an IL-6i was associated with a shorter time to cancer progression but more rapid arthritis control compared to MTX. Results for TNFi were similar to those for IL6Ri but were not statistically significant likely due to sample size. A prospective randomized controlled trial is needed to confirm these findings and to optimize management of patients with high-grade ICI-A.

Ethics Approval This study was approved by the Hospital for Special Surgery IRB # 2017-1898 as well as the IRBs of all participating sites.

1261 INCREASED CONCENTRATIONS OF S100B AND NEUROFILAMENT LIGHT CHAIN IN SERUM INDICATE CHECKPOINT INHIBITOR-INDUCED CNS INFLAMMATION

[1]Sara Bjursten*, [1]Ankur Pandita, [1]Zhiyuan Zhao, [2]Joel Simrén, [2]Henrik Zetterberg, [3]Anna Rudin, [1]Lars Ny, [1]Max Levin. [1]*Sahlgrenska University Hospital, Gothenburg, Sweden*; [2]*Institute of Neuroscience and Physiology, Gothenburg, Sweden*; [3]*Institute of Medicine, Sahlgrenska, Gothenburg, Sweden*

Background Checkpoint inhibitor (CPI)-induced CNS inflammation is a severe neurological adverse event.[1, 2] CPI-induced CNS inflammation can be difficult to diagnose because symptoms indicate more common conditions such as tumor progression or infection.[3-5] There is a clinical need for blood tests to facilitate diagnosis of CPI-induced CNS inflammation.

Our objective was to evaluate if increased concentrations of brain damage markers S-calcium-binding protein B (S100B) and neurofilament light chain (NfL) in serum indicate CPI-induced CNS inflammation.

Methods Medical records and laboratory data were examined in patients with metastatic melanoma or metastatic renal cell carcinoma. The patients were treated with double checkpoint inhibition (nivolumab and ipilimumab) between March 2018 and April 2022 (n=197) at Sahlgrenska University Hospital, Sweden. In patients with suspected CNS-inflammation, brain MRI and analysis of cerebrospinal fluid were performed and brain damage markers S100B and NfL in serum were analyzed repeatedly. S-100B has a dual function as it is secreted by some melanoma metastases as well as damaged astrocytes.[6, 7] S-100B concentrations in patients with melanoma metastases that do not secrete S-100B (n=29) and renal cell carcinoma patients (n=10) were used as double checkpoint inhibitor treated controls. As controls for NfL, we analyzed frozen plasma from melanoma patients treated with double checkpoint inhibition (ipilimumab + nivolumab) or monotherapy nivolumab (n=49).

Results Nine out of 197 patients had a verified CPI-induced CNS inflammation (4.6%) within 200 days from the first double checkpoint inhibitor treatment (table 1). S100B and NfL in serum increased during CNS inflammation (figure 1A-D and F) and normalized when patients were treated with immunosuppression (figure 1A-C, E and G). S100B concentration in serum increased early in patients with CPI-induced CNS inflammation (figure 1A-C), whereas NfL increased later (figure 1A-C). The sensitivity of an increased S100B and NfL to detect a CPI-induced CNS inflammation was 100% for S100B and 79% for NfL and the specificity was 89% for S100B and 74% for NfL (figure 2).

Conclusions The combined analysis of S100B and NfL in serum is a tool for early detection and monitoring of CPI-induced CNS inflammation. Early diagnosis of CPI-induced CNS inflammation may save lives, prevent long-term hospitalization, and reduce neurological complications.

1262 ELEVATED SERUM TNF-α IS A CANDIDATE PROGNOSTIC BIOMARKER FOR IMMUNE CHECKPOINT INHIBITOR MYOCARDITIS

[1]Rebecca Caldwell, [1]Gaspar Pina, [1]Praise Oderinde, [1]Abdelrahman Ali, [2]Jensen Garrett, [1]Bilal Siddiqui, [1]Sumit Subudhi, [1]Cezar Iliescu, [1]Syed Wamique Yusuf, [1]Efstratios Koutroumpakis, [1]Ihab Hamzeh, [1]Shaden Khalaf, [1]Anita Deswal, [1]Nicolas Palaskas*. *[1]UT MD Anderson Cancer Center, Houston, TX, USA; [2]Texas AandM College of Medicine, Houston, TX, USA*

Background Immune checkpoint inhibitors (ICI) can cause a myriad of immune related complications, including myocarditis which has a mortality of 25 to 50%.[1] The impact of peripheral cytokine levels on prognosis and treatment of ICI myocarditis has not been well described.

Methods This was a retrospective cohort of patients with ICI myocarditis treated at MD Anderson Cancer Center between January 2011 and May 2022. ICI myocarditis was defined by the adjudication criteria of myocarditis in the setting of cancer therapeutics.[2] Cytokine levels were obtained during the index hospitalization with ICI myocarditis and measured by two clinical laboratory improvement amendments (CLIA)-certified assays. If cytokine levels were measured more than once, the peak value was used. Major adverse cardiovascular events (MACE) were defined as a composite of heart failure with/without cardiogenic shock, arterial thrombosis (myocardial infarction, stroke, lower limb ischemia), life-threatening arrhythmias (asystole, pulseless electrical activity, third degree heart block, sustained ventricular tachycardia, ventricular fibrillation), pulmonary embolism, and sudden cardiac death. Kaplan Meier curves for MACE free and all-cause mortality with censoring at 90 days and log rank test for comparing survival were used.

Results Ninety-nine patients were identified with ICI myocarditis. The mean age was 67.8 ± 12.7 years and majority were male (70%) and Caucasian (83%). The most common cancer groups were genitourinary (32%), melanoma (22%), and lung (17%). MACE occurred in 13% of patients with the most common being heart failure (62%), life threatening arrhythmia (38%), and sudden cardiac death (31%). Tumor necrosis factor-α (TNF-α), Interferon γ (IFN-γ), and Interleukin (IL)-6 were checked in 65 of the 99 patients. TNF-α and IL-6 were elevated in 69% and 82% of patients, respectively. IFN-γ was elevated in 31% of patients. Other cytokine levels were elevated in less than 20% of patients, except for IL2 receptor at 62% (table 1). MACE and overall mortality of patients with TNF-α levels above the median level of 32.5 pg/mL was higher compared to those with TNF-α in the lower 50% percentile (p-value 0.031) (figure 1). The administration of infliximab showed similar MACE free and overall survival between all patients and those with elevated TNF-α (p-value 0.698 and 0.830 respectively).

Conclusions Elevated TNF-α may be a sign of worse prognosis in patients with ICI myocarditis. However, the selective use of infliximab in this patient group did not improve outcomes. Therefore, peripheral cytokine levels may aid in prognostication but their use to guide myocarditis therapy is limited.

1263 DERMATOLOGIC IMMUNE RELATED ADVERSE EVENT DISEASE DEFINITIONS: A MULTI-INSTITUTIONAL DELPHI CONSENSUS PROJECT PRESENTED ON BEHALF OF THE ONCODERMATOLOGY WORKING GROUP

[1]Steven Chen*, [2]Nicole LeBoeuf, [1]Kerry Reynolds, [1]Yevgeniy Semenov. *[1]MGH, Boston, MA, USA; [2]DFCI, Boston, MA, USA*

Background The accurate diagnosis and management of Dermatologic immune related adverse events (D-irAEs) from immune checkpoint inhibitors (ICI) are challenging because of the lack of specific, standardized disease definitions and severity grading criteria that capture the heterogeneity of possible manifestations of immune toxicity. However, determining the rash subtype is critical for effective treatment and future irAE risk and management.

Our group sought to develop D-irAE subtype definitions for diagnosis and severity grading developed through a modified Delphi consensus process.

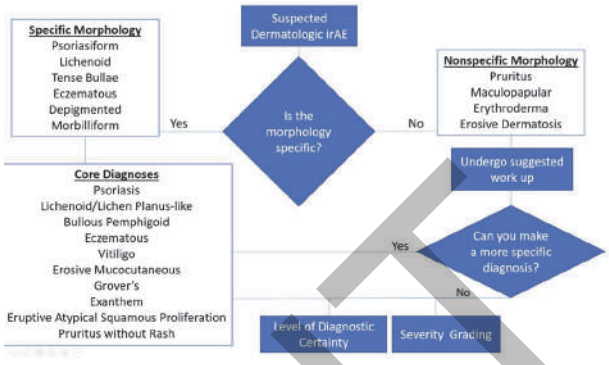
Methods A working group of oncodermatologists drafted a classification system with guidance statements and disease definitions to support the work-up, diagnosis and severity grading of D-irAEs. Core diagnoses for the draft were chosen based on available literature on the presentation and frequency of D-irAEs, choosing the ten most commonly reported D-irAEs. The proposed system of diagnosis and severity grading was then reviewed by a panel of dermatologists, oncologists, oncodermatologists and irAE subspecialists. A modified Delphi consensus process was used, with 2 rounds of anonymous ratings by panelists and 2 virtual meetings to discuss controversial areas. Consensus based on numeric ratings was determined using the RAND/UCLA Appropriateness Method. The Delphi process was exempted by the Massachusetts General Hospital IRB.

Results The panel consisted of 34 members (of 35 invited) who accepted invitations to participate in the modified Delphi consensus process. Participants represented 16 different centers including US medical centers in the northeast (5), mid-west (2), south/southeast (5), and west (3), as well as 1 international clinicians and subject matter experts.

Over two rounds of voting, the panel identified unmet needs for D-irAE disease definitions and reached consensus on a variety of statements related to D-irAE, including the proposed approach (figure 1), typical timing, and other important factors in the work up of these immune toxicities. A standard work up was also proposed and found to be in agreement for all potential D-irAEs (median 8, range 6-9) (figure 2). Finally, the disease definitions, work up considerations, and diagnostic criteria for 10 predeterminted D-irAE subtypes were developed and reached consensus.

Conclusions By properly identifying the patient's D-irAE, the clinician is able to tailor treatment and understand implications about the patient's cancer therapy and toxicities. The proposed system herein allows for a standard algorithm for work-up and investigation that may lead to a core D-irAE diagnosis. We are hopeful that the implementation of said system in clinical trials will allow for more granular adjudication of data.

Acknowledgements Thank you to Project DataSphere (Johnathan Rine, Jon McDunn, Bill Louv, Teillo Schaller) for their assistance and motivation. Thank you to Carina Storrs for her assistance with the drafting of the manuscript and abstract). Our gratitude as well for our colleagues who participated in the Delphi process. We are grateful for our patients and their families for their willingness to allow for our continued research in this field.



Abstract 1263 Figure 1 Proposed algorithm for D-irAE workup toward core diagnosis

Abstract 1263 Table 1 Standard work up proposedProposed standardized work up for all potential D-irAEs

STANDARD D-IRAE WORK UP
Common:
1. Full skin exam by an experienced clinician
2. Full skin exam by a board-certified dermatologist
3. Skin biopsy for H&E
4. Laboratory evaluation to assess of evidence of systemic hypersensitivity reaction (CBC with differential, CMP, UA).
Possible:
1. Skin biopsy for direct immuno-fluorescence
2. ELISAs for Bullous Pemphigoid antibody titers
3. ANA, ENA if photo-sensitivity component is noted
Uncommon/Usually Unnecessary:
For certain subtypes of D-irAE, there are other specific tests that may be considered. These include:
1. Joint exam
2. Indirect immunofluorescence with salt-split skin
3. Serum IL-6 levels

1264 A SET OF EASY AND STRINGENT CRITERIA TO IDENTIFY IMMUNE-RELATED ADVERSE EVENTS (IRAE SCORING SYSTEM, ISS) IMPROVES CORRELATION WITH OUTCOME IN A PHASE 1–2 TRIAL POPULATION

Luca Mazzarella*, Federica Giugliano, Eleonora Nicolo', Edoardo Crimini, Jacopo Uliano, Chiara Corti, Paolo d'Amico, Pamela Trillo Aliaga, Carmine Valenza, Matteo Repetto, Gabriele Antonarelli, Liliana Ascione, Grazia Vivanet, Pierpaolo Berton Giachetti, Ida Minchella, Carmen Belli, Angela Esposito, Marzia Locatelli, Carmen Criscitiello, Giuseppe Curigliano. *European Institute of Oncology, Milan, Italy*

Background The benefit from immune checkpoint inhibitors (IO) is tempered by immune-related adverse events (IrAEs), which involve diverse organs, have varying biology, onset time, and severity. Several reports have found correlation between IrAE and better outcome, suggesting they may even serve as a surrogate of response, but studies are conflicting on the magnitude and significance of this correlation. Estimating the true incidence of IrAEs is particularly important in the early phase 1/2 trial setting, in order to avoid the risk of both over- and under-estimation. A key issue is the lack of IrAE diagnostic criteria, necessary to discriminate pure IrAEs from other treatment-related adverse events not sustained by an autoimmune process.

Methods Of 421 patients enrolled in phase 1-2 trials, we identified patients treated with immune-oncology (IO) drugs and analysed clinical characteristics, temporal dynamics and correlation with survival of treatment-related events, identifying "High Confidence IrAEs" (HC IrAE) by careful reconsideration of available clinical parameters. We developed an IrAE Scoring System (ISS) based on 5 parameters, each ranging 0-2: available biopsy or specific test, response to immunosuppression, temporal correlation, evidence ruling out alternative cause, known IO relationship. Correlation with Overall Survival was explored by multivariate Cox proportional hazard analysis including multiple covariates (BMI, Age, tumor type, NLR, prior IO, prior Autoimmune disease, PS, baseline disease burden). To mitigate immortal time-bias, analyses were conducted i) at 2-month landmark and ii) modeling IrAEs as time-dependent covariate.

Results 204 patients were treated with IO agents (41 with anti-PD(L)1 alone, 33 with non-PD(L)1 agents, 130 with combinations). 53 (25.9%) patients developed $\geq$ 1 treatment-related adverse event (85 total events). ISS score ranged from 0 to 8; by ROC analysis, a cutoff $\geq$ 5 achieved 100% specificity and 90% sensitivity to identify bona fide IrAEs. Based on this, we identified 3 groups of patients: 151 never experiencing an IrAE ("no-IrAE"), 33 low-confidence IrAE with ISS score 0-4 ("LC-IrAE") and 20 high-confidence IrAE with ISS 5-8 ("HC-IrAE"). Compared to no-IrAE, patients experiencing HC-IrAEs had significantly lower Hazard ratio (HR) both in landmark analysis (HR=?0.242, 95% CI 0.117-0.500, p=0.0001) and IrAE as time-dependent covariate analysis ? (HR=0.244, 95% CI 0.116-0.511, p=0.0001); HR for patients experiencing LC IrAE, instead, was not statistically significant (figure 1).

Conclusions ISS criteria provide a simple system to identify high confidence IrAEs, leading to more reliable estimates of IrAE incidence with significant impact on survival.

Ethics Approval The study was approved by the local ethics committee with number UID 3560

1265 VEDOLIZUMAB PLUS ANTI-PD1 ANTIBODY IN ADVANCED MELANOMA PATIENTS WITH INFLAMMATORY ENTEROCOLITIS

Asad Javed, Michele Freesmeier, Yousef Zakharia, Mohammed Milhem. *University of Iowa, Iowa City, IA, USA*

Background Use of immune checkpoint inhibitors in advanced melanoma is challenging in patients with a history of immune therapy related colitis or pre-existing inflammatory bowel disease (Crohn's disease or ulcerative colitis).[1] Vedolizumab is a gut-selective, anti-integrin antibody that binds to the α4β7 integrin on circulating leukocytes and inhibits their trafficking into the intestinal epithelium (figure 1).[2] There is limited clinical experience of using Vedolizumab in combination with anti-PD1 antibody in melanoma patients with inflammatory enterocolitis.[3] We present outcomes of a cohort of advanced melanoma patients with inflammatory enterocolitis who concurrently received Vedolizumab and anti-PD1 antibody.

Methods In this retrospective single-institution study, records of advanced melanoma patients with a history of inflammatory enterocolitis were reviewed. Patients who received anti-PD1 antibody (Pembrolizumab, Nivolumab), concurrently with Vedolizumab were selected for analysis.

Results Nine patients with stage III/IV cutaneous melanoma and pre-existing enterocolitis received Vedolizumab plus anti-PD1 antibody (table 1). A total of 96 doses of anti-PD1 antibody were administered concurrently with Vedolizumab (56 doses), with each patient receiving at least 7 doses of anti-PD1 antibody. Vedolizumab was administered intravenously (300 mg at weeks 0, 2 and 6 weeks and then every 8 weeks) along with Pembrolizumab (200 mg every 3 weeks) or Nivolumab (240 mg every 2 weeks or 480 mg every 4 weeks). Patients had a history of grade 3-4 colitis from prior check-point inhibitor therapy (n=4), Crohn's disease (n= 4), and ulcerative colitis (n= 1). Seven patients were negative for BRAF V600 mutation. Six patients had no recurrence of colitis symptoms while on anti-PD1 antibody therapy. Three patients with recurrence of colitis had a prior history of Crohn's disease (n=2), and grade 3 check-point inhibitor related colitis (n=1). All patients with recurrence of colitis symptoms did not have melanoma progression while receiving Vedolizumab plus anti-PD1 antibody. Overall, seven patients did not experience melanoma progression on therapy. One patient had a complete response. Two patients were able to complete adjuvant treatment with anti-PD1 antibody, without melanoma recurrence on follow-up. Vedolizumab infusions were well tolerated, and no treatment related side effects were noted.

Conclusions Concurrent Vedolizumab appears to allow treatment with anti-PD1 antibody in advanced melanoma patients with pre-existing inflammatory enterocolitis. Prospective studies are needed to definitively determine the safety and anti-melanoma efficacy of this combination.

1266 TOXICITY PROFILES OF WEIGHT-BASED 2-WEEKLY AND FLAT-DOSE 4-WEEKLY NIVOLUMAB REGIMEN – A REAL-WORLD AUSTRALIAN CENTRE EXPERIENCE

Sang Yoon Kim*, Prajwol Shrestha, Andre van der Westhuizen. *Calvary Mater Newcastle, Macquarie University, Australia*

Background Anti-PD1 inhibitor nivolumab gained US FDA approval in 2014 using a weight-based, 2-weekly regimen (Q2W). In 2018, US FDA approved a flat-dose, 480mg 4-weekly regimen (Q4W) based on quantitative pharmacokinetic modelling.[1,2]Whilst the Q4W regimen has since been widely adopted, real-world data on safety across various tumour types remain lacking, with anecdotal reports of differing toxicity profiles due to increased drug exposure.

Methods We conducted a single-centre, retrospective analysis on adults receiving nivolumab for any tumour or treatment intent in Calvary Mater Newcastle between Jan 2015 and July 2020, collecting information on treatment and immune-related serious adverse events (SAEs). Those receiving concurrent systemic therapy other than nivolumab were excluded. Toxicity profiles, including incidence rate, types of events, and timing of onset, were compared, as were SAEs' impact on nivolumab treatment intention long term.

Results 137/43/35 patients received nivolumab on Q2W/Q4W/Q2W switch to Q4W (Q2-4W) regimen. Baseline characteristics were unequal, particularly the dominant tumour types (78% NSCLC in Q2W, 74% melanoma in Q4W) and treatment intention (palliative intent 96% in Q2W vs. 37% in Q4W). Q4W cohort received 29% higher nivolumab dose per week of treatment than Q2W. 23 (17%) and 7 (16%) patients experienced 24 and 9 SAEs on Q2W/Q4W, respectively. SAE per 100 person-weeks on nivolumab was higher in Q4W than in Q2W (0.99 vs. 0.64, OR 1.55), but the difference was statistically insignificant (95% CI 0.63-3.44, p=0.26, table 1). Q4W was associated with significantly earlier SAE onset than Q2W (4.1 vs. 17.7 weeks, OR 4.32, p=0.012, figure 1). Q4W was associated with more colitis (44 vs. 21%) with earlier onset (4.1 vs. 11 weeks). SAEs caused more nivolumab discontinuation in the Q2W cohort, but the difference was statistically insignificant (83% vs. 43%, OR 1.93, p=0.29). Choice of nivolumab regimen did not influence the rate of SAEs in those receiving radiotherapy. Most SAEs required systemic corticosteroid therapy (20/23 vs. 6/7) and hospitalisation (18/23 vs. 7/7), but the majority resolved within six months at a similar rate (71% vs. 75%). The SAE rate was low in the Q2-4W (6%), with no treatment discontinuation.

Conclusions Q4W nivolumab regimen was not associated with an increased incidence of SAE compared to Q2W but was associated with earlier onset with a penchant for colitis. Further research may identify unique toxicity signatures associated with different scheduling and help individualise patient treatment.

1267 THE EFFECT OF IMMUNOSUPPRESSION DURING ANTI-PD-1 TREATMENT FOR STAGE III MELANOMA

Andrew Knight*, John Kirkwood, Lilit Karapetyan, Xi Yang, Sneha Rajendran, Na Bo, Hong Wang, Cindy Sander. *University of PIttsburgh, Pittsburgh, PA, USA*

Background Anti-PD-1 therapy improves recurrence-free survival in patients with resectable Stage III/IV melanoma. Immune-related adverse events (irAEs) represent a challenge for patient care especially in the setting of adjuvant management and may serve as a predictor for therapeutic benefit. We sought to evaluate the incidence of immune related adverse events (irAEs) in melanoma patients receiving adjuvant anti-PD-1 therapy and assess the impact of corticosteroid and non-corticosteroid-based therapy on recurrence-free and overall survival at the University of Pittsburgh Medical Center (UPMC) cohort.

Methods This retrospective, single-center study reviewed adult patients undergoing treatment for Stage III melanoma between 1996 and 2021 who received either pembrolizumab or nivolumab. Patients were further excluded if they did not receive adjuvant treatment with anti-PD-1 therapy, had prior exposure to immunotherapy or BRAF inhibitors, or did not have sufficient follow-up to allow necessary data collection. The resulting 231 patients were stratified into two cohorts – those treated with >10mg prednisone equivalent for longer than two weeks during anti-PD-1 therapy, and those who were not.

Results Of 231 patients reviewed, 123 (53%) developed an irAE of any grade; 57 patients required systemic steroids during adjuvant therapy, with 11 (5%) patients that received steroids and another immunosuppressing agent. Use of steroids did not reduce OS (HR = 1.037, 95% CI 0.4517, 2.381; p=0.93) or RFS (HR = 1.026, 95% CI 0.6198, 1.699; p=0.92). Development of irAEs was associated with improved OS (HR = 0.3698, 95% CI 0.1682, 0.8127; p=0.010), and melanoma specific survival (HR 0.3608, 95% CI: 0.145, 0.8974; p=0.022), but not RFS (HR = 0.8908, 95% CI 0.5659, 1.402; p=0.62). In a multivariable analysis adjusting for age, sex, and stage development of irAEs remained significantly associated with increased overall survival (HR = 0.4079, 95% CT 0.1826, 0.9112; p=0.0288).

Conclusions IrAEs are common in patients treated with adjuvant anti-PD-1 and frequently require treatment with systemic corticosteroids. The development of irAEs during adjuvant therapy is associated with improved OS, but not RFS. Exposure to systemic steroids during adjuvant therapy did not have an impact on OS or RFS. These results provide reassurance that the use of systemic steroids during adjuvant treatment of fully-resected stage III melanoma does not have a negative impact on disease recurrence or survival.

INCREASED RISK OF CUTANEOUS IMMUNE-RELATED ADVERSE EVENTS IN PATIENTS TREATED WITH TALIMOGENE LAHERPAREPVEC AND IMMUNE CHECKPOINT INHIBITORS: A MULTI-INSTITUTIONAL COHORT STUDY

[1]Bonnie Leung*, [1]Guihong Wan, [1]Nga Nguyen, [1]Shijia Zhang, [1]Wenxin Chen, [1]Sonia Cohen, [1]Genevieve Boland, [1]Ryan Sullivan, [1]Riley Fadden, [1]Howard Kaufman, [1]Shawn Kwatra, [2]Nicole LeBoeuf, [1]Yevgeniy Semenov. *[1]Massachusetts General Hospital, Boston, MA, USA; [2]Dana-Farber Cancer Institute, Boston, MA, USA*

Background Previous studies have shown that combining immune checkpoint inhibitors (ICIs) with Talimogene Laherparepvec (TVEC) may improve antitumor responses for metastatic melanoma.[1] However, the risk of developing cutaneous immune-related adverse events (cirAEs) in patients treated with ICI and TVEC has not been studied. We aim to evaluate the differences in cirAE development between patients treated with ICI with or without TVEC.

Methods In this multi-institutional retrospective cohort study, patients with cutaneous malignancy receiving ICI with or without TVEC therapy at the Massachusetts General Brigham healthcare system between September 12, 2014, and May 31, 2022 were included. CirAE development, time from ICI initiation to cirAE, cirAE grade, cirAE morphology, and survival were analyzed. Manual chart review was conducted by two independent trained research analysts to determine cirAE development based on timing, morphology, competing risk factors, and histologic confirmation. To compare the cohorts, Pearson's chi-squared test or Fisher's exact test for categorical variables and t-test or Kruskal-Wallis test for continuous variables were used. To account for immortal time bias, we performed time-varying Cox proportional hazards models, adjusting for sex, race/ethnicity, age at ICI initiation, ICI type, Charlson Comorbidity Index, and cancer type. Hazard ratios (HRs) and 95% confidence intervals were calculated for all variables.

Results A total of 892 cutaneous malignancy patients treated with ICI and/or TVEC therapy were included in this study, among which 93 patients were treated with both ICI and TVEC (ICI+TVEC). While 799 patients were treated with ICI alone. The rate of cirAE development was 33.2% and 38.7% for ICI only and ICI+TVEC, respectively (table 1). After adjusting for covariates, ICI+TVEC was associated with a 2-fold increased risk of cirAE development (HR: 1.96, p=0.009), when compared to patients receiving ICI therapy alone (table 2).

Conclusions These findings underscore the elevated risk of cirAE in those receiving ICI+TVEC and highlight potential opportunities for dermatologists and oncologists in counseling and monitoring patients who are considering or receiving ICI and TVEC. More individualized education and management can improve decision-making and quality of life for patients and caregivers. Limitations of this study include its retrospective nature and limited sample size from a tertiary-level academic healthcare system.

Machine Learning, Artificial Intelligence and Computational Modeling

1269 PRETREATMENT PREDICTION OF ANTI-PD-1 IMMUNOTHERAPY RESPONSE USING MACHINE LEARNING IN PATIENTS WITH METASTATIC MELANOMAS USING TARGETED TRANSCRIPTOMICS IN CIRCULATING CD8 CELLS

Fahad Ahmed*. *ALGHORISMUS, LLC, Detroit, MI, USA*

Background The aim of this study is to access the role of machine learning in identifying patients that will respond to anti-PD1 from expression data from circulating CD8 T-cells in patients with metastatic melanoma.

Methods Normalized RNA expression data was obtained from gene expression omnibus (GEO) a public functional genomics data repository.[1] All project files for GSE166181 were downloaded in clinical, RNA sequencing data, and metadata for each of these patients. Pretreatment data were extracted for each patient labeled "T0" which was used in the prediction. All normalized expression data that had no values were deleted and a final profile of the expression profiles was obtained. The expression of these genes was assigned as high or low. The patients were divided into 70/30 for training and test set. The overall accuracy of each cell and total accuracy for individual patients.

Results A total of 20 patients with 11 responders and 9 non-responders a total of 18250 cells were identified at the pre-treatment stage. A training set of 9 responders and 6 non-responders was used to train the deep learning algorithm for the test set 3 responders and non-responders each were kept out. A 5-layer deep learning algorithm was trained. In the test set, a total of 2237 cells were classified with a total of 1085 cells (48.5%) correctly identified among all test-set patients. In total 3 out of 6 patients (50%) were correctly identified with a threshold of 50% cells were correctly identified see table 1. Two patients were non-responders and 1 was a responder. While the one non-responder and two responders were.

Conclusions The algorithm was partially successful in identifying non-responders in the pretreatment group in this small cohort of patients. However, a larger dataset is required to train and test to develop a more accurate algorithm for patients that will or will not respond to anti-PD-1 treatment prior to treatment.

1270 PRETREATMENT PREDICTION OF NON-RESPONDERS TO PD-1 AXIS INHIBITORS IN ADVANCED UROTHELIAL CARCINOMAS USING A HYBRID MULTIMODAL DEEP LEARNING ALGORITHM

Fahad Ahmed*. *ALGHORISMUS, LLC, Detroit, MI, USA*

Background Post-FDA approval immune therapy for cancer becomes widely used for locally advanced or metastatic urothelial carcinomas. There are patients that may suffer severe side effects from these immune checkpoint blockades (ICBs). The aim of this study was to identify patients that will achieve response or those who do not achieve response to these ICBs.

Methods Pretreatment normalized ribonucleic acid (RNA) Sequencing (Seq), clinical and other data for patients with advanced UC receiving PD-1 axis inhibitors were downloaded from gene expression omnibus (GEO) datasets project PRJNA735749.[1] This data also included responses to treatment data. Responders were categorized as patients with either complete response (CR), partial response (PR), or stable disease (SD) while non-responders comprised patients with progressive disease (PD). The data set was split 70/30 for training and test sets for the deep-learning algorithm. Four distinct algorithms were developed using a complete gene expression profile, targeted normalized RNA or high vs low RNA expression (upper or lower than the 75 percentile) with non-RNA Seq data; total mutational burden (TMB), clinical characteristics of the patient (including age, TNM staging, etc.) and FGFR mutational status. The performance of each of the algorithms was assessed by comparing a matric of test set accuracy, sensitivity, specificity, positive predictive values (PPV), negative predictive values (NPV), and area under the receiver-operating curves.

Results A total of 89 patients of were selected from a total of 103 that had complete RNASeq, DNA and clinical data. The complete RNASeq + non-RNASeq data showed test set; accuracy (18.5%), sensitivity (100%), specificity (0.0%), PPV (25%), NPV (undefined*). The targeted RNASeq + non-RNA Seq data showed test set; accuracy (70.4%), sensitivity (0.0%), specificity (100%), PPV (undefined), NPV (70.4%). The targeted RNASeq (Hi/Low cutoff) + non- RNASeq data using a Multilayer Perceptron (MLP) classifier showed test set; accuracy (81.5%), sensitivity (20.0%), specificity (95.5%), PPV (50.0%), NPV (84.0%). The targeted RNASeq (Hi/Low cutoff) + non-RNASeq data using a TensorFlow (TF) classifier showed test set; accuracy (77.8%), sensitivity (20.0%), specificity (90.9%), PPV (33.3%), NPV (83.3%) see table 1.

Conclusions The MLP/deep-learning classifier for targeted normalized high vs low RNA expression with TMB, clinical characteristics, and FGFR mutational status shows better overall results compared to other algorithms. However, we can these results need external validation and with a larger dataset, we may also be able to predict responders.

Abstract 1270 Table 1 Experiment details

Study	Experiment Type	Split	Total patient characteristics	Training set accuracy (%)	Test set

1272 PROBABILISTIC MIXTURE MODELS IMPROVE CALIBRATION OF PANEL-DERIVED TUMOR MUTATIONAL BURDEN IN THE CONTEXT OF BOTH TUMOR-NORMAL AND TUMOR-ONLY SEQUENCING

[1]Jordan Anaya, [2]John-William Sidhom, [1]Alexander Baras*. [1]*Johns Hopkins, Baltimore, MD, USA*; [2]*Mount Sinai, Baltimore, MD, USA*

Background Tumor mutational burden (TMB) has been investigated as a biomarker for immune checkpoint blockade (ICB) therapy. Increasingly, TMB is being estimated with gene panel-based assays (as opposed to full exome sequencing) and different gene panels cover overlapping but distinct genomic coordinates, making comparisons across panels difficult. Previous studies have suggested that standardization and calibration to exome-derived TMB be done for each panel to ensure comparability. However, these studies often propose to use The Cancer Genome Atlas (TCGA) for calibration despite this data having a matched normal to remove germline variants while many labs perform tumor-only sequencing. We suggest this approach has the potential to bias TMB estimates and we propose the use of an alternative dataset for calibration of tumor-only sequencing. Current approaches also propose linear models for TMB calibration. We demonstrate why linear approaches are inappropriate for this data and provide an alternative model.

Methods Our approach to calibration of panel-derived TMB to exomic TMB proposes the use of deep learning to model the probability distribution of the label. We found that a mixture of lognormal distributions can model the nonlinear relationship between panel inputs and TMB as well as the complex error distributions. Using our model we examined the effect of different panel inputs, including nonsynonymous, synonymous, and hotspot counts along with genetic ancestry. To generate a tumor-only version of the TCGA data we reintroduced the germline variants from the matched-normal samples and filtered the data using gnomAD.

Results We were able to model accurately the distribution of both tumor-normal and tumor-only data with our mixture model while a linear model could not (figure 1). Applying a model trained on tumor-normal data to tumor-only input produced biased TMB predictions (figure 2). Including synonymous mutations resulted in better regression metrics across both data types, but ultimately a model able to dynamically weight the various input mutation types exhibited optimal performance. Including genetic ancestry improved model performance only in the context of tumor-only data. Using the probability distribution can help achieve a given positive predictive or negative predictive value.

Conclusions A probabilistic mixture model approach capable of accurately characterizing the distribution of expected exomic TMB from panel inputs better models the nonlinearity and heteroscedasticity of the data. Synthetic tumor-only panel data can allow for the calibration of tumor-only panels to exomic TMB. Leveraging the confidence of the point estimates better informs cohort stratification in terms of TMB.

Acknowledgements The results here are in whole or part based upon data generated by the TCGA Research Network. NGS gene panel assay coordinates were used from the AACR GENIE consortium. This research was supported by the Mark Foundation for Cancer Research (19-035-ASP), and the philanthropy of Susan Wojcicki and Dennis Troper in support of Computational Pathology at Johns Hopkins.

1273 COMBINING MULTIPLE IMMUNOTHERAPY STUDIES AND REAL-WORLD DATA IMPROVES PREDICTION OF IO TREATMENT EFFICACY AND HIGHLIGHTS KEY DRIVING FEATURES

Gustavo Arango*, Etai Jacob, Elly Kipkogei. *AstrZeneca, Arlington, MA, USA*

Background Despite the clinical success of immune checkpoint blockade therapies, many patients do not respond to treatments or become resistant. Previous attempts to predict treatment efficacy suffered from limited accuracy and deficiency to uncover determinants of response. Here, we introduce an AI framework which addresses these issues.

Methods We present a new explainable deep learning framework based on transformer architecture[1, 2] which combines data with different feature sets (including sparse date) and clinical endpoints for survival prediction or classification. This framework includes: (1) A new loss function based on a sigmoid approximation of Harrell's concordance-index.[3] (2) Explainability module providing feature importance and similarity score between features based on mutual contribution to predictions. (3) Transfer learning strategy to enable leveraging diverse clinical datasets in the public or private domain.

Results We utilized seven data sets comprising of more than 140,000 patients from IO, targeted and Chemotherapy treatments to benchmark our prediction models (table 1) in addition to 10 train/test splits performance evaluations.

Consistently, our framework outperformed other methods previously described in the literature, including CoxPH [4] and random survival forest.[5, 6] For example, using the concordance index, our framework achieved 0.66 (0.04) vs. 0.60 (0.04) of the second-best method (Random survival forest in all cases) on MYSTIC IO arms clinical data. This improvement was a result of including transfer learning in the training process (table 2) which also achieved better performance in less training steps (figure 1).

Utilizing our Explainability module, we identified key features driving response prediction consistent with previous publications. For example, in *Chowell et al.* dataset, we identified Albumin, NLR, Chemo-before-IO-treatment and TMB as the most important features (figure 2). We also identified in sparse mutation calls of 469 genes from *Samstein et al*. dataset, functional modules of several genes only, each with a strong predictive power. For example, the functional module comprising of the genes: AKT2, BTK, CDC73, HLA-B, IKBKE, INPPL1, RFWD2, TRAF2 and WHSC1, related to adaptive immunity, stratified patients to two groups with a Hazard Ratio of 0.58 for the *Samstein* dataset and 0.42 for the validation dataset (figure 3).

Conclusions We propose a new framework with state-of-the-art performance in survival prediction and potential to uncover biological and clinical insights related to patient response and resistance. Importantly, our framework simplifies the process of translating complex AI models to clinical practice and may accelerate the benefit immunotherapy can bring to patients.

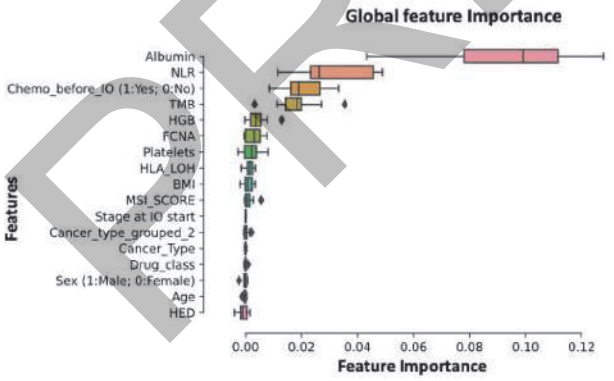
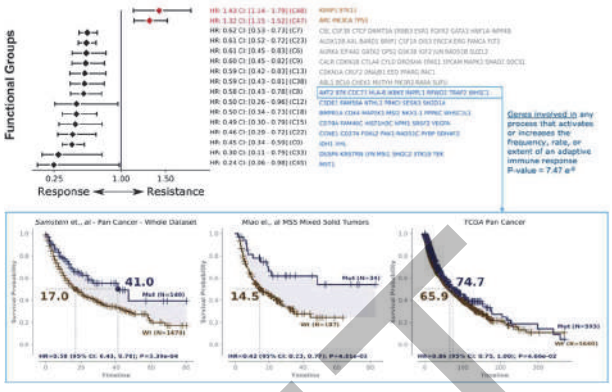
Abstract 1273 Figure 1 Transfer learning positively impact patient response to IO in a pan-cancer and cancer specific settings. A) Prediction of patient response to immunotherapy in a pan-cancer dataset (TMB and Immunotherapy Samstein et., al). Pre-training modeling is performed using self-supervision over the GENIE dataset. Then, to predict patient response to immunotherapy, weights from GENIE pretrained model are transferred to a survival prediction model. Each learning curve describes how the model learnt across different epochs and each line indicates the baseline and transfer learned model. B) Transfer learning impact for predicting response to Immunotherapy in Non-Small Cell Lung Cancer (NSCLC). Learning curves describe the impact of different pre-training iterations over the survival outcome prediction.



Abstract 1273 Figure 2 Model feature importance across 10 random training/testing splits shows consistency on relevant features associated to response to IO. Feature importance is computed by perturbing each feature and computing its effect on the model performance across 10 training/testing splits.



Abstract 1273 Figure 3 Top 16 functional groups associated with response/resistance to treatment discovered using the Samstein et al., dataset with 10 training/testing splits. The forest plot shows the effect on patient survival of mutated/non-mutated functional groups. Pathway analysis indicates that the C8 functional group is associated with adaptive immune response (p-value=7.47e-9) and it has a positive effect on the prediction of response to IO in the training/testing dataset (Left Kaplan Meier plot) and in an independent validation dataset (Miao et., al, Middle Kaplan Meier plot). Interestingly, this pattern is not observed in TCGA pan cancer dataset using the same cancer types (Right Kaplan Meier Plot).

1274 IDENTIFICATION AND CHARACTERIZATION OF IMMUNE CHECKPOINT INHIBITOR INDUCED IMMUNE-RELATED ADVERSE EVENTS FROM ELECTRONIC HEALTH RECORDS USING NATURAL LANGUAGE PROCESSING TECHNIQUES

[1]Hannah Barman, [2]Sriram Venkateswaran, [2]Antonio Del Santo, [1]Krishna Rao, [1]Bharathwaj Raghunatha, [1]Unice Yoo, [3]Lisa Kottschade, [3]Matthew Block, [2]G Scott Chandler, [1]Tyler Wagner, [2]Rajat Mohindra*. *[1]nference, Cambridge, MA, USA; [2]F. Hoffmann-La Roche, Basel, Switzerland; [3]Mayo Clinic, Rochester, MN, USA*

Background Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, yet their use is associated with immune-related Adverse Events (irAEs). Estimating prevalence and patient impact of these irAEs in the Real-World Data (RWD) setting is critical for further characterizing the benefit/risk profile of ICI therapies beyond the clinical trial population. Studies using International Classification of Diseases (ICD) codes have aimed to understand the safety and effectiveness of drugs. However, this approach does not comprehensively illustrate a patient's care journey, sub-optimally captures patients' concurrent medical conditions, and offers no insight into drug-AE causality. The present study aims to more accurately capture the relationship between ICIs and irAEs by using Augmented Curation (AC), a natural language processing (NLP) based innovation, on unstructured data in Electronic Health Records (EHRs).[1-4]

Methods In a cohort of approximately 6,000 patients treated with ICIs at Mayo Clinic, we compared the prevalence of irAEs using ICD codes and AC which leverages SciBERT to perform downstream tasks including entity extraction, classification, and relationship extraction. Each task was performed by a bespoke AC model that was trained using clinical scientist annotated datasets from Mayo's EHRs.[1-4] These models were orchestrated together to create an ensemble workflow that detected mentions of drug-AE pairs in clinical notes with implied textual causality. Finally, select irAEs with high patient impact- myocarditis, encephalitis, pneumonitis and SCAR (MEPS) were analyzed further. AC-extracted corticosteroid/immunosuppressive administration and therapy discontinuations were used as proxies of severity.

Results For all irAEs, only 28.5% of the patients found by AC were also identified with structured codes. For MEPs, only 30.5% of patients found by AC were also identified by ICD codes. Using pneumonitis as an example, AC achieved a sensitivity of 0.94, while ICD codes achieved only 0.26. MEPS patients were found to receive corticosteroids for their respective irAE 69% of the time and subsequently discontinued the ICI due to the irAE 48% of the time.

Conclusions Overall, the AC model identified additional irAEs not detected by ICD codes, and the positive sentiment-based approach helped assess the drug-irAE relationships in unstructured clinical notes thus supporting assessment of causal association with use of ICI therapies. The use of AC to accurately detect key irAEs allows physicians to leverage EHRs to discover risk factors for specific irAEs in RWD settings, as well as to review clinical outcomes to identify best practices in treating irAEs.

1275 MAPPING THE HETEROGENEOUS COLORECTAL TUMOR MICROENVIRONMENT WITH MULTIPLEXED IMAGING AND MACHINE LEARNING

[1]Blanca Cabrera Gil, [2]Laura Gui Levy, [2]Mario Kreutzfeldt, [3]Joanna Kowal*, [3]Giusy Procopio, [3]Deniz Eroglu, [2]Doron Merkler, [1]Andrew Janowczyk, [3]Diego Dupouy, [1]Aitana Neves, [2]Thomas McKee. [1]*Swiss Institute of Bioinformatics, Geneva, Switzerland*; [2]*Hôpitaux universitaires de Genève, Geneva, Switzerland*; [3]*Lunaphore Technologies SA, Tolochenaz, Switzerland*

Background Colorectal carcinoma (CRC) represents a major worldwide health burden and shows an increasing incidence particularly in younger patients. The majority of metastatic CRC (microsatellite stable, MSS) do not respond to current immunotherapies in contrast to the small subset of microsatellite unstable (MSI) patients. However, responses to immunotherapy were recently observed in subsets of primary MSS tumors indicating their potential vulnerability to such therapeutic approaches. Here, we use multiplex imaging coupled with powerful image analysis tools to highlight important phenotypic differences between MSI and MSS.

Methods 100 human CRC sections (30MSI, 70 MSS) were examined on the COMET™ platform (Lunaphore) with a multiplex sequential immunofluorescence (seqIF) panel of 12 biomarkers (CD3, CD31, CD4, CD8, FoxP3, TCF-1, TOX, EOMES, CK, CD45RO, S100, D2-40).

Images were preprocessed by background subtraction and local contrast enhancement.[1] Cell segmentation was done with the Stardist algorithm.[2]Cell phenotypes (CT) were defined by threshold-based classifiers. The epithelium was detected based on CK expression. The density of CT was assessed per area of interest. Cell neighborhoods (CN) were defined as the composition of the 10 closest CTs within 300um. CNs were clustered into CN-classes using DB-SCAN.[3]

Results Cell segmentation and phenotyping algorithms resulted in precise cell detection (figure 1). We compared CT infiltration patterns in MSI vs MSS in the tumor-epithelium and epithelium-stroma interfaces. While we observed no significant differences in CT densities at the interface, CD3 cell density was significantly higher in MSI vs MSS patients in the tumor-epithelium (figure 2), with MSS more heterogeneously distributed with CD3-high and CD3-low outliers.

Differences in cell interactions CRC patients were examined using CN analysis. We observed a CN composed of CD3, CD8 cytotoxic T cells, CD3+CD8+ and tumor cells to be differentially enriched between MSI and MSS patients (figure 3).

Conclusions A more precise characterization of the immune response to cancers is essential to leverage the advantages of immune modulations in the treatment of cancers. We confirm here important differences between MSI and MSS CRCs in part systematic due to the higher antigen load in MSI CRCs but also highlight heterogeneity amongst the MSS tumors. Characterization of the phenotype of the T-lymphocyte population and its localization with respect to elements such as epithelial cells and tertiary lymphoid structures may help to define both the prognosis of tumors and the possibility of a response to immune checkpoint therapy.

1276 FROM TCR-PMHC BINDING KINETIC CHARACTERISTICS TO TCR PHOSPHORYLATION AND INITIATION OF SIGNAL TRANSDUCTION

Jonathan Desponds, Mayra Cruz Tleugabulova, Jeanne Cheung, Shirley Ng Palace, Martine Darwish, Geraldine Strasser, Andrey Shaw, Ira Mellman, Andrei Chernyshev, Darya Orlova*. *Genentech, South San Francisco, CA, USA*

Background The development of adoptive cell therapy has made the understanding of T-cell target recognition and activation crucial to cancer treatment. Indeed, the success of many of these therapies directly depends on our ability to predict or measure the specificity of T-cell receptors (TCR) to neoantigens and understand how these specificities translate into activation. While the dynamics of TCR-pMHC binding have been under careful scrutiny for a long time, many fundamental unknowns remain regarding the aspects of the dynamics that relate to immune function. Among the key factors that have impeded progress is the fact that most experimental approaches have relied on using soluble TCRs, as opposed to receptors properly assembled in the plasma membrane.

Methods To overcome these limitations, we developed a cell-based assay (figure 1A) to monitor the binding and unbinding of whole CD8 T-cells to a variety of target peptide-MHC monomers in solution using flow cytometry (figure 1B). Using anti-CD8 antibodies, we also measured the contribution of co-receptors to the formation and stability of the TCR-pMHC complex. In parallel, we measured the phosphorylation of CD3 ζ (figure 1C) to quantify the first step of T-cell activation (figure 1D) and its relation to the TCR occupancy and TCR-pMHC binding kinetics. Using a mix of deterministic and stochastic mathematical tools, we developed a minimal model that captures the kinetics of TCR-pMHC interaction.

Results We find that binding kinetics exhibit complex, peptide- and concentration-dependent non-linear behavior that is time-sensitive. Our minimal effective model succeeded at separating peptides based on the strength of the interaction (including functional avidity) and recapitulating the key features of binding dynamics. Importantly, that model is able to extrapolate experimental measurements to other ranges of concentrations for a given TCR, making it a precious tool for the selection of optimal cognate TCRs. We explored hypotheses regarding mechanistic interpretation of the observed dynamics. In particular, using blocking anti-CD8 antibodies, we separated effects of TCR binding from those of co-receptor binding. We also examined the connection between TCR occupancy and TCR-pMHC binding kinetic rates and the phosphorylation of the CD3 ζ chain.

Conclusions Our unique approach, combining novel experimental methods and mathematical modeling, can extract biomolecular TCR-pMHC interaction rates from TCRs assembled in the plasma membrane. It captures the complexity of TCR-pMHC interactions and connects it to the intracellular signal transduction.

1277 IDENTIFICATION OF CLINICALLY RELEVANT SPATIAL TISSUE PHENOTYPES IN LARGE-SCALE MULTIPLEX IMMUNOFLUORESCENCE DATA VIA UNSUPERVISED GRAPH LEARNING IN NON-SMALL CELL LUNG CANCER

[1]Robert Egger*, [2]Andrew Fisher, [1]Michael Drage, [2]Jimena Trillo-Tinoco, [1]John Abel, [2]Andrew Browne, [1]Deepta Rajan, [2]Tai Wang, [1]Jake Conway, [2]Catherine King, [1]Jacqueline Brosnan-Cashman, [2]Anne Lewin, [2]Arnaud Amzallag, [2]Thomas Lila, [2]Tyler Simpson, [1]Mike Montalto, [2]Benjamin Chen, [1]Benjamin Glass, [2]Vipul Baxi. *[1]PathAI, Boston, MA, USA; [2]Bristol Myers Squibb, Cambridge, MA, USA*

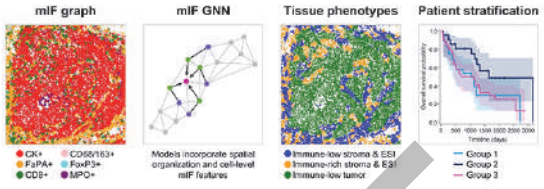
Background Multiplex immunofluorescence (mIF) allows simultaneous spatial interrogation of multiple cell- and tissue-based biomarkers from patient cohorts at scale using whole-slide images (WSI). Identification of spatially-derived insights is limited by conventional approaches that reduce spatial data into human-derived feature sets (e.g., nearest neighbor), necessitating new methods for surveying spatial patterns in full. Here, we utilized a graph neural network (GNN) to identify clinically-relevant, spatially-defined tissue phenotypes with distinct immunogenic profiles in non-small cell lung cancer (NSCLC) and compare this method to traditional approaches.

Methods To identify relevant cancer, stromal, and immune cell types, mIF for cytokeratin, CD8, FoxP3, myeloperoxidase, CD68/CD163, and fibroblast activation protein-A was performed with a DAPI counterstain on clinical NSCLC specimens (N=165). From the same cohort, we extracted bulk mRNAseq and proteomic signatures. mIF images were acquired and spectrally unmixed using the Phenoptic platform and Inform software (Akoya). A convolutional neural network was trained to segment regions of cancer epithelium, stroma, and necrosis, while a pretrained network segmented all cells (HALO-AI, Indica Labs). Cells were converted into graphs, and a GNN autoencoder was trained to discover tissue patterns defined by spatial arrangement and mIF cell/tissue phenotypes. Hierarchical clustering identified patient subsets based on tissue patterns, and Cox proportional hazard models assessed overall survival (OS) (figure 1).

Results Segmentation and post-processing of 165 mIF WSIs resulted in graphs describing 243,646 cells/WSI (mean; range: 3,279-1,552,934). Training the GNN autoencoder on this dataset revealed three tissue phenotypes: (1) cancer epithelium, (2) cancer stroma and epithelial-stromal interface (ESI) with high inflammation, and (3) cancer stroma and ESI with low inflammation. Samples were then classified based on the relative abundance of these phenotypes. While conventional analyses (e.g., nearest neighbor) failed to identify subgroups with prognostic value, our model revealed prolonged OS (HR=0.46 [0.22, 0.96]) in patients with abundant phenotype 2. Furthermore, patients in this subgroup displayed significant overexpression of the MHC-I antigen presentation pathway and downregulation of a general immune exclusion signature, potentially increasing intrinsic anti-tumor immunity to improve prognosis.

Conclusions We developed a novel, unsupervised deep-learning-based GNN for analysis of WSI mIF data in NSCLC. This method identified interpretable tissue phenotypes with clinically-relevant differences in anti-tumor immunity and prognosis. These data show the utility of unsupervised spatial deep-learning methods, compared to traditional approaches, for data-driven discovery of complex patterns in large-scale multiplex images.

Ethics Approval This study was performed in accordance with the Bristol Myers Squibb Bioethics policy (https://www.bms.com/about-us/responsibility/position-on-key-issues/bioethics-policy-statement.html) and adhered to the World Medical Association Declaration of Helsinki for Human Research.



Abstract 1277 Figure 1 Study workflow.From left to right: Graphs are constructed from cell locations, morphology, mIF and tissue features. An unsupervised GNN learns to identify characteristic tissue phenotypes defined by these features and the spatial arrangement of cells. Finally, relative abundance of the different phenotypes is used to stratify patients into groups. Notably, these groups are associated with differences in overall survival

1278 CROSSDOME: AN INTERACTIVE R PACKAGE TO PREDICT T-CELL CROSS-REACTIVITY RISK ON IMMUNOPEPTIDOMICS DATABASES

Andre Fonseca*, Dinler Antunes. *University of Houston, Houston, TX, USA*

Background T cell-based immunotherapy is unquestionably a promising strategy against cancer. Regardless, the efficacy of T-cell therapies depends on mitigating off-target effects during the treatment. Off-target toxicity is associated with T-cell cross-reactivity (CR), i.e., therapeutic T-cell receptors (TCR) recognizing undesirable targets, leading to an auto-immune response. In this context, predicting CR risk remains an unsolved challenge. Here we present Crossdome, a tool that performs peptide screening and predicts cross-reactivity risk based on multi-omics data.

Methods Crossdome was developed by leveraging data from peptide-loaded Human Leukocyte Antigen (pHLA) complexes and TCR molecules, including biochemical properties, immunopeptidomics data, and three-dimensional fingerprints/interactions. Together these data were used i) to predict peptides that are biochemically similar to desirable targets, i.e., putative off-target candidates; and ii) to highlight TCRpHLA interactions associated with shared hotspots among the target and other peptides-HLA. Furthermore, we integrate functional data to evaluate immunogenic potential and expression associated with the putative candidates. As proof-of-principle, we benchmark our approach using well-known cross-reactivity cases, such as MAGEA3, NY-ESO-1, AFP, and TMEM161A.

Results Biochemical properties (BP) can be applied to calculate relatedness between peptides. The validated CR cases were found among the best-scored hits into thousand putative candidates (p-value ≤ 0.01). Particularly, on the MAGEA3 screening, the known cross-reactive peptide ESDPIVAQY (TITIN) was listed as a best-scored candidate, position 20th out of ~25.000 eluted peptides. Other cross-reactivity peptides were also enriched among the highly similar candidates, including MAGEA3 paralogs and synthetic peptides from yeast-displayed experiments (p-value ≤ 0.05). To strengthen our predictions, we implemented a penalty system based on the MAGEA3-specific TCR fingerprint. The hotspot positions were uncovered by molecular dynamics. Positions 1, 4, 5, 7, and 8 were used to recalculate the relatedness scores among the target and candidates. The combination between BP and fingerprints improved the CR predictions to 83%. Finally, we focus on functional characterization among the cross-reactivity candidates associated with the MAGE3A peptide. CR candidates have shown a large variability related to immunogenic prediction and expression pattern, spanning from dangerous to harmless profiles. On the dangerous profile, TITIN and LCAT have shown a high immunogenic level and expression-biased to heart and lung organs, respectively. Curiously, YTDPVGVLY (LCAT) peptide was not reported in previous studies.

Conclusions Crossdome is an interactive R package to predict cross-reactivity risk among peptide databases. Additionally, our method can integrate TCR repertoire data to improve the predictions. Currently, we are focusing our efforts on experimental validation and new antigens discovery.

1279 A NOVEL GRAPHICAL DEEP NEURAL NETWORK LEARNING APPROACH UTILIZING MOLECULAR DATA FOR OPTIMIZING PATIENT SELECTION FOR TREATMENT WITH IMMUNE CHECKPOINT INHIBITORS: AN ORIEN PAN-CANCER STUDY

[1]Issam El Naqa, [1]Payman Ghasemi, [1]Aik Choon Tan, [2]James Chen, [3]Aakrosh Ratan, [4]Martin McCarter, [5]John Carpten, [6]Howard Colman, [7]Alexandra Ikeguchi, [8]Igor Puzanov, [9]Susanne Arnold, [10]Michelle Churchman, [1]Patrick Hwu, [1]Jose Conejo-Garcia, [10]William (Bill) Dalton, [11]George Weiner, [12]Ahmad Tarhini*. *[1]Moffitt Cancer Center and Research Inst., Tampa, FL, USA; [2]The Ohio State University, Columbus, OH, USA; [3]University of Virginia, Charlottesville, VA, USA; [4]University of Colorado Cancer Center, Aurora, CO, USA; [5]USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA; [6]Huntsman Cancer Institute, Salt Lake City, UT, USA; [7]Stephenson Cancer Center, Oklahoma City, OK, USA; [8]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [9]Markey Cancer Center, Lexington, KY, USA; [10]M2GEN, ORIEN, Tampa, FL, USA; [11]University of Iowa Holden Comprehensive, Iowa City, IA, USA; [12]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, USA*

Background Immune checkpoint inhibitors (ICIs) have made significant improvements in the treatment of cancer patients (pts), but many continue to experience primary or secondary resistance. Here, we leveraged clinical and genomic data to identify prognostic biomarkers in pts treated with ICIs utilizing a pan-cancer approach.

Methods Patients were enrolled to the Total Cancer Care protocol (NCT03977402) across 18 cancer centers within the Oncology Research Information Exchange Network® (ORIEN). All included subjects provided an IRB-approved written informed consent at their participating institutions. RNA-seq was performed on tumors following the RSEM pipeline and gene expressions were quantified as Transcript Per Million (TPM) and were logarithmically normalized. A graphical neural network (GNN) architecture was developed based on the prior knowledge of genes and pathways. For comparison, immunoscore for each patient was calculated based on the estimated densities of tumor CD3+ and CD8+ T cells (Galon et. al., 2020) utilizing CIBERSORTx. The quality of overall survival (OS) predictions was assessed using Harrell's concordance index (C-index). Log-rank test was used to assess stratified group differences (by ICI or cancer histology) along with Kaplan-Meier (KM) survival analysis of GNN and immunoscore.

Results Patients (n=522) with 4 cancer types including melanoma (n=125), renal cell carcinoma (n=149), non-small cell lung cancer (n=128) and head and neck cancer (n=120) treated with 6 ICI regimens were included in this analysis. ICI regimens were nivolumab (n=219), pembrolizumab (n=202), ipilimumab+nivolumab (n=69), ipilimumab (n=30), avelumab (n=1) and cemiplimab (n=1). Table 1 summarizes the overall C-index and associated 95% Cls and log-rank *P* values for the entire cohort (regardless of histology) resulting from our proposed GNN and the separate estimated immunoscore categorization. The corresponding KM plots showed significantly wider separations of the survival curves in favor of our proposed GNN relative to the immunoscore with more than 30% improvement in prediction power. Table 2 presents the summary of GNN top selected pathways alongside their hazard rate and their univariate Cox p-value.

Conclusions GNN analysis is a promising tool to identify relevant prognostic biomarkers in cancer patients treated with ICI. This may lead to novel therapeutic predictive signatures and identification of mechanisms of ICI resistance. Our GNN gene expression signature was significantly prognostic and outperformed the estimated CD3+, CD8+ T Cell immunoscore. Further refinements to our prediction power are ongoing along with more advanced neural network architectures to elucidate related functional pathways. Validation and functional studies will follow.

1280 RADIOMIC AND CLINICAL PREDICTION OF OVERALL AND ORGAN-SPECIFIC RESPONSE TO IPILIMUMAB-NIVOLUMAB IN MELANOMA

Zane Gray*, Alexandra Tompkins, Rebekah Dadey, Serafettin Zenkin, Afsaneh Amouzegar, Priyadarshini Mamindla, Vishal Peddagangireddy, Murat Ak, Ryan Augustin, Rivka Colen, Riyue Bao, Jason Luke. *University of Pittsburgh, Pittsburgh, PA, USA*

Background Radiomics converts medical images into quantitative features and has potential in development of non-invasive biomarkers for cancer treatment. Radiomic models have not been described for ipilimumab+nivolumab (I+N) on a patient level or on an organ-specific level.

Methods The Hillman Cancer Center registry (2015-2020) was queried for patients with melanoma treated with I+N. Clinical data was abstracted and radiographic outcomes were calculated by RECIST as well as organ-specific response. Lesions were segmented into discrete volumes-of-interest (VOI) with 400 radiomics texture features extracted. Feature filtering and selection were performed in training set independent of test set after proper normalization. XGBoost was used to construct machine learning models to predict patient level response with training/test split and 5-fold cross validation, or LOOCV in the case of organ-specific models.

Results Of 1106 patients with melanoma, 95 were treated with I+N with 276 individual metastases. Baseline demographics included 47% female, median age of 59, 83% cutaneous (4% uveal), 51% BRAF mutant, 27% M1c (visceral non-lung), and 43% M1d (brain). Patients had a median baseline eosinophil count of 134, neutrophil-to-lymphocyte ratio (NLR) 3.29, and 78% had elevated LDH. 39% had response (CR+PR+SD) and 57% had PD, with mixed response patterns being reported more frequently in PD. Among responders, lung metastases experienced the greatest median reduction in size (-71%) whereas lymph nodes displayed the least regression (-43%). Conversely, liver metastases experienced the greatest median progression in non-responders (+39%). For patients with multiple same-organ target lesions, liver demonstrated the highest inter-lesion heterogeneity. Of the 95 patients, 84 with high-quality images were kept for radiomics model construction. XGBoost models consisting of a 16-feature radiomic signature successfully classified responders from non-responders with an AUC of 0.72. Integration of clinical variables (Age, BMI, Sex, AJCC stage M category, BRAF status, pre-treatment eosinophil, LDH, NLR) to the radiomic signature achieved an AUC of 0.87 (p=0.027). Organ-specific predictive models demonstrated similar performance as the overall response models, for example an AUC of 0.74 in lymph nodes (43 lesions) and 0.77 for liver metastases (22 lesions).

Conclusions In this population of high-risk patients with metastatic melanoma (due to high levels of hepatic/brain involvement and non-cutaneous histology), differential organ-specific response was observed with the greatest benefit in lung, least benefit in hepatic metastases, and highest within-organ heterogeneity in liver. Integrating clinical factors with radiomics signatures improved overall response prediction suggesting priority development of these models for immunotherapy.

1281 RECURRENCE PREDICTION IN CUTANEOUS MELANOMA PATIENTS BY EXPLOITING DEEP LEARNING ON H&E SLIDE IMAGES

[1]Michele Guida, [2]Maria Colomba Comes*, [2]Livia Fucci, [2]Sabino Strippoli, [2]Samantha Bove, [2]Ivana De Risi, [2]Annarita Fanizzi, [2]Martina Milella, [2]Fabio Mele, [2]Alfredo Zito, [2]Raffaella Massafra. *[1]IRCCS Istituto Tumori, Bari, Italy; [2]IRCCS Istituto Tumori Giovanni Paolo II, Bari, Italy*

Background Cutaneous melanoma is one of the most aggressive forms of skin cancer with a high mortality rate.[1] A prognosis improvement in cutaneous melanoma patients is crucial to better plan personalized treatments. Currently, clinical prognosis methods for the evaluation of the risk of recurrence includes multiple parameters, such as Breslow tumor thickness, mitotic rate, ulceration, local or nodal metastasis, which are at the basis of the American Joint Committee on Cancer (AJCC) pathologic tumor stage.[2–4] Despite routinely applied in clinical practice, these methods have some pitfalls.[5] Thus, predicting the risk of recurrence in melanoma patient is urgent.

Methods In this study, we propose a deep learning model, that exploits convolutional neural networks, which mimic the functioning of human brain, to extract features from hematoxylin and eosin (H&E) slide images with the final goal of predicting 1-year disease-free survival (DFS) in patients with I-III stage cutaneous melanoma. H&E images referred to a cohort of 43 patients from Clinical Proteomic Tumor Analysis Consortium Cutaneous Melanoma (CPTAC-CM) public database (31 DF cases, 12 non-DF cases)[6] were firstly analyzed to design the predictive model (table 1). Then, the model was validated on H&E images referred to a validation cohort of 11 cutaneous melanoma patients (table 2), which was provided by our Institute (8 DF cases, 3 non-DF cases). Basically, we developed a computerized system to automatically extract information that are usually evaluated manually and visually by pathologists.

Results The median Area Under the Curve (AUC) and accuracy values in the patients from the CPTAC-CM public dataset were 69.5% and 72.7%, respectively, by implementing a 5-fold cross validation scheme for 5-rounds. AUC and accuracy values in the validation cohort of patients were 66.7% and 72.7%, respectively, by using the CPTAC-CM dataset as training set and the validation cohort as test set.

Conclusions Our model proved to be robust and generalizable. The promising results obtained in this preliminary work suggest that our proposal, after further validation on a larger cohort of patients, may have the potential to better define the risk of recurrence for each patient and better tailor adjuvant therapy.

1282 CONCORDANCE ANALYSIS OF AI-POWERED CD8 QUANTIFICATION AND AUTOMATED CD8 TOPOLOGY WITH MANUAL HISTOPATHOLOGICAL ASSESSMENT ACROSS SEVEN SOLID TUMOR TYPES

[1]Maria Guramare*, [1]Nishant Agrawal*, [2]George Lee, [1]Adam Stanford-Moore, [1]Abhik Lahiri, [1]Diksha Meghwal, [1]Aryan Pedawi, [1]Darren Fahy, [1]Raymond Biju, [1]Archit Khosla, [2]Dimple Pandya, [3]Scott Ely, [2]Jimena Trillo-Tinoco, [2]John Wojcik, [2]Falon Gray, [2]Benjamin Chen, [1]Sergine Brutus, [1]Benjamin Glass, [1]Cyrus Hedvat, [1]Ilan Wapinski, [1]Michael Montalto, [1]Andrew Beck, [1]Charles Biddle-Snead, [2]Vipul Baxi. *[1]PathAI, Boston, MA, USA; [2]Bristol Myers Squibb, Princeton, NJ, USA*

Background The degree of CD8+ lymphocyte infiltration into the tumor microenvironment, as well as the distribution of lymphocytes within the tumor and surrounding stroma (inflamed, excluded, or desert immunophenotypes), are key determinants for the potential efficacy of immunotherapy. Thus, accurate characterization of the tumor immune microenvironment is essential. However, manual histopathological assessment of CD8 topology is subject to many challenges, including subjectivity and reproducibility. We developed machine learning (ML)-based models for the identification and quantification of CD8+ lymphocytes and CD8-based CD8 topology classifiers across seven cancer types: urothelial carcinoma (UC), head and neck squamous cell carcinoma (HNSCC), non-small cell lung cancer (NSCLC), gastric cancer (GC), colorectal cancer (CRC), pancreatic cancer (PC), and hepatocellular carcinoma (HCC).

Methods ML algorithms were developed to quantify CD8+ lymphocytes in UC, HNSCC, NSCLC, GC, CRC, PC, and HCC specimens from clinical trials and commercial sources (N=1603) using CD8+ cell detection models trained on digitized whole slide images of CD8 immunohistochemistry (Agilent-Dako clone C8/144b, Agilent). Annotations were provided by the PathAI network of expert pathologists to train algorithms for classifying tissue regions (including parenchyma and stroma) and cell types. To evaluate the performance of the CD8+ cell model, AI-predicted counts were compared to a consensus count from five independent pathologists for representative fields of view (frames) using Pearson correlation. Inter-pathologist agreement was also calculated. Using a distinct cohort of samples from each cancer type (N=1655), a simple, two-parameter CD8 topology classifier was trained using pathologist-provided CD8 topology scores and CD8 model-derived features. Classifier-predicted immunophenotype scores were compared to pathologist-generated scores using unweighted Cohen's kappa.

Results ML-based quantitation of CD8+ lymphocytes yielded counts with high concordance to manual pathologist consensus counts. Frames-based validation of CD8+ counts on held-out test sets from each cancer type confirmed this high correlation (table 1). For scoring CD8 topology, the performance of the CD8 topology classifier was comparable to that of individual pathologists (table 2), indicating non-inferiority of our models with pathologist-generated scores. Overall, our models met pre-determined success criteria for all seven cancer types.

Conclusions ML model-predicted CD8+ cell counts are highly concordant with pathologist-generated counts across seven solid tumor types, and tumor CD8 topologies were predicted with a simple and highly interpretable two-parameter classifier. These data demonstrate the power of AI-powered digital pathology for accurate and reproducible quantitation of CD8+ lymphocytes and automated immunophenotyping in clinical samples, further confirming the potential for AI-based biomarker measurements in immuno-oncology.

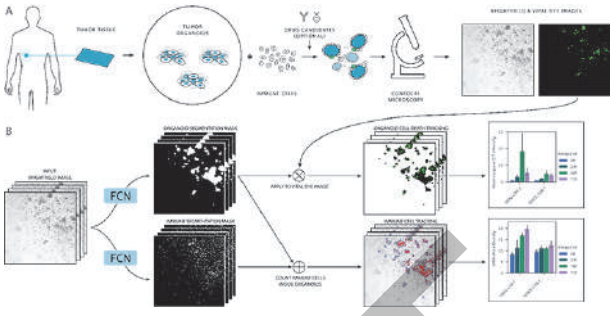
1283 APPLYING MACHINE VISION TO EMPOWER PRECLINICAL DEVELOPMENT OF IMMUNOTHERAPIES IN PATIENT-DERIVED ORGANOID MODELS OF SOLID TUMORS

Chi-Sing Ho*, Sonal Khare, Madhavi Kannan, Michael Streit, Timothy Lopez, Luca Lonini, Brian Larsen, Brandon Mapes, Jenna Shaxted, Martin Stumpe, Ameen Salahudeen, Jagadish Venkataraman. *Tempus Labs, Redwood City, CA, USA*

Background Paradigm shifting next-generation immuno-oncology therapeutics such as CAR-T cells and bispecific engagers are rapidly gaining interest as investigational therapies. However, the discovery and preclinical development of these therapies involve 2-D cell line based assays that require differential labeling, often with fluorescent dyes or transgenic fluorescent proteins. These conventional approaches are limited by cumbersome labeling, optimization for each tumor cell line, and dysregulation of effector cell function including primary immune cells. In this work, we build upon a patient-derived tumor organoid (TO) platform to measure TO-specific responses to next-gen immunotherapies using brightfield-only segmentation models. We utilize machine vision on time-lapse microscopy to obtain multiparameter kinetic readouts of tumor cell death, enabling dissection of mechanisms of both CAR-T cells and effector cell engaging bispecifics. The assay co-localizes target and effector cells spatiotemporally without the need for differential labeling, affording insights into therapeutic potency or resistance. Overall, the automated segmentation and co-localization pipeline enables a highly scalable and high-throughput imaging assay for rapid discovery and validation of candidate next-gen immunotherapies across all solid tumors.
Methods TOs were co-cultured with immune effector cells, optionally in the presence of a drug candidate, and imaged via a confocal microscope as a series of time-lapse images (figure 1A). We independently trained two fully-connected networks (FCNs) to segment the TOs and the immune cells directly from the brightfield channel. We then applied the TO masks to a registered vital dye channel to quantify TO cell death. Simultaneously, we used the TO masks, in conjunction with the immune cell masks from the second FCN, to quantify immune cells surrounding and infiltrating the TOs as a function of time (figure 1B).
Results We find that the rate of immune cell co-localization and infiltration is correlated with TO cell death over time, lending strong biological interpretability to the effectiveness of immunotherapies. We observe a differentiation of response between HER2-targeted and untargeted CAR-T lines, where targeted CAR-T lines exhibit higher infiltration rates with higher corresponding cell death rates. These correlations generate label-free insights into the pharmacokinetics and mechanisms for specific immune therapies.
Conclusions We present an effective solution for scalable, label-free quantification of TOs and immune cells from brightfield images to understand their dynamics in time-lapse imaging. Our machine vision platform enables high-throughput immune oncology preclinical studies to screen and mechanistically probe therapeutic candidates across dozens to hundreds of unique TO models, accelerating their evaluation as immuno-oncology therapeutic candidates in cancer patients.
Ethics Approval Human biospecimens and effector cells were obtained from third parties under IRB approved research protocols.



Abstract 1283 Figure 1 Overview of patient-derived TO-immune co-culture assay. A) Brightfield and vital dye images are collected over time series imaging measurements. B) A cascaded approach consisting of 2 FCN segmentation models and downstream quantification is applied to detect both TOs and immune cells to measure TO-specific cell death along with immune cell clustering and infiltration over time

1284 BIOLOGY-GUIDED DEEP LEARNING PREDICTS PROGNOSIS AND CANCER IMMUNOTHERAPY RESPONSE

[1]Yuming Jiang, [2]Zhicheng Zhang, [3]Wei Wang, [1]weicai Huang, [1]Chuanli Chen, [4]Sujuan Xi, [2]M Usman Ahmad*, [2]Yulan Ren, [2]Shengtian Sang, [5]Jingjing Xie, [6]Wenjun Xiong, [1]Tuanjue Li, [1]Zhen Han, [1]Qingyu Yuan, [1]Yikai Xu, [2]Lei Xing, [2]George Poultsides, [1]Guoxin Lin, [2]Ruijiang Li. *[1]Southern Medical University, Guangzhou, China; [2]Stanford University, Stanford, CA, USA; [3]Sun Yat-sen Univeristy, Guangzhou, China; [4]Sun Yat-sen University, Shenzhen, China; [5]University of California Davis, Davis, CA, USA; [6]Guangzhou University of Chinese Medicine, Guangzhou, China*

Background Substantial progress has been made in using deep learning for cancer detection and diagnosis in medical images.[1-10] However, a significant hurdle for clinical translation of current data-driven deep learning models is lack of interpretability, often attributable to a disconnect from the underlying pathobiology. [11-14] Here, we propose a biology-guided deep learning framework in which a multi-task model is trained to simultaneously predict tumor microenvironment (TME) status and treatment outcomes from radiology images.

Methods 348 patients with gastric adenocarcinoma were used as a training cohort to develop a machine learning algorithm combining radiologic imaging, clinicopathologic data, TME class using ImmunoScore of Gastric Cancer and protein expression of periostin, treatment information, and response to treatment. The model with internally validated with two cohorts of 202 and 636 patients in China. The model was further evaluated with an external validation cohort including 125 and 1062 patients at another Chinese academic medical center. The model was further validated in an American academic medical center cohort consisting of 57 patients. A final immunotherapy cohort of 253 patients was evaluated with advanced gastric cancer undergoing treatment with Anti-PD1 therapy.

Results A total of 2,749 patients were evaluated across training, internal validation, and external validation cohorts. Over 51% of patients with Stage II/III disease received adjuvant chemotherapy. All patients in the immunotherapy cohort had Stage IV disease with 94% harboring mismatch repair deficiency or microsatellite instability-high status. Biology-guided deep learning model was able to accurately predict four distinct TME classes based on computed tomography (CT) imaging 0.81 (95% CI: 0.769-0.851), 0.83 (0.780-0.884), 0.83 (0.780-0.884), and 0.84 (0.776-0.904) which were linked to disease free survival (DFS) and overall survival (OS). The benefit of chemotherapy in DFS and OS was associated with deep learning model and TME class 1-3 ($p<0.05$), but not class 4. Assessing the effect of immunotherapy (figure 1), combined positive score (CPS) with predicted TME class outperformed CPS alone (Area Under the Curve: 0.805, 95% CI 0.75-0.85 vs 0.642 95% CI 0.58-0.70).

Conclusions Machine learning algorithms trained with pathobiology of tumors may successfully predict TME using only CT imaging in gastric cancer. These algorithms may be prognostic for adjuvant chemotherapy. In addition, use of algorithms may improve prognostication of response to PD-1 therapy despite mismatch repair deficiency and microsatellite instability-high status with use of CPS score of PD-1 expression.

Acknowledgements This project would not have been possible without the assistance and collaboration of staff, faculty, and students of four academic medical centers in China and the United States.

1285 SPATIAL ANALYSIS OF TUMOR-INFILTRATING LYMPHOCYTES (TILS) BASED ON HER2 EXPRESSION ACROSS MULTIPLE CANCER TYPES

Sukjun Kim*, Seulki Kim, Yoojoo Lim, Gahee Park, Sanghoon Song, Heon Song, Seonwook Park, Jeongun Ryu, Sergio Pereira, Donggeun Yoo, Kyunghyun Paeng, Chan-Young Ock. *Lunit Inc., Seoul, South Korea*

Background Newer strategies of targeting HER2 such as novel HER2-targeted agents and combination with immune checkpoint inhibitors (ICIs) call for development of newer biomarkers based on deeper understanding of biology. To understand the immune microenvironment of HER2-expressing tumors, we performed spatial analysis of TIL in association with HER2 status, in the The Cancer Genome Atlas (TCGA) pan-carcinoma set.

Methods Hematoxylin and eosin (H&E)-stained slides, copy number alterations, and mRNA expression levels of HER2 for 7,322 patients across 22 cancer types and immunohistochemistry (IHC) results for 622 breast cancer patients were obtained from the TCGA data set. Spatial analysis of TIL distribution was done by an artificial intelligence-powered H&E analyzer, Lunit SCOPE IO. Intratumoral TIL (iTIL) and stromal TIL (sTIL) densities were defined as the number of TILs in each 1mm2 grid of cancer area and stromal area. The HER2 amplified cancers were classified as per annotation of TCGA. Receiver operating characteristic (ROC) analysis was used to determine the optimal thresholds of mRNA expression showing maximal value of sensitivity and specificity, to discriminate HER2-expressed ($\geq$ 1+) against HER2-negative (0) using IHC results. These thresholds were subsequently used in pan-cancer analysis, to define HER2-expressed vs. HER2-negative.

Results Overall, iTIL and sTIL densities of HER2 amplified cancers were lower than those of non-amplified cancers in the TCGA data set. Also, the iTIL and sTIL densities were mostly decreased in HER2-expressed cancers by the RNA-seq-based threshold. However, when breaking down into individual cancer types, TIL densities increased in endometrial cancer (UCEC) and ovarian cancer (OV). In UCEC (n = 148), iTIL density increased from 74.5±75.6 (mean±standard deviation) in HER2-negative to 167.17±322.30 in HER2-expressed and sTIL density increased from 649.2±517.2 to 875.2±1172.0, respectively. In OV (n = 70), although iTIL density was slightly increased from 50.5±53.6 to 52.9±63.5, sTIL density was notably increased from 243.6±215.6 to 540.9±563.9, respectively. Among the HER2-expressed cancers, the iTIL and sTIL levels were higher in those expressing PD-L1 or having high-tumor mutational burden (TMB). The differences were notable in urothelial carcinoma (TMB, PD-L1); breast cancer, cervical cancer, lung cancer, and thyroid cancer (PD-L1).

Conclusions HER2 amplification or expression was associated with lower immune infiltration in the pan-cancer cohort, consistent with previous data.[1] Further investigation in individual tumor types may further identify possible responders for combination therapy with HER2-targeted agents and ICIs.

1286 STRUCTURE-BASED PREDICTION OF NEOANTIGENS PAIRED WITH T CELL RECEPTORS ON PHENOTYPE-SELECTED CD8+ TUMOR-INFILTRATING LYMPHOCYTES

Bo Ryeong Lee*, Sungsik Kim*, Sung-min Kim*, Woong-Yang Park. *Geninus Inc., Seoul, South Korea*

Background Vaccination by tumor neoantigens are promising immunotherapy by providing more tumor-reactive T cell pool, which could be boosted by anti-PD-1. Identification of neoantigens cognate to tumor-reactive tumor-infiltrating lymphocytes (TILs) is critical for clinical efficacy of neoantigen vaccines. Here, we developed *in silico* neoantigen prediction platform by structure-based pairing with T cell receptors (TCR) on pre-existing CD8+ TILs selected by single-cell transcriptome profiles. Neoantigens derived by our strategy reflect in vivo immunogenicity and tumor reactivity.

Methods Tumor resections from solid cancer patients are subject to whole exome and transcriptome sequencing. In addition, TILs from the patients are subject to scRNAseq/scTCRseq to stratify TCRs of TILs into target TILs and non-target TILs by single-cell transcriptome profiles. Neoantigen epitopes are filtered with HLA binding/immunogenicity and prioritized by tricomplex (TCR-peptide-HLA) structure-based TCR binding score from our platform Vacinus. To evaluate the immunogenicity of selected neoantigens, the neoantigen peptides are tested for *in vitro* IFNg ELISPOT assay using peripheral blood mononuclear cells (PBMCs) from the same patients, which sensitively detects antigen-experienced T cells.

Results We have screened the immunogenicity of 286 neoantigens derived from Vacinus platform for 34 solid cancer patients. In particular, we could detect the immunogenic neoantigens in the majority of Hepatocellular carcinoma (HCC) patients (13/14) which had low mutational burden with median 95 (46-373) non-synonymous mutations. Single-cell transcriptome of CD8 TILs from HCC revealed that TILs had primarily exhausted/cytotoxic phenotype (target TIL) and non-exhausted memory phenotypes (non-target TIL). We applied TCRs derived from target or non-target TILs to select cognate neoantigens predicted by Vacinus platform, which are tier1 and tier2 neoantigens, respectively. Interestingly, when those neoantigens were tested for immunogenicity with IFNg ELISPOT assay, higher T cell responses were detected in tier1 (31%) than tier2 neoantigens (17%), reflecting tier1 neoantigens have more capability to induce in vivo immunogenicity in cancer patients. Using mouse tumor models, we are investigating therapeutic efficacy of tier1 neoantigens.

Conclusions It is feasible to develop cancer neoantigen vaccine in HCC which has low mutational burden. Neoantigens paired with TILs in an activated state were identified to have greater immunogenicity compared to TILs in a memory state, underscoring the selection of target TILs. Neoantigen prediction by structure-based pairing of neoantigens and phenotype-selected TILs showed promising potential to better select therapeutically-relevant cancer vaccines.

Ethics Approval The study with samples from HCC patients was approved by the Asan Medical Center Institutional Review Board (IRB) (2022-0263)

1287 RADIOMICS AND DELTA-RADIOMICS SIGNATURES TO PREDICT RESPONSE AND SURVIVAL IN PATIENT WITH NON-SMALL CELL LUNG CANCER TREATED WITH IMMUNE CHECKPOINT INHIBITORS

François Cousin, Thomas Louis, Mariaelena Occhipinti, Wim Vos*, Julien Guiot, Roland Hustinx. *University Hospital of Liège, Liege, Belgium*; *[2]Radiomics, Liege, Belgium*

Background Accurate and early selection of patients with advanced non-small cell lung cancer (NSCLC) who would benefit from immunotherapy is of the utmost clinical importance. The aim of our study was to determine the potential role of CT-based radiomics and delta-radiomics signatures in predicting treatment response and survival in patients with advanced NSCLC treated with programmed death-1 (PD-1) or programmed death ligand-1 (PD-L1) inhibitors. Moreover, we compared the results obtained with both signatures to early RECIST v1.1 assessment (first follow up visit).

Methods In this retrospective multi-centric study, we included 188 patients with NSCLC treated with PD-1/PD-L1 inhibitors who underwent a pre-treatment and at least one follow-up CT scans. The training dataset was composed of 146 patients and the external validation dataset of 42 patients. All the lesions, both target and non-target, according to RECIST v1.1 criteria, were manually segmented by experienced reader. Radiomics analysis was performed on both single and multiple target lesions per patient. A delta-radiomics analysis was also conducted on a subset of 160 patients who underwent a follow-up CT after 2 to 4 treatment cycles. Radiomic features were selected by the Minimum Redundancy Maximum Relevance method. Linear and Random Forest (RF) models were tested to predict response at 6 months and overall survival (OS). Performances of the models were expressed in term of Area Under the Curve (AUC) and survival prediction with Cox concordance index.

Results The baseline CT radiomics signatures did not show any significant results for prediction of treatment response or survival. The RF delta-radiomics model showed the best performance for treatment response prediction with an AUC of 0.81 (95% CI: 0.66-0.95). The GLM delta-radiomics model was the most accurate at predicting survival with a concordance index of 0.68 (95% CI: 0.56-0.80) (p=0.02). The comparison between the delta radiomics signatures and early RECIST v1.1 assessment showed a clear improvement in survival prediction with an AUC of 0.66 (95% CI:0.54-0.78) for early RECIST against an AUC of 0.77 (95% CI: 0.61-0.93) and 0.81 (GLM and RF signatures respectively) for delta radiomics signature and a concordance index of 0.56 (95% CI: 0.47-0.65) on the validation dataset.

Conclusions Our delta radiomics models were able to early identify patients with advanced NSCLC who were more likely to benefit from immunotherapy.

Ethics Approval This study received approval from institutional review board of University Hospital of Liège, and the need for informed consent was waived based on its retrospective design.

1288 SPATIAL TRANSCRIPTOMICS-ENABLED INTEGRATED MORPHOLOGY-TRANSCRIPTOME TUMOR CELL PHENOTYPING USING MACHINE LEARNING

[1]Nga Luong*, [1]Wei Yan, [2]Jeffrey Lim, [2]Yuezhen Xue, [1]Abu Bakr Azam, [2]Joe Poh Sheng Yeong, [2]Mai Chan Lau, [1]Yiyu Cai. *[1]Nanyang Technological University, Singapore, Singapore; [2]A*STAR, Singapore, Singapore*

Background In routine cancer diagnosis, pathologists manually characterize tumor cells based on hematoxylin and eosin (H&E)-stained images. On the other hand, transcriptomic-based tumor molecular subtypes were shown to be associated with important clinical features including tumorigenesis and prognosis. Leveraging recent development of spatial transcriptomics (ST) which allows in-situ transcriptomic profiling of tissues,[1] we aim to develop a first-of-its-kind machine learning (ML)-enabled integrated morphology-transcriptome tumor single-cell phenotyping approach.

Methods Two tissue sections each from tumor and adjacent-normal areas collected from a hepatocellular carcinoma (HCC) patient were profiled using 10× Visium ST platform. Using the companion H&E image, individual epithelial cells were segmented (StarDist algorithm) with 53 morphological and staining features extracted (QuPath v0.3.2). These cells were unsupervisedly clustered using encoder-based ensemble method where the optimal clustering solution was determined based on a consensus score of three clustering metrics. Phenotypic gene signatures of the cell clusters were determined through deconvoluting the ST data. Gene ontology (GO) analysis was done using single sample gene set enrichment, based on the molecular signatures database.

Results At the optimal clustering setting, 4 epithelial cell clusters, characterized by differential nuclear size, were detected individually in each HCC tissue (figure. 1). Manual inspection by a pathologist (YZ) confirmed that the tumor epithelial cells demonstrated different nuclear sizes and revealed that the two smaller cell clusters looked relatively more well-differentiated, and ~1% found outside the tumor nest, suggesting potential epithelial to mesenchymal transition (EMT) activity. Whereas the two larger clusters were moderately-differentiated and demonstrated hyperchromatic nuclei and pleomorphism. GO analysis confirmed the upregulation of EMT in the smallest cluster, in both tumor tissues. While epithelial cells in the two normal-adjacent tissues appeared morphologically non-cancerous, the corresponding cell clusters contributed to similar cell fractions as that of the tumor tissues; two smaller clusters contributed to ~70% of the total cells across all tissues (figure. 2). Cell clusters with similar nuclear size shared 30%-65% of the top 20 pathways across tissues, indicating inter-tissue phenotypic consistency. Cells were found near cell-type of its own followed by cell-type of similar size, suggesting preferential cell clustering of similar phenotypes (figure 3).

Conclusions Our ML approach revealed four morphologically-transcriptomically distinct tumor cell subsets in the HCC tissues, with the smallest cells appeared EMT-like. We revealed intra-patient tumor cell heterogeneity yet phenotypic consistency across tissue sampling sites. Altogether, our proposed approach would enable more refined tumor cell phenotyping, advancing our understanding of tumor biology.

PREDICTING RESPONSE TO IMMUNE CHECKPOINT INHIBITORS (ICI) IN NON-SMALL-CELL LUNG CANCER (NSCLC) BY COMBINING SPATIAL ANALYSIS OF CELLS AND RNA SEQUENCING DATA FROM BIOPSIES USING DEEP LEARNING (DL)

[1]Ettai Markovits*, [2]David Soong, [1]Becky Arbiv, [1]Alon Groisman, [1]Maya Lipinsky, [1]Yoni Yedidia, [1]Yoad Cohen, [1]Yuval Gabay, [1]Yuval Shachaf, [1]Eyal Oren, [1]Roman Gluskin, [1]Ido Weiss, [2]Hisham Hamadeh, [2]Kate Sasser, [1]Gali Golan, [2]Brandon Higgs, [2]Suzana Couto, [1]Ori Zelichov. *[1]Nucleai, Tel Aviv, Israel; [2]Genmab, Princeton, NJ, USA*

Background ICI have transformed treatment of metastatic NSCLC, however, only a small proportion of patients respond. Spatial biology plays a significant role in further understanding the complexities of the tumor microenvironment and drivers of response to ICI. Here, we utilized DL to analyze whole slide images (WSI) of sequential biopsies stained for H&E and five IHC stains and combined it with RNA sequencing data to identify features associated with response to ICI.

Methods 103 NSCLC patients treated with second line ICI were procured. For each patient, a total of 12 WSI from pre- and post-treatment biopsies, sequentially stained for H&E, CD3, CD8, CD163, CD137 and PD-L1 IHC were analyzed. RNA sequencing data of pre-treatment biopsies from 81 patients were also analyzed. Endpoints included overall response rate (ORR) and progression-free survival (PFS). DL models were trained to classify tumor cells, lymphocytes, fibroblasts, and tumor versus stromal areas from H&E, and positivity of IHC markers per cell. Based on biological hypotheses, 362 spatial and 72 RNA features were pre-defined and calculated for each patient. Univariate analysis identified features associated with clinical outcomes and the best performing features were selected to genretae a binary classifier for response prediction. Cross-validation was performed.

Results Multiple spatial and RNA features were significantly correlated with ORR and PFS. Responders had greater density of CD3 in the invasive margin and closer proximity between PD-L1+ tumor cells and CD8+ cells in pre-treatment biopsies compared to non-responders ($p<0.01$). Gene set enrichment analysis identified upregulation of hallmark TNF-alpha signaling and IFN gamma response genes in responders to ICI pre-treatment ($p<0.0001$). When comparing pre- and post- treatment biopsies, responders had greater increases in density of CD8+ cells in the tumor microenvironment following ICI ($p=0.02$). The resulting classifier combined 7 spatial and 3 RNA features and reached an AUC=0.76 when correlated with ORR (figure 1). 62 patients with both RNA and spatial features were classified as positive (n=46) or negative (n=16). In a Kaplan-Meier (KM) analysis, PFS was significantly longer in positive-scored compared to negative-scored patients (HR=0.48, 95% CI 0.26-0.86, $p<0.02$) (figure 2).

Conclusions DL for spatial analysis of cells combined with pathway modulation, as measured by RNA sequencing can elucidate unique tumor contexture relevant for response to ICI in NSCLC.

1290 A DEEP LEARNING ANALYSIS PIPELINE FOR MULTIPLEX IMAGING IDENTIFIES SPATIAL FEATURES ASSOCIATED WITH CLINICAL OUTCOME IN COLORECTAL CANCER

Ettai Markovits*, Roman Gluskin, Tomer Dicker, Ido Weiss, Sun Dagan, Ron Elran, Amit Bart, Oleg Kuybeda, Becky Arbiv, Ori Zelichov. *Nucleai, Tel Aviv, Israel*

Background Multiplex immunofluorescence (mIF) can provide invaluable insights on spatial biology and the complexities of the immune tumor microenvironment (iTME), however, current analysis methods are laborious and user dependent. We applied a novel end-to-end deep learning (DL) pipeline (figure 1) to mIF tumor-microarray (TMA) images, to investigate associations between iTME composition and clinical outcome.

Methods A publicly available CODEX dataset,[1] consisting of 140 tissue cores from 35 colorectal cancer (CRC) patients stained with 56 protein markers and matched H&E slides was analyzed. 7,000 cell annotations on 57 tissue cores were used to train DL models to segment cells and classify them to 13 subpopulations (figure 2). Performance was evaluated quantitatively on 1,800 annotations from 14 test cores, and qualitatively on all cores by expert pathologists. In addition, positivity for 8 immunomodulatory markers was predicted per cell, using a DL binary classifier trained on 100,000 binary single channel annotations, which were automatically extracted from the 7,000 cell annotations by prior knowledge of lineage marker expression. The model performance was evaluated on novel annotations for each phenotypic marker. H&E slides were utilized to annotate tumor and stromal areas and identify fibroblasts and marker-negative tumor cells. 12 Cell neighborhoods were identified by clustering the 10 nearest-neighbors for each cell (figure 3). Over 600 spatial features were calculated and correlated with good vs. bad prognosis defined by 2-year OS cutoff.

Results Cell typing model reached a 91.9% accuracy (figure 4) and good performance (>75% accuracy) by qualitative assessment in 97.7% of cores, thus markedly outperforming existing clustering-based cell typing approaches showing 65.9% accuracy (figure 5). Phenotypic marker classification demonstrated 93.5% accuracy (figure 6). Stromal abundance of a plasma cell-enriched neighborhood was associated with bad prognosis (p=0.009), while higher fraction of LAG3+ (p=0.01) and VISTA+ (p=0.004) plasma cells in the same neighborhood was associated with good prognosis. In addition, LAG3+CD4 + T-cells upregulation in a CD8+ enriched neighborhood was also associated with better prognosis (p=0.006, figure 7 and table 1). Taken together, we demonstrate the importance of complex spatial features, which capture cell type, neighborhood and functional state information for clinical outcome prediction.

Conclusions A novel DL pipeline for mIF analysis demonstrated high accuracy in classifying cell types and phenotypic markers, thus enabling the identification of multiple cellular and spatial features associated with prognosis in CRC.

1291 A MULTI-TUMOR MACHINE LEARNING MODEL TO IDENTIFY TERTIARY LYMPHOID STRUCTURES IN HISTOPATHOLOGICAL H&E IMAGES AS A POTENTIAL CLINICAL BIOMARKER

[1]Vanessa Matos-Cruz*, [1]Rachel Sargent, [2]Varsha Chinnaobireddy, [2]Maryam Pouryahya, [1]George Lee, [2]Darren Fahy, [2]Christian Kirkup, [2]Kathleen Sucipto, [2]Sai Gullapally, [2]Jacqueline Brosnan-Cashman, [2]Archit Khosla, [2]Nishant Agrawal, [2]Benjamin Glass, [2]Sergine Brutus, [2]Limin Yu, [1]Benjamin Chen, [2]Vipul Baxi, [1]Scott Ely. *[1]Bristol Myers Squibb, Princeton, NJ, USA; [2]PathAI, Boston, MA, USA*

Background Tertiary lymphoid structures (TLS) are ectopic lymphoid structures that develop in benign and tumor tissues with chronic inflammation. TLS are highly organized structures composed of B cells, T cells, and supportive cells within a structural matrix. They are classified as lymphoid aggregates (LA), immature TLS (imTLS), or mature TLS (mTLS) with the presence of a germinal center (GC). The presence and maturity of TLS have been associated with favorable outcomes in multiple tumor indications and with immune-checkpoint inhibitor (ICI) efficacy. We aimed to develop a digital pathology method to quantify TLS presence, prevalence, and localization as a predictive biomarker of ICI clinical outcome We developed a machine-learning (ML) algorithm trained on hematoxylin and eosin (H&E)-stained whole slide images (WSIs) to: (1) accurately and reproducibly identify LAs and TLS; (2) to predict TLS subregions and maturity; and (3) extract TLS model-derived features.

Methods A multi-tumor ML-based TLS detection model was trained by expert pathologists to predict mTLS/GCs, imTLS, and LAs in H&E-stained WSIs (N=2777) from TCGA bladder cancer (BLCA), breast cancer (BRCA), stomach adenocarcinoma (STAD), lung adenocarcinoma (LUAD), and lung squamous cell carcinoma (LUSC). Pre-trained indication-specific tissue segmentation models were applied to distinguish cancer, cancer-associated stroma, and necrosis from normal tissue. Features quantitatively derived from TLS and tissue regions were extracted, and correlations with an RNA-seq-derived TLS-associated gene expression signature were calculated. Log-rank analysis was performed to assess the impact of TLS on prognosis.

Results Our model accurately and reproducibly detected and distinguished LA, imTLS, and mTLS/GC in five indications and performed comparably to manual pathologist-derived annotation. Four model-derived TLS features (proportional area of LA, proportional area of iTLS, proportional area of mTLS, and mean perimeter of imTLS) correlated with a published TLS-gene signature, and three gene-expression clusters were found to be concordant with TLS maturity. The proportional area of mTLS was significantly associated with improved progression-free survival in BRCA ($p=0.01$) and overall survival in LUAD ($p=0.04$).

Conclusions We developed a robust ML-based algorithm that can accurately distinguish and classify TLS structures across five indications. We demonstrated that novel TLS model-derived features correlated with gene expression and survival in several indications. These data highlight the promise of ML-based approaches for the accurate and reproducible evaluation and potential implementation of prognostic TLS biomarker assays in oncology.

1292 A REPRODUCIBLE PIPELINE FOR ANALYSIS OF MULTIPLEX IMAGING (MIBI) DATA WITH APPLICATION TO UNCOVERING NOVEL FEATURES OF THE TUMOR-IMMUNE MICROENVIRONMENT

[1]Jessica Maxey*, [1]Marshall Thompson*, [2]Katie Campbell, [1]Benjamin Kamphaus, [1]Zaid Bustami, [1]Sandra Santulli-Marotto, [1]Daniel Wells, [3]Silvia Boffo, [3]Lisa Salvador, [2]Philip Scumpia, [1]Christine Spencer, [4]Adam Schoenfeld, [2]Antoni Ribas, [1]Lacey Kitch. *[1]Parker Institute for Cancer Immunotherapy (PICI), San Francisco, CA, USA; [2]University of California Los Angeles (UCLA), Los Angeles, CA, USA; [3]Bristol Myers Squibb, Princeton, NJ, USA; [4]Memorial Sloan Kettering Cancer Center, New York, USA*

Background Although immune checkpoint inhibition (ICI) has been transformational, tumor-associated factors regulating response have not been elucidated. High-dimensional spatial profiling technologies have enabled simultaneous investigation of many protein targets on individual cells within the spatial context of the tumor microenvironment (TME). Analysis of these data to uncover immune and tumor profiles relies on identification of individual cells and characterization of their specific marker expression to classify lineage and functional state. However, robust automated cell type assignment remains a key challenge in multiplex image data analysis. Here, we describe a reproducible pipeline for single cell identification and typing from multiplex ion beam imaging (MIBI) data utilizing lineage protein expression, which has applications in the context of precision immunotherapy and beyond.

Methods Biopsies from melanoma (n = 80) or non-small cell lung cancer (NSCLC, n = 38) patients treated with anti-PD-1 were profiled by MIBI for spatial analysis of 32 protein markers. Following cell segmentation, an automated pipeline was developed to assign cell types based on bootstrap sampling of lineage-specific marker expression within each region of interest (n = 395), on a per-pixel basis. This pipeline was further optimized by integrating marker lineage-specificity to improve the identification and segmentation of cells with irregular shapes or sizes (e.g. fibroblasts, macrophages) by expanding cell outlines based on pixel type identity. The overall approach was benchmarked against existing automated and manual methods. Feature extraction and downstream harmonization with clinical and other molecular data was facilitated by our multi-omic data integration platform (CANDEL).

Results Our cell typing and segment expansion approach outperformed several alternatives in proportion of cell types confidently assigned, increasing the proportion of identified segments by 15-55% across all samples tested. The additional improvement in segmentation demonstrated by the pixel expansion method enabled clearer visualization of TME context and cellular structure, increasing the overall inclusion of macrophage and fibroblast markers by 14.9% and 30.47%, respectively. Exploration of the association between image features and clinical response to anti-PD-1 is currently underway.

Conclusions Multiplex imaging data can provide new insights into mechanisms, targets, and biomarkers for cancer immunotherapy. These insights depend on reliable segmentation and cell typing, and manual methods can be unreliable and do not scale. Our toolchain provides a foundation for reliable and scalable analysis of high-dimensional spatial profiling data. These analytical improvements will facilitate generation of new insights into mechanisms of PD-1 resistance and features of the TME that correlate with clinical outcomes.

1293 ESTABLISHING THE PRECLINICAL PKPD RELATIONSHIP FOR NM32–2668 A ROR1 TARGETING T CELL ENGAGER

[1]Hitesh Mistry, [1]Fernando Ortega*, [2]Bithi Chatterjee, [2]Nicole Bassler, [2]Niels Kirk, [2]Julia Tietz, [2]Belinda Wickihalder, [2]Simone Muntwiler, [2]Simon Carnal, [2]Daniel Snell, [1]Christophe Chassagnole. *[1]Physiomics, Oxford, UK; [2]Numab Therapeutics, Wadenswil, Switzerland*

Background NM32-2668 is a fragment-based multispecific antibody therapeutic[1] that has been designed to activate T-cells (via CD3) in the presence of tumour antigen receptor tyrosine kinase-like orphan receptor 1 (ROR1). The objective of this work was to build a mathematical model to establish a PKPD relationship using both *in vitro* and *in vivo* data for NM32-2668.

Methods Data were collected from *in vitro* studies measuring CD4/8 activation and cytotoxicity from a panel of cell lines and patient samples to increasing concentrations of NM32-2668, and from *in vivo* tumour growth inhibition (TGI) data from a humanised mouse model in one cell line with two different donors with increasing doses of NM32-2668. Nonlinear mixed-effects models were used to assess the variability in cytotoxicity as a function of drug concentration and immune system activation. The translatability of *in vitro* potency values for immune system activation was assessed by linking PK to *in vitro* data and to TGI *in vivo* data.

Results The combination of ROR1 expression and CD8 activation fully explained the variance in cytotoxicity across all *in vitro* data. The estimated *in vitro* potency for CD8 activation could successfully be used to provide a link between PK and TGI in vivo.

Conclusions A PK-PD-Efficacy model based on the *in vitro* data was established showing that the cytotoxicity response was strongly correlated to ROR1 expression and CD8 activation. Building on this *in vitro* model, we developed an *in vivo* PK-TGI model that can link immune system activation to TGI.

1294 AN AUTOMATED MACHINE LEARNING FRAMEWORK FOR RAPID QUANTIFICATION AND ANALYSIS OF MULTIPLEXED ION BEAM IMAGES (MIBI)

Raghav Padmanabhan, Mate Nagy, Stanislaw Nowak, Peng Si, Sweta Bajaj, Mate Nagy*, Monirath Hav. *Ionpath Inc., Menlo Park, CA, USA*

Background Multiplexed Ion Beam Imaging (MIBI) offers high-parameter tissue imaging that is well suited for describing complex immuno-spatial features in tissues, including the enumeration of various cell phenotypes, expression of immune checkpoint proteins, and quantitative description of spatial distributions between different populations.[1] The high imaging resolution combined with the rich mass spectral information in each image allows for the quantification of up to 40 biomarkers in a single slide and enables immediate processing without the need for additional imaging rounds. Leveraging this, we outline an automated machine learning framework that enables rapid, deep phenotypic and spatial profiling of tissues at the subcellular level.

Methods Our framework consists of five steps, linked together using Apache Airflow with Kubernetes. The five steps are: 1) Background correction, 2) Cell and region segmentation, 3) Cell classification, 4) Expression quantification, and 5) Spatial analysis. Background correction defines each channel in the staining panel by ensuring that there are no image artifacts that will interfere with subsequent steps. Segmentation is based on deep learning models that leverage multiple biomarker channels to delineate cells, including challenging ones that lack dsDNA signal in the plane of imaging. Cell classification uses deep learning models that leverage staining patterns alongside known phenotypic hierarchies to first define major cell lineages, then further divide them into specific sub phenotypes. Expression quantification calculates the expression levels for each checkpoint or inducible marker of interest and computes counts and densities of each cell phenotype. Lastly, spatial analysis allows for the quantitation of immune infiltration and various cell-to-cell and cell-to-region proximity features.

Results We demonstrate end-to-end analysis of multiple tissue types with diverse morphology and tissue architecture. The robust algorithms adapt to a wide range of tissue background and noise and achieve a high degree of accuracy in segmentation and classification. This obviates the need for multiple iterations and parameter tuning to optimize algorithm performance. The high-quality results generated by the framework have been used to discover interesting associations and spatial patterns of immune cells in the tumor microenvironment.

Conclusions We introduce an automated machine learning based framework for deep tissue profiling from MIBI images. The combination of pre-trained deep learning models connected through Airflow's directed acyclic graphs on a Kubernetes cluster, leads to a rapid and scalable bioinformatics solution for MIBI images that can be used to uncover novel biology.

Acknowledgements The authors would like to acknowledge Ablimit Keskin and Murat Aksoy for their contributions to the development of the framework.

1295 SYSTEMS BIOLOGY ANALYSIS OF ANTI-TUMOR IMMUNITY

[1]Mohammad Nikmaneshi*, [2]James Baish, [1]Timothy Padera, [1]Lance Munn. [1]*Massachusetts General Hospital, Boston, MA, USA*; [2]*Bucknell University, Lewisburg, PA, USA*

Background Initiation of an immune response requires activation of one or more naïve T cells. Each naïve T cell has a unique T cell receptor, and these cells traffic through the blood and lymphatic vasculatures, visiting each of the ~500 lymph nodes in search of matching antigen. If a match is made, then the naïve T cell activates and proliferates. This process is potentially rate-limiting, given the few naive T cells capable of recognizing tumor antigen and the random nature of their entry into each lymph node. We propose that stochastic nature of this process affects the probability of T cell activation and may contribute to the poor response to ICB therapy seen in most patients.

Methods Here, we use multiscale computational modeling to identify potential reasons for clinical failure of immune checkpoint therapies and develop strategies for improving naïve T cell activation and tumor killing. The model provides a mechanistic framework for optimizing cancer immunotherapy and developing testable solutions to unleash anti-tumor immune responses for more patients with cancer.

Results The results show that tumor antigen production rate is a critical parameter, and that patients with low tumor antigen production rate need additional treatment to enhance antigen level and improve immune checkpoint inhibition therapy.

Conclusions The co-localization of antigen with appropriate naive T cells is a critical step in immune activation, and affects the anti-tumor response in the context of immune checkpoint therapy.

1296 RADIOMICS-BASED MULTI-MODAL PREDICTION OF TREATMENT RESPONSE TO PD-1/PD-L1 IMMUNE CHECKPOINT INHIBITOR (ICI) THERAPY IN STAGE IV NON-SMALL CELL LUNG CARCINOMA (MNSCLC)

Background Currently approved biomarkers that predict response to ICIs in mNSCLC are limited to PD-L1 expression levels by immunohistochemistry (IHC) and tumor mutation burden (TMB). However, the predictive performance of PD-L1 IHC and TMB are limited, and rates of testing are suboptimal. Radiomic biomarkers may offer an automated and scalable method to predict ICI response.[1,2] We developed and validated multi-modal models predicting responses to ICIs in mNSCLC. In contrast to previously published models, our work focuses on generalizable models using a large multi-institutional "real-world" dataset and combines radiomics features with demographic, molecular, and laboratory values routinely available in patients' electronic medical records [EMR].

Methods We analyzed radiomic characteristics of 6,028 primary and metastatic lesions from 1,169 mNSCLC patients treated with anti-PD-1/anti-PD-L1 ICIs from 8 institutions across the US and Europe. Data were randomly split into training (N=707 patients, n=3,625 lesions) and validation (N=462 patients, n=2,403 lesions) sets. Baseline and follow-up CT scans were manually annotated by board-certified radiologists using RECIST 1.1 criteria and all lesion volumes were manually segmented. We developed two predictive models using gradient-boosted decision tree algorithms, using 1) only manually curated baseline radiomic features quantifying textural heterogeneity and spicularity; and 2) a multi-modal model with radiomic features combined with known demographic, molecular (e.g. PD-L1 IHC), and laboratory (e.g. neutrophil-to-lymphocyte ratio) predictors of ICI response. Primary endpoints were 3- and 6-month radiological progression, defined by a 20% increase in lesion diameter. The primary evaluation metric was the area under the receiver operating characteristic curve (AUC). Models predicting response of lung lesions and lymph nodes were validated on two cohorts: ICI monotherapy and ICI plus concurrent chemotherapy. Patients with unavailable PD-L1 IHC, imaging follow-up, or oncogenic driver mutations were excluded from analysis.

Results The radiomics model showed predictive accuracy comparable to tissue-based PD-L1 IHC for both endpoints and patient cohorts (tables 1, 2). However, the multi-modal model predicted lung and lymph node radiological progression with significantly higher AUC than PD-L1 IHC in all cohorts and endpoints, with 3- and 6-month progression AUCs of 0.86 (P=.00007) and 0.79 (P= .00001) in lung lesions and 0.78 (P=.003) and 0.80 (P=.002) in lymph nodes.

Conclusions Radiomics-based multi-modal prediction of ICI response is feasible and accurate and may provide an opportunity for more personalized management, such as risk-based escalation/de-escalation of concurrent chemotherapy in mNSCLC patients. We will evaluate this methodology in prospective studies.

Ethics Approval Ethics approval for US data:

The study was conducted under IRB-approved procedures using de-identified data for patients diagnosed with Stage-IV NSCLC and treated between Jan. 1, 2017 and December 31, 2021. All records were de-identified per HIPAA guidelines at the institution level. Upon transfer, the data was quarantined and then re-inspected by authorized personnel prior to ingestion to ensure compliance and that no PHI was present in the records.

Ethics approval for EU data:

The study was conducted under IRB-approved procedures using de-identified data for patients diagnosed with Stage-IV NSCLC and treated between Jan. 1, 2017 and December 31, 2021. All records were de-identified per GDPR requirements at the institution level. The patients were also notified that their de-identified data would be part of a study and were given the required time and opportunity to respond if they had any objection. Upon transfer, the data was quarantined and then re-inspected by authorized personnel prior to processing to ensure compliance and that no PHI was present in the records.

1297 UNCOVERING THE HIDDEN STRUCTURE OF T CELL COMPOSITIONS IN PERIPHERAL BLOOD AFTER IMMUNE CHECKPOINT INHIBITOR

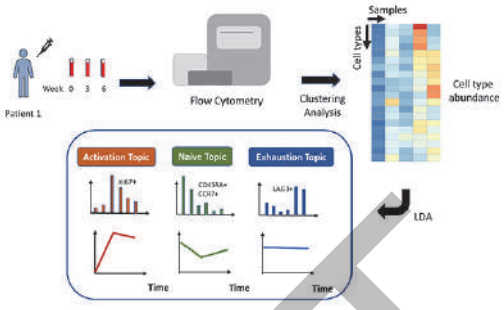
Xiyu Peng*, Jasme Lee, Matthew Adamow, Colleen Maher, Margaret Callahan, Katherine Panageas, Ronglai Shen. *Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background Immune checkpoint inhibitors (ICIs) are a promising treatment option for many cancer patients, however heterogeneous outcomes within and across cancer types are a challenge in guiding treatment decisions. Additional biomarkers to guide the selective use of ICI would address an unmet clinical need. We have shown that pre-treatment peripheral blood immune characteristics detected by flow cytometry are related to clinical outcomes after ICI[1]. Our goal is to further mine high-parameter flow cytometry data from blood samples obtained longitudinally during ICI treatment to explore ICI's immunological mechanisms and pharmacodynamics in cancer patients. However, the current field lacks effective statistical and computational approaches to take full advantage of this complex dataset.

Methods We adapt a Latent Dirichlet Allocation (LDA) model, widely applied for topic discovery in text mining analysis, to explore the temporal evolution of T cell compositions from longitudinal single-cell flow cytometry data (figure 1). The LDA model considers cells as words, patient samples as documents, and biological processes as topics. With an analysis involving ~17 million T cells obtained from 138 pre- and on-treatment samples, we show the model's utility in delineating immune cell compositions and tracking dynamic changes over time in the peripheral blood from a cohort of 51 melanoma patients receiving combination CTLA-4 and PD-1 blockade. Without providing prior domain knowledge, LDA explores the hidden structure and identifies latent topics with great interpretability, allowing the discovery of possible clinical biomarkers.

Results We applied LDA and identified three latent topics in an unsupervised fashion; based on the topic contents, we labeled them the activation topic, naive topic, and exhaustion topic. The activation topic is mainly contributed by memory T cell clusters, which capture the major pattern of T cell expansion after ICI. The naive and exhaustion topics consist of naive T cell clusters and terminally differentiated T cell clusters, respectively. Patients with a large proportion of naive topics were shown to be more likely to experience severe ICI-related toxicity ($P = 0.02$). Moreover, the exhaustion topic is strongly related to the LAG+ immunotype, which has been linked to poor clinical outcomes in the earlier study[1].

Conclusions Here, we present a novel statistical and computational framework for investigating temporal dynamics of T cell compositions with the potential to characterize pharmacodynamics under ICI. We demonstrated LDA is effective in deconvoluting the high-parameter flow cytometry data and characterizes immunological topics that provide novel biological insights.



Abstract 1297 Figure 1 LDA reveals hidden structures in flow cytometry data

1298 A WEAKLY SUPERVISED DEEP LEARNING FRAMEWORK TO PREDICT KRAS-STK11 AND KRAS-TP53 CO-MUTATIONS IN LUNG ADENOCARCINOMAS USING H&E TISSUE SECTIONS

[1]Daniel Jiménez-Sánchez*, [1]Carlos De Andrea, [1]Álvaro López-Janeiro, [1]Maria D Lozano, [2]Carlos Ortiz-de-Solórzano, [1]Aida Romano-Martínez, [1]Cristina Sainz, [2]Luis Montuenga, [1]Ignacio Melero, [2]Ruben Pio. *[1]Clínica Universidad de Navarra, Pamplona, Spain*; *[2]Cima-University of Navarra, Pamplona, Spain*

Background Lung adenocarcinomas (LUAD) with co-mutations in KRAS (K-only) and the SKT11/LKB1 (KS) or TP53 (KP) genes define patient subgroups with distinct responses to anti-PD1/PD-L1 immunotherapy. In fact, multicentric studies showed that objective response rates to PD-1 blockade differed significantly among KS (7.4%), KP (35.7%), and K-only (28.6%) subgroups.[1] The association of such specific genetic profiling with morphological patterns assessed on routine H&E tissue slides may contribute to a better selection for personalized immunotherapy treatments.[2]

Methods We developed a weakly supervised deep learning[3] (WSDL) model to predict the mutational status of LUAD patients using routine H&E tissue slides. N=125 KRAS-mutated patients with genomic profile available were obtained from two public databases (CPTAC[4] and TCGA)[5] and one in-house cohort (Clinica Universidad de Navarra). 59 patients were K-only, 36 KS, and 30 KP. Our developed model was composed of two neural networks. A convolutional neural network that learns cellular features from 90x90 pixel image patches unsupervisedly, and a graph neural network that learns patient-specific patterns using only the patient mutational status. Abundances of these patterns predict the patient´s mutation type. To assess the predictive value of our WSDL model a five-fold cross-validation scheme was used. A Mann-Whitney test was applied to associate learned tissue patterns with patient mutations.

Results Figure 1(a) shows the ROC curves of the model for predicting patient co-mutations. AUC for K-only vs. KP mutations was 0.76 with a 95% CI of [0.66,0.86]. AUC for K-only vs. KS was 0.64 with a 95% CI of [0.54,0.75]. KP vs. KS was 0.78 with a 95% CI of [0.67,0.88]. Figure 1(b) shows, as an example, four WSDL-identified tissue patterns consisting of image patches containing acinar tumor, acinar tumor margin, stromal lymphocytes, and stroma. Figure 1(c) shows abundances of the total of tissue patterns learned showing the complex tumor heterogeneity across patient co-mutations. Figure 1(d) shows a tumoral stroma with absence of immune infiltration pattern that was associated with KS compared to KP (p=0.046). Figure 1(e) shows a mucinous pattern and tumor glands more frequent in KS compared to KP and K-only (p=0.008 and p=0.013, respectively).

Conclusions WSDL learns tissue patterns without the requirement of manual expert annotations, potentially revealing previously unappreciated or underappreciated facets of the tumor linked to specific mutation types. This model can be especially useful in complex tasks such as the determination of LUAD co-mutations from H&E tissue slides. A validation study in two independent cohorts is ongoing.

1299 PREDICTING CD8+ CELL DENSITY AND TUMOR-IMMUNE PHENOTYPES IN NON-SMALL-CELL LUNG CANCER (NSCLC) FROM STANDARD H&E SLIDES USING DEEP LEARNING (DL)

[1]David Soong*, [2]Becky Arbiv, [2]Ettai Markovits, [2]Alon Groisman, [2]Yuval Shachaf, [2]Tomer Dicker, [2]Yoni Yedidia, [1]Hisham Hamadeh, [1]Kate Sasser, [2]Gali Golan, [1]Brandon Higgs, [1]Suzana Couto, [2]Ori Zelichov. *[1]Genmab, Princeton, NJ, USA; [2]Nucleai, Tel Aviv, Israel*

Background Tumor infiltrated lymphocytes (TIL), namely CD8 + TILs play a major role in antitumor immunity and tumor cell eradication. High-density infiltration of CD8+ cells in the tumor, in contrast to CD8+ cell excluded regions, is associated with improved prognosis and response to immunotherapy in multiple cancer types, however, CD8 evaluations require IHC staining, often not performed routinely in clinical practice. Here, we used DL to predict CD8+ cell density and immune phenotypes from standard H&E slides.

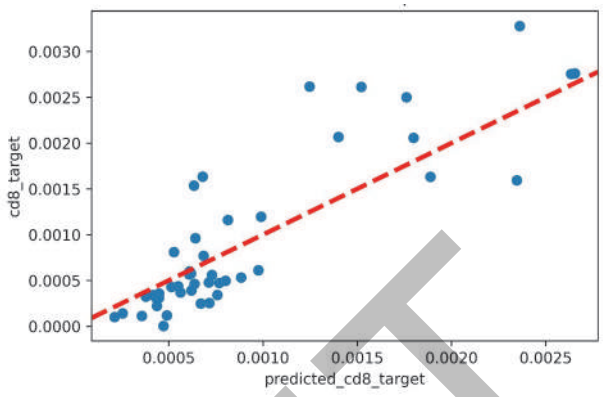
Methods 188 pairs of H&E slide and a sequential CD8 stained slide from 103 patients with metastatic NSCLC were procured. DL models were trained to classify tumor cells, lymphocytes, fibroblasts, and tumor versus stromal areas on H&E, as well as positivity of CD8 per cell by IHC. 354 spatial features were calculated from the H&E slides and CD8+ density in the whole tumor region from IHC slides. A training (n=143) and test (n=45) cohort was created and linear regression modeling predicted CD8 density from H&E features. Two board certified pathologists classified IHC slides into immune phenotypes: inflamed, desert and excluded, based on CD8 density (table 1) and a multinomial logistic regression model was train to predicet these phenotypes from the H&E images.

Results The H&E features most predictive of CD8 density were related to lymphocyte densities, tumor-lymphocyte proximity in the invasive margin, and lymphocyte density in the tumor area. Correlation using this 3 H&E feature model on the test set was r=0.87 (p<0.0001, figure 1). The H&E features most predictive to immune phenotype were proximity between lymphocytes and tumor cells or granulocytes, as well as lymphocyte:fibroblast density ratio. Model accuracy on the test set reached an accuracy of 74% (95% CI 57%-85%, p<0.0001) in classifying slides to the correct immune phenotypes.

Conclusions Spatial analysis of immune and tumor cells from standard H&E slides using DL can accurately predict CD8 cell density and identify immune phenotypes. By only requiring H&E images, these biomarkers important for checkpoint inhibitor therapy can be measured in clinical practice without the requirement of IHC staining.

Abstract 1299 Table 1 Criteria for Immune Phenotyping

Immune phenotype	Criteria
Inflamed	Density of CD8 positive lymphocytes in the tumor cell area > 5%
Excluded	CD8+ lymphocyte presence in >50% of the invasive margin in a non-inflamed slide
Desert	Criteria for inflamed or excluded do not apply



Abstract 1299 Figure 1 Correlation between test set predicted CD8 density from H&E analysis and real test set CD8 density calculated on IHC slides

1300 CT SCAN NORMALIZATION TO IMPROVE RADIOMICS GENERALIZABILITY AND ASSESS PROGRESSION-FREE SURVIVAL IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER TREATED WITH IMMUNE CHECKPOINT INHIBITORS: A MULTICENTRIC STUDY

[1]Marion Tonneau*, [2]Kim Phan, [2]Cécile Low-Kam, [2]Francis Dutil, [3]Suzanne Kazandjian, [4]Davy Vanderweyen, [3]Justin Panasci, [1]Julie Malo, [5]François Coulombe, [1]Arielle Elkrief, [1]Wiam Belkaïd, [2]Lisa Di Jorio, [5]Michèle Orain, [6]Nicole Bouchard, [3]Thierry Muanza, [2]Kam Kafi, [2]Florent Chandelier, [5]Philippe Joubert, [1]Bertrand Routy. *[1]CRCHUM, Montréal, Canada; [2]Imagia Canexia Health, Montreal, Canada; [3]Jewish General Hospital, Montreal, Canada; [4]Centre Hospitalier de Sherbrooke, Sherbrooke, Canada; [5]IUCPQ, Québec, Canada; [6]CHUS, Sherbrooke, Canada*

Background Recent development in the field of artificial intelligence suggests that radiomics may represent a promising non-invasive biomarker to predict response to immune checkpoint inhibitors (ICI). Nevertheless, validation of radiomics algorithms in independent cohorts remains a challenge in part due to variations in image acquisition and reconstruction. Using radiomics as a biomarker for ICI response in non-small cell lung cancer (NSCLC) patients, we investigated the importance of scan normalization as part of a broader statistical framework to enable model external generalizability.

Methods Discovery cohort was composed of pre-ICI CT scans of 514 advanced NSCLC patients from three academic centers (n=223 CHUM, n=130 JGH and n=161 IUCPQ). A validation cohort included 144 patients from a fourth center (CHUS). Power calculation for the validation cohort was determined with an AUC threshold of 0.67 in the discovery cohort to predict progression-free survival at 6 months (PFS-6), alpha-risk was 0.10, leading to n=140 patients. Radiomics features were extracted from original clinical scans using the established open source PyRadiomics, and a proprietary DeepRadiomics technology (leveraging deep learning). We harmonized images to account for variations in reconstruction kernels, slice thicknesses, and device manufacturers. Multivariable models, evaluated using leave-one-center-out cross validation, were used to estimate the predictive value of clinical variables (ECOG, line of treatment, stage, smoking), PD-L1 expression, and PyRadiomics or DeepRadiomics for PFS-6.

Results In this cohort, the best prognostic factor for PFS-6 excluding radiomics, was combination of clinical + PD-L1 expression with an AUC of 0.66 and 0.62 in the discovery and validation cohort. Without image harmonization, combining clinical + PyRadiomics or DeepRadiomics, AUC were 0.69 and 0.69 respectively in the discovery cohort, but depicting significant drops to 0.57 and 0.52, respectively in the validation cohort. This lack of generalizability was consistent with observations in principal component analysis clustering by center. Subsequently, image harmonization eliminated these clusters and when combining clinical + DeepRadiomics model, we obtained an AUC of 0.67 and 0.63 in the discovery and validation cohort, respectively. The combination of clinical + PyRadiomics failed generalizability validations, with AUC of 0.66 and 0.59, without improvement with the addition of PD-L1 (table 1).

Conclusions We demonstrated that a risk prediction model that combined clinical + DeepRadiomics was generalizable and had similar performances to clinical + PD-L1, when scan harmonization methods were in place. Altogether, this study showed the strong potential of radiomics as a future non-invasive strategy to predict ICI response in advanced NSCLC.

Ethics Approval Number of the approval: MP-02-2019-8091

1301 CONDITIONAL BISPECIFIC T CELL ENGAGER DESIGN AND DOSING OPTIMIZATION VIA MECHANISTIC MODELING

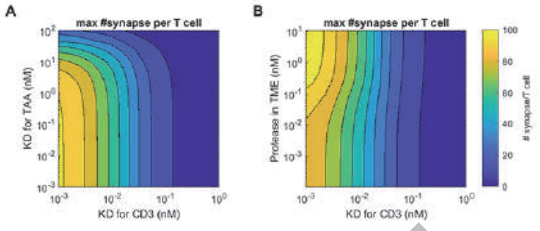
Jess Wu*, Michael Vilkhovoy, Sara Shum, Johara Chouitar, Patrick LeRoy, Leticia Fridman, Eilene Kwok, Glendon Wu, Matyas Ecsedi, Antara Banerjee, Dean Bottino. *Takeda Pharmaceuticals, Inc., San Diego, CA, USA*

Background Conditionally activated bispecific T cell engagers (TCEs) have the potential to provide a larger therapeutic window by reducing off-site on-target toxicity. Conditionally Bispecific Redirected Activation (COBRAs) are novel TCEs designed to be activated preferentially in the tumor microenvironment (TME).[1,2] The conditionality of the COBRA prodrug is mediated upon binding of the high affinity target binding domain to the tumor antigen and by cleavage of the prodrug by matrix metalloproteases such as MMP9/2. The cleavage of the prodrug results in the release of the inactive CD3e VH/VL domains leading to the formation of the active dimer, responsible for tumor killing. In order to understand the dependence of treatment effect on drug and patient properties for this novel modality, we developed a mathematical model of COBRA's mechanism of action.

Methods A mechanistic model was developed to describe the preclinical pharmacokinetics, target engagement and immune synapse formation in the TME, and tumor volume change due to resulting T-cell dependent tumor cell-mediated cytotoxicity (TDCC). Unknown parameters were optimized using *in vitro* TDCC data and *in vivo* efficacy data. Sensitivity analyses were conducted to investigate the influence of molecule- and TME-specific characteristics on synapse formation and treatment effect.

Results The model recapitulates the experimental data *in vitro* and *in vivo*. We used the model to identify parameters that govern the synapse formation and treatment outcome, such as COBRA affinity to TAA and CD3 (figure 1A), and the active protease concentration in the TME (figure 1B). The model also suggests that the drug-induced antigen internalization along with the abundance of target cells and effector T cells can impact the predicted treatment effect of COBRA and that COBRA concentration-synapse formation relationship does not exhibit the bell-shaped TCE concentration-synapse profile due to its conditionality on homodimerization once cleaved.

Conclusions The model framework was used to integrate preclinical datasets and project the short-term treatment response in human. This work demonstrates the impact of conditionality of the COBRA design on its dose-response relationship. Importantly, factors such as target abundances and protease activity in the TME can strongly influence synapse formation and the resulting anti-tumor effect, and therefore may serve as baseline biomarkers for patient stratification.



Abstract 1301 Figure 1 Local sensitivity analysis showing the effect on the maximal number of synapses formed by varying KD for CD3 and A) KD for the TAA or B) the active protease concentration in the TME

1302 SPATIAL ANALYSIS OF THE TUMOR MICROENVIRONMENT USING MACHINE LEARNING-ENABLED INTEGRATED MORPHOLOGY-TRANSCRIPTOMIC CELL PHENOTYPES

[1]Wei Yan*, [1]Nga Luong, [2]Jeffrey Lim, [2]Yuezhen Xue, [1]Abu Bakr Azam, [2]Joe Poh Sheng Yeong, [2]Mai Chan Lau, [1]Yiyu Cai. *[1]Nanyang Technological University, Singapore, Singapore; [2]Institute of Molecular and Cell Biology, Singapore, Singapore*

Background In recent years, immunotherapy has advanced the cancer field by achieving more durable patient response with a relatively tolerable toxicity. However, the overall response rates remain low (< 20%),[1] mainly due to a lack of understanding of the underlying tumor-immune interactions that determine patient responsiveness. Existing tissue-based assays are restricted to dozens of known transcriptomic or proteomic markers, limiting their usefulness in generating new immunological insights. While recently emerged spatial transcriptomics (ST) technology enables an unbiased whole-transcriptomic profiling, it does not provide single-cell resolution read-outs,[2] leading to potential masking of rare cell signals and loss of cell-to-cell spatial information. Here, we propose a machine learning (ML) approach to characterize single-cell phenotypic traits, through integrating haematoxylin and eosin (H&E) histology and ST data.

Methods One tumor and one adjacent-normal tissue section collected from a hepatocellular carcinoma (HCC) patient were profiled using 10× Visium ST platform. Using the companion H&E image, tissue regions were categorized as tumor epithelium and stroma, and individual cells were segmented (StarDist) with 53 histological features extracted (QuPath v0.3.2). Unsupervised cell clustering and cluster-specific gene signatures were determined simultaneously whereby genetic algorithm was used for feature selection and gene signatures were obtained by deconvoluting ST. Optimal clustering results were determined through maximizing clustering quality and cell-type specificity for individual clusters, where single-sample gene set enrichment on PanglaoDB database was used for cell-type annotation.

Results More immune cells infiltrated into epithelium in the adjacent-normal tissue (18.2% of total 17,480 stromal cells) as compared to that of the tumor tissue (11.6% of total 10,807 stromal cells). Cell clusters with strong T-cell and B-cell signatures were detected in both tissues (figure 1), with higher tumor infiltration in the adjacent-normal tissue (~16% of the total T or B cells, respectively; figure 2) than in the tumor tissue (~5% of the total T or B cells, respectively). Despite the same morphological feature, i.e., nucleus-to-cell area ratio, was selected in both tissues, comparable values were observed in T and B-cells (~0.56) within the adjacent-normal tissue, whereas an average higher area ratio of B-cells (~0.52) than T-cells (~0.47) within the tumor tissue (figure 3).

Conclusions Our data suggests that, during tumorigenesis, T-cells might undergo morphological changes, and reduced T and B-cells infiltration into the epithelium. Our proposed ML approach not only allows single-cell spatial analysis of tumor-immune interactions, but also provides more refined cell phenotypes defined by both morphology and transcriptomic features.

1303 PREDICTION OF BEST RESPONSE FOR NSCLC PATIENTS RECEIVING IMMUNOTHERAPY BY MACHINE LEARNING MODELS

[1]Yili Zhang*, [1]Samir Gupta, [1]Anas Belouali, [1]Shaked Lev-Ari, [2]Neil Shah, [1]Kanchi Krishnamurthy, [1]Micheal Serzan, [1]Adil Alaoui, [1]Peter McGarvey, [1]Michael Atkins, [1]Subha Madhavan. *[1]Georgetown University, Washington DC, DC, USA; [2]Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background Immune checkpoint inhibitors (ICIs) have been used to treat many distinct cancers, including non-small cell lung cancer (NSCLC). Better tools are needed to predict which patients will benefit from ICI therapy. This study aims to use machine learning (ML) models to predict the tumor response of patients with NSCLC to immunotherapy.

Methods The Georgetown-Lombardi Comprehensive Cancer Center has developed a centralized Immuno-Oncology (IO) registry encompassing patients treated with ICI within the MedStar Health hospital system from 2011 until April 2018. Data on demographics, immunotherapy information, and lab tests after diagnosis for 220 NSCLC patients were collected from the registry. Responses included complete response (CR), partial response (PR), progressive disease (PD), and stable disease (SD) at 12 weeks from starting the immunotherapy. In this study, we predicted if patients responded to the immunotherapy (CR and PR) or not (PD and SD). Ten ML models were employed for binary prediction with five-fold cross-validation adopted. The area under the receiver-operating curve (AUROC) was used to assess ML model, and important features affecting the model were subsequently analyzed.

Results Among curated patients, 74 (33.64%) responded to the immunotherapy. Nivolumab was used in 107 (48.38%) patients, followed by carboplatin + pembrolizumab + pemetrexed in 20 (9.09%) patients. Ten ML models were performed such as logistic regression, support vector machine, naive Bayesian (NB), random forest, and Bernoulli NB. The AUROC values for the top three performing models were logistic regression (77.91%), naive Bayesian (73.93%), and random forest (73.88%). The 3 most important features selected from the logistic regression model are A/G ratio, line of therapy, and pre-treatment ECOG PS. Features considered unimportant include age, sex, BMI, ALT (SGPT), AST (SGOT).

Conclusions This study leveraged ML algorithms to predict the tumor response to ICI therapy for patients with NSCLC. This novel approach utilizing EMR in the computational models can help predict the outcome of ICI therapy in patients with NSCLC. The best prediction model had an AUROC score of 77.91%. The limitations of this study are the relatively small sample size and the lack of molecular information. These will be addressed with the updating and expansion of the IO registry participation of other institutions and linking to a growing collection of omics data together leading to more robust ML models.

Microbiome and Other Environmental Factors

1304 DIETARY PATTERNS ASSOCIATED WITH INCREASED ABUNDANCE OF *AKKERMANSIA MUCINIPHILA* POTENTIATES ANTI-PD-L1 IMMUNE CHECKPOINT BLOCKADE RESPONSE IN TRIPLE-NEGATIVE BREAST CANCER

Kenysha Clear*, Elizabeth Stirling, Adam Wilson, David Soto-Pantoja, Katherine Cook. *Wake Forest School of Medicine, Winston-Salem, NC, USA*

Background Immune checkpoint blockade (ICB) therapies targeting programmed cell death protein 1 pathway (PD-1/PD-L1) have advantageously impacted triple-negative breast cancer (TNBC) patient survival; however, there remains a need to improve responses. Recent studies associated gut *Akkermansia muciniphila* as an ICB-response related microbe in other cancer types. As diet is a main modifier of the gut microbiome, we investigated whether diet-gut microbiome interactions potentiate ICB response in TNBC.

Methods Using EMT-6 (n=5-7/group) and E0771 (n=8-10/group) syngeneic models of TNBC, tumor-bearing mice consuming low-fat control, high-fat Western, or a Mediterranean diet were treated with 200 μg of IgG or anti-PD-L1 antibodies and response to therapy was determined by tumor progression. To assess modulation on the gut bacterial microbiome by diet and ICB, 3M read depth metagenomic sequencing was performed on DNA isolated from fecal samples from both models. To further implicate the microbiome, we performed a fecal microbiota transplant (FMT) model (n=8-10/group), where mice consuming a control diet were supplemented via oral gavage with either a control diet-derived FMT, a Western diet-derived FMT, or Mediterranean diet-derived FMT. EMT-6 bearing-mice on each FMT were treated with IgG or PD-L1. Immune response (F4/80 macrophages, granzyme B, and CD8 + cytotoxic T cell infiltrate) in the tumor microenvironment (TME) were examined in residual tumor tissue by immunohistochemistry (n=9/group). Regulation of PD-L1 protein by diet was assessed by Western blot hybridization in tumor sample lysates (n=3/group). Short chain fatty acid (SCFA) analysis was measured in plasma (n=8/group) by LC/MS-MS metabolomics.

Results In EMT-6 bearing-mice, PD-L1 treatment and consumption of a Western or Mediterranean diet significantly reduced both tumor volume and tumor weight when compared to control diet-fed mice ($p<0.05$). In E0771 bearing-mice, consumption of a Western diet and PD-L1 treatment resulted in a modest increase in ICB response (56%), with the highest efficacy observed in Mediterranean diet-fed mice (70%), when compared with IgG control animals. Western and Mediterranean-fed mice displayed a 25-45% increase in gut *Akkermansia muciniphila* proportional abundance. Anti-PD-L1 therapy in mice given an *A. muciniphila* enriched FMT showed enhanced ICB responsiveness ($p<0.05$, 70-80%). Mediterranean-diet fed animals treated with anti-PD-L1 antibodies showed elevated plasma butyrate SCFA metabolites. E0771 model results show Western and Mediterranean diet intake regulated expression of PD-L1, macrophages, and cytotoxic T cell function proteins in the TME.

Conclusions Taken together, these data indicate PD-L1 response in TNBC is potentiated by diet-microbiota interactions and suggests increasing levels of *Akkermansia* may enhance ICB efficacy.

1305 IMPACT OF TET2-MUTANT CLONAL HEMATOPOIESIS ON SOLID TUMOR IMMUNOLOGY AND RESPONSE TO CHECKPOINT BLOCKADE

Shelley Herbrich*, Swetha Anandhan, Padmanee Sharma. *MD Anderson Cancer Center, Houston, TX, USA*

Background Clonal hematopoiesis (CH) is an age-related phenomenon characterized by the overrepresentation of blood cells arising from a single, mutant clone and is detectable in 10-20% of individuals over 70.[1] CH has now been implicated in a variety of non-hematological disorders, such as cardiovascular diseases and Covid-19 infections, by exacerbating the innate inflammatory response.[2-4] However, the impact of CH in solid tumors and response to immune checkpoint blockade (ICB) is unknown.

Methods To assess the prevalence and role of CH in patients with solid tumors, we analyzed publicly available data from the MSKCC-IMPACT study.[5, 6] To mechanistically study CH in solid tumors, we established an orthotopic model of pancreatic adenocarcinoma (PDAC) in mice with *Tet2*$^{+/-}$ CH. CH and WT mice were treated with either ICB (αCTLA-4 + αPD-1) or vehicle control. Single-cell (sc-) RNAseq was performed on tumor infiltrating lymphocytes (n=3/group) while remaining mice were observed for disease progression and overall survival (n=10/group).

Results Analyzing CH frequencies in a cohort of patients with solid tumors, we observed that the prevalence of CH was approximately 5 times higher in patients with cancer when compared to healthy age-matched controls. Further, patients with detectable CH clones had significantly worse overall survival (figure 1A). *In vivo*, sc-RNAseq data revealed that myeloid cells present within the pancreatic tumors of mice with *Tet2*$^{+/-}$ CH were significantly enriched for both type I and type II interferon (IFN) signaling (figure 1B). Further, these IFN+ myeloid cells were ablated after ICB therapy in *Tet2*$^{+/+}$ WT mice but persisted in mice with *Tet2*$^{+/-}$ CH (figure 1C). PDAC tumors from mice with *Tet2*$^{+/-}$ CH had approximately half the total number of infiltrating CD8 T cells at baseline when compared to those from *Tet2*$^{+/+}$ WT mice. Upon ICB treatment, CD8 effector cells only expanded in the tumors from *Tet2*$^{+/+}$ WT mice. Functionally, this translated to more rapidly progressing tumors, resistance to ICB, and reduced overall survival in mice with *Tet2*$^{+/-}$ CH (figure 1D).

Conclusions CH is present in upwards of 30% of patients with solid tumors and is associated with significantly worsened prognosis. Modeling PDAC in the presence of *Tet2*$^{+/-}$ CH *in vivo* revealed distinct alterations in the tumor microenvironment that ultimately influenced tumor progression and response to ICB. This proposed research bridges the fields of solid tumor immunology and clonal hematopoiesis to address novel mechanisms of immunotherapy resistance that will span cancer type and, ultimately, improve patient care.

1306 PREVENTION OF ANTIBIOTIC-INDUCED DYSBIOSIS IN HUMAN VOLUNTEERS BY DAV132 AND PRESERVATION OF RESPONSIVENESS TO ANTI-PD-1 THERAPY DEMONSTRATED BY TRANSPLANTATION OF HUMAN FECES INTO TUMOR-BEARING MICE

[1]Meriem Messaoudene*, [2]Nathalie Saint-Lu, [2]Frédérique Sablier-Gallis, [2]Stéphanie Ferreira, [2]Clément Le Bescop, [2]Thomas Loppinet, [1]Mayra Ponce, [3]Céline Féger, [2]Antoine Andremont, [2]Jean De Gunzburg, [1]Bertrand Routy. *[1]CRCHUM – Centre de recherche du CHUM, Montreal, Canada; [2]Da Volterra, Paris, France; [3]EMI Biotech, Paris, France*

Background Antibiotics (ATB) induce intestinal dysbiosis and decrease the efficacy of immune checkpoint inhibitors (ICI).[1,2] DAV132 is an orally administered colon-targeted ATB adsorbent designed to prevent ATB-induced dysbiosis.[3] We investigated whether DAV132 co-administered with ATB could protect gut microbiota diversity and composition. Moreover, in murine avatar tumor model, we assessed anti-PD-1 efficacy through fecal microbiota transplantation (FMT) in germ-free (GF) or antibiotic-treated specific pathogen-free (SPF) mice.

Methods Twenty-four human healthy volunteers (HV) were randomized to receive either ceftazidime-avibactam (CZA, 2g/0.5g q8h IV for 5 days) or CZA+DAV132 (12g PO tid for 7 days). CZA plasmatic and fecal pharmacodynamic levels were measured using HPLC-MS/MS. Microbiome was profiled with 16S and shotgun metagenomics at different timepoints. FMT in GF or ATB-treated SPF mice was performed using fecal samples from 3 HV and 2 HV respectively, in each group before (D1) or after 6 days (D6) of CZA+/-DAV132; subsequently mice were inoculated with MCA-205 tumor and treated intraperitoneally with anti-PD-1, 4 times every 3 days. Immunological population of tumor infiltrating lymphocytes were analyzed by flow cytometry.

Results DAV132 did not impact plasmatic CZA concentrations, but significantly reduced ceftazidime concentration in feces compared to HV treated with CZA alone ($p<0.001$). DAV132 significantly prevented the reduction in microbiota alpha-diversity at D6 ($p=0.0019$) and was associated with a more rapid return to baseline microbiota composition (figure 1). Significantly more bacteria associated with better response to ICI were preserved in the DAV group compared to CZA, among which *Faecalibacterium praunistzii and* several *Alistipes spp*. FMT in GF mice transplanted with feces collected at D1 exhibited a significant anti-PD-1 activity. This anti-tumor response was inhibited in mice transplanted with D6 feces from any of the 3 CZA-treated HV. Conversely, the anti-tumor response was maintained in mice transplanted with D6 feces from any of the 3 HV treated with CZA + DAV132 (figure 2). Similar results were observed upon FMT using samples from HVs into ATB-treated SPF mice. Flow cytometry on tumor T cell infiltrates demonstrated that CZA decreased $CD8^+$T cell infiltration and $CD8^+$/Tregulatory ratio, compared to CZA + DAV132 treated HVs (figure 3).

Conclusions DAV132 strongly prevented CZA-induced dysbiosis in HV without influencing plasmatic concentrations. In avatar mice FMT from HV treated with CZA+DAV132 was able to preserve anti-PD-1 cancer efficacy. These results provide rationale to launch clinical trials combining DAV132 in patients on ATB amenable to ICI.

1307 THE MICROBIOME-DERIVED METABOLITE TMAO DRIVES IMMUNE ACTIVATION AND BOOSTS RESPONSE TO IMMUNE CHECKPOINT BLOCKADE IN PANCREATIC CANCER

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1307

[1]Gauri Mirji*, [1]Alison Worth, [1]Sajad Bhat, [1]Mohamed El Sayed, [1]Toshitha Kannan, [1]Aaron Goldman, [1]Hsin Yao Tang, [1]Qin Liu, [1]Noam Auslander, [1]Chi Dang, [1]Mohamed Abdel-Mohsen, [1]Andrew Kossenkov, [2]Ben Stanger, [1]Rahul Shinde. *[1]Wistar Institute, Philadelphia, PA, USA; [2]University of Pennsylvania, Philadelphia, PA, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal cancer with poor prognosis. Although pancreatic tumors exhibit prominent leukocyte infiltrates, immunotherapy has so far failed to improve clinical outcomes in patients with PDAC. The immunotherapy responses can be improved through strategies that shift the PDAC tumor microenvironment (TME) from an immunosuppressive state to a more immune-activated state. The composition of the gut microbiome controls innate and adaptive immunity and has emerged as a key regulator of tumor growth and the success of immune checkpoint blockade (ICB) therapy. However, the underlying mechanisms remain unclear.

Methods The main objectives of this study were to elucidate how the gut microbe-derived metabolite trimethylamine N-oxide(TMAO) influences the host immune responses in PDAC TME, to determine if TMAO would synergize with immune checkpoint therapy to reduce tumor growth, and to assess whether there is a clinical correlation between TMAO production and survival in cancer patients. The overall design did employ some *in vitro* approaches but relied on *in vivo* mouse model systems, including orthotopic tumor implantation, to achieve the first two objectives; to test for a clinical correlation, we assessed datasets of bacterial species generated by three other groups. We employed flow cytometry and multiomic approaches to determine the impact of TMAO on phenotype of immune infiltrates in the TME.

Results Using a non-targeted, LC-MS/MS-based metabolomic screen, we identified that TMAO enhanced anti-tumor immunity to PDAC. Delivery of TMAO intraperitoneally or via a dietary choline supplement to orthotopic PDAC bearing mice reduced tumor growth and was associated with an immunostimulatory tumor-associated macrophage (TAM) phenotype and activated effector T cell response in the tumor microenvironment. Mechanistically, TMAO potentiated the type-I interferon (IFN) pathway and conferred anti-tumor effects in a type-I IFN-dependent manner. Notably, delivering TMAO-primed macrophages intravenously produced similar anti-tumor effects. Combining TMAO with ICB (anti-PD1 and/or anti-Tim3) in a mouse model of PDAC significantly reduced tumor burden and improved survival beyond TMAO or ICB alone. Finally, the levels of trimethylamine (TMA)-producing bacteria and of the CutC gene (an enzyme that generates TMA, the TMAO precursor) expression correlated with improved survival and response to anti-PD1 in cancer patients.

Conclusions Our study demonstrated that the microbial metabolite TMAO enabled TAMs to become immunogenic and promote effector T cell activity, transformed the TME to an immune activated state, and rendered PDAC sensitive to checkpoint immunotherapy, suggesting that strategies that alter levels of TMAO could be a promising clinical intervention to manage PDAC.

Ethics Approval Mouse experiments were performed following National Institutes of Health (NIH) guidelines and were approved by the Institutional Animal Care and Use Committee (IACUC) of The Wistar Institute.

1308 BACTERIA SPECIFIC IL-10 SECRETING T-CELLS DERIVED FROM THE GUT ARE CROSS-REACTIVE WITH TUMOR ANTIGENS AND ACCELERATE TUMOR GROWTH IN MOUSE MODELS

[1]Denise Cecil, [2]Jean Feng, [2]Alex Paynter, [2]Jessica Perry, [2]Noah Simon, [2]Nicholas Drovetto, [2]Lauren Corulli, [2]Erin Rodmaker, [3]Susan Strenk, [3]David Fredricks, [1]Mary Disis*. *[1]UW Medicine Cancer Vaccine Institute, Seattle, WA, USA; [2]University of Washington, Seattle, WA, USA; [3]Fred Hutch Cancer Center, Seattle, WA, USA*

Background We developed a method of CD4 epitope identification that includes selecting Class II interacting sequences via a multi-algorithm followed by functional phenotyping. We have evaluated 152 epitopes from 17 non-mutated tumor antigens (TA) and demonstrated Class II restricted epitopes could be identified which elicit either a selective Type I (IFN-gamma) or Type II (IL-10) response across multiple human PBMC (n=40). IL-10 inducing TA epitopes often shared a >50% identity and cross reactivity with multiple gut bacterial species. We questioned how prevalent these bacteria-tumor antigen (BAC-TA) cross reactive T-cells were in humans and whether these cells had any effects in cancer.

Methods IL-10 ELISPOT quantified BAC-TA T-cells in human PBMC, murine spleen, and tumor infiltrating lymphocytes (TIL). Human and murine T-cell lines were tested against bacteria, TA, and controls to show cross reactivity and specificity. Murine BAC-TA T-cells were used for adoptive transfer. T-cells were characterized by cytokine array, PCR, and flow cytometry. The C3(1)-Tag transgenic model of mammary cancer was used to assess effects of BAC-TA T-cells on tumor growth.

Results Measurable BAC-TA T-cells occurred in in up to 90% of PBMC. TA epitopes with the highest incidence of response shared significant sequence homologies with greater than 10 bacterial species. TA specific T-cell lines from multiple donors showed significant reactivity to homologous bacteria and recombinant TA protein, but not unrelated bacteria and protein. Human BAC-TA T-cells secreted IL-6 and IL-10, were memory T-cells, and expressed genes similar to intraepithelial lymphocytes. Similar BAC-TA T-cells were identified in mice. P. aeruginosa-specific T-cells generated from FVB mice secreted significantly more IL-10 when stimulated with the 70% homologous peptide YB1-p82-96 as compared to HIV peptide; p=0.0004. We implanted a syngeneic tumor cell line into C3 (1)-Tag. After tumor was established, fluorescently-labeled P. aeruginosa-YB1 specific T-cells were injected. Significantly increased florescence was seen in 100% of tumors and no fluorescence in mice injected with labeled naïve splenocytes (p<0.0001). Tumor volume 20 days after transfer was increased 55% in mice receiving P. aeruginosa/YB1-T-cells compared to splenocytes (p<0.0001). When C3(1)-Tag developed spontaneous tumors (500±75 mm^3) TIL analysis revealed numerous IL-10-secreting BAC-TA T-cells that had migrated from blood to tumor.

Conclusions A select group of bacteria are associated with the majority of homologies driving generation of BAC-TA T-cells. We have also identified bacteria never associated with TA homologies. These data lay the foundation for precision probiotics designed to reduce the BAC-TA memory T-cell pool.

1309 DIFFERENTIAL MICROBIAL ENRICHMENT IS ASSOCIATED WITH ORAL CANCER AND PERINEURAL INVASION

[1]August Culbert, [2]Adrian Chow, [3]Raad Gharaibah, [3]Naseer Sangwan, [3]Mohammed Dwidar, [2]Rachel Newsome, [3]Jin Dai, [3]Siming Ma, [2]Kristiann Fredenburg, [3]Emrullah Yilmaz, [3]Shlomo Koyfman, [3]Daniel McGrail, [3]Jamie Ku, [2]Christian Jobin, [1]Natalie Silver*. *[1]Cleveland Clinic Lerner College of Medicine, Cleveland, USA*; *[2]University of Florida, Gainesville, USA*; *[3]Cleveland Clinic, Cleveland, USA*

Background Advanced oral cavity squamous cell carcinoma (OSCC) is an aggressive disease, with 5-year overall survival rates below 50%.[1] While smoking and alcohol are the most established risk factors, there is growing evidence implicating the role of the oral microbiome in promoting immunosuppressive states in OSCC.[2-6] The objective of this study was to evaluate the taxonomic profile of oral bacteria in advanced OSCC patients and correlate with clinicopathologic features.

Methods The Institutional Review Board approved this prospective study of patients diagnosed with OSCC treated surgically from 2016-2020. Samples were taken from tumor and paired adjacent normal tissues at the time of surgery and snap frozen. Demographics, clinical and pathologic information was collected. DNA from 51 samples was isolated and 16s rRNA gene sequencing was performed after PCR amplification of the V1-V3 regions of the 16s rRNA gene for paired samples. 16S rRNA sequences were processed using DADA2, implemented in QIIME2 package, and taxonomic assignments were made using RDA classifier using the Human Oral Microbiome Database V15.22 as the reference database. Sequencing reads processing, denoising, dereplicating, chimeras filtering, and amplicon sequence variants (ASVs) generation was done using DADA2. The association between clinicopathological factors and bacterial profiles was evaluated using R Software.

Results In our cohort, the most common OSCC subtypes were oral tongue (47%) and floor of mouth (25.5%), with 83.4% of patients at advanced stage. The median age was 68 years old, and 84% were either current or former smokers. 16S rRNA gene sequencing and analysis revealed 9 ASVs that were significantly enriched in cancer samples and 22 enriched in normal samples using LEfSe (Linear discriminant analysis effect size). On the genus level, *Fusobacterium* (a known pathobiont), *Lactobacillus*, and *Bacteroides* were enriched in tumor samples, while *Rothia* and *Streptococcus* were enriched in normal tissue samples. Beta diversity was significantly different in cancer vs. normal tissue samples (p=0.03, PERMANOVA). Normal tissue had significantly higher alpha diversity than tumor tissue (p=0.003, Chao1 GLS). Interestingly, decreased alpha diversity was associated with more aggressive perineural invasion (p=0.03, Chao1 GLS).

Conclusions Among patients with OSCC, the bacterial diversity of primary tumor tissues was found to be significantly reduced compared to normal tissue in the same patients. For patients with decreased alpha diversity, there was increased likelihood of tumor perineural invasion, but no other associations found with aggressive pathologic factors. Additional studies are needed to further elucidate the role of microbes in oral cancers.

Background The use of probiotic supplementation by cancer patients is increasing, including amongst those undergoing immune checkpoint inhibitor (ICI) therapy. While probiotic supplementation has been identified as an important factor influencing cancer patient responses to ICI therapy in melanoma, the underlying mechanisms of how gut probiotics shape systemic tumor immunity and thereby modulate ICI therapy efficacy remain poorly understood.

Methods We used a preclinical melanoma model to identify various probiotic bacteria capable of suppressing tumor growth, and identified the mechanism by which the host-microbial crosstalk enables the most potent tumor-suppressing strain, *Lactobacillus reuteri*, to bolster a strong spontaneous antitumor immunity and increase anti-PD-L1 therapy efficacy. We interrogated the clinical relevance of our findings in a cohort of advanced melanoma patients that either responded or failed to respond to ICI therapy.

Results Probiotic bacterium, *L. reuteri*, induces antitumor immunity and promotes ICI therapy in B16 preclinical melanoma via inducing interferon-gamma production by CD8 T cells. *L. reuteri* translocates to, colonizes and persists within melanoma tumors, and this intra-tumoral localization of L.reuteri is both necessary and sufficient to mediate antitumor effects in melanoma. *L. reuteri*-mediated tumor suppression occurs in a tumor- and *L. reuteri*-antigen independent fashion. The mechanism by which *L. reuteri* induces this antitumor response is via catabolization of a dietary tryptophan catabolite, indole-3-aldehyde (I3A). I3A is required and sufficient to promote antitumor immunity and facilitate ICI therapy efficacy, and it mediates antitumor immunity via activation of aryl hydrocarbon receptor (AhR) within CD8 T cells. The translational relevancy of I3A's impact on clinical melanoma is supported by our evidence for a role of I3A in promoting anti-PD-1 immunotherapy efficacy and survival in advanced melanoma patients.

Conclusions We show that probiotic bacterium *L. reuteri* can translocate to gut-distal melanoma tumors and reveal that its presence within the tumor is required to promote antitumor Tc1 cell immunity and facilitate ICI therapy in preclincial melanoma. Collectively, our findings elucidate a critical microbial-host crosstalk between the microbial released AhR agonist I3A and CD8 T cells within the tumor microenvironment that potently enhances spontaneous antitumor immunity and facilitates ICI therapy efficacy in preclinical melanoma.

Ethics Approval Animal care and experimentation were conducted in accordance with NIH guidelines and approved by the Institutional Animal Care and Use Committee at the University of Pittsburgh. Approval to treat patients was obtained from the University of Pittsburgh's Hillman Cancer Center (HCC) Institutional Review Board (No. PRO14030075), and authors attest that signed informed consent was obtained from all patients involved in the study.

Consent N/A- no sensitive or identifiable information is included in this study.

1311 THE MELANOMA TUMOR MICROBIOME AS A PREDICTOR OF OUTCOMES IN PATIENTS WITH METASTATIC DISEASE TREATED WITH IMMUNE CHECKPOINT INHIBITORS

[1]Caroline Wheeler*, [1]Rebecca Hoyd, [2]Aik Choon Tan, [3]Neli Ulrich, [1]Gabriel Tinoco, [1]Dwight Owen, [3]Jennifer Ose, [4]Martin McCarter, [1]Vineeth Sukrithan, [5]Alexandra Ikeguchi, [6]Carlos Chan, [7]Yousef Zakharia, [7]Rebecca Dodd, [3]Sheetal Hardikar, [7]George Weiner, [2]Youngchul Kim, [1]Ning Jin, [1]YunZhou Liu, [1]Nicholas Denko, [1]Marium Husain, [8]John Carpten, [9]Eric Singer, [2]Lary Robinson, [10]William (Bill) Dalton, [10]Michelle Churchman, [1]Daniel Spakowicz, [2]Ahmad Tarhini. *[1]The Ohio State University, Columbus, OH, USA; [2]Moffitt Cancer Center, Tampa, FL, USA; [3]University of Utah, Salt Lake City, UT, USA; [4]University of Colorado, Aurora, CO, USA; [5]The University of Oklahoma, Oklahoma City, OK, USA; [6]University of Iowa, Iowa City, IA, USA; [7]University of Iowa, Holden Cancer Center, Iowa City, IA, USA; [8]University of Southern California, Los Angeles, CA, USA; [9]Rutgers Cancer Institute of New Jersey, Belle Mead, NJ, USA; [10]M2Gen, Tampa, FL, USA*

Background Emerging evidence supports an important role for the tumor microbiome in relation to oncogenesis, cancer immune phenotype, cancer progression and treatment outcomes in a number of malignancies. In this study, we investigated the metastatic melanoma tumor microbiome and potential roles in association with clinical outcomes, such as survival, in patients with metastatic disease treated with immune checkpoint inhibitors (ICIs).[1–3]

Methods Baseline tumor samples were collected from 71 patients with metastatic melanoma prior to treatment with ICIs. Bulk RNA-seq was conducted on the FFPE tumor samples. Clinical outcome following ICI treatment was evaluated as overall survival (> 24 versus < 24 months). The RNA-seq reads were processed to carefully identify exogenous sequences using ExoTIC (Exogenous sequences in Tumor and Immune Cells.[4,5] Reads that did not align to the human reference genome were filtered of (1) common laboratory contaminants, (2) taxa that inversely correlate with input RNA quantity, and (3) taxa commonly found in the negative controls of microbiome experiments. DESeq2 was used to perform a differential abundance analysis on the comparison groups at every taxonomic level.

Results The 71 patients with metastatic melanoma ranged in age from 24 to 83 years, 59% were male, and 55% survived > 24 months following the initiation of ICI treatment. Exogenous taxa were identified in the tumor RNAseq, including bacteria, fungi, and viruses (figure 1). Within the tumors responsive to immunotherapy (> 24 months survival), we found a significant enrichment of several microbes, including *Fusobacterium nucleatum*, *Porphyromonas asaccharolytica*, *Nocardia mangyaensis*, and *Mollivirus sibericum*. Comparatively, the cohort of non-responsive tumors (< 24 months survival) was found to have a significant intra-tumoral enrichment of Fungi, as well as the bacteria *Delftia lacustris*, *Enterobacter hormaechei*, *Pseudomonas fluorescens*, and *Moraxella osloensis* (figure 2).

Conclusions In investigating the melanoma tumoral microbiome utilizing baseline tumors (prior to initiating ICI) we found significant variations in the exogenous taxa associated with patient outcomes following ICI treatment. Our findings warrant further investigations and potentially support therapeutic strategies to modify the tumor microbiome in order to improve treatment outcomes with ICIs. Ongoing research is evaluating whether these correlations are causally associated with outcomes and evaluating their effect on the tumor immune microenvironment and immune cell infiltration.

1312 GUT DYSBIOSIS SUPPRESSES ANTI-TUMOR ILC2S IN PANCREATIC CANCER

Abderezak Zebboudj*, Masataka Amisaki, Pablo Guasp, Luis Rojas, Zachari Sethna, Waters Theresa, Adrienne Chandra, Rebecca Yu, Zagaa Odgerel, Kevin Soares, Vinod Balachandran. *Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background Symbiotic microbes that colonize gut promote host immunity.[1] Cancer disrupts this homeostasis to alter microbial populations ("dysbiosis") that suppresses anti-cancer immunity. Yet, the mechanisms of how dysbiosis suppresses anti-tumor immunity remain unclear. Group 2 innate lymphoid cells (ILC2s) are innate lymphocytes that reside in tissues including the gut, respond to the alarmin interleukin-33 (IL-33), and maintain microbial homeostasis in barrier surfaces.[2] ILC2s also activate anti-tumor immunity in multiple cancers.[3-7] Yet, links between dysbiosis, ILC2s, and anti-tumor immunity, remain unexplored.

Methods To investigate if cancer dysbiosis modulates ILC2s, we examined dysbiosis in pancreatic ductal adenocarcinoma (PDAC), where dysbiosis correlates with fewer intratumoral T cells and worse survival.[8,9] PDAC is also infiltrated by anti-tumor ILC2s.[7] Briefly, we analyzed dysbiosis by 16S-rRNA gene sequencing in fecal samples of PDAC mice deficient or not for ILC2s or *IL33*. To study the effect of dysbiosis on ILC2s, we ablated dysbiosis using antibiotics or reconstituted it in germ-free mice, we explored ILC2s migration using parabiosis.

Results We found that PDAC induced *Bacteroidetes* overgrowth, thus phenocopying PDAC dysbiosis in patients.[8,10,11] Interestingly, PDAC-dysbiosis suppressed intestinal ILC2s frequencies, as dysbiosis ablation with antibiotics increased, and fecal transplantation in germ-free mice conversely decreased intestinal ILC2 frequencies. Reciprocally, we found that ILC2 and *IL33*-deficient mice evidenced *Bacteroidetes* overgrowth at steady state, thus phenocopying the PDAC-induced dysbiosis. Interestingly, ILC2 and *IL33*-deficient mice also evidenced accelerated PDAC growth, and worse survival compared to wild-type mice (WT). Thus, PDAC-dysbiosis suppresses intestinal ILC2s that serve to maintain optimal gut homeostasis.

We next investigated how dysbiosis-induced ILC2s suppression modulates tumor growth. We previously reported that IL-33 responsive ILC2s infiltrate PDAC to activate antigen-specific $CD8^+$T cells.[7] We identified these anti-tumor ILC2s as unique migratory ILC2s that traffic to tumors. We thus hypothesized dysbiosis may promote tumors by modulating ILC2s migration from the intestine reservoir. Consistently, in parabiotic mice, recombinant IL-33 (rIL-33) induced ILC2s to migrate hematogenously to PDACs in different tissues, and antibiotic ablation of dysbiosis lowered donor-derived ILC2s frequencies in recipient blood and intestine. Thus, dysbiosis modulates anti-tumor ILC2s frequencies in circulation and gut reservoirs. Interestingly, in WT PDAC mice, rIL-33 expanded intestinal ILC2s, restored microbiome composition, increased tumor-infiltrating ILC2s, and reduced PDAC growth.

Conclusions We find that cancer dysbiosis suppresses anti-tumor immunity by suppressing gut-derived ILC2s. Moreover, rIL-33 expands ILC2s in the gut and circulation to restore dysbiosis-suppressed ILC2s and controls PDAC. We thus introduce the therapeutic potential of IL33-based immunotherapies to reverse the dysbiotic state in cancer.

Novel Single-Agent Immunotherapies

1313 CHARACTERIZATION OF THE ANTI-TUMOR IMMUNE ACTIVATION POTENTIAL OF AUR107, A NOVEL SMALL MOLECULE P300/CBP BROMODOMAIN INHIBITOR

Girish Daginakatte*, Chandrasekhar Abbineni, Saravanan Thiyagarajan, Mamon Dey, Aravind Basavaraj, Amit Dhudashiya, Sivapriya Marappan, Sandeep Sadashiv Patil, Naveen Kumar R, Raghavendra NR, Avinash Kumar, Uma Bharathi B V, Girish Renukappa, Venkata Siva Reddy, Amith A, Lavanya CS, Subhendu Mukherjee, Samiulla DS, Thomas Antony, Rajesh Eswarappa, Kavitha Nellore, Shekar Chelur, Murali Ramachandra, Susanta Samajdar.
Aurigene Discovery Technologies Ltd, Bangalore, India

Background Ubiquitously expressed histone acetyl transferases (HAT), E1A binding protein (p300) and its paralog CREB binding protein (CBP or CREBBP) are critical regulators of gene expression in both tumor and immune cells. Conditional deletion of either p300 or CBP in mouse Tregs or inhibition of their HAT activity resulted in impairment of Treg suppressive function, reduced peripheral Treg generation, and Treg apoptosis. These effects led to allograft rejection and decreased murine tumor growth. We have identified a novel small molecule p300/CBP bromodomain inhibitor, AUR107, as therapeutic agent for solid and hematological cancers. AUR107 has significant activity in a broad range of cancer cell lines with good selectivity. Here, we demonstrate the relevance of CBP/p300 bromodomain inhibition by AUR107 on function of Tregs cells and modulation of T helper cells in addition to its potent activity against various haematological and solid tumour models.

Methods AUR107 was profiled in human Treg differentiation assay, human Th17 assay and MDSC proliferation assay. AUR107 combination efficacy studies with anti-PD-1/anti-CTLA-4 antibodies are in progress in syngeneic models

Results Inhibition of CBP/p300 bromodomains by AUR107 resulted in decrease in differentiation of human Tregs in an *ex vivo* assay. AUR107 caused dose-dependent increase in the $CD127^{+}CD25^{-}FoxP3^{-}$ effector cells with corresponding decrease in the $CD127^{+}CD25^{+}$ cells in the differentiated $CD4^{+}$ cells population. In the human PBMC assay, AUR107 caused increase in Th1 cell population with decrease in Th2 cell population. These observations indicate that inhibition of CBP/p300 bromodomains affects the function of regulatory T cells. Recruitment of regulatory T cells to tumors is known to be one of the major mechanisms of immune evasion by cancer cells, and hence AUR107 is expected to produce antitumour immunity. These results demonstrate that CBP/p300 bromodomain inhibition could be a novel approach for cancer immunotherapy in addition to their development as direct anti-cancer agents

1314 TRILACICLIB, AN INTRAVENOUS CYCLIN-DEPENDENT KINASE 4/6 INHIBITOR, ENHANCES ANTITUMOR RESPONSES BY MODULATING T CELLS

Sarah Ahn*, John Yi, Subing Cao. *G1 Therapeutics, Inc., Research Triangle Park, NC, USA*

Background Cyclin-dependent kinase (CDK)4/6 inhibitors, including trilaciclib, have been shown to augment antitumor immunity.[1,2] In an open-label, phase 2 trial in patients with metastatic triple-negative breast cancer (mTNBC), administration of trilaciclib prior to gemcitabine plus carboplatin improved overall survival, potentially through protection and direct activation of immune function.[3,4] Here, we report the effects of transient, trilaciclib-mediated CDK4/6 inhibition on immune function *in vitro*.

Methods Peripheral blood mononuclear cells (PBMCs) or naïve $CD4^+$ and $CD8^+$ T cells were purified from 6 healthy human donors and activated with CD2/3/28 beads with or without trilaciclib. To visualize phenotypic and functional changes, trilaciclib was added to naïve $CD4^+$ and $CD8^+$ T cells 0-, 1-, and 3-days post-activation. Activated T cells were collected and stained for flow cytometric analyses 3-, 7-, and 14-days post-activation. Supernatant from activated PBMCs was harvested after 72 hours and added to human breast cancer cells. Following 24 hours' incubation, levels of programmed death-ligand 1 (PD-L1) and human leukocyte antigen (HLA) class I and II were quantified by flow cytometry, and CXCL9 and CXCL10 chemokines by enzyme-linked immunosorbent assay.

Results Irrespective of when trilaciclib was added to $CD4^+$ and $CD8^+$ T cells, significant increases in the frequency of $CD45RO^+$ memory T cells were observed. Within $CD45RO^+$ memory T cells, T cells incubated with trilaciclib had increased frequencies of $CD62L^{lo}CD69^{hi}$ effector $CD4^+$ and $CD8^+$ T cells, with increases in $CD62L^{lo}CCR7^{lo}$ effector memory T cells also observed. Furthermore, trilaciclib significantly increased CXCL9 and CXCL10 levels ($P=0.0001$). Surface expression of PD-L1 and HLA class I and II was increased in breast cancer cell lines cultured with supernatant from T cells activated in the presence of 50 and 100 nM of trilaciclib, resulting in a greater frequency of cells being double-positive for HLA class I and II or HLA class I and PD-L1.

Conclusions Trilaciclib may enhance antitumor immunity by modulating essential steps in the cancer-immunity cycle. Our data suggest trilaciclib may increase antigen presentation by promoting HLA class I and II expression and the recruitment of T cells to the tumor site via CXCL9 and CXCL10. Trilaciclib also augments the differentiation of T cells by promoting the formation of memory T cells. These data support a role for trilaciclib in improving antitumor efficacy, as observed in the phase 2 trial in mTNBC, and provide a rationale to combine trilaciclib with immunotherapy to enhance immunogenicity within the tumor microenvironment.

Acknowledgements We thank Dr. Jason Grayson for immune profiling services.

1315 MVDELTAC, A NEW THERAPEUTIC VACCINE DEMONSTRATES PROMISING PRECLINICAL IMMUNO-ONCOLYTIC ACTIVITIES

[1]Aleksandr Barinov, [2]Chantal Combredet, [2]Claude Ruffié, [2]Valérie Najburg, [3]Nicolas Boisgerault, [1]Marc Gregoire, [1]Véronique Riebbels, [1]Jean-François Le Bigot, [1]Frederic Tangy*. [1]*Oncovita, Paris, France*; [2]*Institut Pasteur, Paris, France*; [3]*Inserm, Nantes, France*

Background Oncovita, a biotech company spin-off from Institut Pasteur, is developing a therapeutic vaccine in oncology based on Measovir®, a proprietary technology derived from the safe and highly immunogenic measles attenuated vaccine virus (MV). MV is a paramyxovirus with a negative strand RNA genome. The MV specific tropism for cancer cells is due to the overexpression of its entry receptor CD46 on the surface of most cancer cells.

Methods We constructed MVdeltaC, a genetically modified MV by deletion of its virulence factor C. We evaluated its immuno-oncolytic activity *in vitro* on over 40 human tumoral cell lines, including mesothelioma, lung adenocarcinoma, bladder, ovarian, cervical cancer and hepatocarcinoma, and *in vivo* by i.p. or i.t. administration in different patient-derived xenograft (PDX) mesothelioma and bladder models, and finally in a syngeneic model of neuroblastoma in immunocompetent A/J mice. The mode of action (MOA) has been investigated *ex vivo* using human primary immune cells.

Results *in vitro,* MVdeltaC exhibited a strong oncolytic capacity which was 2 to 3 times greater than standard MV against a series of human tumor cell lines. MVdeltaC was active in more than 70% of the tested cell lines. *In vivo*, a single low dose given intraperitoneally in NOD/SCID mice grafted with human malignant mesothelioma induced a strong reduction of tumor mass two weeks after treatment. This potential was confirmed in PDX models of mesothelioma and bladder tumors by weekly administration of MVdeltaC. Finally, in immunocompetent A/J mice, only three i.t. administrations resulted in tumor regression and even total disappearance in 66% of mice. The animals that completely rejected the tumors were re-challenged on the other flank 3 months later with the same amount of tumor cells. No tumor growth was observed, suggesting an immune protection. In *ex-vivo* MOA experiments with human autologous primary cells, we demonstrated that the infection of cancer cells by MVdeltaC triggers the release of danger signals and tumor associated antigens (TAA), activation of mDC and pDC, phagocytosis of dying cancer cells and cross-presentation of TAA to autologous T lymphocytes.

Conclusions MVdeltaC demonstrated a very efficient immuno-oncolytic activity. Based on these promising preclinical data, Oncovita plans to initiate a FIH trial in patients with solid tumors. The activity on CPI resistant tumors will be of particular interest to investigate. We have already improved the mode of production of genetically stable MVdeltaC.

1316 **A NOVEL CLASS OF T CELL-ACTIVATING ANTIBODY THAT SELECTIVELY TARGETS THE TCR B CHAIN TO PROMOTE ANTITUMOR ACTIVITY THROUGH ACTIVATION AND EXPANSION OF A NOVEL, POLYCLONAL EFFECTOR MEMORY T CELL SUBSET**

[1]Andy Bayliffe*, [1]Zhen Su, [2]John Wherry, [1]Jonathan Hsu, [1]Madan Katraggada, [1]Jacques Moisan, [1]Gurkan Guntas, [1]Karunya Srinivasan, [1]Jessica Lowry, [3]Rajesh Chopra, [1]Roya Servattalab, [1]Wei Huang, [1]Jian Tang. *[1]Marengo Therapeutics, Cambridge, MA, USA*; *[2]University of Pennsylvania, Philadelphia, PA, USA*; *[3]Apple Tree Partners, London, UK*

Background Limitations with agents that enhance endogenous T cell responses to cancer, particularly in solid tumors, supports the study of alternative approaches. Directly targeting the variable (V) regions of the T cell receptor (TCR) is a novel approach to inducing T cell activation. STAR0602 is a bispecific antibody-fusion molecule that selectively activates and expands a subset of human aβ T cells expressing the germline-encoded Vb6 and Vb10 TCRs that are enriched in tumor infiltrating lymphocytes. STAR0602 simultaneously engages a novel, non-clonal mode of TCR activation with cytokine co-stimulation.

Methods The effects of STAR0602 on activation and expansion of primary human T cells was assessed *in vitro* by flow cytometry, homogeneous time-resolved fluorescence, TCRseq, and NanoString. A murine surrogate (mSTAR0602) was tested in murine syngeneic tumor models with tumor re-challenge and cellular depletion studies to assess potential for long-term protection and cell-specific activities, respectively. EMT6 tumors were excised for IHC staining and phenotyping of tumor-infiltrating lymphocytes (TILs) using flow cytometry and scRNAseq/TCRseq.

Results In vitro, STAR0602 induced TCR signalling and IL-2R pathway activation in human T cells that preceded expansion of Vb6/Vb10 T cell subsets to 80-90% of the T cell compartment. Compared to controls, 80-90% of STAR0602-stimulated human T cells adopted a novel, activated central memory (T_{CM}) phenotype. In multiple syngeneic murine tumor models, mSTAR0602 monotherapy eradicated tumors, or led to substantial regressions (60-70% tumor growth inhibition) with long-term protection from tumor rechallenge. In vivo anti-tumor activity was dependent on the accumulation of Vb T cell subsets, and analysis of TILs showed expanded Vb T cells were almost exclusively polyclonal effector memory T cells (T_{EM}) or T_{CM} cells with minimal exhausted T cells or Tregs and were associated with a novel gene signature with upregulation of memory and effector programs, and downregulation of exhaustion pathways.

Conclusions STAR0602 is a first-in-class bi-specific fusion molecule that selectively binds and activates subsets of the germline TCR repertoire. In vitro, STAR0602 promotes a novel T cell phenotype with hallmarks of both effector and central memory cells, and in vivo mSTAR0602 demonstrates potent and durable single-agent anti-tumor activity in several solid tumor models that is dependent on expanded Vb T cells. The modulation of the tumor microenvironment (TME), striking increase in TCR diversity, and functional immune memory observed in murine models suggests that STAR0602 could remodel the adaptive immune response to solid tumors that are refractory to checkpoint inhibitor therapy, and thus represents a novel therapeutic strategy for patients.

1317 CITRULLINATED GLUCOSE-REGULATED PROTEIN 78 IS A NOVEL CANDIDATE TARGET FOR CANCER IMMUNOTHERAPY

Victoria Brentville, Jia Chua, Peter Symonds, Anne Skinner, Ian Daniels, Katherine Cook*, Lindy Durrant. *Scancell, Nottingham, UK*

Background Post translational modification of proteins produces altered epitopes and can play a significant role in immune recognition. Citrullination is the modification of the positively charged arginine amino acid to a neutral charged citrulline residue. This modification is mediated by PAD enzymes and is increased during cellular stress (autophagy). Citrullination results in altered epitopes that can be presented upon MHC class II molecules for recognition by CD4 T cells. Citrullination also occurs in tumour cells as a result of continuous environmental stresses and increased autophagy. We have shown in animal models that the efficient stimulation of citrullinated epitope specific CD4 T cells results in dramatic elimination or regression of tumours. The ER chaperone glucose-regulated protein 78 (GRP78) is required for stress-induced autophagy and is directly linked to autophagosome formation. GRP78 is known to be highly expressed by many tumour types. In this study we investigated the potential of targeting citrullinated GRP78 for cancer therapy.

Methods *In vivo* experiments were performed with HLA-transgenic mice under an approved home office licence. Mice were immunised with citrullinated peptides in combination with CpG/MPLA adjuvant. Immune responses were determine using IFNγ ELISpot. Anti-tumour studies were carried out by implanting HLA-matched mouse tumour cells subcutaneously and immunising as above. Mass spectrometry analysis was performed to assess peptides presented on tumour cells. Blood samples from healthy individuals were obtained under ethical approval from the University of Nottingham. PBMC responses to citrullinated peptide were assessed using flow cytometry and proliferation assays.

Results Five peptides were selected for screening in HLA-transgenic mouse models. One citrullinated GRP78 peptide was identified that gives an CD4 T cell responses that is restricted through the HLA DP*0401 and HLA-DR*0101 alleles. In addition, this peptide is detected by mass spectrometry in B16 melanoma grown *in vivo*. Anti-tumour studies demonstrated that the citrulline modification-specific CD4 responses to this epitope mediates efficient therapy of established B16 melanoma tumours ($p<0.0001$) in a HLA-transgenic HHDII/DP4 mouse model. Finally, the existence of a repertoire of responses to the citrullinated GRP78 peptide in healthy individuals has been demonstrated with 13/17 (76%) of health individuals showing a response to the peptide ($p=0.0023$).

Conclusions Together this data leads us to propose that citrullinated GRP78 is a candidate tumour antigen and that vaccination against citrullinated GRP78 may provide a promising approach for future tumour therapy.

1318 A NEXT GENERATION DNA VACCINE CODING FOR THE IMMUNODOMINANT SEQUENCE OF ALPHA-ENOLASE WITH ENHANCED ABILITY TO INDUCE EFFECTOR T CELL RESPONSES TO CURE PANCREATIC CANCER

[1]Silvia Brugiapaglia*, [1]Claudia Curcio, [2]Daniele Giordano, [2]Rosella Spadi, [2]Ennia Dametto, [2]Monica Berrino, [1]Alessandro Scagliotti, [1]Antonio Amoroso, [1]Paola Cappello, [1]Francesco Novelli. *[1]University of Turin, Turin, Italy; [2]A.O.U. Città della Scienza e della Salute di Torino, Turin, Italy*

Background Pancreatic ductal adenocarcinoma (PDA) is one of the most aggressive malignancies with a 5-year survival rate of 11%.[1] Only the 15% of patients have a resectable disease eligible for surgical resection followed by adjuvant chemotherapy to reduce the risk of relapse.[2] The glycolytic enzyme alpha-Enolase (ENO1) has been identified as PDA associated antigen.[3,4] A non-integrating plasmid DNA vaccine encoding for full-length human ENO1 (FL-ENO1 vaccine) was able to slow tumor progression, inducing an integrated anti-tumor immune response, in mice engineered to spontaneously develop PDA (KPC).[5] However, in FL-ENO1 vaccinated mice myeloid derived suppressor cells and regulatory T cells arose again, leading eventually to tumor recurrence. To optimize the ENO1 vaccine, we focused the research on the identification of the most immunogenic long epitopes widely presented by HLA molecules.

Methods A library of 14 peptides covering the sequence of ENO1 was synthetized to screen healthy donors and PDA patients for their capacity to recognize fractions of ENO1 through the stimulation of T cells with ENO1 peptides. According to the proliferative response and the cytokine release, the most immunogenic sequences of ENO1 were identified and cloned into the pVax plasmid (ENO3PEP vaccine). KPC mice were vaccinated at 8 weeks and every two weeks for a total of four rounds and sacrificed at 18 weeks of age either with empty, FL-ENO1 or ENO3PEP vaccine. The presence of anti-ENO1 specific antibodies and the number of specific T cells secreting IFN-gamma in response to ENO1 were assessed respectively by ELISA and ELISpot. Pancreas tumoral areas were analyzed on hematoxylin and eosin-stained sections, while the immune infiltrate was characterized through immunohistochemistry.

Results Three portions of ENO1 emerged as immunodominant as T cells from healthy donors and PDA patients stimulated with the related peptides showed the highest proliferation index and ratio of secreted IFN-gamma/IL-10 both compared to those stimulated with full-length ENO1. In KPC mice, the ENO3PEP vaccine i) significantly reduced the pancreatic tumor lesions, ii) increased the production of anti-ENO1 antibodies, iii) enhanced the secretion of IFN-gamma by ENO1-stimulated T cells, iv) recruited more T cells at tumor site compared to FL-ENO1 vaccine.

Conclusions The ENO3PEP vaccine, coding for the most immunogenic sequences of ENO1, was able to efficiently delayed tumor progression, inducing a strong integrated humoral and cellular response, emerging as potential next generation DNA vaccine suitable for immunotherapy in virtually all PDA patients.

1319 NEXT-GENERATION TCR BISPECIFICS (TCER®) TARGETING PEPTIDE-HLA ANTIGENS FOR THE TREATMENT OF PATIENTS WITH SOLID TUMORS

[1]Sebastian Bunk*, [1]Martin Hofmann, [1]Gabriele Pszolla, [1]Meike Hutt, [1]Felix Unverdorben, [1]Frank Schwoebel, [1]Nadine Aschmoneit, [1]Claudia Wagner, [1]Maike Jaworski, [1]Christoph Schraeder, [1]Heiko Schuster, [1]Sarah Missel, [2]Toni Weinschenk, [1]Dominik Maurer, [2]Carsten Reinhardt. [1]*Immatics Biotechnologies GmbH, Tuebingen, Germany*; [2]*Immatics N. V., Tuebingen, Germany*

Background T cell engaging bispecifics have emerged as a promising therapeutic opportunity for patients with solid cancers. However, challenges related to target specificity and drug safety profiles remain and many efforts are being made to generate optimized molecules with improved pharmacodynamic characteristics while reducing T cell engager-associated toxicities. We have developed a pipeline of novel bispecific molecules comprising a T cell receptor (TCR) for giving access to intracellular tumor antigens presented as peptide-HLA molecules and a unique T cell recruiting antibody aiming at conferring a favorable safety profile.

Methods We designed a novel TCR-incorporating bispecific format, called T cell engaging receptor (TCER®). TCER® molecules targeting different peptide-HLA antigens and using different recruiting moieties were generated and assessed for preclinical characteristics such as *in vitro* efficacy, *in vitro* safety and anti-tumor responses in tumor xenograft models.

Results Based on comparative preclinical testing of different TCR bispecific formats and T cell recruiting antibodies, we have developed a next-generation bispecific (TCER®) consisting of a high-affinity TCR capable of targeting tumor-specific peptide antigens and a low-affinity T cell recruiter designed to maximize efficacy while minimizing toxicity. The TCER® format harbors an effector function-silenced Fc part for the extension of serum half-life and improved manufacturability. For the development of different TCER® candidates, TCRs with promising functional avidity and high target-specificity are identified from the human repertoire and matured via yeast surface display to enhance TCR stability and to increase TCR affinity towards the target-peptide by at least 1,000-fold while retaining the target-specific binding pattern. TCER® molecules built with the maturated TCRs show *in vitro* activity at picomolar concentrations against tumor cell lines presenting the target peptide at similar copy numbers as found on patient tumors. Further, the TCER® molecules demonstrate consistent tumor regression including complete remissions in tumor xenograft models in mice and thereby also uncovered an essential role for the type of T cell recruiting antibody. For our clinical lead TCER® candidates we confirmed a favorable *in vitro* safety profile with a broad therapeutic window between tumor and normal cell reactivity against more than 20 different human normal tissue cell types.

Conclusions We have developed a next-generation, half-life extended TCR Bispecific format that in preclinical tests demonstrated higher potency than multiple other established formats. By incorporating an innovative T cell recruiter we aim to reduce the risk for toxicities, specifically CRS, in patients. For each TCER® candidate we generate a robust preclinical data package before entering clinical development.

1320 NON-CLINICAL CHARACTERIZATION OF CYT-303 FLEX-NK™ ENGAGER ANTIBODY SUPPORTS CLINICAL EVALUATION

Liang Lin*, Vishal Khairnar, Harish Potu, Hao-Ming Chang, Elisabetta Burchi, Armin Rath, Stanley Frankel, Jean Kadouche, Daniel Teper, Wei Li, Antonio Arulanandam. *Cytovia Therapeutics, Natick, MA, USA*

Background CYT-303 is a multifunctional bispecific NK engager (NKE) targeting NK cell activating receptor NKp46 and tumor antigen Glypican-3 (GPC3) expressed in HCC (hepatocellular carcinoma). Cytovia's proprietary FLEX-NK^{TM} platform utilizes a novel FLEX-linker and human IgG1 back bone to allow for simultaneous binding to targeted cancer cells and NK cells. We evaluated additional CYT-303 Fc effector functions and the impact of CYT-303 when added to peripheral blood NK cells (PBNK) in Hep3B tumor spheroid cytolysis and Hep3B tumor serial killing assays. CYT-303 pharmacokinetics and safety in non-human primates were also evaluated.

Methods CYT-303 Fc effector function against Hep3B tumors was evaluated for antibody dependent cellular phagocytosis (ADCP) using human macrophages differentiated from purified monocytes isolated from peripheral blood and for complement dependent cytotoxicity (CDC) in the presence of rabbit complement. Hep3B tumor spheroids were established in special U-bottom adhesive plates and tumor spheroid killing assays were conducted with PBNKs and CYT-303 using the Incucyte ^{TM} Live Cell Analysis System. Serial killing assays were conducted by repeatedly adding the same PBNK cells to fresh tumor cells and CYT-303 following each round of tumor killing. CYT-303 single dose range finding pharmacokinetics and safety and 4-week repeat dose safety studies were conducted in cynomolgus monkeys by intravenous infusion dosing at 6, 20 and 60 mg/kg doses.

Results CYT-303 showed dose dependent ADCP by human macrophages against Hep3B tumors that was maximal at 0.4 ug/ml. CYT-303 also showed maximal CDC against Hep3B tumors at 0.4 – 2 ug/ml concentrations. CYT-303 in the presence of freshly isolated PBNKs showed increased time dependent killing of Hep3B tumor spheroids that peaked at 2-3 days following initiation of killing. This killing was enhanced in the presence of CYT-303 in a dose dependent manner. Furthermore, PBNK serial killing of Hep3B tumors was also enhanced by CYT-303. In the CYT-303 single dose range finding pharmacokinetics study in cynomolgus monkeys the C_{max} and $AUC_{0\text{-}168h}$ values increased with dose and increases were approximately dose-proportional. CYT-303, half-lives ($T_{1/2}$) ranged from 39 to 47.6 hrs and exposures persisted up to 1-week. No evidence for any cytokine release was observed. In the 4-week repeat dose toxicity study no CYT-303 related toxicities were observed, enabling CYT-303 clinical development.

Conclusions CYT-303 demonstrated potent ADCP and CDC against Hep3B tumors as well as Hep3B tumor spheroid and serial killing activities in the presence of PBNKs. Preclinical pharmacokinetics and safety study results in cynomolgus monkeys support CYT-303 clinical development.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1320

1321 A BIPARATOPIC ANTI-HER2 ANTIBODY ENABLED WITH CONDITIONAL 4–1BB AGONISM INDUCES POTENT ANTI-TUMOR EFFICACY

[1]Liandi Chen, [2]Weifeng Huang, [1]Xiaoniu Miao, [2]Shaogang Peng, [1]Chao Wang, [1]Yao Yan, [1]Chuan-Chu Chou*, [1]Andy Tsun, [1]Yi Luo. *[1]Biotheus Inc., Zhuhai, China; [2]Biotheus (Suzhou) Co., Ltd., Suzhou, China*

Background HER2 is a well-established therapeutic target that is overexpressed in multiple cancers. Monoclonal antibodies (mAbs) targeting HER2 such as Herceptin (trastuzumab) and Perjeta (pertuzumab) have been used in the clinic for many years. Despite good outcomes, there remains an unmet medical need that requires the further development of novel agents for recurrent or metastatic patients. The combination of HER2 mAbs have shown synergistic activity with improved clinical benefit. Moreover, biparatopic antibodies that are composed of trastuzumab and pertuzumab binding domains have shown promising results in the clinic. 4-1BB is a potent stimulator of T cells and NK cells, and when activated, can improve effector and/or memory responses. However, inherent hepatotoxicity has been observed during the clinical development of 4-1BB agonists. PM1234 is a trispecific antibody that binds to two different epitopes of HER2 (ECD4 and ECD2), and the CRD4 domain of 4-1BB. PM1234 stimulates immune cells such as T cells via HER2-mediated cross-bridging and 4-1BB activation, which results in potent anti-tumor efficacy. Moreover, Fc-effector function was shown to be essential for the *in vivo* anti-tumor efficacy of PM1234.

Methods PM1234 was generated as a biparatopic heterodimeric (1+1) IgG-like antibody composed of both trastuzumab and pertuzumab binding domains with anti-4-1BB VHHs fused to the C-terminus of the Fc. The immunomodulatory functions of PM1234 were evaluated using luciferase reporter cell assays, PBMC/primary T cell activation assays, and human 4-1BB KI mouse tumor models.

Results PM1234 displayed strong HER2 binding and signal inhibition activity due to its biparatopic binding nature. The binding mode of PM1234 may allow up to double the available HER2 binding domains that can facilitate 4-1BB cross-linking and activation and was thus more potent than non-biparatopic anti-HER2 x 4-1BB bispecifics (trastuzumab x 4-1BB and/or pertuzumab x 4-1BB). PM1234 retained Fc effector function towards HER2 but with negligible activity towards the 4-1BB-targeting arm. PM1234 showed more potent activity in *in vivo* CT26 and MC38 tumor models than the control molecules containing Fc-silencing mutations, the combination of trastuzumab and pertuzumab, and anti-HER2-ADC. Importantly, PM1234 induced immune memory and potent anti-tumor efficacy to both HER2+ primary tumors and distal tumors without HER2 expression.

Conclusions PM1234 exhibited potent anti-tumor activity with the induction of strong immunological memory to suppress both primary HER2+ tumors and distal tumors. The differentiation of PM1234 shows the next-generation potential of HER2-targeted therapies in this competitive space and provides an insight into further improvements for benefiting patients with HER2+ tumors.

Ethics Approval All mice were maintained under specified pathogen-free conditions, and all studies were approved by the Animal Care and Use Committee of HUST-Suzhou Institute for Brainsmatics.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1321

1322 TARGETING IMMUNOSUPPRESSIVE MACROPHAGES AND TREGS BY REPURPOSING METABOLIC DRUGS

[1]Shipeng Chen*, [1]Ana Milena Vizcaino, [2]Yuzhen Gao, [1]Baukje Nynke Hoogenboom, [1]Toos Daemen, [3]Cesar Oyarce. *[1]University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [2]Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China; [3]Amsterdam University Medical Center, University of Amsterdam, Amsterdam, Netherlands*

Background Accumulating evidence demonstrates that the immunosuppressive tumor microenvironment (TME) contributes to tumor progression and invasion, and hampers response to cancer therapies. Among the immune suppressive cells and mediators in the TME, regulatory T cells (Tregs) and M2-like tumor-associated macrophages are known to suppress tumor-specific $CD8^+$ T cells activity and contribute to the development of an immunosuppressive TME. The differentiation/function of Tregs and the phenotype/activity of macrophages are related to their metabolism. Thus, we hypothesized that metabolic drugs could be repurposed to target these immune suppressive cells.

Methods Clinically relevant metabolic drugs were selected to target different metabolic pathways (glutaminolysis, fatty acid oxidation, and mitochondrial respiration) of human peripheral blood mononuclear cells (PBMCs)-derived Tregs/macrophages and murine bone-marrow-derived macrophages. The effect of the drugs on the differentiation and polarization of Tregs/macrophages was determined by flow cytometric analysis. And the cytotoxic activity of re-polarized macrophages was measured by co-culturing with tumor cells.

Results It was demonstrated that targeting fatty acid oxidation or mitochondria of M2-like macrophages, resulted in M2-to-M1 polarization with strong tumor-cytotoxic activity. Moreover, targeting mitochondria or glutaminolysis inhibited the differentiation of T cells to Tregs, reduced the number of the differentiated Tregs, and decreased the expression of the immunosuppressive marker without affecting the proliferation and activation of $CD4^+$ and $CD8^+$ conventional T cells.

Conclusions These results demonstrate that targeting the metabolism of Tregs and tumor-associated macrophages could reverse the immune suppressive tumor microenvironment into an environment that could support cancer immunotherapies. This study opens a new avenue to repurpose clinically available metabolic drugs for metabolic reprogramming of the tumor microenvironment.

1323 CUE-102 SELECTIVELY ACTIVATES AND EXPANDS WT1-SPECIFIC T CELLS FOR THE TREATMENT OF PATIENTS WITH WT1+ MALIGNANCIES

Natasha Girgis*, Yu Christie, Zohra Merazga, Steven Hatfield, Alex Histed, Fan Zhao, Raymond Moniz, Kristin Yeung, Fulvio Diaz, Wynona Bautista, John Ross, Saso Cemerski, Anish Suri, Matteo Levisetti, Steven Quayle. *Cue Biopharma, Boston, MA, USA*

Background Wilms' Tumor 1 (WT1) was ranked as the highest priority antigen for therapeutic targeting in an effort by the National Cancer Institute. Development of novel modalities targeting WT1 provide a significant opportunity to address high unmet medical need in WT1-positive malignancies, including AML, ovarian, endometrial, breast, lung, colorectal and pancreatic cancer. Leveraging the Immuno-STAT™ platform of targeted IL-2 therapies, and the ongoing development of CUE-101, CUE-102 is being developed as a novel therapeutic fusion protein to selectively activate tumor antigen-specific T cells to treat WT1-expressing cancers. CUE-102 consists of two human leukocyte antigen (HLA) molecules presenting a WT1 peptide, four affinity-attenuated human interleukin-2 (IL-2) molecules, and an effector attenuated human immunoglobulin G (IgG1) Fc domain.

Methods Cellular activity and specificity of CUE-102 were demonstrated in human PBMCs, while the in vivo activity of CUE-102 was assessed in HLA-A2 transgenic mice. HLA-A2/WT1-specific TCRs were validated and expressed in primary human CD8+ T cells. Antigen-specific cells were identified by flow cytometry using tetramer staining, activation markers and cytokine production.

Results Multiple in vitro assessments demonstrated that CUE-102 selectively binds, activates, and expands naturally occurring $WT1_{37\text{-}45}$-specific $CD8^+$ T cells from PBMCs of healthy and cancer patient donors, consistent with its design. These $CD8^+$ T cells exhibit polyfunctional and cytotoxic responses upon challenge with WT1-presenting target cells. In addition, significant functional attenuation of the IL-2 components of CUE-102 was shown, similar to preclinical results obtained with CUE-101. In vivo studies in HLA-A2 transgenic mice confirmed that CUE-102 elicits and expands polyfunctional WT1-specific $CD8^+$ T cells from naïve and previously immunized mice without significantly altering the frequencies of other immune lineages. The WT1-specific $CD8^+$ T cells expanded in vivo exhibit polyfunctional cytokine responses upon restimulation and selectively kill target cells presenting WT1 peptide in vivo. WT1-specific CD8+ T cells elicited in vivo by CUE-102 were detectable for >180 days following the last CUE-102 treatment, demonstrating the establishment of a long-term memory response to this tumor antigen.

Conclusions CUE-102 elicits selective expansion of WT1-specific cytotoxic $CD8^+$ T cells both in vitro and in vivo. These results, together with its similarity to CUE-101, support its anticipated tolerability profile and potential for clinical efficacy in an ongoing Phase 1 clinical trial (NCT05360680).

Ethics Approval Studies using animals were conducted in accordance with guidelines established by the Smart Labs Institutional Animal Care and Use Committee under protocol 21SL09-0007.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1323

1324 INHIBITION OF ACID SENSING BY GPR65 NORMALISES GENE EXPRESSION IN MACROPHAGES, INCREASES IMMUNE CELL INFILTRATION IN TUMORS, AND RESTRAINS SUBCUTANEOUS MC38 GROWTH IN MICE

[1]Alastair Corbin*, [1]Stuart Hughes, [2]Mussa Quareshy, [3]Tobias Bopp, [1]Barbara Cipriani, [1]David Miller, [1]Alan Naylor, [2]Gavin Milne, [4]Darryl Turner, [2]Barbara Young, [4]Anastasia Nika, [4]Preeti Singh, [2]Rupert Satchell, [2]Sourav Sarkar, [4]Gavin Knox, [3]Toszka Bohn, [1]Tom McCarthy. *[1]Pathios Therapeutics Ltd., Oxford, UK; [2]Sygnature Discovery Ltd., Nottingham, UK; [3]University Medical Centre Mainz, Mainz, Germany; [4]Malvern Panalytical, Edinburgh, UK*

Background High frequencies of Tumor Associated Macrophages (TAMs) are related to poor patient prognosis. The Tumor Microenvironment (TME) is characterised by resource scarcity, toxic metabolic by-products, and low pH, together creating an immunosuppressive environment which polarises TAMs towards a pro-tumorigenic state.

Methods We identified the proton-sensing G-Protein-Coupled Receptor 65 (GPR65) as a key determinant of low-pH-induced immunosuppression in human cancers, specifically via modulating TAM phenotype in response to the acidic TME. The importance of GPR65 in human cancers is highlighted by three key findings: (1) cancer patients homozygous for the hypomorphic I231L variant exhibit a pronounced survival benefit, (2) GPR65 and downstream pathway genes are highly expressed in innate immune cells from all human solid tumors when assessed by single cell RNA sequencing, and (3) low pH treatment of macrophages *in vitro* leads to a marked suppression of inflammatory genes and an upregulation of a tissue repair signature.

Results We have identified potent and selective small-molecule antagonists of human GPR65 that inhibit the low pH-induced accumulation of cAMP in recombinant cell systems and primary human macrophages with single-digit nanomolar potencies. These compounds dose-dependently prevent the low pH-driven suppression of inflammatory cytokine and chemokine genes and counteract the upregulation of pro-tumorigenic and tissue repair genes in both human and mouse macrophages.

Oral administration of our exemplar compound PTT-3213 in subcutaneous MC38 tumor-bearing mice caused gene expression changes consistent with those observed in primary macrophages *in vitro*, indicative of a dramatic impact on the TME. Weekly dosing of PTT-3213 significantly reduced MC38 Tumor Volume (TV) compared to vehicle (46%). This monotherapy activity was comparable to bi-weekly administration of anti-PD1, whilst combination of PTT-3213 and anti-PD-1 led to a more pronounced curtailment of TV vs vehicle-treated animals (61%). In accordance with the increased expression of chemokine genes, PTT-3213 monotherapy in MC38-bearing mice markedly elevated the frequency of tumor-infiltrating NK cells (up to 22-fold). There was also an increase in the CD8 +/CD4+ T cell ratio which attained statistical significance in combination with anti-PD-1.

Conclusions Taken together, we have identified GPR65 as a key innate immune checkpoint and therapeutic target in solid tumors and propose that macrophage conditioning via GPR65 inhibition may provide an efficacious strategy to counteract the immunosuppressive action of the acidic TME on TAMs in patients.

Ethics Approval Protocols or procedures involving the care and use of animals in studies in China were reviewed and approved by the Institutional Animal Care and Use Committee of Crown Bioscience. During studies, the care and use of animals was conducted in accordance with the regulation of the Association for Assessment and Accreditation of Laboratory Animal Care

Studies involving the welfare and use of animals within the UK complied with the UK Animals Scientific Procedures Act 1986 (ASPA) in line with Directive 2010/63/EU of the European Parliament and Council of 22/September/2010 on the protection of animals used for scientific purposes and UK Home Office guidance on the implementation of the Act and applicable codes of practice for the care and housing of laboratory animals.

1325 PRECLINICAL ACTIVITY AND SAFETY PROFILE OF JANX007, A NOVEL PSMA-TARGETING TUMOR-ACTIVATED T CELL ENGAGER FOR TREATMENT OF METASTATIC CASTRATION-RESISTANT PROSTATE CANCER

Thomas DiRaimondo, Natalija Budimir, Simon Shenhav, Hua Wu, Vanessa Cicchini, Renee Jocic, Lina Ma, Fabrece Roup, Calvin Campbell, Carolina Caffaro, Hans Aerni, Ugur Eskiocak, Wayne Godfrey, Charles Winter, Marc Nasoff, Neil Gibson, David Campbell, Shahram Salek-Ardakani*. *Janux Therapeutics, San Diego, CA, USA*

Background Metastatic castration-resistant prostate cancer (mCRPC) remains an incurable disease. Bispecific T cell engagers (TCEs) targeting prostate-specific membrane antigen (PSMA) and CD3 on T cells showed great clinical potential for the treatment of mCRPC. However, cytokine release syndrome (CRS) and poor pharmacokinetic (PK) profile hinder their further development. To overcome these challenges, Janux has developed JANX007, a tumor-activated T cell engager (TRACTr) with enhanced safety and PK properties. JANX007 is a humanized trispecific protein that contains PSMA- and CD3-binding domains, an albumin binding domain to extend circulating half-life, and a CD3 inhibitory peptide mask fused to the molecule through tumor protease cleavable linker. Only when tumor-resident proteases cleave the TRACTr and enable mask separation can the resulting active molecule bind CD3. This cleavage-dependent CD3 agonism can potentially limit systemic toxicity associated with broad T cell activation.

Methods Peptide masks against the CD3 binding domain were identified via phage display. Mask efficiency was evaluated using human CD3 ELISAs. Masking and cleavable linker stability was characterized in human (healthy and mCRPC donor) and cynomolgus monkey serum. JANX007-induced cleavage-dependent activation of T cells was evaluated in human PBMC/prostate tumor cell in vitro co-culture assays. The pharmacokinetic and safety profile of JANX007 was evaluated in non-human primate (NHP) studies.

Results Engagement of CD3 target by JANX007 was shown to be cleavage dependent where masking reduced CD3 binding by >600x. In vitro, JANX007 exhibited a ~500x decrease in potency to activate T cells and induce T cell-mediated tumor cell killing relative to non-masked TCE. JANX007 was highly stable in healthy and mCRPC human donor serum, with ≤1% cleavage per day. While proteolytic cleavage of JANX007 in the tumor microenvironment is expected to drive anti-tumor activity, the maintenance of masking in the blood compartment is expected to mitigate the safety risks associated with potential off-tumor toxicity and CRS. JANX007 was found to be highly stable in NHPs with minimally detectable cleavage. The lack of TCE accumulation in NHPs mitigated on-target healthy tissue toxicities and minimized CRS. Clinical chemistry, hematology, and pathology data package support No-Observed-Adverse-Effect-Level (NOAEL) ≥1.5 mg/kg/dose. Finally, the cleavable albumin-binding domain extended the circulating half-life of JANX007 to ~120h in NHPs, relative to the 2h half-life of non-masked TCE, supporting its projected once-weekly clinical dosing.

Conclusions Cleavage-dependent activity, half-life extended PK, the potential for superior safety and manufacturability properties of JANX007 support its further development as an attractive mCRPC therapeutic.

1326 A BIFUNCTIONAL TUMOR ACTIVATED IMMUNOMODULATOR (TRACIR) TARGETING PD-L1 AND CD28 IS A POTENT ENHANCER OF T CELL-MEDIATED ANTI-TUMOR ACTIVITY

Thomas DiRaimondo, Natalija Budimir, Lina Ma, Simon Shenhav, Vanessa Cicchini, Robert Navert, Hua Wu, Renee Jocic, Cuiling Yu, Diane Aceveda, Hannah Best, Clara Prentiss, Kai Muskat, Jason Chang, Farhad Dastmalchi, Fabrece Roup, Carolina Caffaro, Hans Aerni, Wayne Godfrey, Charles Winter, Marc Nasoff, Neil Gibson, David Campbell, Shahram Salek-Ardakan*. *Janux Therapeutics, San Diego, CA, USA*

Background While PD-(L)1 blocking antibodies have demonstrated unprecedented clinical response rates, most patients fail to respond. Preclinical studies have shown that CD28 costimulatory pathway is essential for effective PD-(L)1 therapy. However, the first phase 1 clinical trial of the CD28 agonistic antibody TGN1412 failed due to an unexpected and rapid systemic proinflammatory cytokine response. To overcome the limitation of PD-(L)1 blockade, toxicity of systemic CD28 agonism, and potential healthy tissue toxicity, we engineered a Tumor Activated Immunomodulator (TRACIr). The TRACIr is a tri-specific protein that contains PD-L1- and CD28-binding domains, an albumin-binding domain that extends circulating half-life, and an inhibitory peptide mask bound to the CD28-binding domain via a tumor protease cleavable linker. Only when tumor-resident proteases cleave the TRACIr and enable mask separation can the resulting active molecule bind CD28. This cleavage-dependent CD28 agonism can potentially limit systemic toxicity while enhancing the activity of T cells in the tumor.

Methods Peptide masks against the CD28 binding domain were identified via phage display. Mask efficiency was evaluated using CD28-specific ELISAs. The functional engagement of TRACIr binding arms was evaluated in bioluminescent PD-L1/CD28 cell reporter assays. TRACIr-induced T cell activation was evaluated in human PBMC/tumor cell co-culture assays. Functional activity was confirmed in human renal (RCC) and non-small cell lung cancer (NSCLC) patient-derived TILs. In a mouse model of triple-negative breast cancer (TNBC; MDA-MB231), the cleavage-dependent antitumor activity of TRACIr was demonstrated in combination with CD3 stimulation. The pharmacokinetic and safety profile of TRACIr was evaluated in non-human primate studies.

Results Non-masked PDL-1xCD28 bispecific molecule exhibited potent binding to PD-L1 (1 nM KD) and CD28 (3 nM KD). While the presence of the mask decreased binding to CD28 by >1,000x, PD-L1 binding remained unaffected. PD-L1 blocking activity was comparable with atezolizumab, avelumab, nivolumab, and pembrolizumab. In contrast, CD28 agonistic activity was significantly compromised by the presence of the mask. Moreover, the TRACIr enhanced activation of peripheral blood T cells and TILs was signal 1- and cleavage-dependent and superior in magnitude compared to anti-PD-(L)1 and anti-CD28 monoclonal antibodies. In the TNBC tumor model, TRACIr dramatically enhanced the antitumor activity of a CD3 targeted bispecific antibody in a cleavage-dependent manner. Finally, TRACIr was well tolerated in NHPs at high doses and exhibited half-life extended pharmacokinetics.

Conclusions Preclinical activity and safety profiles of PDL1xCD28 TRACIr support its further development as an attractive bifunctional T cell modulator.

Acknowledgements We acknowledge Marque Todd for providing insightful comments and help with interpretation of NHP safety studies.

Ethics Approval All animal experiments were approved by the Institutional Animal Use and Care Committee of the institutions conducting the studies and in compliance with the Animal Welfare Act, the Guide for the Care and Use of Laboratory Animals, and the Office of Laboratory Animal Welfare.

1327 NOVEL GCN2 MODULATOR HC-7366 DECREASES PULMONARY METASTASES AND REDUCES MYELOID-DERIVED SUPPRESSOR CELLS

[1]Jeremy Drees*, [1]Anissa SH Chan, [1]Yunfang Li, [1]Takashi Kangas, [1]Weiyu Zhang, [1]Maria Fumagalli, [1]Iman Dewji, [1]Kathryn Bieging-Rolett, [1]Sho Fujisawa, [1]Sharon Huang, [1]Ben Harrison, [1]Ashley LaCayo, [1]Xiaohong Qiu, [1]Nick Collette, [1]Gemily Wang, [1]Feven Tameire, [1]Paulina Wojnarowicz, [1]Crissy Dudgeon, [2]Eric Lightcap, [1]David Surguladze, [1]Nandita Bose. *[1]Hibercell, Inc., Roseville, MN, USA; [2]Hibercell, Boston, MA, USA*

Background General controlled nonderepressible 2 (GCN2) is a central kinase in the integrated stress response (ISR) that responds to amino acid deprivation. Cancer cells can utilize the ISR for survival, but prolonged or hyperactivation of the ISR reduces proliferation and induces apoptosis. We are developing HC-7366, a First-in-Class, First-in-Human GCN2 modulator that activates GCN2, resulting in anti-tumor activity. HC-7366, currently in a phase 1 trial (NCT05121948), has demonstrated robust efficacy in multiple pre-clinical solid tumor and AML models.

Myeloid-derived suppressor cells (MDSC) inhibit anti-tumor T cell immunity and promote metastatic spread. Immature myeloid cells are also marked by ISR activation. We hypothesized that HC-7366 treatment could further activate the ISR in MDSCs, leading to cell death or reduced suppressive function and improving anti-tumor immunity. To test this, we used the 4T1 murine breast cancer model, which is characterized by expansion of MDSCs that facilitate lung metastasis.

Methods 4T1 cells were orthotopically transplanted into BALB/c mice. Tumor volume was monitored, and tissues or blood were collected at various timepoints for flow cytometry, IHC, or JESS analysis. Mouse bone marrow derived MDSCs were cultured with T-cells in the presence of HC-7366 *in vitro*, and anti-proliferative function was evaluated.

Results HC-7366 treatment showed consistent anti-metastatic efficacy, reducing lung metastases by an average of ~75% across multiple studies. Primary tumors and metastases in treated mice demonstrated GCN2 pathway activation by increases in downstream signaling proteins, including the amino acid biosynthesis proteins ASNS and PSAT1. Anti-tumor efficacy was correlated with significantly decreased Ly6G+ PMN-MDSC frequency in the lungs, spleen, and blood. Additionally, significantly increased expression of the activation markers CD86 and MHCII was observed on PMN-MDSC in both lungs and spleen. Lungs also showed significantly increased T-cell and NK-cell infiltration, activation, and proliferation as measured by increased expression of IL-2, Ki67, T-bet, and Granzyme B. HC-7366 treatment also significantly reduced the S100A8/A9 calcium binding proteins in CD11b+ cells in both metastatic and normal lung tissue, which have been implicated in facilitating MDSC recruitment and proliferation. Reductions in S100A8/A9 were also detectable in PBMCs isolated from peripheral blood and plasma. *In vitro* suppression assays of bone marrow derived MDSCs co-cultured with T-cells in the presence of HC-7366 showed reduced Arginase 1 expression and T-cell inhibition.

Conclusions Collectively, these data demonstrate the anti-metastatic efficacy of HC-7366 and its inhibitory effects on MDSCs, outlining its potential as a monotherapy and in combination with other immunotherapeutics to treat MDSC-enriched metastatic cancers.

Ethics Approval All in vivo experimental procedures were performed in accordance with the NIH Guide for Care and Use of Animals and were approved by the Institutional Animal Care and Use Committee of University of Minnesota. IACUC protocol: 2009A38458

1328 A NOVEL HUMANIZED T CELL-ENGAGING CD24XCD3 BISPECIFIC ANTIBODY FOR CD24-POSITIVE SOLID TUMORS

Madelyn Espinosa-Cotton*, Hong-fen Guo, Nai-Kong Cheung. *Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background CD24 is a small, heavily-glycosylated glycosylphosphatidylinositol (GPI)-anchored protein.[1] It is overexpressed in a variety of adult solid tumors, including breast, ovarian, pancreatic, and colorectal cancers, as well as pediatric cancers such as neuroblastoma, Wilms tumor, and desmoplastic small round cell tumor (DSRCT).[2] In normal tissue, CD24 is expressed transiently during development but is largely absent from mature, differentiated cells.[1] Functionally, CD24 serves as a "don't eat me" signal to macrophages, binding to Siglec-10 and preventing phagocytosis.[3] It is known as a marker of cancer cell stemness and dysregulates numerous signaling pathways involved in proliferation, invasion, and metastasis.[4] The presence of CD24 has been strongly correlated to poor clinical outcome for multiple tumor types.[4-7] For these reasons, CD24 is a strong candidate for targeting with T cell-engaging bispecific antibodies (BsAbs).

Methods We used immunohistochemical (IHC) staining on patient specimens and flow cytometry on cancer cell lines to evaluate CD24 expression in a variety of tumor types. We then generated a panel of CD24xCD3 BsAbs of different formats including a humanized IgG-[L]-scFv BsAb and assessed purity and stability using high-performance liquid chromatography. To evaluate the ability of the BsAbs to engage T cells against CD24-expressing tumor cell lines, we performed standard chromium release assays. We used immunocompromised mice bearing luciferase-transduced intraperitoneal xenografts to test the ability of the BsAbs to redirect T cells to CD24-expressing tumor cells *in vivo*, and monitored tumor growth using *in vivo* bioluminescent imaging.

Results CD24 was found to be strongly expressed by DSRCT, NB, rhabdomyosarcoma, Ewing sarcoma, mesothelioma, liver cancer, breast cancer, ovarian cancer, and pancreatic cancer. CD24xCD3 BsAbs had high purity (<90%) and were stable for several weeks at 40 C. The humanized CD24xCD3 IgG-[L]-scFv BsAb retained binding ability, indicating that the humanization process did not affect its affinity for CD24 on tumor cells. All the CD24xCD3 BsAbs induced T cell-mediated cytotoxicity against DSRCT cell lines *in vitro*. However, as we have shown previously with BsAbs targeting other tumor antigens,[8] the IgG-[L]-scFv format is superior *in vivo*, completely ablating established intraperitoneal DSRCT and ovarian cancer xenografts.

Conclusions CD24 is expressed on a variety of solid tumors and is a viable target for T cell-engaging BsAbs. A novel humanized CD24xCD3 BsAb built on an IgG-[L]-scFv platform is effective at clearing disseminated intraperitoneal CD24-positive xenograft tumors. This strategy warrants further study and could eventually be tested in human trials for patients with advanced tumors.

1329 ULTRA-PH SENSITIVE NANOPARTICLES INCREASE THERAPEUTIC INDEX OF IL-2-FC

[1]Qiang Feng*, [1]Gang Huang, [1]Raymundo Pantoja, [1]Zhichen Sun, [1]Wei Li, [1]Katy Torres, [1]Jonathan Wilhelm, [2]Zirong Chen, [2]Tian Zhao, [2]Ruolan Han, [1]Jinming Gao. [1]*University of Texas Southwestern Medical Center, Dallas, TX, USA*; [2]*OncoNano Medicine Inc, Southlake, TX, USA*

Background Aldesleukin (IL-2) is clinically approved for the treatment of melanoma and renal cancer, but its use is restricted by short half-life and dose limiting toxicities. Protein engineering and prodrug approaches are under extensive investigation but with limited success.[1] Fc fusion of bivalent IL-2 (IL-2-Fc) increases the half-life and efficacy of IL-2 when administered intravenously, but also elevates toxicity compared to IL-2. We developed ON-BOARD, an ultra-pH sensitive nanoparticle technology for tumor-targeted delivery of drug payloads, including biologics to acidic tumor microenvironment (TME).[2, 3] The clinical safety and feasibility of ON-BOARD has been demonstrated by the effective delivery of fluorophores to solid tumors for imaging of multiple cancer types in Phase I/II clinical trials by pegsitacianine.[4] Herein we report ONM-405, an ON-BOARD-encapsulated IL-2-Fc, which is designed to mask toxicity in normal tissues after systemic administration, while achieving pH-activable release of IL-2-Fc at the tumor site against solid cancers.

Methods ONM-405 was formulated through non-covalent self-assembly. pH-dependent protein release was analyzed by fast protein liquid chromatography. Anti-tumor efficacy was evaluated by tumor growth inhibition and survival in murine cancer models. Toxicity was evaluated through bodyweight loss, cytokine release syndrome, lung edema and major organ histology in mice and cynomolgus macaques.

Results ONM-405 shows pH-dependent protection and release of IL-2-Fc. Intravenous injection of ONM-405 in mice demonstrates dramatically reduced toxicity and similar antitumor efficacy compared to IL-2-Fc (figure 1). The maximum tolerated dose (MTD) of IL-2-Fc was determined as 2.1 mg/kg , Q2D×3. Using the same IL-2-Fc equivalent dose, mice treated with ONM-405 show no bodyweight loss, >100-fold reduction in systemic IFN-γ compared to unencapsulated IL-2-Fc, and undetectable lung edema. At 9-fold higher doses over the MTD of IL-2-Fc (i.e., equivalent IL-2-Fc dose of 18.9 mg/kg), ONM-405 only displayed minor, reversible adverse responses such as temporary bodyweight loss. In tumor-bearing mice, ONM-405 inhibited tumor growth at 0.14 mg/kg in immune hot MC38 tumors and 0.7 mg/kg in cold B16F10 tumors, which are comparable to IL-2-Fc. At a dose of 6.3 mg/kg (3-fold higher than MTD of IL-2-Fc), ONM-405 achieved complete response in 5/7 MC38-bearing mice. ONM-405 has significantly widened therapeutic window (>135-fold, 0.14-18.9 mg/kg) compared to IL-2-Fc (15-fold, 0.14-2.1 mg/kg). The enhanced safety profile of ONM-405 is further validated in non-human primates.

Conclusions ON-BOARD technology offers an effective tumor-directed on/off switch achieving antitumor efficacy in solid tumors in response to the acidic TME, while minimizing systemic toxicity of IL-2-Fc in normal tissues.

1330 CHARACTERISING THE IMMUNOTHERAPEUTIC CAPABILITIES OF BACTERIAL OUTER-MEMBRANE VESICLES

[1]Jack Firth*, [2]Jingjing Sun, [2]Jiandong Huang, [1]Kenth Gustafsson, [1]Mona Bajaj-Elliott. *[1]UCL, London, UK; [2]University of Hong Kong, Hong Kong, Hong Kong*

Background Outer-membrane vesicles (OMVs) are highly immunogenic particles shed by Gram-negative bacteria, utilised for a variety of functions from nutrient acquisition to antibiotic resistance. Their potent immunogenicity, in combination with an inability to replicate, has led to these vesicles being developed as a novel class of vaccines. Increasing evidence also suggests that the innate immune activation stimulated by OMVs can facilitate the recognition and destruction of malignant cells, inducing a sustained elimination of tumours in various animal models.[1] At present however, the mechanistic pathways underlying the anti-tumour response remains poorly understood. Herein, we sought to investigate OMV-mediated immune interactions, elucidating key cells able to be leveraged in the context of a potential immunotherapy.

Methods OMVs were isolated from a hypervesiculating *E.coli* K-12 MG1655 strain expressing penta-acylated LPS, achieved via *pal* and *lpxM* deletions. Co-cultures were performed using peripheral blood mononuclear cells (PBMCs) from healthy donors, with cytokine and cell marker expression determined using ELISA and flow cytometry. Negatively-isolated OMV-activated lymphocytes were co-cultured with various cancer cell lines, and cytotoxicity investigated using the MTS assay and flow cytometry.

Results Our findings demonstrate that MG1655 Δ*pal* Δ*lpxM* OMVs induce a broad increase in activation markers on NK cells, □β T cells and γδ T cells. We observed a concordant release of IFN-γ and granzyme B, suggesting the cells exhibit a cytotoxic phenotype upon OMV stimulation. γδ T cells were found to be the predominant cell type to proliferate, expanding from 3% to 40% of the total lymphocyte population. Noticeably, the majority of γδ T cells were of the Vγ9Vδ2 type, which possess the ability to respond to both bacterial metabolites as well as stress markers present on malignant cells. Since Vγ9Vδ2 T cells present an MHC-independent innate-like activation mechanism, they are well positioned to respond to OMV stimulation whilst maintaining oncolytic capabilities. Indeed, we observe robust cytolytic activity of Vγ9Vδ2 T cells against both breast cancer and leukaemia cell lines (SkBr3 and Nalm6 respectively) after OMV-mediated expansion. These data therefore identify Vγ9Vδ2 T cells as able to directly respond to OMV-stimulus whilst maintaining anti-tumour capabilities.

Conclusions Our findings support the hypothesis that Vγ9Vδ2 T cells are a crucial component of the OMV-mediated anti-tumour immune response, cells that may be used to improve future immunotherapies.

1331 DUAL BLOCKADE OF THE EP2 AND EP4 PGE2 RECEPTORS WITH TPST-1495 IS AN OPTIMAL APPROACH FOR DRUGGING THE PROSTAGLANDIN PATHWAY

[1]Justine Lopez, [1]Anja Holtz, [1]Dave Freund, [1]Dara Burdette, [2]Dingzhi Wang, [2]Raymond Duboise, [1]Sam Whiting, [1]Thomas Dubensky, [1]Brian Francica*. *[1]Tempest Therapeutics, South San Francisco, CA, USA; [2]MUSC, Charleston, SC, USA*

Background Prostaglandin E2 (PGE2) is a bioactive lipid produced by tumor cells that drives disease progression through stimulating tumor proliferation, enhancing angiogenesis and suppressing immune function in the TME. PGE2 is also a mediator of adaptive resistance to immune checkpoint inhibitor therapy via the upregulation of cyclooxygenase-2 (COX-2). While the role of PGE2 signaling in cancer is clear, how best to inhibit PGE2 for cancer treatment remains under investigation. Inhibition of COX-1 and/or COX-2 has shown promising results in observational studies and meta-analyses, but inconsistent results in prospective studies. While COX-2 and single EP inhibitors continue to be developed, the nature of PGE2 signaling supports our rationale to inhibit PGE2 by dual antagonism of the pro-tumor EP2/EP4 receptors, while sparing the pro-immune EP1/EP3 receptors. To our knowledge, TPST-1495 is the first clinical-stage dual inhibitor of both the EP2 and EP4 receptors.

Methods We utilized in vitro murine and human whole blood assays to isolate individual effects of EP inhibitors, as well as multiple syngeneic, xenograft, and GEM models to elucidate the effects of PGE2 pathway antagonism in vivo.

Results In mouse and human blood assays, dual blockade of EP2 and EP4 receptors with TPST-1495 reversed PGE2-mediated suppression of T cells and monocytes, while single receptor antagonists were unable to block suppression at higher PGE2 concentrations. In vivo, TPST-1495 monotherapy significantly reduced tumor outgrowth in five of seven syngeneic, xenograft and genetically engineered mouse models. CT26-bearing mice treated with TPST-1495 showed significant increases immune cell infiltration by CD8+, CD4+ and NK cells, and increased M1:M2 ratio among macrophages. APC-min/+ mice treated with TPST-1495 displayed almost complete reduction in tumor burden, which was not observed with other PGE2 pathway inhibitors, and increased in immune cell presence as demonstrated by histopathology. Transcriptional analysis of resected tumors demonstrated an increase in interferon gamma signature, as well as an increase in a gene profile associated with PGE2 inhibition.

Conclusions These results demonstrate the redundancy of EP2 and EP4 receptor signaling and the requirement for EP2 and EP4 to be blocked to achieve full therapeutic effect of PGE2 inhibition in tumors. The data further define the simultaneous effect of TPST-1495 on immune and non-immune compartments that lead to tumor regression. TPST-1495 is currently being evaluated in an ongoing Phase 1 first-in-human study (NCT04344795) to characterize PK, PD, safety, and to identify a recommended phase 2 dose for expansion cohorts in key indications and biomarker-selected patients.

1332 **ANTI-CD161 ANTIBODY IMT-009 IS A NOVEL IMMUNOTHERAPEUTIC AGENT THAT REINVIGORATES T AND NK CELL FUNCTION AND ANTI-TUMOR EFFICACY THROUGH BLOCKING INTERACTION OF CD161 WITH ITS LIGAND CLEC2D**

Alexandria Fusco, Elizabeth Scanlon, Frano Irvine, Flavian Brown, Jeffrey Colbert, Andy Tu, Stephanie Gaerlan, Kelly Nichols, Teresse de Rham, Matthew Huggins, Kendall Dionne, Ming Tang, Heather Flick, Alison Tisdale, Seng-Lai Tan, Shruti Malu*. *Immunitas Therapeutics, Waltham, MA, USA*

Background The CLEC2D/CD161 axis is a novel ligand-receptor pathway for immunotherapeutic intervention. IMT-009 is a monoclonal, aglycosylated human IgG1 antibody directed against CD161, a C-type lectin-like receptor, which is broadly expressed on NK cells and subsets of both CD4+ and CD8+ T cells [Mathewson et al. 2021]. Its cognate ligand, CLEC2D (LLT1), is expressed on the surface of both malignant cells and immune cells, including activated B cells and myeloid cells.

Methods Functional inhibition of CD161 by IMT-009 was demonstrated by using several in in vitro pharmacological and cellular assays which assessed NK cell degranulation, cytokine production and cellular cytotoxicity towards tumor targets, as well as T cell receptor signaling and polyfunctionality using primary antigen-specific human T cells. To prioritize indications that will likely benefit from CD161 blockade therapy, multiplexed immunofluorescence analysis of over 30 solid tumor types was performed.

Results IMT-009 binds CD161 with high affinity and selectivity, blocking its interaction with CLEC2D at an IC50 of 0.94 nM. In presence of CLEC2D-expressing target cells K562, NK cell degranulation, cytokine production and cellular cytotoxicity towards tumor targets is highly suppressed; IMT-009 can overcome this inhibition with an EC50 of 0.2 nM. Similarly, IMT-009 reversed CLEC2D-mediated inhibition and restored T cell receptor signaling and cytokine production in a Jurkat cell reporter system (EC50 = 3.5 nM), as well as enhanced polyfunctionality of primary antigen-specific human T cells, including secretion of TNF-α, IL2, and IFNγ (EC50 = 0.2 nM, 0.4 nM, and 1.4 nM, respectively), and direct T cell mediated cytotoxicity. IMT-009 also released CD161-mediated suppression on effector memory CD161+ CD4+ T cells, resulting in an increased frequency of IFN-γ+ cells and an increase in their proliferation indicative of a stronger recall response to antigen. Finally, multiplexed immunofluorescence data of over 30 solid tumor types showed the highest density of CLEC2D+ and CD161+ cells in the following indications: NSCLC-squamous cell carcinoma, NSCLC- adenocarcinoma, Head and Neck squamous cell carcinoma (HNSCC), Triple negative breast cancer (TNBC), Cutaneous squamous cell carcinoma and Colorectal carcinoma.

Conclusions These results support the development of IMT-009 as a novel cancer immunotherapy for application in several solid tumor indications.

1333 DEVELOPMENT OF IMGS-001, A NOVEL ANTI-PD-L1/PD-L2 DUAL SPECIFIC, MULTI-FUNCTIONAL ANTIBODY, TO TREAT IMMUNE EXCLUDED TUMORS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1333

[1]Christine Gagliardi*, [1]Federica Pericle, [1]Ahmad Salameh, [1]Paul Blezinger, [2]Michael Curran.
[1]ImmunoGenesis, Inc., Houston, TX, USA; [2]MD Anderson Cancer Center, Houston, TX, USA

Background Interruption of the programmed cell death-1 (PD-1) inhibitory pathway by binding PD-1 or its ligand PD-L1 is an effective treatment for various cancers,[1] although resistance is common.[2] PD-1 has a second ligand, PD-L2, that can be expressed by a variety of immunosuppressive stromal cells, endothelial cells, and tumor cells.[3] IMGS-001 is a dual specific monoclonal antibody designed to bind PD-L1 and PD-L2 and block their engagement with PD-1. The Fc region is engineered to induce robust cell-mediated cytotoxicity, enabling depletion of PD-L1$^+$ and PD-L2$^+$ immunosuppressive cells throughout the tumor microenvironment. Here we describe the development of IMGS-001, including potency, specificity, cytokine release potential, pharmacokinetics (PK), and repeat-dose toxicity

Methods Affinities were measured with the Octet system. Reporter cell assays assessed PD-1 pathway blockade, antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent cellular phagocytosis (ADCP). Specificity was evaluated by Retrogenix microarray technology. Potential for spontaneous cytokine release was measured by co-culturing with healthy donor peripheral blood mononuclear cells. PK was measured in mice and in cynomolgus monkeys. In a GLP toxicity study, IMGS-001 was dosed weekly over 4 weeks at 10, 50, or 100mg/kg with a 4-week recovery.

Results The affinity of IMGS-001 to monomeric PD-L1 and PD-L2 is 7.62nM and 1.90nM, respectively. Dimer affinities are 1.28nM and 600pM. It has an EC_{50} of 0.3-1.1nM in a PD-1 blockade assay, the same range as pembrolizumab and avelumab. IMGS-001 has an EC_{50} of <0.5nM in ADCC and ADCP assays. Specificity screening showed no relevant off-target binding and there was no evidence of specific cytokine release. Mouse PK showed drug exposure of ~$1.0x10^4$ µg-hr/ml at the efficacious dose. Half-life was 3.2 days in mice, and 3.7 days in cynos. Repeat-dose toxicity showed mild to moderate hematological and pathological changes, all of which had evidence of reversal within the recovery period. IMGS-001 was manufactured with a titer of 5.95g/L, 98.9% monomer, and 98% purity in the first GMP batch.

Conclusions These data indicate that IMGS-001 binds PD-L1 and PD-L2 and functions per its design. It shows no biologically relevant off target effects, was administered up 100 mg/kg without toxicity, and has a viable PK profile for human administration. It's mechanisms of elimination of immunosuppressive cells with PD-1 pathway blockade could benefit patients that are resistant to existing PD-(L)1 drugs by restoring immune driven anti-tumor activity. IMGS-001 is poised to enter clinical trial in immune excluded tumors by the end of 2022.

1334 AVA-ADR-001 SUPRESSES TUMOR GROWTH AND INDUCES ANTI-TUMOR IMMUNITY BY SELECTIVELY INHIBITING ADAR1 P150

Arun B Papaiah, Avijit Goswami, Sandeep Goyal, Kawaljit Singh, Princy Khurana, Aditya Kulkami*. *Avammune Therapeutics Inc., Levittown, PA, USA*

Background Adenosine deaminase, RNA specific (ADAR1), catalyzes the hydrolytic deamination of adenosine (A) to inosine (I) in double-stranded (ds) RNAs. There are 2 isoforms of ADAR1 (p110 in the nucleus; p150 in cytoplasm) and both modify self dsRNA in coding and non-coding regions. The ADAR1 p150 isoform is expressed from an interferon (IFN)-response promoter and has a Z-DNA/Z-RNA binding domain at the N-terminus. ADAR1 p150 edits 3′-untranslated region dsRNAs comprising of inverted *Alu* repeats and thereby suppresses MDA5-MAVS-IFN signaling. ADAR1 is commonly overexpressed in multiple myeloma, breast, lung, liver, skin and esophageal cancer where it promotes cancer progression. Inhibition of ADAR1 has promising anti-tumor efficacy as monotherapy and in combination with checkpoint inhibitors, radiotherapy and chemotherapeutic modalities. Herein, we outline the discovery of a potential first-in-class ADAR1 inhibitor for cancer immunotherapy.

Methods AVA-ADR-001 was identified through a high throughput p110 knockout cell-based assay. The ability of AVA-ADR-001 to induce interferons was confirmed in various cell lines like A549 p110 KO, HCT116 and B16F10. Finally, the anti-tumor efficacy of AVA-ADR-001 was evaluated in B16F10 syngeneic melanoma mice model as monotherapy and in combination with anti-PD-1.

Results We have identified a first-in-class small molecule inhibitor of ADAR1, which shows significant IFN response *in vitro* in an MDA5 dependent manner. *In vitro* binding studies have confirmed direct binding of AVA-ADR-001 with the Zαdomain of ADAR1 thus confirming its selectivity to the p150 isoform. AVA-ADR-001 demonstrates micromolar EC50 and anti-tumor efficacy against B16F10 melanoma syngeneic mouse model. 100 μg of AVA-ADR-001 treatment resulted in 45% tumor growth inhibition (TGI), 1.5x superior to Anti-PD1 treatment. Combining AVA-ADR-001 with Anti-PD1 demonstrated a synergistic effect 2x superior to Anti-PD1 alone. Additionally, several interferon stimulated genes like IFIH1, IFN-β and CXCL-10 were significantly upregulated in the tumor samples of the AVA-ADR-001 monotherapy and combination groups.

Conclusions To our knowledge no selective small molecule inhibitors of ADAR1 have been reported so far and AVA-ADR-001 is the first disclosure of such an inhibitor. AVA-ADR-001 is a potent and selective first-in-class ADAR1 inhibitor which has shown significant IFN induction in various cancer cell lines and *in vivo* in the tumor microenvironment resulting in substantial tumor growth inhibition as monotherapy and synergistically in combination with Anti-PD1. Considering the immune-suppressive and pro-metastatic role of ADAR1, AVA-ADR-001 serves as a promising starting point for novel ADAR1 inhibitors as therapeutic modalities in cancer immunotherapy.

1335 AVA-NP-695 POTENTLY AND SELECTIVELY INHIBITS ENPP1 TO ACTIVATE STING PATHWAY AND ABROGATE TUMOR METASTASIS IN 4T1 BREAST CANCER SYNGENEIC MOUSE MODEL

Aditya Kulkarni*, Avijit Goswami, Sandeep Goyal, Princy Khurana, Arun Papaiah. *Avammune Therapeutics Inc., Levittown, PA, USA*

Background Innate immune modulators such as STING agonists have become attractive approaches to improve the efficacy of Immune Checkpoint Inhibitors (ICI) due to their ability to turn cold tumors hot. Owing to the modest clinical efficacy of STING agonists, there is a need for other approaches for activating the cGAS-STING pathway for cancer immunotherapy. One such approach is through the inhibition of the enzyme ENPP1, a negative regulator of the STING pathway which directly hydrolyses 2′3′- cGAMP. *ENPP1* is overexpressed in several tumor cells like human astrocyte tumors and TNBC cells like 4T1 and MDA-MB-231, and plays a key role in tumor progression and block T cell infiltration in breast and lung cancer patients. ENPP1 not only abolishes the cGAS-STING mediated immune activation but also produces adenosine, an immune suppressor which promotes cell migration. AVA-NP-695 is a highly potent orally available ENPP1 inhibitor being developed for cancer immunotherapy.

Methods The inhibition potency of AVA-NP-695 was confirmed by enzymatic assays using various substrate like p-Nitrophenyl-5′-TMP, cGAMP and ATP. The efficacy of AVA-NP-695 was depicted in 4T1 Tumor bearing BALB/c mice as monotherapy and in combination with anti-PD-L1, Olaparib and Paclitaxel. Efficacy of AVA-NP-695 in combination with radiation (6.2Gy X 4) was also evaluated in ENPP1 overexpressing ANV5 tumors.

Results Herein, we demonstrate that AVA-NP-695, a selective and potent ENPP1 inhibitor showed no adverse effect at 1000mg/kg BID in 7 Day repeated dose in BALB/C mice, thereby demonstrating an excellent therapeutic window?. Results from in vivo studies have shown superior tumor growth inhibition (TGI) and impact on tumor metastasis by AVA-NP-695 (6mg/kg BID) compared to Olaparib and Anti-PD1 in a syngeneic 4T1 breast cancer mouse model. Subsequently, combination of AVA-NP-695 with Anti-PDL1, Olaparib and Paclitaxel and demonstrated encouraging combinatorial efficacy of AVA-NP-695 along with Paclitaxel. Monotherapeutic arm for Paclitaxel and AVA-NP-695 depicted 40% and 44% TGI respectively, however their combined treatment resulted in ~60% TGI. Additionally, the AVA-NP-695 treatment alone showed 50% enhanced mean survival time followed by 68%, 68% and 72% when given in combination with anti-PD-L1, Olaparib and Paclitaxel respectively. Finally, AVA-NP-695 showed complete tumor ablation of ANV5 ENPP1 overexpressed tumors when given in combination with radiation. Combination group showed significantly delayed recurrence compared to only radiotherapy.

Conclusions The potent anti-tumor efficacy of AVA-NP-695 both as monotherapy and combination along with its safety profile provides a strong rationale for the therapeutic potential of AVA-NP-695 against solids tumors, particularly breast cancer.

1336 DPX-BASED IMMUNE EDUCATION RECRUITS AND ACTIVATES UNIQUE SUBSETS OF ANTIGEN PRESENTING CELLS TO DRIVE IMMUNOGENICITY OF PEPTIDE ANTIGENS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1336

Brennan Dirk*, Moamen Bydoun, Ava Vila-Leahey, Erin Kelly, Olga Hrytsenko, Jeremy Graff.
IMV inc., Dartmouth, Canada

Background For peptide-based cancer vaccines, successful eradication of tumors relies on the effective and persistent delivery of antigenic peptides to antigen presenting cells (APCs) to prime potent antigen-specific, cytotoxic T cells. Peptide-based vaccines have historically been either; (1) water-based formulations, which provide short exposure of peptides to immune cells; or (2) oil-in-water emulsions that provide longer peptide exposure but can elicit dysfunctional and exhausted T cell phenotypes. By contrast, the DPX® technology is a non-aqueous, lipid-in-oil, immune-educating therapeutic delivery platform. Antigenic peptides formulated in DPX elicit a robust, targeted, and persistent tumor antigen-specific T cell response that for our lead DPX product, Maveropepimut-S, has translated into clinical benefit in multiple cancer indications, including DLBCL and ovarian cancer.

Methods Herein, we compare DPX to aqueous and emulsion-based formulations for the dynamics of immune cell recruitment to the site of injection (SOI), peptide antigen consumption, and trafficking by immune cells. Immune cell composition and antigen uptake at the SOI were assessed by multi-parameter flow cytometry and confocal microscopy using model peptide antigens administered in C57/Bl6 mice. Antigen-specific immune responses were assessed in draining lymph nodes and/or spleens by IFN-γ ELISPOT.

Results These data reveal that aqueous formulations were poorly able to retain lymphocytes at SOIs and consequently did not elicit a detectable IFN-γ ELISPOT response. Both formulations containing an oil component (DPX and emulsion) were superior in recruiting APCs cells to the SOIs and inducing antigen-specific immune responses. Significant increases in immune cell infiltration were detected as early as 2 days post DPX injection. Antigen uptake was confirmed using confocal microscopy. Both DPX and emulsion platforms induced a prompt increase in antigen presentation in the context of MHC. However, antigen presentation driven by the DPX platform had a distinct profile enriched in $CD11b^{+}CD11c^{+}MHCII^{+}$ APCs co-expressing the CD80, CD86, and CD40 activation/costimulatory markers. The recruitment and activation of this subset was evident regardless of whether a peptide was present in DPX. By contrast, the emulsion incites a distinctly different $CD11b^{-}CD11c^{-}$ population. Interestingly, $CD11b^{+}CD11c^{+}$ cells have tendency to express higher number of peptide-MHC complexes per cell compared to the $CD11b^{-}CD11c^{-}$ population.

Conclusions Collectively these findings highlight quantitative, qualitative, and temporal differences in immune cell recruitment amongst three delivery platforms and show the unique character of the immune response triggered by the DPX platform typified by the recruitment of $CD11b^{+}CD11c^{+}$ APCs that have intrinsically higher capacity for antigen uptake, presentation, and activation.

Ethics Approval Experiments were conducted in accordance with ethics protocols approved by the University Committee on Laboratory Animals at Dalhousie University, Halifax, N.S., Canada.

1337 PRECLINICAL EVALUATION OF STAR0602, A NOVEL, FIRST-IN-CLASS ANTI-TCR VB TARGETED BISPECIFIC ANTIBODY WITH POTENT ANTI-TUMOR ACTIVITY FOR PD-1 REFRACTORY SOLID TUMORS

[1]Zhen Su, [2,3]James Gulley*, [2]Jeffrey Schlom, [4]Lillian Siu, [5]Ryan Sullivan, [6]E John Wherry, [1]Ke Liu, [3]Renee Donahue, [1]Madan Katraggada, [7]Rajesh Chopra, [1]Jacques Moisan, [1]Jonathan Hsu, [3]Yo-Ting Tsai. *[1]Marengo Therapeutics, Cambridge, MA, USA; [2]NCI, Bethesda, MD, USA; [3]NIH, Bethesda, MD, USA; [4]Princess Margaret Cancer Center, Toronto, Canada; [5]MGH, Boston, MA, USA; [6]UPENN, Philadelphia, PA, USA; [7]Marengo Therapeutics, London, UK*

Background Despite recent advancements with immune checkpoint inhibitors (e.g., anti-PD1 inhibitors) many cancer patients develop treatment resistance, which supports the study of alternative approaches to induce potent and safe anti-tumor T cell responses. STAR0602 is a bifunctional antibody-fusion molecule that selectively activates and expands a sub-set of human aβ T cells expressing variable (V) b6 and b10 regions of the T cell receptor (TCR). STAR0602 simultaneously engages a novel, non-clonal mode of TCR activation with cytokine co-stimulation.

Methods The prevalence of STAR0602-targeted Vb T cells in tumor-infiltrating lymphocytes (TILs) from human tumor tissues was investigated by flow cytometry and by interrogating TIL TCRseq data from a large cancer database. The effects of STAR0602 on T cells from healthy donors and cancer patients were assessed *in vitro* by flow cytometry and NanoString. Using high tumor mutational burden (TMB) and anti-PD1-insensitive murine and human models, we investigated anti-tumor activity, mechanism of action, and an enrichment strategy for patient trials. Finally, the pharmacokinetics (PK) and pharmacodynamics (PD) of IV STAR0602 were investigated in Cynomolgus monkeys.

Results Presence of STAR0602-targeted Vb T cells were confirmed in tissue from a range of human tumors, and present as 10-12% of TILs. Stimulation of T cells with STAR0602 resulted in potent expansion with ~80% adopting a novel memory phenotype, and significant boosting of antigen-specific T cells. In human autologous tumor organoid models, STAR0602 induced potent expansion of TILs and killing of tumors, including several PD1 refractory tumors. Dose-related anti-tumor activity (100% cure rate with a murine surrogate (mSTAR0602)) in EMT6-bearing mice correlated with expansion of memory Vb $CD8^+$ T cells. In Cynomolgus monkeys, IV STAR0602 induced robust expansion of Vb $CD8^+$ T cells in blood, with limited cytokine release or expansion of Treg. These data were used to build a PK/PD model to simulate human pharmacology and design a first-in-human trial with an enriched patient population.

Conclusions STAR0602 is a first-in-class T cell activator that targets subsets of the germline TCR repertoire that are enriched in TILs. STAR0602 potently expands both naive and antigen-specific human T cells. In PD1 refractory human and murine tumor models with a high TMB, STAR0602 and mSTAR0602 induce potent anti-tumor activity as monotherapy, mediated by selective expansion of Vb $CD8^+$ memory T cells. This pharmacology was translated into monkeys with IV dosed STAR0602 and supports the design of a novel Phase 1/2 precision-oncology trial with STAR0602 planned to commence in 2022.

1338 SRF114, AN AFUCOSYLATED ANTI-CCR8 ANTIBODY, DEPLETES INTRATUMORAL TREG CELLS AND REDUCES TUMOR GROWTH

Robert Haines*, Marisella Panduro, Andrew Lake, Vito Palombella, Jonathan Hill, James Mohan. *Surface Oncology, Cambridge, MA, USA*

Background Intratumoral regulatory T (Treg) cells promote an immunosuppressive tumor microenvironment, and their increased frequency correlates with poor clinical prognosis.[1-4] Gene expression profiling has identified chemokine receptor 8 (CCR8) as being highly upregulated by intratumoral Treg cells compared to their lymphoid tissue and blood counterparts, as well as other immune cell types.[5,6] Because of this restricted expression, using anti-CCR8 antibodies capable of inducing antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP) to deplete intratumoral Treg cells represents an attractive therapeutic hypothesis for cancer treatment. Treatment of mouse cancer models with anti-CCR8 antibodies depleted intratumoral Treg cells and reduced tumor growth.[7,8] Furthermore, anti-CCR8 treatment can synergize with anti-PD-1 treatment in anti-PD-1–susceptible and –resistant cancer models, highlighting the therapeutic potential of anti-CCR8 antibodies.

SRF114 is a fully human, afucosylated anti-CCR8 antibody designed to preferentially deplete $CCR8^+$ Treg cells within the tumor microenvironment. Here, we explore the ability of SRF114 to activate effector immune cells associated with ADCC and ADCP, deplete Treg cells, and reduce tumor growth in a mouse cancer model.

Methods Surface expression of CCR8 on human intratumoral and peripheral immune cells was characterized by flow cytometry. Human peripheral blood mononuclear cells (PBMCs) and dissociated tumor cells (DTCs) were cultured with SRF114 to examine immune cell activation and Treg cell depletion. The efficacy of SRF114 was assessed in MC38 tumor–bearing human CCR8 knock-in (hCCR8 KI) mice.

Results CCR8 surface expression was highest on intratumoral Treg cells compared with peripheral Treg cells and other immune cells. In PBMC cultures, Fc gamma receptor (FcγR)–expressing cells, including natural killer (NK) cells and monocytes, exhibited dose-dependent activation from SRF114 bound to $CCR8^+$ cells. DTC cultures treated with SRF114 also displayed dose-dependent NK cell activation and selective Treg cell depletion, with marginal impacts on effector T cell populations. The potency of SRF114 to activate $Fc\gamma R^+$ cells in DTCs was enhanced compared with that in PBMCs due to increased CCR8 expression on Treg cells. In a syngeneic tumor model, hCCR8 KI mice treated with SRF114 exhibited a significant reduction in tumor growth and depletion of intratumoral Treg cells, with minimal impact on their peripheral counterparts.

Conclusions SRF114 can induce ADCC and/or ADCP pathways to deplete $CCR8^+$ Treg cells in vitro. Demonstrated depletion of intratumoral Treg cells and reduction of tumor growth in vivo support SRF114 as a therapeutic candidate to deplete intratumoral Treg cells and drive antitumor immunity in human cancer patients.

1339 **ALD2510: NEXT GENERATION FC-ENHANCED, T_{REG}-SELECTIVE AND IL-2-SPARING ANTI-CD25 ANTIBODY WITH PROMISING POTENTIAL FOR THE TREATMENT OF GYNECOLOGICAL CANCERS**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1339

[1]Jemila Houacine, [1]Riad Abes, [2]Anne Marie-Cardine, [1]Aude LeRoy, [3]Jerôme Giustiniani, [4]Anne-Sophie Chrétien, [4]Stéphane Fattori, [4]Laurent Gorvel, [2]Armand Bensussan, [5]Daniel Olive, [1]Arnaud Foussat*. *[1]Alderaan Biotechnology, Paris, France; [2]INSERM U976, Hôpital Saint Louis, Paris, France; [3]INSERM U955, Hôpital Henri Mondor, Créteil, France; [4]Institut Paoli Calmettes, Marseille, France; [5]Institut Paoli Calmettes, INSERM UMR1068, Marseille, France*

Background Regulatory T cells (T_{REG}) inhibit immune responses in many solid cancers and are associated with worse prognosis when they infiltrate tumours. ALD2510 is a low-fucose IL-2-sparing anti-CD25 antibody designed for the selective depletion of T_{REG}, allowing the boost of immune effector functions within the tumor micro-environment (TME) and making it a promising candidate for therapy of solid tumors.

Methods ALD2510 potency and mechanisms of action were investigated in T_{REG} depletion, ADCC, ADCP and trogocytosis assays and in syngeneic or humanized animal models of cancer. Characterization of T_{REG} subpopulations within the TME was achieved by flow and mass cytometry followed by t-sne analysis using biopsies from gynecological cancer patients. ALD2510 safety, tolerability and pharmacokinetic (PK) profile were determined in cynomolgus monkey, with doses up to 100mg/kg. ALD2510 manufacturability was assessed through fed-batch production and analytical characterization.

Results ALD2510 showed strong T_{REG} depletion, ADCC and ADCP activities, while sparing $CD4^+$ and $CD8^+$ T cell compartments, demonstrating its selectivity for T_{REGS} and a mode of action involving multiple effector cell types. ALD2510 also promoted trogocytosis of induced T_{REG}, suggesting that tumour-infiltrating neutrophils may contribute to its function. In vivo, as monotherapy, ALD2510 confirmed selective and potent T_{REG} depletion together with significant tumor growth inhibition, which could be further improved when combined with checkpoint inhibitors, leading to complete tumor regressions.

Immunophenotyping of tumor biopsies and related PBMCs from gynecological cancer patients and further t-sne analysis allowed the identification of four T_{REG} subsets. That with the highest CD25 expression was shown to be tumour specific and presented the most immunosuppressive phenotype, thus constituting a preferential target for ALD2510.

In a cynomolgus exploratory toxicology study, ALD2510 showed excellent safety and tolerability with doses up to 100mg/kg. PK and exposition parameters were found in line with those of typical humanized IgG1 in NHP.

The manufacturability of the ALD2510 CHO cell line was demonstrated through 10L fed-batch production, where productivity reached ~4g/L. Analytical characterization of purified ALD2510 materials revealed excellent purity and activity, together with very low levels of process-/cell-related impurities.

Conclusions ALD2510 is a next generation Fc-enhanced, T_{REG}-selective and IL-2-sparing anti-CD25 mAb showing *in vitro* and *in vivo* efficacy, fully satisfactory safety and tolerability in NHP and excellent manufacturability. ALD2510 thus appears as a promising candidate for treatment of solid tumor patients, especially those suffering from gynecological malignancies, where highly immunosuppressive $CD25^{high}$ T_{REGS} were identified in the TME.

1340 BT7455, A FULLY SYNTHETIC *BICYCLE* TUMOR-TARGETED IMMUNE CELL AGONIST®, LEADS TO POTENT EPHA2-DEPENDENT CD137 AGONISM AND ROBUST ANTI-TUMOR EFFICACY

Kristen Hurov*, Lia Luus*, Johanna Lahdenranta, Punit Upadhyaya, Heather Cohen, Chinmayee Shah, Julia Kristensson, Peter Brown, Gemma Mudd, Carly Campbell, Elizabeth Repash, Eric Haines, Sailaja Battula, Mike Kelly, Phil Jeffrey, Paul Beswick, Liuhong Chen, Kevin McDonnell, Philip Brandish, Nicholas Keen. *Bicycle Therapeutics, Lexington, MA, USA*

Background To address the limitations of antibody-based agonists of immune costimulatory receptors, we have developed a new class of modular synthetic drugs, termed *Bicycle*® tumor-targeted immune cell agonists (*Bicycle*® TICAs), which are multifunctional molecules comprised of constrained bicyclic peptides (*Bicycles*).[1] The first molecule of this class, BT7480, a Nectin-4-dependent CD137 (4-1BB) agonist, entered clinical trials in 2021 in patients with solid tumors associated with Nectin-4 expression. Compelling preclinical data characterizing BT7480[2] led us to develop a second *Bicycle* TICA™ molecule, BT7455, which is designed to deliver highly potent CD137 agonism to Ephrin receptor A2 (EphA2)-positive cancers. EphA2 is a receptor tyrosine kinase overexpressed in several human cancers and its high expression correlates with poor clinical prognosis in certain cancer types.[3, 4]

Methods BT7455 bioactivity was assessed *in vitro* using a CD137 reporter assay and by measuring proinflammatory cytokine production in human PBMC/tumor cell co-cultures. BT7455 *in vivo* pharmacological activity was evaluated in efficacy studies in syngeneic EphA2-positive mouse tumor models and pharmacodynamic studies using transcriptional profiling of the tumor immune microenvironment by NanoString.

Results BT7455 engages EphA2 and CD137 with high affinity resulting in picomolar potency in co-culture assays consisting of EphA2-expressing tumor cells and CD137-expressing Jurkat NF-kB-luciferase reporter cells. Moreover, BT7455 led to EphA2-dependent production of interleukin-2 (IL-2) and interferon gamma (IFNg) in primary human PBMC/tumor cell co-culture assays. Treatment of MC38 tumors in immunocompetent mice with BT7455 with an intermittent dosing regimen led to robust anti-tumor activity, including complete responses. Gene expression profiling of BT7455-treated tumors revealed modulation of the tumor immune microenvironment, including a rapid increase in cytokine expression (both myeloid and T cell origin) and an increase in cytotoxic cell scores. The kinetics and extent of the immune microenvironment modulation differentiated BT7455 from both a checkpoint inhibitor (anti-mouse PD-1) as well as an anti-CD137 agonist antibody (Urelumab analogue). BT7455 treatment also led to the increase in checkpoint gene expression, suggesting that combination with checkpoint inhibitor therapy may be effective. BT7455 exhibits linear pharmacokinetics in non-human primates and appears well-tolerated at exposures more than the predicted efficacious exposure in humans without significant elevation of cytokines or liver enzymes.

Conclusions BT7455 is a highly potent EphA2 expression-dependent CD137 agonist with optimal target binding, pharmacologic, and pharmacokinetic properties that enable intermittent dosing for curative effect through modulation of the tumor immune microenvironment in syngeneic mouse models. BT7455 is currently being evaluated in IND-enabling safety studies.

1341 CD27 AN EMERGING IMMUNO-ONCOLOGY TARGET AT THE CROSS-ROADS OF INNATE AND ADAPTIVE ANTI-TUMOR IMMUNE RESPONSES

Thierry Guillaudeux*, Shawn Iadonato, Jessica Cross, Nathan Eyde, Emily Frazier, Neda Kabi, Chen Katz, Remington Lance, Yulia Ovechkina, Kurt Lustig, David Peckham, Shaarwari Sridhar, Carla Talbaux, Isabelle Tihista. *Kineta Inc., Seattle, WA, USA*

Background CD27 is a member of the TNF-Receptor superfamily expressed on CD4+ and CD8+ T cells, on NK and NKT cells and on B cells. It promotes T cell co-activation, proliferation, clonal expansion and differentiation into antigen specific cytotoxic and memory T cells after stimulation with its ligand CD70. Its stimulatory signal is mediated via the NFkB pathway, but also via the phosphatidylinositol 3 kinase and the protein kinase B. Moreover, CD27 signaling influences the innate immune response via a direct activation of NK cells and a subsequent secretion of interferon-gamma (IFN-γ). CD27 plays a central role in immunological responses and by promoting T cell and NK cell activation it contributes to anti-tumor immunity. Previous studies have demonstrated tumor growth inhibition with anti-CD27 agonistic monoclonal antibodies in different mice models for solid and hematological tumors. This mechanism of action can be partly explained by the recruitment of IFN-γ producing CD8+ T cells within the tumor. CD27 is a promising target for antitumor therapy.

Methods Kineta has generated a library of 147 fully human anti-CD27 monoclonal antibodies after immunization of Trianni mice.

Results From this library, a lead candidate with strong agonistic proprieties has been selected. This anti-CD27 antibody originates from a unique clade after alignment of the variable heavy chains. Kineta's lead candidate demonstrates selectivity and cross-reactivity with Non-Human Primate (NHP)-CD27 but not with the mouse-CD27. It also induces strong NFkB signaling in a Jurkat T cell-reporter, either soluble or cross-linked. It also induces T cell proliferation and secretion of pro-inflammatory cytokines in vitro. This T cell activation occurs only in the presence of a TCR engagement preventing future risks of spontaneous activation of naïve T cells *in vivo*. Our lead antibody also induces direct activation of NK cells demonstrated by the expression of CD69 on their surface. We have evaluated the anti-tumor properties of our lead antibody as a single agent in vivo in human CD27 Knock-In (KI) mice. Our anti-CD27 candidate induces a significant anti-tumor activity in the EG7 thymoma model. We have also demonstrated the anti-tumor efficacy of this lead candidate in Raji cells implanted in Scid mice. Preliminary experiments performed in human CD27 KI mice have demonstrated a long half-life of our antibody at different concentrations.

Conclusions Epitope characterization, NHP pharmacokinetic analysis and additional in vivo studies of our lead anti-CD27 antibody in different tumor models use as a single agent and in combination with different check-point inhibitors are ongoing.

1342 THERAPEUTIC TARGETING OF MARCO WITH PY265 ANTIBODY PROMOTES MYELOID CELL REPROGRAMMING AND UNLEASHES ANTI-TUMOR IMMUNITY

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1342

Linnea Haeggblom*, Subhadra Dash, Yelena Vayn, Josh Rudolph, Rachael Palmer, Xi Yang, Sergio Lacayo, Cesar Juarez, Erin Mayes, Rachel Greathouse, Kara Mojica, Carlos Santamaria, Johanna Ramoth, Ranna Mehta, Maryam Yousefi, Nadine Jahchan, Svetlana Gratch, Amy-Jo Casbon, Joshua Pollack, Marc Chamberlain, Leonard Reyno, Matthew Myers, Vladislava Juric, Linda Liang, Kristen Pierce, Kevin Baker, Nadine Jahchan. *Pionyr Immunotherapeutics, South San Francisco, CA, USA*

Background The tumor microenvironment (TME) contains immunosuppressive myeloid cells that contribute to checkpoint inhibitor (CPI) resistance. One approach as part of Pionyr Immunotherapeutics' Myeloid Tuning™ strategy is to reprogram immunosuppressive myeloid cells to acquire an immunostimulatory anti-tumor phenotype. Macrophage Receptor with a Collagenous Structure (MARCO) is an attractive target for myeloid reprogramming, considering its immunomodulatory function and expression on tumor-associated macrophages (TAMs) and monocytic myeloid derived suppressor cells (mMDSCs) in the TME. Pionyr has developed a humanized IgG1 k anti-MARCO monoclonal antibody, PY265, to investigate the potential of MARCO modulation as an anti-cancer immunotherapeutic strategy.

Methods MARCO expression on TAMs and mMDSCs from multiple solid tumor indications was determined by single-cell RNA sequencing and by using immunohistochemistry (IHC). PY265 activity on human monocyte derived macrophages (hMDMs) in vitro was evaluated by transcriptional profiling, phosphoprotein array, flow cytometry, and cytokine/chemokine measurements. In vivo efficacy and pharamacodynamic studies using a surrogate anti-mouse MARCO antibody, PY265m, as single agent or in combination with anti-PD-1, were evaluated using syngeneic mouse tumor models.

Results MARCO is specifically enriched in a cluster of TAMs and mMDSCs that correlates with immunosuppressive signatures in multiple solid tumor types. Moreover, IHC profiling shows that MARCO is commonly expressed in the TME of these tumors, and maintain expression in metastatic lesions, as well as in chemo- and CPI-treated tumors. PY265 induces reprogramming in hMDMs in vitro through induction of rapid phosphorylation events, transcriptional activation of pro-inflammatory pathways, production of cytokines and chemokines, and upregulation of cell surface activation receptors. PY265m demonstrates significant anti-tumor activity in syngeneic mouse models as single agent in CPI-sensitive models and in combination with anti-PD-1 in CPI-resistant models. Pharmacodynamic studies suggest that PY265m induces immune activation by reprogramming pro-tumorigenic, M2-like TAMs and mMDSCs to pro-inflammatory anti-tumor M1-like macrophages and monocytes, leading to an increase in infiltration of effector cells in the tumor, spleen, and tumor draining lymph nodes. In a non-human primate toxicokinetic study, PY265 was generally well tolerated at all dose levels tested.

Conclusions Our study demonstrates that targeting MARCO reprograms myeloid cells and remodels the TME to unleash anti-tumor immunity and convert CPI-resistant tumors into treatment responsive tumors. Collectively, these preclinical data support PY265 immunotherapy, alone or in combination with a CPI, in cancer patients resistant or refractory to CPI therapies, to potentially improve both the overall response rate as well as durability of response. First-in-human testing of PY265 will be initiated in 2023.

1343 ANTITUMOR EFFECT OF DA-4507, A NOVEL GCN2 INHIBITOR AS AN IMMUNOTHERAPY IN THE TUMOR MICROENVIRONMENT

Youngjee Jeong*, Jun-Hwan Moon, Ik-Soo Jang, Kyu Hwan Kim, Na Yeon Park, Hyung Ki Lee, Cheonhyoung Park, Tae-Hun Kim, Do Young Choi, Ha Yoon Kim, Ki Moon Ryu, Min Jung Lee, Hyounmie Doh. *Dong-A ST, Yong-in, Korea, Republic of*

Background General control nonderepressible 2 (GCN2) kinase is an integrated stress response (ISR) kinase that responds to amino acid deficiency.[1] Activation of GCN2 in tumor microenvironment (TME), where nutrients are scarce, leads to suppression of immune system and upregulation of translation of proteins for amino acid replenishment.[2] In this study, it was investigated whether immune cells whose function was suppressed in the tumor microenvironment were recovered through selective pharmacological inhibition of GCN2 and whether antitumor effects were exhibited through this. Also, inhibition effects of the tumor intrinsic signaling of GCN2 was evaluated using several cancer cell lines. Taken together, we have shown that inhibition of GCN2 activity could exert anti-tumor efficacy in various ways in the tumor environment.

Methods We have discovered a novel small molecule GCN2 inhibitor, DA-4507, that is highly potent and selective *in vitro*. Recovery of effector T cell function and macrophage polarization by DA-4507 were evaluated using mouse primary immune cells under tryptophan-deprived condition. T cell rescue was evaluated using co-culture system with MDSCs accumulated in tumor tissues of syngeneic mouse model. Tumor-intrinsic activities were validated *in vitro* in human leukemia, melanoma, breast cancer, and colorectal cancer cell lines. Also, antitumor effects of DA-4507 were evaluated in the murine syngeneic colorectal, breast cancer and human xenograft leukemia models.

Results DA-4507 exhibited high potency (IC50=5 nM) and selectivity for GCN2 over other ISR kinases. DA-4507 restored proliferation of cytotoxic T cells and suppressed differentiation of regulatory T cell in low-tryptophan media, where proliferation of T cell was reduced and differentiation of regulatory T cell was increased. DA-4507 also mitigated the suppressive function of MDSCs on T cells and induced macrophage polarization toward inflammatory macrophage phenotype (M1). By blocking the tumor-intrinsic activity, DA-4507 showed anticancer effects in various cancer cell lines in a context-dependent manner. Oral administration of DA-4507 induced a significant reduction of the tumor growth in several murine syngeneic mouse models and a human leukemia xenograft model and decreased ATF4 and phospho-eIF2α in tumor tissues. We also confirmed that the antitumor effect of DA-4507 is $CD8^+$ T cell-dependent.

Conclusions The activation of GCN2 is known to result in functional suppression of the immune cells and activation of survival pathway of cancer cells in the TME. Our results show that DA-4507, a potent and selective GCN2 inhibitor restores T cell suppression and promotes antitumor activity, demonstrating that GCN2 is a promising therapeutic target for cancer treatment.

1344 PRECLINICAL PK/PD PROFILE, BIOMARKER IDENTIFICATION AND RATIONALE FOR INDICATION SELECTION OF EXOASO-STAT6™, A SELECTIVE TUMOR-ASSOCIATED MACROPHAGE TARGETING CANDIDATE

Sushrut Kamerkar*, Charan Leng, Kelvin Zhang, Olga Burenkova, Su Chul Jang, Tong Zi, Sílvia Sisó, Kyriakos Economides, Karl Schmidt, Timothy Soos, Dalia Burzyn, Sriram Sathyanaryanan. *Codiak Biosciences, Cambridge, MA, USA*

Background exoASO-STAT6™ is an investigational therapeutic candidate consisting of exosomes loaded with an antisense oligonucleotide (ASO) targeting STAT6. By leveraging exosome tropism to tumor-associated macrophages (TAM), exoASO-STAT6™ is the first systemically administered exosome designed to selectively silence STAT6 in TAMs, inducing their reprogramming from 'M2' immunosuppressive to 'M1' proinflammatory phenotype, resulting in the induction of an antitumoral immune response and potent monotherapy activity in mouse models. A Phase I study in hepatocellular carcinoma (HCC) patients is currently enrolling.

Methods Here, we evaluated Pharmacokinetics (PK) and Pharmacodynamics (PD) of systemically dosed exoASO-STAT6 in mouse and non-human primates (NHP), identified PD biomarkers with clinical translatability and generated bioinformatic-based rationale for the selection of tumor indications in the clinic.

Results PK analysis in mice and NHP treated with a single IV dose of exoASO-STAT6 (mouse: 0.2-1.5 mg/kg; NHP: 0.3-2.7 mg/kg) suggested rapid clearance of ASO from the plasma within hours. exoASO-STAT6 accumulated in the liver in a dose-proportional manner and was detectable for up to 28 days at all dose levels. Repeated (weekly) administration of exoASO-STAT6 resulted in increased ASO exposure in the liver. PD analysis of STAT6 mRNA expression in liver tissue after a single IV dose showed dose-dependent and durable target gene knockdown (KD) that persisted for up to 28 days with maximal KD between days 4 and 7 in mouse (1.5 mg/kg dose: 69.2±0.7% KD, $p<0.0005$ vs. control), and at day 9 in NHP (first timepoint measured) (2.7 mg/kg dose: 50±3% KD, $p<0.0001$ vs. control). The extent of STAT6 KD in the liver is proportional to liver exposure, demonstrating a direct relationship between exoASO-STAT6 dose and PD response. Gene expression analysis from NHP liver showed durable modulation of several genes, including IL-4 receptor (IL4R), a gene directly regulated by STAT6 (day 9, 2.7 mg/kg dose: 58±7% KD, $p<0.0001$ vs. control). Histological analysis confirmed that STAT6 and IL4R are expressed by TAMs in human HCC tumors, supporting the rationale to use these two biomarkers in the clinic. Analysis of The Cancer Genome Atlas database identified several tumor indications in which high expression of a macrophage-STAT6 signature correlates with poor survival, including HCC, stomach, and bladder cancer ($p=0.012$, $p=0.00056$, and $p=0.0021$, respectively).

Conclusions In summary, we demonstrated that exoASO-STAT6 has a durable PK/PD profile in the liver of preclinical species, identified PD biomarkers with good clinical translational potential and described a rationale for selecting cancer subtypes that could benefit from treatment with exoASO-STAT6.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1344

1345 **EXOASO-C/EBPβ™: AN ENGINEERED EXOSOME THERAPEUTIC THAT SELECTIVELY TARGETS MDSCS AND INDUCES POTENT SINGLE-AGENT ANTI-TUMOR ACTIVITY IN CHECKPOINT REFRACTORY TUMOR MODELS**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1345

Sushrut Kamerkar*, Charan Leng, Olga Burenkova, Su Chul Jang, Kelvin Zhang, Samuel Kasera, Tong Zi, Sanah Langer, Silvia Siso, Timothy Soos, Dalia Burzyn, Sriram Sathyanaryanan. *Codiak BiSciences, Cambridge, MA, USA*

Background Myeloid-derived suppressor cells (MDSCs) are pathologically activated monocytes and neutrophils that promote an immunosuppressive milieu by inhibiting T-cell activation and recruitment, leading to resistance to immune checkpoint therapies and poor clinical outcomes. C/EBPβ is a critical transcription factor that regulates the immunosuppressive state of MDSCs and is activated by prostaglandin E2 (PGE2) and interleukin 10 (IL10). Both PGE2 and IL10 are involved in MDSC development, accumulation and functional stability.

Methods We have developed a proprietary engineered exosome loaded with antisense oligonucleotides (ASO) targeting C/EBPβ (exoASO-C/EBPβ™), that selectively delivers ASOs to MDSCs, thereby inhibiting C/EBPβ expression, promoting the immune-modulation of MDSCs to a pro-inflammatory phenotype, and demonstrating single agent anti-tumor activity in checkpoint refractory tumor models.

Results Human MDSCs were generated and characterized *in-vitro* using a combination of putative cell surface markers: CD11b, CD33, HLA-DR, CD14 and CD15. Exosome surface glycoproteins enabled preferential delivery of ASO to MDSCs, as demonstrated by a 3-fold improvement in delivery with exoASO vs free ASO. Treatment of MDSCs with exoASO-C/EBPβ resulted in a dose-dependent target gene knockdown, and a cytokine secretion profile consistent with a proinflammatory phenotype. Biodistribution in tumor-bearing mice of systemically administered exoASO demonstrated up-to 11-fold improvement in selective ASO delivery as compared to free ASO, in MDSCs and other myeloid cells in the tumor, blood, and bone marrow. Administration of exoASO-C/EBPβ as a single agent demonstrated significant anti-tumor activity and survival benefits in multiple MDSC rich, checkpoint refractory tumor models: E0771-breast cancer (30% complete responses (CRs)), MB49-bladder cancer (70% CRs) and 4T1-breast cancer (44% Tumor growth inhibition (TGI)). Combination treatment with anti-PD1 further increased the anti-tumor efficacy, while the complete responders were resistant to tumor re-challenge, demonstrating immunological memory associated with exoASO-C/EBPβ treatment. In a lung metastasis model of B16F10 with disseminated tumors in the abdominal cavity, IV administration of exoASO-C/EBPβ significantly attenuated tumor growth (92% TGI with monotherapy, 98% TGI with a combination with anti-PD1), as observed with ex-vivo IVIS imaging. Additionally, exoASO-C/EBPβ treatment resulted in a significant infiltration of cytotoxic CD8 T cells in the lung and tumor. Finally, a myeloid cell specific C/EBPβ/PGE2/IL10 gene signature was generated to identify cancer indications where exoASO-C/EBPβ therapy may have the most therapeutic significance.

Conclusions exoASO-C/EBPβ is a novel therapeutic that selectively targets and attenuates a critical transcription factor in immunosuppressive myeloid derived suppressor cells, resulting in their immune-modulation and potent anti-tumor activity across multiple MDSC rich tumor models.

1346 ANTIBODIES AGAINST GLYCOTARGETS AS NOVEL PLATFORM APPROACH TO ADDRESS UNMET NEEDS IN CANCER THERAPY

Patrik Kehler*, Theresa Neumann, Anika Jaekel, Manon Weis, Johanna Gellert, Antje Danielczyk, Evelyn Hartung, Timo Lischke, Stephanie Gurka, Naomi Kast, Manon Weiske. *Glycotope GmH, Berlin, Germany*

Background Highly potent therapeutic approaches require clean targets. However, the majority of antibodies in clinical development or approved for cancer therapy address protein targets that are only overexpressed in cancer and yet often show significant expression in healthy organs. Besides protein expression, glycosylation is strongly altered in cancer, reflecting changes in tumor metabolism. Aberrant glycosylation is reasoned by mutated or mislocated glycosyltransferases, glycosidases, substrates and chaperones, giving rise to truncated or highly fucosylated or sialylated glycans.[1] Therefore, tumor-associated carbohydrates like the Thomsen-Friedenreich (TF), Thomsen novelle (Tn) or sialylated Tn (sTn) antigen are expressed on proteins in different carcinomas, leukemias, lymphomas and their metastases.[2]

To increase the tumor-selectivity of protein-targeting antibodies, we developed antibodies against protein/carbohydrate combined epitopes (GlycoTargets), which bind their protein target only in presence of tumor-associated carbohydrates and thereby avoid binding to the protein if it is expressed in healthy tissues.

Methods The general presence of tumor-associated carbohydrates in cancerous tissues was analyzed using immunohistochemistry. HPLC and mass spectrometry (MS) or bioinformatic prediction was applied to further confirm their presence on specific proteins. Different cell lines were developed and characterized by ELISA and MS to recombinantly express proteins carrying distinct carbohydrates. These GlycoTargets were used for immunization and antibody discovery. Specificity, glycosylation dependency and cell binding properties of antibody lead candidates were characterized by ELISA, flow cytometry and immunohistochemistry on tumor and healthy tissues.

Results We have identified 220 potential GlycoTargets using bioinformatic predictions or cellular screenings. Using our proprietary cell lines as toolbox for antigen production, we were able to generate highly pure and fully characterized GlycoTargets for tailored immunization approaches and antibody screenings. Two case studies show that our approach is suitable to generate antibodies that bind to the protein of interest only if a specific tumor-associated glycosylation is present and do not cross-react with the non-glycosylated protein or the glycan on irrelevant carrier-proteins. Due to this glycan dependency, our antibodies show markedly decreased off-tumor binding. We will show that our antibodies lack unwanted binding to healthy immune cells in contrast to conventional anti-protein antibodies and stain different cancer indications but not related normal tissues.

Conclusions Our approach is suitable to target protein/carbohydrate combined epitopes with specific antibodies. With proper tools for target identification, antigen production, immunization and screening, a platform was installed to generate antibodies with markedly decreased off-tumor binding. The increased tumor selectivity may improve safety for highly potent therapeutic approaches like ADCs, CARs or radiopharmaceutics.

1347 TARGETING OF A CANCER-ASSOCIATED LYPD3 GLYCOFORM FOR TUMOR THERAPY

Patrik Kehler*, Theresa Neumann, Anika Jaekel, Johanna Gellert, Antje Danielczyk, Lisa Weiß, Luisa Willmann, Stephanie Gurka, Naomi Kast, Manon Weiske. *Glycotope GmH, Berlin, Germany*

Background LYPD3 (C4.4A) is a glycosylphosphatidylinositol (GPI)-anchored, highly glycosylated cell surface protein that was first described as a metastasis-associated protein.[1] Since then, it has been associated with carcinogenesis in several different cancers and is reported to be overexpressed in squamous cell carcinoma (SCC) of the head and neck, esophageal SCC, colorectal cancer as well as non-small cell lung cancer. However, it is also highly expressed in healthy epithelia of the proximal digestive tract, female reproductive organs as well as skin keratinocytes.[2] This may cause unwanted side effects in cancer therapy with an antibody unable to discriminate between cancer-associated LYPD3 and LYPD3 in normal tissue.

One of the most drastic changes in cancer is the altered glycosylation of proteins and lipids, giving rise to truncated or highly fucosylated and highly sialylated glycans which are almost absent on normal cells.[3] Therefore, targeting protein/carbohydrate combined epitopes (GlycoTargets) comprising these specific glycans offers reduced off tumor toxicity, which is key for highly potent therapies. We have developed an antibody which binds to tumor-associated LYPD3 in an O-glycosylation-dependent manner and shows superior tumor specificity compared to conventional protein-binding anti-LYPD3 antibodies.

Methods The specificity of our antibody for glycosylated LYPD3 was determined using differentially glycosylated proteins in an ELISA format and confirmed using cell lines with specific glycosylation patterns as well as tumor cell lines expressing varying levels of LYPD3. Furthermore, binding to healthy and tumor tissues was analyzed by immunohistochemistry.

Results We have generated an anti-LYPD3 antibody that binds to its target protein only if a specific tumor-associated carbohydrate is present. It does not cross-react with non-glycosylated LYPD3 or the carbohydrate structure on other carrier-proteins. The carbohydrate-dependent anti-LYPD3 antibody called GT-002 binds to various tumor cell lines and stains tumor tissues of different cancer indications. Notably, GT-002 elicits markedly reduced binding to normal human tissues compared to anti-LYPD3 polyclonal control antibodies or Lupartumab, an anti-LYPD3 antibody previously in clinical development as ADC (BAY1129980).

Conclusions By using our expertise in cancer-associated glycosylation, we successfully generated GT-002, a highly tumor-specific anti-LYPD3 antibody that targets neither glycan nor LYPD3 protein alone, but only the combination thereof – a tumor-specific protein/carbohydrate combined epitope on LYPD3. By using this approach, we were able to develop an anti-LYPD3 antibody that stains cancer tissue of various indications while showing drastically reduced off-tumor binding towards healthy LYPD3-positive tissues. We believe that this highly specific antibody is exceptionally suitable for potent therapies like ADCs, radio-conjugates and CARs.

1348 BDC-3042: A DECTIN-2 AGONISTIC ANTIBODY FOR TUMOR-ASSOCIATED MACROPHAGE-DIRECTED IMMUNOTHERAPY

Justin Kenkel*, Rishali Gadkari, Jess Nolin, Fang Xiao, Po Ho, Cindy Kreder, Laughing Bear Torrez, David Omstead, Katelynn McEachin, Jason Ptacek, Lu Xu, Duy Nguyen, Karla Henning, Steven Chapin, David Dornan, Michael Alonso, Shelley Ackerman. *Bolt Biotherapeutics Inc, Redwood City, CA, USA*

Background Tumor-associated macrophages (TAMs) generally support tumor progression through their immunosuppressive effects on the tumor microenvironment (TME) and are the predominant immune cell population in most cancers. TAMs express the pattern recognition receptor Dectin-2 (*CLEC6A*), an activating C-type lectin receptor (CLR) that binds to high-mannose glycans on fungi and other microbes and induces protective immune responses against infectious disease. Dectin-2 ligation mediates enhanced phagocytosis, antigen processing and presentation, and proinflammatory cytokine production. Agonism of Dectin-2 on TAMs using naturally derived ligands drives potent anti-tumor immunity in syngeneic mouse tumor models. Given these findings, we developed a human Dectin-2-targeted agonistic antibody, BDC-3042, which is capable of robustly activating TAMs as a novel approach to myeloid-directed immunotherapy.

Methods Dectin-2 expression was assessed by flow cytometry, immunohistochemistry, and using public databases. Human whole blood, monocyte-derived macrophages, and single-cell suspensions from dissociated human tumors were stimulated overnight with BDC-3042. Activation was assessed through cytokine analysis. Immune profiling and anti-tumor efficacy were assessed in vivo utilizing MDA-MB-231 tumor-bearing CD34+ HSC engrafted mice (huNOG-EXL, Taconic Biosciences).

Results Dectin-2 is expressed by TAMs across many tumor types, including breast, colon, and lung cancers, but exhibits minimal expression in most normal tissues. BDC-3042 binds to recombinant Dectin-2 and Dectin-2-expressing cells with low-nanomolar affinity. BDC-3042 elicits robust activation of primary TAMs and in vitro-generated macrophages, leading to secretion of proinflammatory mediators characteristic of tumor-destructive "M1" macrophages, such as TNFa, IL-1b, and CCL3/4. Low levels of BDC-3042 binding are detected on blood monocytes, with minimal binding to other peripheral immune cells. Importantly, BDC-3042 elicits little to no activation of peripheral monocytes or cells in whole blood. BDC-3042 activity is dependent on both Dectin-2 and FcgRs, as indicated by the increased activation of macrophages elicited with an Fc-enhanced IgG1 backbone. Systemically administered BDC-3042 activates TAMs and mediates anti-tumor efficacy in mice with humanized immune systems.

Conclusions The data presented demonstrate the therapeutic potential of targeting Dectin-2 expressed by TAMs with the agonistic antibody BDC-3042 as a novel pan-cancer approach for myeloid cell-directed tumor immunotherapy.

1349 TROCEPT MEDIATED *IN-TUMOR* DELIVERY OF IMMUNE CHECKPOINT INHIBITORS REDUCES SYSTEMIC TOXICITY RISKS AND BOOSTS IMMUNE ACTIVATION

[1]David Cole, [1]Rahul Khanolkar, [1]James Davies, [1]Alexander Baker, [1]Thomas Webb, [2]Alicia Teijeira Crespo, [2]Hanni Uusi-Kerttula, [3]Lucy Williams, [1]Samantha Moore, [1]Johanne Pentier, [1]Bent Jakobsen, [1]Alan Parker, [1]Jez Gerry*. *[1]Accession Therapeutics LTD, Oxford, UK; [2]Cardiff university, Cardiff, UK; [3]Accession Therapeutics LTC, Cardiff, UK*

Background Immune checkpoint inhibitors (ICIs) have revolutionized immunotherapy, but their efficacy is limited to certain cancers, and response rates are largely dependent on the ability of the patients T cells to recognize and activate against tumor antigens. Additionally, systemic delivery can lead to dose limiting toxicity.[1]

TROCEPT is a novel tumor-selective delivery technology, based on type 5 adenovirus, engineered not enter normal human tissues. The removal of normal tissues tropisms addresses the main limitation of other viral therapies, which show limited efficacy due to rapid removal by the liver.[2] TROCEPT has been further engineered to specifically bind to a tumor marker expressed on most carcinomas.[3] The TROCEPT platform can be loaded with transgenes encoding protein-based drugs for *in-tumor* delivery (i.e., TROCEPT can deliver the transgene into the cancer cell, turning the cancer cell into a drug factory, which releases the payload into the local tumor environment). TROCEPT-01 enables tumor-localized generation of high concentrations of ICI payloads (figure 1).

Methods Selective cell entry of TROCEPT-01 was assessed *in vitro* using infectivity assays in target-positive and -negative tumor and healthy cell lines. Further *in vitro* assays confirmed the production of ICIs in multiple tumor cell lines, and functionality of the *in-tumor* generated ICI was confirmed using primary T cell activation experiments. Finally, an immune-deficient murine model, engrafted with a human tumor, was used to assess biodistribution of TROCEPT-01, after intravenous delivery, using a bioluminescence *in vivo* imaging system (IVIS®) and qPCR.

Results *In vitro* testing confirmed TROCEPT-01's exquisite selectivity for tumor cells and demonstrated functional production of ICIs from treated tumor cells. *In vivo* experiments demonstrated tumor-localized biodistribution of TROCEPT-01, with a low amount of TROCEPT-01 detected in healthy organs (including the liver) and peripheral blood.

Conclusions TROCEPT's tumor selective transgene delivery and *in-tumor* production of ICIs enables high local dosing only in the tumor, addressing systemic toxicity and potentially increasing efficacy. Additionally, several pre-clinical studies have demonstrated that oncolytic viruses can induce anti-viral immunity against infected tumor cells, recruiting cytotoxic T cells and other pro-inflammatory cell types.[4] Thus, TROCEPT delivery of ICIs has the potential to generate a synergistic effect, first attracting and activating T cells, and then delivering tumor-localized ICIs at high concentrations to boost the anti-tumor T cell response and increase response rates in several tumor types. TROCEPT has the potential for delivery of new and powerful therapeutic drugs for the in-tumor treatment of cancer.

1350 **AI/ML-DRIVEN DISCOVERY OF COLLAGEN TRIPLE HELIX REPEAT-CONTAINING 1, CTHRC1, A NOVEL PROTEOGLYCAN FOR DISRUPTION OF STROMAL BARRIERS AND ENHANCEMENT OF IMMUNOTHERAPY RESPONSES IN DESMOPLASTIC TUMORS**

Elizabeth Koch, Amy Berkley, Sean Phippen, Max London, Kerry White, Amanda Hanson, Sam Cooper, Christopher Harvey, Michael Briskin*. *Phenomic AI, Toronto, Canada*

Background While checkpoint inhibitors (CPIs) such as anti-CTLA-4 and anti-PD-1/L1 have demonstrated efficacy in many solid tumor indications, those with high stromal presence have been difficult to treat. We aimed to use a proprietary machine learning/artificial intelligence platform to identify novel stromal targets that, upon targeting, will relieve this immunosuppressive barrier and increase CPI responsiveness in difficult-to-treat indications.

Methods Based on bioinformatic analysis using a large single-cell RNA atlas, we assessed cancer-associated fibroblasts (CAFs)/fibroblastic cells in cancer tissue for the identification of novel targets, including proteoglycans. Antibodies were generated by immunization of humanized mice. Lead antibodies demonstrated potent *in vitro* activity in inhibiting cell adhesion and reducing survival of pancreatic cancer cells in CAF conditioned media. We assessed efficacy and PD (flow cytometry and IHC) in the EMT6 orthotopic tumor model in immunocompetent mice.

Results Analysis of a large single-cell RNA atlas spanning many solid tumors identified CTHRC1 as one of the most upregulated CAF targets in the genome. CTHRC1 was also highly associated with CAFs from immune-excluded and desert-like tumor samples. Finally, we also find that CTHRC1 is highly expressed by both cancer cells and CAFs within the tumor, in key indications such as breast, ovarian, and pancreatic, with the potential for Fc-mediated depletion of both tumor and fibroblast cells. Profiling by scRNAseq of syngeneic tumor cells identified EMT6 breast cancer model as representative of human tumor, mirroring both CAF and tumor CTHRC1 expression. Assessment of efficacy demonstrated monotherapy activity with strong combination activity and enhanced survival when we combined anti-CTHRC1 mAbs with anti-PD-1.

Conclusions We have identified CTHRC1 as a novel proteoglycan expressed by both CAFs and tumor cells that appears to be an ideal target for inhibiting of stromal barrier function with therapeutic monoclonal antibodies that may also serve as ideal for targeting payloads to the tumor microenvironment. These data demonstrate the power of large scRNA atlases for novel target ID and show the potential of breaking down stromal barriers in opening up tumor microenvironments to immune attack.

Ethics Approval Animal studies were conducted in accordance with an Animal Use Protocol 6323.3 approved by the University Health Network Animal Care Committee.

PRECLINICAL MECHANISM OF ACTION AND PHARMACODYNAMIC BIOMARKER STUDIES OF DUOBODY®-CD3XB7H4 IN SOLID CANCER MODELS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1351

[1]Louise Koopman*, [1]Madelon Paauwe, [1]Laura Smits-de Vries, [1]Frosso Karaiskaki, [1]Marcel Brandhorst, [1]Patrick Franken, [1]Theo Plantinga, [1]Stefanie De Poot, [1]Mischa Houtkamp, [2]Kate Sasser, [1]Esther Breij. [1]*Genmab B.V., Utrecht, Netherlands*; [2]*Genmab US, Inc., Princeton, NJ, USA*

Background The immune checkpoint protein B7H4 is expressed on malignant cells in various solid cancers, whereas expression is highly restricted in normal tissue. DuoBody-CD3xB7H4 (GEN1047) crosslinks CD3 on T cells with B7H4 on tumor cells, thereby inducing T-cell mediated cytotoxicity in B7H4-expressing tumor cells. Here, we evaluated the prevalence of B7H4 expression in solid cancers and investigated the preclinical mechanism of action (MoA) and pharmacodynamic (PD) markers associated with DuoBody-CD3xB7H4 biological activity *in vitro* and *in vivo*.

Methods B7H4 protein expression was determined by immunohistochemistry in human tumor biopsies, and by semi-quantitative flow cytometry for tumor cell lines. T-cell mediated cytotoxicity was assayed *in vitro* using co-cultures of B7H4+ tumor cells and healthy donor T cells. Antitumor activity *in vivo* was tested in a patient-derived xenograft (PDX) screen using several tumor models engrafted subcutaneously in mice with a humanized immune system (HIS). Antitumor activity and exploratory biomarkers were further evaluated in a follow-up study in ovarian cancer PDX HIS mice.

Results In tissue microarrays of primary NSCLC-SCC, ovarian, endometrial, and breast cancer, over 25% of the tumor biopsies contained at least 50% B7H4-positive tumor cells. *In vitro*, DuoBody-CD3xB7H4 induced target-specific, dose-dependent, and complete tumor cell kill in a panel of tumor cell lines expressing varying levels of B7H4, while B7H4 expression levels correlated with the EC_{50}. DuoBody-CD3xB7H4 demonstrated antitumor activity in ovarian and breast cancer PDX models with high B7H4 expression. Antitumor activity of DuoBody-CD3xB7H4 in an ovarian cancer PDX model was confirmed in a dose-response study and was associated with the number of circulating human $CD3^+$ T cells before randomization, an indicator of the humanization rate of the HIS mice. In the periphery, DuoBody-CD3xB7H4 treatment was associated with a transient decrease in circulating immune cells, increased T-cell activation, and elevated levels of granzyme B and cytokines. In the tumor, DuoBody-CD3xB7H4 treatment increased the number of tumor-infiltrating lymphocytes.

Conclusions High prevalence of B7H4 expression was observed in primary NSCLC-SCC, ovarian, endometrial, and breast cancer tissue. *In vitro*, DuoBody-CD3xB7H4 showed antitumor activity across a range of B7H4 expression levels. DuoBody-CD3xB7H4 showed dose-dependent antitumor activity *in vivo*, associated with increased numbers of intratumoral T cells and peripheral PD biomarkers of T-cell activation and cytokine production. Currently, DuoBody-CD3xB7H4 is being investigated in a first-in-human clinical trial for the treatment of solid tumors known to express B7H4 (NCT05180474), in which the MoA and PD, including biomarkers of response, will be clinically explored.

Ethics Approval Animal experiments were performed according to the guidelines of the Institutional Animal Care and Use Committee (IACUC) and in accordance with the regulations of the Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC).

1352 SELECTIVE SMALL MOLECULE INHIBITOR OF INTEGRIN $\alpha_V\beta_8$ AND $\alpha_V\beta_1$ HAS SINGLE AGENT ACTIVITY AND POTENTIATES IMMUNE CHECKPOINT BLOCKADE THERAPY

Vishal Kothari*, Colin Magowan*, Darren Finkelstein, Gail Lee, Chun Chen, Tim Hom, Manuel Muñoz, Dennis Monteleone, Subramanian Karur, Marta Bogaczynska, Erin Budi, Prerna Kotak, Shamra Martin, Katherine Jenkins, Simon Wong, Timothy Machajewski, Fernando Rock, Scott Turner. *Pliant Therapeutics, South San Francisco, CA, USA*

Background Across several cancer types, activated transforming growth factor-β (TGFb) helps support an immuno-suppressive microenvironment that contributes to immune checkpoint blockade (ICB) resistance and treatment failure. Alpha-V integrins, specifically $\alpha_V\beta_8$, $\alpha_V\beta_6$ and $\alpha_V\beta_1$, are the primary activators of TGFb from the latent complex. These integrins have a limited cell-expression profile that make them potential targets to safely and potently inhibit the activation of TGFb in cancer. Targeting $\alpha_V\beta_8$ has recently emerged as a promising approach to realizing the potential of anti-TGFb therapies to address ICB resistance. In the stroma, integrin $\alpha_V\beta_1$ is the major source of activated TGFb. Here, we describe the development of PLN-1095, a dual small molecule inhibitor of $\alpha_V\beta_8$ and $\alpha_V\beta_1$ and characterize this approach in ICB-resistant mouse tumor models.

Methods In vivo efficacy and activities of a dual $\alpha_V\beta_8$ and $\alpha_V\beta_1$ integrin inhibitor, PLN-1095, in combination with anti-programmed death receptor-1 antibody (anti mPD-1) was evaluated in EMT6, Pan02, and CT26 cancer syngeneic mouse models by monitoring animal survival, tumor growth, gene expression, and infiltrating CD8+ lymphocytes. In addition, PLN-1095 single agent proinflammatory and antifibrotic activities was assessed using mouse EMT6 tumors in vivo and human breast tumor tissues *ex vivo*.

Results PLN-1095 showed selective inhibition of integrins $\alpha_V\beta_8$ and $\alpha_V\beta_1$ at nanomolar concentrations. Treatment of mice bearing EMT6 tumors with PLN-1095 alone and in combination with anti-mPD-1 significantly reduced tumor growth. Anti-mPD-1 treatment showed a peripherally restricted CD8+ and CD4+ pattern, whereas PLN-1095 treatment significantly increased intra-tumoral CD8+ T cell infiltration. PLN-1095 treatment, both alone and in combination with anti-mPD-1 was associated with elevated gene expression of CXCL9 and other pro-inflammatory cytokines, enhanced expression of genes involved in antigen presentation, reduced TGFβ signaling, diminished expression of pro-fibrogenic and angiogenic transcripts across the models tested. A significant increase in granzyme B positive T cells was observed in human breast cancer tissues treated with PLN-1095 ex vivo.

Conclusions PLN-1095 sensitized immunologically cold murine tumors to anti mPD-1 ICB. PLN-1095-mediated inhibition of integrins $\alpha_V\beta_8$ and $\alpha_V\beta_1$ effectively reduced the immunosuppressive effects of TGFβ by activating the immune system thereby promoting CD8+ cytotoxic T cell infiltration in the tumors. Based on these results, a first-in-human clinical trial investigating the effects of PLN-1095 is being planned.

Ethics Approval All the animal Studies were approved by Pliant IACUC protocol # PLI-010-2019. Fresh breast tumor samples were collected from the Biological Resource Center of the Centre Léon Bérard by Marie's laboratory, according to the institutional review board and ethics committee and with fully informed patient consent (French Ministry of Research agreement number: AC-2013-1871 and AC-2019-3426).

1353 TARGETING COMPLEMENT FACTOR H MEDIATED TUMOR IMMUNE AND COMPLEMENT EVASION AS A NEXT GENERATION APPROACH

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1353

Matthew Kraman*, Carlo Zimarino, Danielle Minns, Jorge Dias, Chelsea Povall, Helen Graves, Bradley Holub, Ralph Minter, Jacob Galson, Jane Osbourn, Donna Finch. *Alchemab Therapeutics, Cambridge, UK*

Background The complement system plays a crucial part in innate immunity, aiding the destruction of pathogens and removing anomalous cells. Complement Factor H (CFH) regulates the complement system through interactions with C3b (both soluble and membrane associated) to prevent unwarranted activation. This forms the basis of a self-versus non-self-recognition process, which in certain cancers, aberrant expression, or abnormal levels of CFH may protect and promote growth of tumors by impairing the activation of the complement system. An analysis of human antibody repertoire data retrieved convergent sequence clusters amongst both viral and cancer (pancreatic, prostate and melanoma) patient cohorts, and led to identification of human derived antibodies that are naturally tolerated with unique properties[1,2,3]. A representative heavy chain from this cluster was paired with an appropriate light chain and engineered for desirable biophysical characteristics. Target identification revealed CFH, as a potential antigen.

Methods In this study, we tested the ability of human derived antibodies to CFH to activate direct cell killing via complement deposition, and to alter immune cell responses (potentially via alterations in complement receptor activation). This was performed using human in vitro co-culture, immunomodulatory assays, and in vivo syngeneic mouse systems. Additionally, pharmacokinetics and associated measurements were assessed to understand basic tolerability and exposure.

Results Anti-CFH resulted in increased CD11b+ cell tumor infiltration and subsequent C3d deposition in a B16/F10 syngeneic model. Macrophages adopted an inflammatory phenotype characterised by cytokine release profiles and lymphocyte activation.

Immune cell co-culture with tumor cells resulted in myeloid activation, altered cell populations, indirect activation of additional immune cell types, and reduction in viable cancer cells. Both single and dose range pharmacokinetic studies confirmed a lack of binding to circulating CFH, and unaffected levels of C3 that might be associated with systemic complement activation. In a preliminary assessment, no safety issues were identified in the study. Monotherapy in high CFH syngeneic models, suggests a unique epitope recognised by anti-CFH which is primarily associated with membrane associated C3b. Interfering with this binding uniquely enables localised inflammation associated with the alternative pathway of the complement system. Additional mechanistic studies are ongoing.

Conclusions A human derived antibody cluster against CFH is convergently present in various disease state patient groups and has novel immunostimulatory function through engagement of myeloid cells and the complement cascade.

1354 CBL-B INHIBITION SHOWED DIFFERENTIATED EFFECTS IN A MIXED LYMPHOCYTE REACTION VERSUS OTHER IMMUNO-ONCOLOGY TARGETED APPROACHES

Yilin Qi*, Jun Kuai, Yingzhi Bi, Huadong Sun, David Greco, Ken Carson, Timothy Reilly, Geraldine Harriman, Fang Wang. *Hotspot Therapeutics, Boston, MA, USA*

Background The mixed lymphocyte reaction (MLR) mimics an immune reaction between T cells and antigen presenting cells and has been used to assess a variety of immune-oncology (I-O) agents as a potential predictor of clinical effects. Inhibition of the E3 ligase, Casitas B-Lineage Lymphoma Proto-Oncogene B (CBL-B), is a novel I-O approach shown to lower the threshold for antigen-specific T cell activation, even in the absence of co-stimulatory signaling or in the presence of an immunosuppressive environment. Moreover, genetic ablation of CBL-B and functional inactivation of its E3 ligase activity in mice or primary human T cells enhanced immune-mediated anti-tumor effects. Previously, Hotspot has disclosed a series of allosteric CBL-B inhibitors (CBL-Bi) with potent *in vitro* effects on T cells and NK cells and immune-mediated anti-tumor effects *in vivo*.

Methods A human allogenic MLR assay was applied to compare the effects of CBL-Bi and antibodies directed against PD1, CTLA4, LAG3, TIGIT and TIM3 on cytokine release and T cell proliferation, followed by evaluation of CBL-Bi effects on dendritic cells maturation and antigen specific CMV response.

Results CBL-Bi significantly enhanced interferon-gamma production comparable to anti-PD1 treatment, with an additional profound effect on CD8 T cell proliferation. Antibodies directed against CTLA4, LAG3, TIGIT and TIM3 had no effect on either endpoint in this assay format. The effects of CBL-Bi extended to CD4 T cells and interleukin-2 (IL-2) production; anti-PD1 also showed similar effects on IL-2. CBL-Bi effects were concentration-dependent, suggesting potential to optimize the extent of desired immune enhancement. The combination of CBL-Bi plus anti-PD1 demonstrated additive or possibly synergistic effects on both cytokine release and T cell proliferation. Combination of CBL-Bi plus other I-O agents did not show any enhancement. Mechanistically, CBL-Bi promoted immature dendritic cell activation and increased the sensitivity to antigen-specific T cell activation in a CMV challenge assay. An integrated literature review further suggested that the MLR assay has been generally correlated with clinical effects of I-O agents as monotherapy and/or in combination with anti-PD1.

Conclusions In summary, CBL-Bi had robust single agent effects on both cytokine release and T cell proliferation in the human MLR assay. These effects were differentiated from a range of other I-O mechanisms and CBL-Bi plus anti-PD1 showed substantial combination effects. These data support the potential for CBL-Bi to drive anti-tumor immunity in patients as both monotherapy and in combination with anti-PD1 standard of care therapy.

1355 NOVEL PHARMACOLOGICAL APPROACH TO INDUCE DIRECT KILLING OF CANCER AND ACTIVATE ANTITUMOR IMMUNITY VIA INHIBITION OF MONOCARBOXYLATE TRANSPORTERS

Sambad Sharma*, Nicole Bowman, Sanath Wijerathna, Maolin Yu, Jennifer Duffy, Jaime Escobedo, Nelly Kuklin, Vincent Sandanayaka. *Nirogy Therapeutics, Framinghtam, MA, USA*

Background Tumor progression and metastasis is driven by metabolic rewiring of cancer cells as well as cell types involved in the tumor microenvironment (TME). One key hallmark of tumor progression is the aberrant increase in glycolytic flux which creates a TME rich in lactate. The abundance of lactate in the TME serves as a great source of energy to immunosuppressive cell populations, such as Tregs and MDSCs, that thrive on lactate. Increase in immunosuppressive cells in tumors diminish the cytotoxic/effector function of CD8+ T cells thereby converting tumors to be immune-cold and resistant to therapies. Therefore, simultaneous blockade of lactate export by cancer cells and lactate import by suppressive immune cells is a novel therapeutic strategy to treat cancer.

Methods Cytotoxicity was evaluated in cancer cells by MTS assay. Lactate import/export was quantified using Lactate-glo assay (Promega). *In vivo* efficacy in CDX and PDX models was evaluated in NOD/SCID mice model. 4T1 and MC38 syngeneic tumor models were used to study synergistic effect of NGY-091 in combination with immune checkpoint blockade therapies. Activated/differentiated human CD4 T, CD8 T, MDSCs and Tregs were analyzed for markers/cytokines/viability by flow cytometry.

Results NGY-091 exhibited a potent cytotoxicity in cancer cells *in vitro* by modulating transport of monocarboxylates. The mode of action of NGY-091 involved the blockade of lactate import through MCT1 and MCT4-mediated lactate export. Furthermore, NGY-091 demonstrated significant direct killing of cancer cells *in vivo* in human CDX and PDX models. In syngeneic models of 4T1 and MC38 murine tumors, NGY-091 treatment showed synergistic tumor growth inhibition when combined with immune checkpoint inhibitors, in addition to a significant tumor growth reduction by NGY-091 treatment alone. Immune profiling of 4T1 tumors by flow cytometry indicated a robust activation of antitumor immunity. Specifically, increases in effector T cell populations, CD8/Treg ratio and tumor-suppressive M1 macrophages was evident in NGY-091 treated tumors. On the other hand, tumor supporting M2 macrophages were found to be downregulated. These observations were further validated by *in vitro* studies using human immune cells where NGY-091 treatment strongly increased and activated effector CD4 and CD8 T cells. Importantly, NGY-091 significantly reduced the growth and functionality of Treg and MDSCs.

Conclusions Therefore, NGY-091 intervenes with two key hallmarks of cancer – metabolism and immunity and has a strong therapeutic utility in cancer treatment.

1356 TRANSCRIPTIONAL PROFILING OF *BICYCLE*® TUMOR-TARGETED CD137 AGONIST-TREATED MOUSE TUMORS REVEALED AN EARLY AND RAPID ACTIVATION OF MYELOID CELLS FOLLOWED BY INFILTRATION OF CYTOTOXIC T CELLS INTO THE TUMOR

Johanna Lahdenranta*, Kristen Hurov, Heather Cohen, Punit Upadhyaya, Kevin McDonnell, Philip Brandish, Nicholas Keen. *Bicycle Therapeutics, Lexington, MA, USA*

Background CD137 (4-1BB) is an immune costimulatory receptor that has been recognized for its potential as an immunotherapy drug target in cancer alongside checkpoint inhibitors.[1-2] We have developed a new class of modular synthetic drugs, termed *Bicycle*® tumor-targeted immune cell agonists (*Bicycle*® TICAs), which are multifunctional molecules comprised of constrained bicyclic peptides.[3] The first molecule of this class, BT7480, a Nectin-4-dependent CD137 agonist, entered clinical trials in 2021. Preclinical data demonstrates that BT7480 induces highly potent, tumor localized CD137 agonism leading to tumor regressions and immunogenic memory in a syngeneic mouse model.[4]

Methods In vivo pharmacodynamic responses to treatment with CD137 *Bicycle*® TICAs in a huCD137 MC38 syngeneic tumor mouse model were evaluated using mRNA in situ hybridization (ISH), NanoString, and scRNA sequencing.

Results NanoString RNA profiling of tumors excised from mice treated with BT7480 at multiple timepoints revealed a two-step process – an early and rapid increase of genes relating to myeloid cell activation that precedes the upregulation of cytotoxicity-related genes. These data indicate that a wider reprogramming of the immune microenvironment beyond T cells may occur early after BT7480 administration. These pharmacodynamic changes were also observed following treatment with an EphA2/CD137 *Bicycle* TICA™ (BT7455), indicating a common feature of targeted CD137 *Bicycle*® TICAs. To better understand the cellular mechanism of action of CD137 *Bicycle*® TICAs, we used mRNA ISH to attempt to identify the source of Ccl17 and Ccl22 mRNAs, which ruled out Cd3 and Itgam mRNA positive cells as the source of the chemokine expression. Depletion of CD8+ T cells from the mice prior to CD137 *Bicycle* TICA™ treatment did not alter the early increase in gene expression of distinct chemokines, further indicating the involvement of other immune cell types than just effector T cells. To pinpoint the cells responsible for the early burst of signaling activity, we next turned to single cell RNA sequencing of CD137 *Bicycle* TICA™-treated tumors, which highlighted the involvement of other cell populations such as dendritic cells in the early steps of CD137-driven anti-tumor immunity by CD137 *Bicycle*® TICAs.

Conclusions Altogether, these data highlight that CD137 *Bicycle*® TICAs like BT7480 and BT7455 impact immune cell populations beyond T cells. This suggests that abundant T cell infiltrates may not be required for *Bicycle*® CD137 agonists to initiate tumor rejection, which broadens the patient population that may benefit from CD137 *Bicycle* TICA™ treatment to also include myeloid-rich tumors with lower T cell infiltration ("colder" tumors).

1357 **REVERSIBLE CHEMICAL MODULATION OF ANTIBODY EFFECTOR FUNCTION MAINTAINS ANTI-TUMOR ACTIVITY WHILE MITIGATING PERIPHERAL IMMUNE ACTIVATION**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1357

Matthew Levengood*, Chris Leiske, Noah Bindman, Xinqun Zhang, Nicole Duncan, Weiping Zeng, Serena Wo, Abbie Wong, Clark Henderson, Karalyne Crowder, Haley Neff-LaFord, Django Sussman, Shyra Gardai, Philip Moquist. *Seagen, Inc., Bothell, WA, USA*

Background Antibody effector functions including antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis (ADCP) are mediated through the interaction of the antibody Fc region with Fc gamma receptors present on immune cells. Several approaches have been used to modulate antibody Fc-Fc gamma receptor interactions with the goal of driving an effective antitumor immune response. One such approach is removal of fucose on the antibody core glycan to increase binding to Fc gamma receptor IIIa (CD16a) and drive increased ADCC and immune agonism. However, robust antibody Fc engagement and immune cell binding of non-fucosylated antibodies in the periphery can lead to unwanted induction of systemic cytokine release and other dose-limiting infusion-related reactions. Identifying a balance between effective engagement of Fc gamma receptors that can induce antitumor activity without incurring systemic immune activation is an ongoing challenge in the field of antibody and immuno-oncology therapeutics.

Methods A method for the reversible modulation of antibody Fc interactions was designed and applied to a series of non-fucosylated antibodies. This methodology utilizes chemical conjugation of polyethylene glycol (PEG) linkers to the interchain disulfides of an antibody to initially impair binding to Fc gamma receptors on peripheral cells upon administration but allow for restoration of antibody effector function through de-conjugation over time. Impacts of PEGylation on Fc gamma receptor binding, signaling, and restoration of function were assessed in vitro and in vivo.

Results In vitro binding and signaling assays with various loaded conjugates were used to identify a preferred linker format that reduces binding and activity of non-fucosylated antibodies to the level of fucosylated parent antibodies. Plasma stability experiments demonstrated that the preferred linker technology can partially de-conjugate over time, allowing for restoration of Fc binding and function in a time-dependent manner. The lead technology was applied to an agonist CD40 antibody, which resulted in significant reductions in cytokine production in human CD40 mice and non-human primates, while demonstrating retained efficacy and improved pharmacokinetics compared to the parent antibody.

Conclusions A simple, modular approach using chemical conjugation can reversibly attenuate Fc gamma receptor binding and antibody-driven acute systemic immune activation. This approach can be rapidly applied to antibodies that suffer from systemic immune activation that occurs due to peripheral Fc binding immediately upon infusion. As a proof of concept, the technology was applied to an agonist CD40 antibody and resulted in significantly decreased pro-inflammatory cytokine production despite higher plasma concentrations and the same antitumor activity to the parent antibody.

Acknowledgements We would like to thank Bianka Haro and Jamie Mitchell for conjugation support.

Ethics Approval All animals studies were were conducted in accordance with protocols reviewed and approved by the Institutional Animal Care and Use Committee at Seagen.

1358 NOVEL EGFR/PI3K DUAL-TARGETING NANOPARTICLES INDUCE IMMUNOGENIC CELL DEATH IN BLADDER CANCER

[1]Zheng Zhu*, [2]Xiangdong Xue, [3]Gang Zhou, [4]Zewen Song, [5]Guoyin Li. [1]*Harvard Medical School, West Roxbury, MA, USA*; [2]*Shanghai Jiao Tong University, Shanghai, China*; [3]*Fourth Millitary Medical University, Xi'an, China*; [4]*Central South University, Changsha, China*; [5]*Zhoukou Normal University, Henan, China*

Background Bladder cancer (BCa) is one of the most common malignancies worldwide. Epidermal Growth Factor Receptor (EGFR) overexpression is seen in up to 74% of BCa tissue specimens, however, current EGFR-based target therapy shows little benefit for BCa patients as the EGFR downstream pathways could be circumvented by other receptor tyrosine kinases (RTKs). Dual targeted therapy, which can bind and inhibit the EGFR and its downstream PI3K to affect tumor progression, could be a potential strategy for BCa treatment.

Methods Herein, we identified two natural products triptolide (TPL) and hesperidin (HSP), dual targeting EGFR and PI3Kin BCa by network pharmacology and molecular modeling. By applying a succinic acid linker was added between these two products, we synthesized amphiphilic TPL-HSP-EGFR targeting prodrug (THE) which further self-assembles into nanoparticles (THE NPs). Once binding to the EGFR on BCa surface, THE NPs could be internalized into BCa cells and released into lysosome to achieve further biofunctions.

Results THE NPs harbor the high drug-loading (91.99%) and low toxicity properties in utilizing natural products as tumor therapeutics. THE NPs could target BCa cells and internalized into lysosome. After hydrolyzed in low pH environment, THE NPs could release TPL and HSP targeting and inhibiting EGFR and PI3K. Immunogenic cell death markers HMGB1 and CRT levels were evaluated both in vitro and in vivo after treatment so as to inhibit BCa proliferation and tumor growth.

Conclusions Dual targeting nanoparticle may emerge as a novel paradigm in BCa treatment, providing a new approach for inducing immunogenic cell death in BCa care.

1359 HALF-LIFE EXTENDED ENGINEERED IL18 VARIANTS THAT ESCAPE THE NEGATIVE REGULATION OF IL18BP

[1]Xiaofan Li*, [2]Cristina Abrahams, [1]Amandeep Gakhal, [1]Junhao Yang, [1]Kevin Brar, [1]Daniel Calarese, [1]Robert Henningsen, [1]Grace Lee, [1]Katie Neighbors, [1]Jennifer Smith, [1]Andrew McGeehan, [1]Millicent Embry, [1]Abigail Yu, [1]Alan Nguyen, [1]Krishna Bajjuri, [1]Miao Wen, [1]Young Park, [1]Cuong Tran, [1]Mary Rose Masikat, [1]Gang Yin, [1]Alice Yam, [1]Kristin Bedard, [1]Trevor Hallam. *[1]Sutro Biopharma, Inc., South San Francisco, USA; [2]Seagen, South San Francisco, CA, USA*

Background Interleukin-18 (IL18) is a proinflammatory cytokine secreted by monocytes and macrophages to promote T and NK cells activation. While wild type IL18 was shown to be efficacious in inhibiting tumor growth in animal models, limited efficacy was observed for recombinant wild type IL18 in clinical trials. IL18 binding protein (IL18BP) is a decoy receptor for IL18 that binds to IL18 with much higher affinity than IL18 receptors (IL18Ra and IL18Rb). IL18BP is upregulated upon IL18 treatment and acts as a negative feedback for IL18 signaling pathway, which likely contributes to the limited efficacy observed for wild type IL18 in clinic.

Methods Engineered IL18 that escape the negative regulation of IL18BP could greatly improve the efficacy of IL18 in clinic. Sutro's ribosome display technology and XpressCF expression platform enabled fast engineering and testing cycles of IL18 variants. Ribosome display library was constructed based on site directed mutations and selected for IL18Ra binding in the presence of IL18BP. The resulting IL18 variants were further screened for IL18 pathway activation and thermostability. To increase the half-life of IL18 variants, a non-natural amino acid was introduced at an optimized site in the sequence to enable conjugation to a PEG molecule. Additional protein engineering was also employed to improve the expression, stability and PK profile of our IL18 variants.

Results IL18 variants that maintained binding to IL18Ra in the presence of IL18BP were identified from the ribosome display library. In biacore binding assay, the variants showed higher binding affinity to IL18 receptor (IL18Ra) compared to wild type IL18, while no binding observed to IL18BP. The identified IL18 variants induced potent IFNg secretion by human PBMCs from healthy donors, which was not affected by high concentration of IL18BP. Conjugation of PEGs to the nnAA inserted into an optimized site in the IL18 sequence enabled half-life-extension. Additional mutations were introduced on the IL18 variants to stabilize the molecule, which also improved the expression, thermal stability and serum clearance profile in mice. The final Sutro IL18 lead activates T and NK cells in the presence of high concentration of IL18BP and exhibited favorable PK profile in mice.

Conclusions Sutro's engineered IL18 variant induces potent T and NK cells activation without the negative regulation of IL18BP. The favorable immune stimulation, pharmacokinetics and adjustable half-life extension make it a compelling product concept for future cytokine therapy in broad oncology indications.

Ethics Approval All in vivo procedures were conducted in compliance with the guidelines of the Institutional Animal Care and Use Committee (IACUC) at Sutro Biopharma

1360 PHARMACODYNAMICS OF JNJ-70218902, A TMEFF2 × CD3 BISPECIFIC ANTIBODY, IN CYNOMOLGUS MONKEY

[1]Cassandra Lowenstein, [2]Subhasree Basu*, [2]Joshua Rusbuldt, [3]Sathya Venkataramani, [2]Robin Ernst, [2]Steve Jarantow, [2]Scott Brodeur, [4]Daniel Rubio, [2]Pharavee Jasiprasart, [2]Margaret Yu, [2]Brent Rupnow, [1]Michael Russell. [1]*Proteovant Therapeutics, King of Prussia, USA*; [2]*Janssen RandD, Spring House, USA*; [3]*Amgen, Inc, Thousand Oaks, USA*; [4]*EQRx International, Inc, Cambridge, USA*

Background TMEFF2 is a transmembrane protein with epidermal growth factor-like and 2 follistatin-like domains. The enriched expression of TMEFF2 in prostate cancer and its restricted expression in healthy brain and prostate make it an attractive candidate for targeted prostate cancer therapy. JNJ-70218902 (JNJ-902) is a bispecific TMEFF2 × CD3 antibody that binds to human TMEFF2 on prostate cancer cells and to human CD3 on T cells to promote T cell-mediated killing of tumor cells. Given the 100% sequence homology and analogous biodistribution of TMEFF2 in humans and monkey, the pharmacodynamics of JNJ-902 was studied in cynomolgus monkeys.

Methods Two dosing regimens of JNJ-902 were evaluated in cynomolgus monkeys: single, fixed dosing (0.075 mg/kg) and step-up dosing (0.075 mg/kg followed by 0.3 mg/kg 1 week later). Blood, serum, and prostate tissue were collected for flow cytometry to assess number of T cell infiltrates and myeloid cells, and surface markers of T cell function (activation, proliferation, and suppression).

Results An approximately dose proportional increase in JNJ-902 exposure was observed in this study. Both dosing regimens increased CD4+ and CD8+ T cell infiltration in the prostate, including activation and proliferation of CD4+ and CD8+ T cells (measured by granzyme B, CD25, CD69, and Ki-67), and in the periphery, minimal suppressive biomarkers (CD4+CD25hi Foxp3+) were observed. Interestingly, greater infiltration of CD8+ T cells was observed with step-up dosing. Both dosing regimens led to an influx of pro-inflammatory cells (dendritic cells, myeloid cells, macrophages, and B cells) into the prostate.

Conclusions Redirecting T cell activity to TMEFF2-expressing tumors by JNJ-902 is a promising immunotherapy for prostate cancers. In cynomolgus monkeys, treatment with JNJ-902 induced the infiltration of activated and proliferating T cells and inflammatory cells into the prostate, suggesting the potential to mediate an effective immune response. The clinical evaluation of JNJ-902 is currently underway in a phase 1 dose escalation trial in patients with metastatic castration-resistant prostate cancer (NCT04397276).

Ethics Approval The procedures involving the care and use of animals in this study were reviewed and approved by CR-MWN Institutional Animal Care and Use Committee before conduct (Testing Facility Study Number 886-526). 1361 **HBM1022: AN AFUCOSYLATED ANTI-CCR8 ANTIBODY, DEPLETES SPECIFICALLY TUMOR INFILTRATING TREGS AND INHIBITS TUMOR GROWTH WITH EXCELLENT SAFETY PROFILE IN PRECLINICAL STUDIES**

Shuang Lu*, Yiping Rong, Xin Gan, Joe Zhao. *Harbour biomed, Shanghai, China*

Background Tumor-infiltrating lymphocyte-Treg cells (TIL-Tregs) contribute to establishment of an immunosuppressive tumor microenvironment (TME). Several immunotherapies, such as anti-CD25 antibodies, are designed to target this type of cells. However, the possibility of undesirable targeting Treg cells in peripheral blood hampers their clinical benefits. CCR8 is a chemokine receptor selectively upregulated on TIL-Tregs from cancers such as clear cell renal cell carcinoma (ccRCC), breast, and bladder cancers, but rarely on Tregs in peripheral blood. This tumor specific expression of CCR8 provides us with an opportunity to develop an immunotherapy targeting TIL-Tregs selectively.

Methods

Results

Conclusions HBM1022 is a novel Fc-optimized CCR8 antibody with a high affinity to both human and cynomolgus monkey CCR8. It acts through dual mechanisms of action (MOA). HBM1022 recognizes patient-derived TIL-Tregs, and potently depletes CCR8+Treg cells via enhanced antibody-dependent cellular cytotoxicity (eADCC) activity. Furthermore, it inhibits CCL1-CCR8 signaling pathway and blocks CCL1 induced cell migration. HBM1022 exhibits a potent antitumor activity as monotherapy and in combination with anti-PD (L)1 antibodies. HBM1022 has favorable pharmacokinetic properties and an excellent safety profile in cynomolgus monkey, which suggests a potential good safety profile in human.

1362 NONCLINICAL CHARACTERIZATION OF ICVB-1042, A NOVEL E2F-TUMOR SELECTIVE ONCOLYTIC VIRUS WITH THE POTENTIAL TO TREAT SOLID TUMORS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1362

Michael Lyman*, Jessica Field, Joshua Messinger, Nathaniel Rice, Matthew Lanahan, Alex Kato, Michael Pokrass, Heba Nowyhed. *IcoOVir Bio, San Diego, CA, USA*

Background A major challenge in oncolytic virotherapy is to engineer potent tumor-killing viruses that can be delivered systemically for treatment of metastatic disease while leaving normal cells unharmed. Here we report the nonclinical characterization of ICVB-1042, an optimized E2F-dependent oncolytic adenovirus rationally engineered with specific genomic modifications to confer tumor selective replication and enhanced tumor cell killing. ICVB-1042 has been further engineered with a chimeric fiber to enhance its tumor tropism and a modified capsid hexon protein to allow intravenous (IV) delivery. This combination of rationally designed modifications enables ICVB-1042 to be used for the treatment of a wide range of solid tumor types.

Methods Using a proprietary iterative adenovirus design and screening platform, IconOVir has engineered ICVB-1042, a potent, tumor selective oncolytic adenovirus. A multi-faceted nonclinical strategy was designed to characterize key therapeutic properties of ICVB-1042 through *in vitro* and *in vivo* studies. Tumor cell selectivity was assessed by testing the replication of ICVB-1042 in a comprehensive panel of primary normal human cells compared to tumor cells. Anti-tumor efficacy was evaluated in multiple human xenograft immunocompromised mouse models. Tolerability, biodistribution and PK were assessed in human CD46 transgenic mice where particle-mediated toxicity and effects on host immune response could be assessed. Biodistribution and pharmacokinetics were evaluated in human tumor xenograft models and in CD46 transgenic mice.

Results ICVB-1042 displayed replication and cell killing against a broad range of human tumor cell lines including breast, prostate, bladder, lung, and glioblastoma. However, replication was tumor selective, and the multiplicity of infection required to kill primary normal cells was 100 to >10,000-fold greater than the concentration of virus required to kill tumor cells. The anti-tumor activity of IV-dosed ICVB-1042 was demonstrated in several subcutaneous and orthotopic models. ICVB-1042 virus particles increased in both tumors and plasma over time suggesting virus replication in tumors, which correlated with efficacy. IV dosing of ICVB-1042 was well tolerated in CD46 transgenic mice. ICVB-1042 distributed throughout CD46 transgenic mice and cleared to less than 0.1% of the administered dose by Day 15 post first dose. There was no preferential distribution into the liver over other organs.

Conclusions ICVB-1042 is a novel, potent, tumor selective, systemically administrable oncolytic virus with the potential to treat a broad range of solid tumors. The *in vitro* and *in vivo* results presented demonstrate ICVB-1042's selective replication in tumor cells compared to quiescent primary normal cells, broad tumor tropism, and safety and anti-tumor efficacy with IV dosing.

Ethics Approval All procedures carried out were conducted in compliance with the applicable laws, regulations and guidelines of the National Institutes of Health (NIH) and with the approval of Labcorp Drug Development PCO's Animal Care and Use Committee. Labcorp Drug Development (Greenfield) is an AAALAC accredited facility.

1363 EVALUATION OF THE ANTI-TUMOR ACTIVITY OF ICVB-1042, A NOVEL E2F-TUMOR SELECTIVE ONCOLYTIC VIRUS, SELECTIVELY TARGETING TUMOR CELLS IN AN ESTABLISHED HUMAN GLIOBLASTOMA MOUSE MODEL

Michael Lyman*, Jessica Field, Jinkil Jeong, Valentino Gantz, Nathaniel Rice, Heba Nowyhed. *IcoOVir Bio, San Diego, CA, USA*

Background A major challenge in oncolytic virotherapy is to engineer potent tumor-killing viruses that can be delivered systemically for the selective treatment of metastatic disease while leaving normal cells unharmed. ICVB-1042 is a novel E2 transcription factor (E2F)-dependent oncolytic adenovirus rationally designed with genomic modifications to confer tumor selective replication, allow intravenous delivery, enhance potency and tumor tropism, and aid in screening clinical samples. The goal of this study was to compare anti-tumor activity and tumor selectivity of ICVB-1042 to that of ICVB-940, an Ad5-based oncolytic virus (OV) engineered with a 24 base pair deletion in E1A and an RGD-4C motif in HI loop of the fiber knob (D24RGD). ICVB-940 is similar to another D24RGD Ad5 OV that has been evaluated in clinical trials in glioblastoma patients.[1,2] This analysis, performed *in vitro* on a panel of glioblastoma tumor cell lines and *in vivo* in an established nonobese diabetic/severe combined immunodeficiency gamma mouse-based human glioblastoma model, showed overall enhanced activity of ICVB-1042.

Methods The replication and cell killing of ICVB-1042 and ICVB-940 were compared in primary astrocytes and in glioblastoma tumor cell lines to evaluate baseline killing in primary brain cells versus tumor cells *in vitro*. Both viruses were compared *in vivo* at doses of 1.00E+08 or 2.00E+08 plaque forming units administered intratumorally in the human glioblastoma model with time to progression (TTP) and mean tumor volume for the treated versus control groups (median $\Delta T/\Delta C$) as endpoints.

Results ICVB-1042 demonstrated enhanced tumor cell killing over ICVB-940 in 11 of 13 human glioma tumor lines *in vitro*. ICVB-1042 showed significant decreases in tumor volume and significant increases in TTP between treated and control animals at both doses. ICVB-940 showed significant decreases in tumor volume but nonsignificant increases in TTP at the high dose; no significant differences in tumor volume or TTP at the low dose were observed. Comparison between ICVB-1042 and ICVB-940 at the low dose resulted in significant decreases in Day 38 tumor volume and significant increases in TTP for ICVB-1042 over ICVB-940. All treatments were well-tolerated, resulting in no deaths or group mean body weight loss in the treatment window.

Conclusions ICVB-1042, a novel E2F-tumor selective rationally designed OV engineered with enhanced tropism and tumor killing potency, produced higher anti-tumor activity *in vitro* and *in vivo* in GBM tumors compared to the D24RGD virus ICVB-940.

1364 **BISPECIFIC ANTIBODIES THAT BLOCK TIM-3 AND CD39 INDUCE ANTI-TUMOR EFFICACY AND IMMUNE RESPONSE BY BLOCKING MULTIPLE SUPPRESSIVE MECHANISMS**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1364

Noriko Matsumoto*, Yuji Mishima, Kanto Nakajima, Takahiko Aramaki, Mamoru Shiraishi, Haruka Matsumura, Norihiro Nakamura. *BrighPath Biotherapeutics Co., Ltd., Kawasaki, Japan*

Background TIM-3 and CD39 are co-expressed in tumor-infiltrating T cells and antigen-presenting cells and considered to act as negative regulators of anti-tumor immunity. TIM-3 has multiple ligands including galectin-9, phosphatidylserine, CEACAM-1 and HMGB1. Although galectin-9 induces apoptosis in T cells via TIM-3, most of the TIM-3 antibodies under clinical development only partially block the galectin-9-binding to TIM-3. Adenosine is an immunosuppressive metabolite that suppresses T and NK cells. Inhibition of ATP-hydrolysis by purinergic ectoenzyme CD39 may recover anti-tumor immunity through reducing adenosine level in tumor microenvironment. We report herein BP1210, a novel TIM-3 biparatopic antibody (BpAb), that blocks the binding of multiple ligands including galectin-9 and BP1212, a bispecific antibody (BsAb) against TIM-3 and CD39, that blocks TIM-3-signaling and adenosine-mediated immune suppression.

Methods The antibodies against TIM-3 and CD39 were cloned from mice immunized with recombinant proteins. Optimal combinations of clones were selected by functional assay for BpAb and BsAb, then the CDRs were grafted to human framework in effector null scFv-Fc format with knobs-into-holes mutations. Binding affinities and blocking/inhibiting activities were analyzed using recombinant proteins and cells endogenously expressing TIM-3 or CD39. The proliferation and cytokine production of T cells induced by antibodies were determined using human peripheral blood mononuclear cells (PBMCs). Anti-tumor efficacy of BP1210 was investigated in tumor models in huTIM-3 knock-in mice or in NOG mice transplanted with PBMCs.

Results BP1210 BpAb that fully blocks the interaction of TIM-3 to both galectin-9 and phosphatidylserine, enhanced the activation of T cells stimulated by the antigen. i.e., BP1210 increased the population of IFNγ^+ T cells, the production of cytokines, and suppressed the apoptosis of T cells, which are higher than other TIM-3 antibodies that fully blocks the binding to phosphatidylserine but not to galectin-9. *in vivo* studies showed that BP1210 retards the tumor growth and enhances the tumor-growth suppression by anti-PD-L1 antibody. BP1212 BsAb preferentially bound to the CD39$^+$TIM-3$^+$ cells (exhausted T cells and APCs) and effectively blocked the enzymic activity of CD39 and binding to TIM-3 ligands in these cells. BP1212 augmented the proliferation and cytokine production of T cells, suggesting that BP1212 enhances the T cell immunity even in immunosuppressive tumor microenvironment.

Conclusions BP1210 and BP1212 show the advantages over conventional TIM-3 and CD39 antibodies in T cell-mediated tumor immunity. Our engineered antibodies with novel combinations of antibody clones against immune checkpoints will provide new therapeutic options of tumor immunotherapy.

Ethics Approval The present study was approved by the Institutional Ethics Committee of BrightPath Biotherapeutics Co., Ltd.(approved number: ERD-01). Animal studies were approved by the Institutional Animal Care and Use Committee (approved number: 22012A and 22014A).

1365 **AN ACTIVE SITE PTPN2/N1 SMALL MOLECULE INHIBITOR PROMOTES ANTI-TUMOR EFFICACY BY SENSITIZING TUMOR CELLS TO INFLAMMATORY SIGNALS AND ENHANCING IMMUNE CELL ACTIVITY**

[1]Kathleen McGuire*, [1]Christina Baumgartner, [1]Carey Backus, [1]Rebecca Mathew, [1]Kelly Klinge, [1]Joseph Klahn, [2]Prasanthi Geda, [1]Kyle Halliwill, [1]Jacqueline Aguado, [1]Liang Mu, [1]Ryan Duggan, [1]Cara Hrusch, [1]Elliot Farney, [1]Zhaoming Xiong, [1]Marinka Bulic, [1]Patricia Trusk, [1]Loren Lasko, [3]Hakimeh Ebrahimi-Nik, [3]Kathleen Yates, [3]Robert Manguso, [1]Keith Hamel, [4]Marcia Paddock, [1]Jennifer Frost, [1]Philip Kym. *[1]Abbvie Inc, North Chicago, IL, USA; [2]Bristol Myers Squibb, Summit, NJ, USA; [3]Broad Institute of MIT and Harvard, Cambridge, MA, USA; [4]Calico Life Sciences LLC, South San Francisco, CA, USA*

Background The tyrosine phosphatases PTPN2 and PTPN1 are important negative regulators of immune signaling pathways and genetic deletion of these proteins in tumor or immune cells has been shown to overcome unresponsiveness to checkpoint blockade and increase anti-tumor immunity *in vivo*. Thus, these proteins should be promising immunotherapy targets, but drugging phosphatases has proven difficult.

Methods Here, we demonstrate that our active site PTPN2 and PTPN1 small molecule inhibitor, ABBV-CLS-484 (AC-484), promotes anti-tumor immunity in several syngeneic mouse tumor models upon oral administration. This first-in-class PTPN2/N1 inhibitor sensitizes tumor cells to inflammation and augments the activity of a variety of immune cell subsets *in vitro* and *in vivo*.

Results Specifically, AC-484 sensitizes tumor cells to inflammation by augmenting interferon signaling, leading to enhanced growth arrest and antigen presentation. AC-484 also promotes T cell activation and function upon TCR stimulation and enhances activity of dendritic cells and macrophages *in vitro*. Consistent with our *in vitro* findings, immunophenotyping and single-cell RNA sequencing analyses demonstrate AC-484 treatment leads to a more inflamed tumor microenvironment characterized by increased abundance of inflammatory macrophages producing pro-inflammatory chemokines such as IP-10, which are important for immune cell recruitment. Further, AC-484 leads to an increased abundance and activation of intratumoral NK and CD8 T cells not only in inflamed but also in less inflamed tumors. Interestingly, PTPN2/N1i also decreased the frequency of dysfunctional/exhausted T cells and increased the frequency of polyfunctional CD8 T cells. To directly confirm these effects on exhausted T cells, we assessed how AC-484 affected T cell dysfunction under T cell exhaustion conditions *in vitro*. Consistent with our *in vivo* findings, AC-484 reduced the frequency of exhausted T cells and promoted polyfunctional T cells with improved cytotoxic activity under chronic antigen stimulation.

Conclusions Taken together, PTPN2/N1 inhibition appears to promote anti-tumor activity by acting on tumor cells directly and promoting the anti-tumor activity of several immune cell subsets including dysfunctional CD8 T cells, which are enriched in the tumor microenvironment. This two-pronged mechanism leads to efficacy in murine tumor models unresponsive to PD-1 pathway blockade. Based on our preclinical data on this novel and efficacious therapeutic approach, ABBV-CLS-484 is currently under Phase I clinical evaluation in cancer patients with solid tumors.

Acknowledgements We thank Geoff Halvorsen (deceased AbbVie employee) for his integral part in the discovery and synthesis of ABBV-CLS-484.

1366 ANTI-PD-1/IL-7V BISPECIFIC ANTIBODY PROMOTES TCF1 + STEM LIKE T CELLS EXPANSION AND LONG-LASTING IN VIVO EFFICACY

Aurore Morello*, Margaux Seite, Justine Durand, Isabelle Girault, Geraldine Teppaz, Virginie Thepenier, Vanessa Gauttier, Caroline Mary, Nicolas Poirier. *OSE Immunotherapeutics, Nantes, France*

Background Immunocytokines can strengthen anti-PD-(L)1 therapy by promoting T-cell survival, but their shortened half-life and systemic toxicity limit their clinical development. We propose to selectively deliver IL-7 to PD-1^+ T-cells using a bispecific anti-PD1/IL-7v mutein fused to reinvigorate $PD1^+IL\text{-}7R^+$ tumor-specific T cells and sustain long-term response. RNAseq and TILs scRNAseq analyses illustrate that IL-7R and IL-7R pathway gene expression is significantly correlated with better long-term OS and/or PFS across several cancers Higher IL-7R and IL-7R pathway expression by tumor-specific T-cell clonotype is significantly correlated with ICI response, higher stemness & proliferative signature,lower exhaustion and apoptosis markers, providing a strong rationale of co-targeting IL-7 to PD-1 to sustain durable tumor-specific T-cells response. Despite low IL-7R expression on Tumor-specific T-cell clonotype a high concentration of IL-7 can rescue them. We propose with the anti-PD-1/IL-7v to cis-target and provide a survival/proliferative specific signal.

Methods Proliferation, IL-7R signaling assays were tested to determine the mechanism. For the suppressive assay, CD4 Treg and autologous CD8 Teff were co-cultured. In vivo experiments were performed in hPD-1KI immunocompetent mice.

Results A high-affinity antagonist anti-PD-1 mAb was fused to a single IL-7 mutein (IL7v) having lower affinity to IL-7R complex allowing a preferential and optimal cis-potentiation of PD-1+ T-cells. Anti-PD1/IL7v restores proliferation and maintains long-term survival of chronically stimulated human T-cells in vitro (over 5 stimulation). scRNAseq and FACs analyses demonstrated that anti-PD1/IL7v triggers the expansion of TCF1+ stem-like memory T-cells (CCR7+PD1+KI67+), whereas IL-2 and IL-15 promote differentiation of T-cells into exhausted T-cells (TCF1-Tim3+Ki67+). Furthermore, anti-PD1/IL7v preferentially stimulated T_{eff} over T_{reg} as opposed to IL-2 & IL-15 and abrogated the T_{reg} suppression by restoring IFN-γ secretion and proliferation of CD8 T_{eff}.

In vivo, anti-PD1/IL-7v has impressive monotherapy efficacy in PD-1 sensitive model (orthotopic mesothelioma,>90%CR) and in a PD-1 resistant model (orthotopic HCC,>65% CR) in which anti-PD-1 or IL-7 has no effect. Further analyses in HCC model demonstrate that anti-PD1/IL7v enhanced quality and biodistribution of T-cells by promoting intratumoral TCF1 +CD8+stem-like T-cells proliferation and favoring T-cell migration into the tumor nest whereas anti-PD-1 promotes T-cell exclusion. Combination with sorafenib chemotherapy in HCC model further enhances in vivo efficacy.

Conclusions Our data validate the rational of selective delivery of IL-7 to tumor-specific T-cells to sustain long-lasting response, proliferation, and survival of these key effectors upon ICI therapy. Anti-PD1/IL-7v preferentially cis-potentiates PD1+-tumor-specific-T-cells limiting the risk of I-O/I-O immunotoxicity and induces the expansion of stem-like T-cell capable to strengthen PD-1 therapy efficacy.

1367 A HIGHLY-SELECTIVE HPK1 INHIBITOR ENHANCES T CELL RECEPTOR SIGNALING AND T CELL ACTIVATION POTENTIAL, INCREASING ANTIGEN RECOGNITION AND EFFICACY OF PD-1 THERAPY

[1]Andrew Nager*, [2]David Schaer, [1]Rebecca Gallego, [1]Eleanore Hendrickson, [1]Sergei Timofeevski, [1]Manqing Li, [1]Allison Rohner, [1]Ruth Seelige, [1]Samuel Stoner, [1]Christopher Dillon, [1]Paulina Cuenca, [1]Cinthia Jones, [1]Sarah Firdaus, [1]Robert Amezquita, [1]Clifford Restaino, [1]Derek Bartlett, [1]Timothy Fisher. *[1]Pfizer, San Diego, CA, USA; [2]Bayer, New York, NY, USA*

Background Recognition of neoplastic transformed cells as foreign is the cornerstone to effective immune surveillance of cancer. Neo-antigens generated by mutations that accumulate in tumors are the basis of immune rejection, and higher levels correlate with responses to PD1 blockade. Unfortunately, most patients have insufficient tumor mutation burden (TMB) to benefit from current immunotherapies, and/or their mutations do not produce sufficiently robust antigens that can break central immune tolerance. Enhancing the ability of a patient's immune system to respond to existing TMB is paramount to overcoming primary resistance to PD1 blockade.

The HPK1 kinase is critically involved in T cell receptor (TCR) signaling, initiating a negative-feedback loop that raises the threshold of stimulus required for T cell responses. Genetic ablation of HPK1 kinase activity has been shown to increase T cell responsiveness to antigen stimulus and improve activity of PD-1 blockade in preclinical models, making HPK1 an attractive target for immunotherapy. However, the high homology of the HPK1 active site with other kinases, including kinases necessary for productive TCR signaling, results in off target liabilities that can limit small-molecule inhibitors from unlocking the full-potential of HPK1 inhibition.

Methods Through structure-based drug design and optimizing for enhanced T cell proliferation, we identified the highly-selective HPK1 inhibitor PF-07265028. Kinome selectivity of PF-07265028 was verified through biochemical profiling and in-cell chemical probes.

Results Treatment of primary human T cells from multiple human donors with PF-07265028 shows a dose-dependent inhibition of SLP76 phosphorylation (pSLP76) while increasing proliferation following suboptimal TCR stimulation. By virtue of HPK1 selectivity, PF-07265028 maintains the ability to enhance immune responses at concentrations well-above that required for 90% inhibition of pSLP76. Inhibition of HPK1 with PF-07265028 increased both CD8 and CD4 cytokine recall responses to MHC-presented peptides, and enabled resistance to immunosuppressive metabolites (PGE_2 and adenosine) that can otherwise activate HPK1 through their receptors. Combination of PF-07265028 with an anti-PD-1 antibody in co-cultures of human T cells and cancer cells led to increased tumor cell killing through synergistic enhancements of T cell activation and cytokine production. PF-07265028 displayed immunostimulatory activity in non-human primates including markers of T cell activation.

Conclusions Based on its ability to enhance multiple axes of T cell activation, PF-07265028 has the potential to improve anti-tumor responses in patients resistant to immunotherapy. Therefore, a phase one study has thus been initiated to evaluate the safety and efficacy of PF-07265028 alone and in combination with PD-1 blockade in patients with advanced solid tumors.

1368 A NOVEL BISPECIFIC BCA356 TARGETING TUMOUR ANTIGEN CAIX CONJUGATED TO AN ATTENUATED IL12 DEMONSTRATES PRE-CLINICAL EFFICACY WITH POTENTIAL FOR LIMITED SYSTEMIC TOXICITY

[1]Pradip Nair*, [1]Arvind Goswamy, [1]Jaya Bhatnagar, [1]Srinivas Boreddy, [1]Reshmi Nair, [1]Shiv Krishn, [1]Anshu Kuriakose, [1]Prashanth Pandey, [1]Hanumant Kulkarni, [1]Kishore Punnath, [1]Milind Sagar, [1]Prashanthakumara V, [1]Thulsi TK, [1]Abhishek Sinha, [1]Ravindra DR, [2]Rachel Salazar. *[1]Biofusion therapeutics, Bangalore, India; [2]Bicara Therapeutics, Boston, MA, USA*

Background IL-12 is a potent cytokine linked to activation of innate and adaptive immune system for anti-tumour immunity.[1] The clinical development of IL-12 therapy has been constrained with severe toxicity reported from systemic administration of IL-12. Toxicity is attributed to poor pharmacokinetics of IL-12, necessitating frequent dosing, and nonspecific distribution. Recently, there has been a renewed interest in IL-12 therapy with various strategies to improve half-life and reduce toxicity, with lead candidates in preclinical and early clinical stages of development.[2] Here, we describe novel bispecific BCA356 with an affinity matured humanized anti-CAIX antibody and attenuated IL-12 subunits fused to each of the heavy chains at the C-terminus by a linker in a knob-in-hole format.

Methods *In silico* mutational screening was performed on the p40 and p35 subunits of IL-12 to identify optimally attenuated IL-12 variants (IL-12vs). CAIX as a tumour-targeting antigen was selected based on high expression of CAIX across several solid tumour types. Expression of cellular and soluble CAIX across tumour types was evaluated by immunohistochemistry (IHC) on tissues and ELISA on tumour-matched plasma. BCA356 was identified after IL-12vs were screened in a HEK-Blue™ IL-12 assay (figure 1) followed by phosphorylated STAT4 expression on $CD8^+$ T cells and IFNγ release by PHA-stimulated PBMCs/IL-2 primed NK-cells. In *in vitro* 2 and 3D co-culture assays with CAIX-overexpressing cell line and PBMCs, cytotoxicity and cytokine/chemokine release were assessed across days. Efficacy and safety of BCA356 were evaluated in PBMC-based humanized mice models and human IL-12 and IL-12 receptor gene knock-in transgenic mice.

Results IHC studies confirmed high CAIX expression in clear cell renal carcinoma[3] and multiple other tumour types, a significant number of samples, expressed high and moderate CAIX expression (figure 2). BCA356 significantly attenuated IFNγ release by stimulated PBMCs, activated NK-cell and pSTAT4 expression in CD8 T cells as compared to IL-12(wt). In co-culture assays, BCA356 showed cytotoxicity of cancer cells comparable to IL12(wt) (figure 3) without significant cytokine release unlike IL12(wt) (figure 4). Finally, efficacy studies in PBMC-based humanized mice models and transgenic mice models confirm that BCA356 is efficacious and safe in CAIX-overexpressing tumour bearing mice.

Conclusions BCA356 specifically targets CAIX-expressing tumour cells and similar to wild type IL-12 cytokine, has the potential to reduce tumour proliferation with optimal activation of pro-inflammatory cytokines. Through these in vitro and in vivo studies, we demonstrate that BCA356 by its CAIX-targeted IL-12v delivery approach is both efficacious and safe.

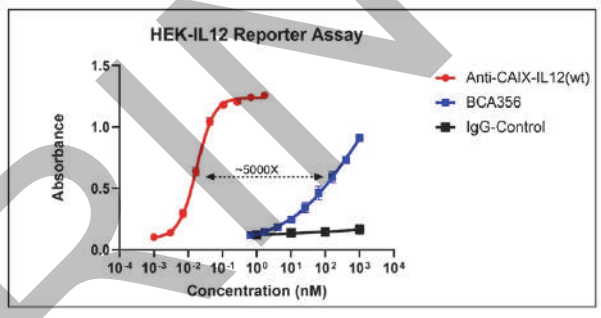
Ethics Approval Mice were maintained as per the regulations of Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA), Government of India and Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC) guidelines. All animal experiments were approved by institutional ethical committee and performed under approved protocols. All animals were maintained at dedicated Syngene vivarium



Abstract 1368 Figure 1 Evaluating IL-12 activity by HEK–IL-12 reporter assay. The binding of IL-12 to the IL-12R on the surface of HEK-Blue™ IL-12 cells (Invivogen) triggers a signaling cascade leading to the activation of STAT-4 with the subsequent production of SEAP. HEK-IL-12 cells were incubated with different concentrations of test compounds for 18-24 hours, and IL-12 activity was measured by addition of Quanti-Blue solution. Anti-CAIX-IL-12(wt) showed similar activity as rh-IL-12.

1369 CD64-DIRECTED SCFV FUSION PROTEIN EXHIBITS CYTOTOXICITY AND IS A TOOL FOR SITE-SPECIFIC DIAGNOSIS OF ACUTE MYELOID LEUKEMIA

[1]Siew Tai, [2]Sikozile Ncembu*, [2]Stefan Barth, [2]Sue Harrison. [1]*Stellenbosch University, Stellenbosch, South Africa*; [2]*University of Cape Town, Cape Town, South Africa*

Background Cancer immunotherapy is a promising innovative and effective treatment for many forms of cancer. Among haematological malignancies, acute myeloid leukemia (AML) remains an unmet medical need as it is mainly treated with chemotherapy, which is associated with serious side effects.[1,2] Therefore, antibody-based targeted therapy is preferred as it can target and specifically eliminate malignant cells. An immunotoxin (IT) is a chimeric molecule consisting of a targeting molecule and a toxic component that specifically kills target cells. H22(scFv) ETA' is an immunotoxin consisting of a humanised single-chain fragment (scFv) antibody that targets CD64, which is overexpressed on the surface of AML cells and a truncated version of *Pseudomonas* exotoxin A (ETA') that kills CD64-positive AML cells.[3] CD64 is highly expressed on monocytic blast cells in patients with AML and not on normal haematopoietic stem cells, making it a suitable target antigen.[4]

Methods H22(scFv) ETA' was recombinantly expressed in *E. coli* Bl21 (DE3) and channelled into the periplasmic space and purified by metal ion affinity chromatography and size exclusion chromatography. The cytotoxic efficacy of H22(scFv) ETA' was assessed by the Annexin V bioassay and binding assays were assessed using flow cytometry. A diagnostic fusion protein version of H22(scFv) ETA' was constructed in which the toxic component ETA' was removed and replaced with the protein SNAP tap to generate H22(scFv) SNAP. SNAP tag enables efficient tumour targeting and diagnosis of molecular biomarkers for cancer.

Results This study showed that H22(scFv) ETA' is cytotoxic to AML cancer cells expressing CD64. H22(scFv) ETA' showed significant toxicity in vitro against CD64-positive cell lines HL-60 and U937. Binding studies showed specific binding to both cell lines HL-60 and U937. Specific binding of H22 (scFv) SNAP to HL-60 and U937 was also demonstrated.

Conclusions The results described show promising results in vitro not only for the treatment of AML, but also provide technology for the effective diagnosis of AML. The development of successful scale-up production of H22(scFv) ETA' and H22(scFv) SNAP is critical for large-scale production to enable further preclinical/clinical studies. The current phase of this study is focused on optimizing productivity and large-scale production of both fusion proteins described above.

1370 DISTINCT ANTI-TUMOR RESPONSE TO LISTERIA-BASED VACCINES BETWEEN ORTHOTOPIC AND SUBCUTANEOUS SYNGENEIC MOUSE MODELS OF RENAL CELL CARCINOMA

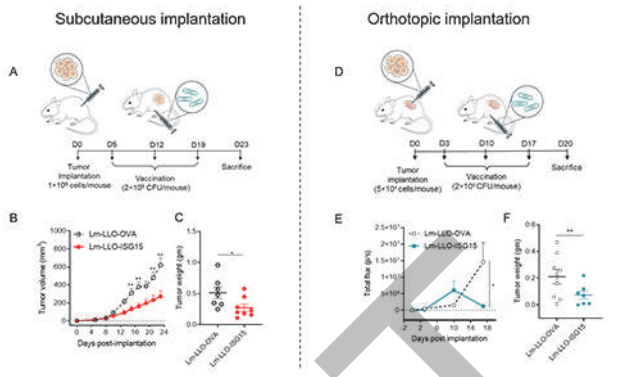
Hong-My Nguyen*, Laurence Wood. *Texas Tech University Health Sciences Center, Abilene, TX, USA*

Background In the past few decades, subcutaneous tumors have been used extensively in vivo studies to test the therapeutic efficacy of several forms of anti-cancer agents including immunotherapy. However, the recent growing demand for preclinical models that reflect human diseases more accurately, has led to the attention of orthotopic tumor models. There is a growing body of evidence demonstrating the difference in response to immunotherapy between orthotopic and subcutaneous mouse models. Our work illustrated the distinct anti-tumor response to immunotherapy between subcutaneous versus orthotopic syngeneic mouse models of renal cell carcinomas (RCC).

Methods For subcutaneous studies, 1×10^6 Renca cells were implanted subcutaneously (s.c.) into the right hind flank and mice were subsequently vaccinated i.p. on day 5, 12, and 19 with Lm-based vaccines. For orthotopic studies, 5×10^4 Renca cells expressing luciferase (Renca-luc) were implanted directly into the right kidney as previously described and mice were subsequently vaccinated i.p. on day 5, 12, and 17 with Lm-based vaccines. All mouse experiments were performed in accordance with the regulations of the Institutional Animal Care and Use Committee (IACUC) at the TTUHSC. For flow cytometry analysis, tumor tissues were harvested to prepare single-cell suspensions and stained with appropriate fluorochrome-conjugated anti-mouse monoclonal antibodies. Data were acquired on BD Fortessa and analyzed with FlowJo software version 10.7.0. All statistical analysis was done with Prism 8 GraphPad software version 8.3.0., using unpaired student t-test.

Results Listeria-based vaccines targeting interferon-stimulated gene 15, Lm-LLO-ISG15, significantly controlled tumor burden in both subcutaneous and orthotopic models as compared to that of controlled Lm (figure 1). Interestingly, while anti-tumor efficacy of Lm-LLO-ISG15 in the subcutaneous model was associated with activation of both CD8+ and CD4+ T cells, anti-tumor response in orthotopic models was mainly engaged by the activation of CD4+ T cells. The multi-cytokines producing T cells were higher in subcutaneous tumors as compared to that of orthotopic models (figure 2). In addition, treatment with Lm-LLO-ISG15 increased a higher influx of total myeloid cells as well as both monocytic- and polymorphonuclear-monocytic-derived suppressor cells (MDSCs) to the tumor microenvironment (TME) compared to Lm-LLO-OVA in subcutaneous tumors. In contrast, total myeloid cells, m-MDSCs, and pmn-MDSCs were significantly lower in Lm-LLO-ISG15 group compared to controlled Lm in orthotopic models (figure 3).

Conclusions Vaccination with Lm-LLO-ISG15 significantly controlled RCC tumor burden in both subcutaneous and orthotopic models, as compared to that of controlled Lm. Interestingly, treatment with Lm-LLO-ISG15 resulted in distinct anti-tumor responses in subcutaneous versus orthotopic RCC tumors.



Abstract 1370 Figure 1 Listeria-based vaccines is efficacious against RCC tumors
Listeria-based vaccines is efficacious against both subcutaneous and orthotopic tumors. (A) Experimental schema for subcutaneous studies. Briefly, 1×106 Renca cells in 100 µl PBS were implanted subcutaneously into the right hind flank and mice were subsequently vaccinated i.p. with Lm-based vaccines. (B) Tumor kinetic curve throughout the course of the experiment and (C) final tumor mass at the end of the experiment of both Lm-based vaccines. (D) Experimental schema for orthotopic studies. Briefly, 5×104 Renca cells expressing luciferase (Renca-luc) were implanted directly into the left kidney and mice were subsequently vaccinated i.p. with Lm-based vaccines. D-luciferin (150mg/kg, Perkin Elmer) was injected i.p. to the mice and bioluminescence signals was detected by IVIS Imaging system at 10 min post-injection. (E) The tumor kinetic curve was plotted by using total flux (photon/sec) of the region of interest (ROI). (F) Final tumor mass at the end of the experiment of both Lm-based vaccines. 1371 IDENTIFICATION OF VASOACTIVE INTESTINAL PEPTIDE (VIP)-SPECIFIC SINGLE-CHAIN ANTIBODY FRAGMENTS (SCFVS) VIA YEAST SURFACE DISPLAY

David Zaharoff, Khue Nguyen*. *NC State University and UNC, Chapel Hill, Raleigh, NC, USA*

Background Vasoactive intestinal peptide (VIP) is a 28-amino acid neuropeptide expressed in various tissues including the pancreas, intestines and central nervous system.[1, 2] The over-expression of VIP and its receptors is associated with increased growth and metastasis of breast, prostate, and lung malignancies.[3] In addition, the interaction of VIP with its receptors on activated T cells results in immune suppression which further supports tumor growth.[4, 5] Furthermore, tumor-supporting regulatory T cells have been found to be promoted by VIP-dependent mechanisms.[6] Altogether, prior literature implies that blockade of VIP signaling may inhibit tumor-mediated immune suppression and augment antitumor immune responses. Recent preclinical studies in acute myeloid leukemia and T lymphoblastic leukemia demonstrated that VIP receptor antagonists increase T cell-dependent anti-tumor responses.[2]. Unfortunately, the short-half lives of peptide antagonists limit their clinical utility. A more translatable approach is the development of long circulating antibodies that bind VIP and inhibit its immunosuppressive activities.

Methods In this study, we utilized a yeast display of a non-immune human single-chain variable fragment (scFv) library to identify VIP-binding scFvs.[7-9] VIP binders were screened by several rounds of selection using magnetic-activated cell sorting (MACS) and fluorescence-activated cell sorting (FACS). The enriched binder population was cloned into single colonies of yeast cells by limited dilution. The binding affinities of VIP-binding clones were evaluated via flow cytometry by titrating fluorescence-labeled VIP. Clones with high binding affinity (Kd < 500 nM) were selected for sequencing (figures 1-5).

Results Sequences of the isolated scFv revealed that a unique section of complementarity-determining region 3 (CDR3) of the heavy chain played an important role in VIP binding. Multiple clones with similar but distinct CDR3 sequences produced a useful range of binding affinities for further development (figure 6).

Conclusions Yeast display is an effective technology for identifying human scFvs that bind to the immunosuppressive neuropeptide, VIP. CDR3 of scFv heavy chains were influential in VIP recognition. Ongoing studies are focused on the production, purification, and validation of novel anti-VIP human antibodies.

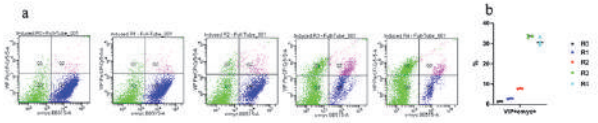
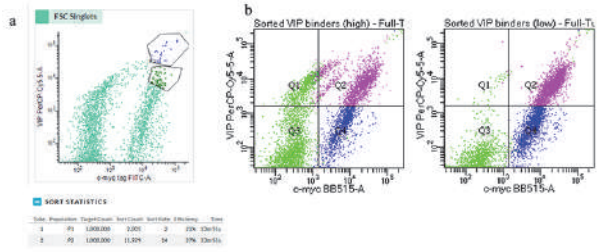
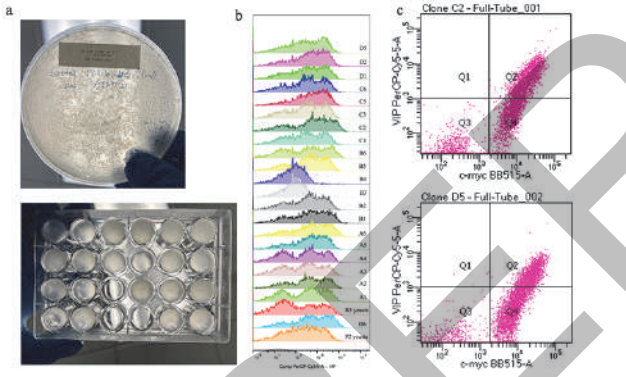
Abstract 1371 Figure 1 isolation process of anti-VIP scFv utilizing yeast display a) Workflow illustrating the process for isolating protein binders from large combinatorial libraries on yeast using magnetic bead separation followed by flow cytometry-based selection. (b) Illustration of protein scaffolds displayed on the surface of yeast and a related plasmid map.



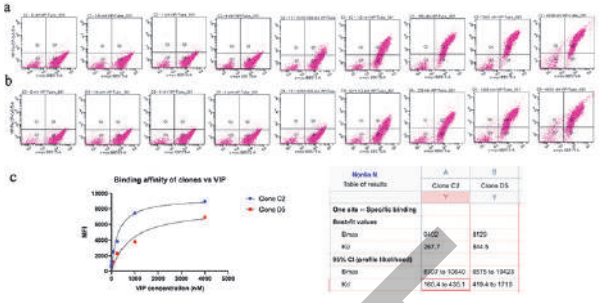
Abstract 1371 Figure 2 Four enrichment rounds of VIP binders using MACS selection
(a) Dot plots show the binding events of VIP to yeast library analyzed by flow cytometry. VIP binders were selected by MACS in four rounds. Selections include a brief incubation of yeast library and VIP-magnetic beads, then binders were pulled out using a magnet. Selected yeasts were expanded and induced by specific culture media before analyzed by flow cytometry. Flow cytometry experiments were performed as staining each round of yeast library by anti-c-myc antibody-FITC (RMYC45FZ, Immunology Consultants), VIP-biotin (P001353, Aapptec), and Streptavidin PerCP-Cyanine5.5 Conjugate (45431782, Invitrogen). Stained cells were analyzed by BD FACSCelesta flow cytometer. (b) Dot plot shows representative binding percentages of VIP+c-myc+ events from 4 rounds of enrichment.



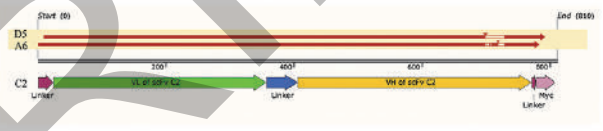
Abstract 1371 Figure 3 Isolation of VIP binders (round 3) by FACS sorting
(a) VIP binders after 3 rounds of selection (R3 yeasts) were subjected to a FACS sorting. Cells were stained with anti-c-myc antibody-FITC (RMYC45FZ, Immunology Consultants), VIP-biotin (P001353, Aapptec), and Streptavidin PerCP-Cyanine5.5 Conjugate (45431782, Invitrogen). FACS sorting was performed on a BD FACSMelody Cell Sorter. Two populations of VIP high signal and low signal were collected. Sorted yeasts were expanded and induced by specific culture media before analyzed by flow cytometry. (b). Comparison of VIP binding between VIP high signal (left) and low signal(right) populations. Flow cytometry experiments were performed as staining yeast cells by anti-c-myc antibody-FITC (RMYC45FZ, Immunology Consultants), VIP-biotin (P001353, Aapptec), and Streptavidin PerCP-Cyanine5.5 Conjugate (45431782, Invitrogen). Stained cells were analyzed by a BD FACSCelesta flow cytometer.



Abstract 1371 Figure 4 Cloning of VIP binders using limited dilutions
(a.top) Yeast cells from low signal population (P2 yeasts) were streaked onto an agar plate using limited dilutions. Single colonies were then picked and cultured in single wells of a 24 well plate (a.bottom). Cells were then expanded and induced by specific culture media. (b). VIP+ signals of different clones analyzed by flow cytometry. (c). Comparison of VIP binding between clone C2 (top) and clone D5 (bottom). Flow cytometry experiments were performed as staining yeast cells by anti-c-myc antibody-FITC (RMYC45FZ, Immunology Consultants), VIP-biotin (P001353, Aapptec), and Streptavidin PerCP-Cyanine5.5 Conjugate (45431782, Invitrogen). Stained cells were analyzed by a BD FACSCelesta flow cytometer.



Abstract 1371 Figure 5 Comparison of VIP-binding affinity between clones C2 vs D5
Cells of clone C2 (a) and D5 (b) were incubated with a gradient of VIP concentrations before stained and analyzed by flow cytometry. (c) Mean fluorescent intensity (MFI) of VIP+c-myc+ events were analyzed and used to calculate the Kd values of each clone by Prism 9.0. Flow cytometry experiments were performed as staining yeast cells by anti-c-myc antibody-FITC (RMYC45FZ, Immunology Consultants), VIP-biotin (P001353, Aapptec), and Streptavidin PerCP-Cyanine5.5 Conjugate (45431782, Invitrogen). Stained cells were analyzed by a BD FACSCelesta flow cytometer.



Abstract 1371 Figure 6 Comparison of DNA sequences of different VIP binder clones
DNA plasmids of 3 clones (C2, A6, and D5) were purified from yeast cells, then they were transformed into E. coli for expansion. Plasmids were purified from E. coli, subjected to Sanger sequencing, and analyzed by SnapGene. The DNA sequence of scFv clone C2 was used as a template to compare with clone D5 and A6. The isolated scFv sequences indicated that a specific region in the heavy chain's complementarity-determining region 3 (CDR3) played a key role in VIP binding.

1372 XMAB143, AN ENGINEERED IL18 HETERODIMERIC FC-FUSION, FEATURES IMPROVED STABILITY, REDUCED POTENCY, AND INSENSITIVITY TO IL18BP

Alex Nisthal*, Sung-Hyung Lee, Christine Bonzon, Ruschelle Love, Kendra Avery, Rumana Rashid, Panida Lertkiatmongkol, Nicole Rodriguez, Sher Karki, Norman Barlow, Seung Chu, Gregory Moore, John Desjarlais. *Xencor, Monrovia, CA, USA*

Background Interleukin-18 (IL18) is a proinflammatory cytokine that modulates both innate and adaptive immune responses. Mature IL18 promotes the expansion, survival, and cytotoxicity of T and NK cells expressing the heterodimeric IL18 receptor. Preclinical studies with recombinant IL18 have demonstrated anti-tumor activity in animal models, including impressive synergy with both immune checkpoint inhibitors and CAR-T therapy. However, clinical development as a single agent exhibited poor pharmacokinetics and an overall lack of efficacy despite heavy dosing. IL18 participates in a negative feedback loop with IL18 binding protein (IL18BP), a very high affinity natural inhibitor induced by IFNγ. As IL18BP upregulation was observed in early phase clinical trials, it likely limited the efficacy of recombinant IL18.

Methods Prior work at Xencor demonstrated that reduced-potency IL15/IL15Rα-Fc fusion proteins exhibited superior pharmacokinetics, pharmacodynamics, and safety in non-human primates through reduction of receptor-mediated clearance. Following that principle, we generated monovalent IL18-Fc fusions upon our XmAb® heterodimeric Fc platform and introduced substitutions that could modulate IL18 stability, affinity toward the IL18 heterodimeric receptor, and affinity toward IL18BP.

Results To address IL18's poor native stability, we engineered a disulfide bridge into the cytokine's structure which increased the thermal denaturation temperature from 45 °C to 65 °C. This had beneficial effects on the cytokine's yield and solution behavior, and translated into a significant improvement of PK in mice. Variants at IL18 positions along the IL18 receptor and IL18BP interfaces were explored in vitro by measuring PD-L1 induction on KG-1 cells, with and without a high concentration of IL18BP. Recombining hits generated a potency series with variants exhibiting over a 2,000-fold reduction in PD-L1 induction potency as compared to WT IL18-Fc. Importantly, we identified variants that no longer detectably bound IL18BP, relieving natural inhibition of our engineered IL18-Fc. In vivo immune-mediated inflammation by our lead IL18-Fc, XmAb143, was explored in human PBMC engrafted mouse models of graft versus host disease (GvHD). We observed dose-dependent exacerbation of GvHD, with corresponding dramatic increases in the numbers, activation, and IFNy release of T and NK cells as compared to a human PBMC only control. Conversely, XmAb143 pharmacodynamics in cynomolgus monkey pilot tox studies was observed only at higher doses, and serum half-life improved from hours to days over WT IL18-Fc.

Conclusions XmAb143, our engineered monovalent IL18-Fc fusion demonstrates insensitivity to IL18BP inhibition, robust inflammation activity in vivo, and improved pharmacokinetics in mice and cynomolgus monkeys.

1373 STC-15, AN ORAL SMALL MOLECULE INHIBITOR OF THE RNA METHYLTRANSFERASE METTL3, INHIBITS TUMOUR GROWTH THROUGH ACTIVATION OF ANTI-CANCER IMMUNE RESPONSES AND SYNERGISES WITH IMMUNE CHECKPOINT BLOCKADE

[1]Yaara Ofir -Rosenfeld, [1]Oliver Rausch, [1]Jerry McMahon*, [1]Lina Vasiliauskaite, [1]Claire Saunders, [1]Alexandra Sapetschnig, [1]Georgia Tsagkogeorga, [1]Mark Albertella, [2]Marie Carkill, [2]Jezrom Self-Fordham, [1]Josefin-Beate Holz. *[1]Storm Therapeutics, Cambridge, UK; [2]Charles River Laboratories, Portishead, UK*

Background METTL3 is an RNA methyltransferase responsible for the deposition of N-6-methyladenosine (m^6A) modification on mRNA and long non-coding RNA (lncRNA) transcripts, to regulate their stability, splicing, transport and translation. Small molecule inhibitors of METTL3 catalytic activity have previously demonstrated direct anti-tumour efficacy in models of acute myeloid leukemia (AML). Here we present pre-clinical data showing that STC-15, an orally bioavailable small molecule inhibitor of METTL3, restrains cancer growth and induces anti-cancer immunity

Methods To characterise transcriptomic changes following METTL3 inhibition, RNA sequencing studies were performed on several cancer cell lines treated with STC-15. Induction of specific genes was validated by qPCR and Western Blots. The functional consequence of the upregulation of innate immune pathways was investigated in vitro using a co-culture system of SKOV3 ovarian cancer cells and human peripheral blood mononuclear cells (PBMC) or purified primary CD8+ T-cells, and animal studies using subcutaneous A20 and MC38 mouse syngeneic tumour models

Results Inhibition of METTL3 by STC-15 in cancer cell lines leads to prominent upregulation of genes associated with innate immunity, including type-I and type-III IFNs, as well as many interferon stimulated genes. Cells treated with STC-15 accumulated double-stranded RNA suggesting that activation of IFN signalling is triggered by innate pattern recognition sensors.

In an in vitro co-culture system, STC-15 demonstrated strong and dose-dependent enhancement of PBMC-mediated killing of cancer cells. Similar results were obtained when replacing PBMC with purified CD8+ T-cells.

In MC38 colorectal and A20 lymphoma syngeneic models, oral treatment of immune-competent tumour bearing mice with STC-15 significantly inhibited tumour growth. In vivo depletion of CD8+ T-cells abrogated the response to STC-15.

Combination of STC-15 with anti-PD1 antibody resulted in tumour regression in both models, with mice remaining tumour-free long after treatment ceased. When regressed mice from the A20 model were re-challenged with a new batch of A20 cells, no new tumour growth was observed, further demonstrating the induction of durable anti-tumour immunity

Conclusions In pre-clinical cancer models, STC-15 treatment results in activation of innate immune pathways, inhibits tumour growth via activation of CD8+ T-cell mediated tumour cell killing, and enhances the anti-tumour properties of anti-PD1 therapy to generate a durable anti-tumour immune response. These data provide the rationale for the development of STC-15 both as monotherapy and in combination with checkpoint inhibition for the treatment of solid tumour malignancies. A Phase I, First-in-Human clinical trial is planned to begin in 2022

Ethics Approval Animal welfare for this study complies with the UK Animals Scientific Procedures Act 1986 (ASPA) in line with Directive 2010/63/EU of the European Parliament and the Council of 22 September 2010 on the protection of animals used for scientific purposes.

1374 CHARACTERIZATION AND VALIDATION OF A HUMANIZED LEAD ANTIBODY AGAINST OX003, A NOVEL IMMUNO-ONCOLOGY TARGET

[1]Arnima Bisht, [1]Murray Cox, [2]Antonn Cheeseman, [1]Christian Rohlff, [1]Chander Peddaboina*, [1]Abderrahim Fandi. *[1]Oxford BioTherapeutics Inc, San Jose, CA, USA; [2]University of Manchester, Manchester, UK*

Background Immunotherapy, an approach to target or manipulate the immune system, has changed the field of oncology and cancer treatment. Antibodies targeting checkpoint proteins CTLA-4, PD-1, and PD-L1 have shown great success, at the same time some of these checkpoint inhibitors are known to eventually induce immunotherapy resistance in several cancers leading to poor treatment prognosis.[1]At Oxford BioTherapeutics, using the proprietary OGAP database, novel targets on TILs (Tumor infilitrating Lymphocytes) have been identified that can lead to a breakthrough in the field of cancer immunotherapy. From proteomic analysis, OX003 is identified as a surface protein on T cells with a co-stimulatory function. OX003 is expressed on most lymphocytes with TILs showing the highest expression.

Methods Immunohistochemistry technique is used to evaluate the expression of OX003 in TILs and wide variety of solid tumors. *In vitro* evaluation of OX003 expression on T cells is performed using flow cytometry technique. A fully humanized agonistic mAb is developed against OX003 and its functional activity on T cells is evaluated *in vitro*. T cell proliferation measured by CFSE dye dilution, IFN? (interferon gamma) cytokine and Granzyme B secretion via ELISA, Perforin accumulation via flow cytometry, ELISpot assay, and 1-way Mixed lymphocyte reaction (MLR) assays are used for T cell functional activity.

Results Evaluation of OX003 by immunohistochemistry shows abundant expression on TILs, and in a variety of solid tumors. OX003 positive TILs are observed both intratumorally and in the stromal components of the TME (Tumor micro environment). *In vitro* evaluation of OX003 expression on T cells shows upregulation upon activation of naïve T cells which persists between activated and exhausted phenotypes and decreases upon resting, closely following the time course of activation and exhaustion markers. This humanized antibody against OX003 shows a strong agonistic effect in a dose-dependent manner on CD8+ T cells promoting proliferation , IFN? cytokine secretion, Granzyme B release and Perforin accumulation indicating a strong cytolytic ability. In an allogenic one-way MLR setup, it enhances functional activity of T cells in co-culture with PBMC as stimulators, showning dose-dependent increase in IFN? release compared to an isotype control. Ex vivo assays conducted with the antibody on fresh tumor samples showed increased IFN? release as compared to Isotype as measured by the ELISpot assay.

Conclusions This data show that OX003 is a novel immunostimulatory receptor on CD8+ T cells and the lead agonistic antibody targeting OX003 enhances T cell functional activity critical for successful immunotherapy response.

1375 A HORMONE-BASED BISPECIFIC T CELL ENGAGER (BITE)-LIKE MOLECULE FOR THE TREATMENT OF NEUROENDOCRINE TUMORS

[1]Eleonora Pelle*, [2]Mauro Cives, [1]Elliot Medina, [1]Charlotte Mason, [1]Sebastian Snedal, [1]Xiomar Bustos Perez, [1]Leticia Tordesillas, [1]Miguel Gomez Fontela, [1]Renata Rossetti, [3]Gabriele Maiorano, [1]Vincent Luca, [1]Patrick Hwu, [1]Daniel Abate-Daga, [1]Jonathan Strosberg. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]University of Bari Aldo Moro, Bari, Italy; [3]National Research Council, Lecce, Italy*

Background We designed a novel bispecific T-cell engager (BiTE) targeting the somatostatin receptor (SSTR), which is overexpressed by well-differentiated neuroendocrine tumors (NETs). In our BiTE, the single chain variable fragment (scFV) based anti-SSTR domain is replaced by 2 molecules of somatostatin-14 (SST14), the hormone that physiologically activates the SSTR.

Methods The sequence of the SST14-scFV anti-CD3 BiTE was optimized and cloned into a pAcGP67avector. The recombinant protein was expressed by Trichoplusia-ni (High Five) using Baculovirus and isolated from the supernatant using nickel affinity chromatography. The binding potential of the BiTE towards CD3 and SSTR was determined by flow cytometry and confocal microscopy. The SSTR-specific T cell activation and the BiTE-induced cytotoxicity were measured after coincubation of $CD3^+$ T cells isolated from the peripheral blood of healthy donors with 293T cells stably transduced to concurrently express SSTR and GFP, in presence of the BiTE. The same conditions in absence of BiTE or with the $SSTR^-$ parental 293T were used as negative control, while anti-CD3/CD28 beads were added as a positive control. The BiTE-induced cytotoxicity was assessed by real-time quantitative live-cell imaging using the Incucyte system. The BiTE-induced T cell activation was evaluated measuring the secretion of IFN-γ, and granzyme-B by ELISA.

Results At a concentration of 100 nM, the BiTE bound the CD3 receptor of approximately 85% of T cells. By confocal microscopy, the BiTE was found to coat $SSTR^+$293T cells. When added to $SSTR^+$293T cell cultures, the BiTE by itself exerted antiproliferative activity ($p < 0.0001$), possibly as result of an agonist activity on the SSTR. Such a cytotoxic effect was significantly more pronounced when T cells were also present in the cultures ($p<0.0001$). IFN-γ and granzyme-B secretion was significantly higher when the T cells were co-cultured with $SSTR^+$293T cells in the presence of the BiTE as compared with parallel preparations with $SSTR^-$293T cells or without the BiTE, suggesting that the BiTE-induced T cell activation is specific.

Conclusions To our knowledge, this is the first BiTE to incorporate a hormone in one binding site. Our preclinical data indicate that the BiTE specifically engages the SSTR, the T cell receptor and induces a high level of cytotoxicity in the presence of T cells.

1376 NOVEL, BRAIN PENETRANT SMALL MOLECULE INHIBITOR OF PD-L1 FOR TARGETING GLIOBLASTOMA AND BRAIN METASTASIS

Dhanalakshmi Sivanandhan, Sridharan Rajagopal*, Sridharan Rajagopal, Chandru Gajendran, Naveen Sadhu M, Mohammed Zainuddin, Ramachandraiah Gosu, Luca Rastelli. *Jubilant Therapeutics Inc, Bedminister, NJ, USA*

Background The PD-1/PD-L1 molecular pathway is one of the primary mechanisms of immune evasion deployed by cancer cells. Activation of PD-1/PD-L1 pathway induces anergy and exhaustion of cytotoxic T-cells and enhances the function of regulatory T-cells causing an immune suppressive environment. Therefore, blocking this pathway restores T-cell proliferation and enhanced tumor cell killing. Approved monoclonal antibodies targeting PD-1/PD-L1 pathway require intravenous injections and have a long half-life that could contribute to the well-documented drug-related adverse effects. Also, efficacy of these antibodies appears to be marginal in malignancies associated with CNS due to poor brain penetrance. Therefore, small molecule inhibitors of the PD-1/PD-L1 pathway with oral bioavailability, better tumor and brain penetrance and shorter half-life will be highly valuable in cancer therapy. In this regard, JBI-2174 shows excellent ADME properties, brain exposure, pharmacokinetics and comparable efficacy as approved mAbs in preclinical studies.

Methods Structure based drug design was used to design PD-L1 inhibitors; potency of these inhibitors was assessed in an *in-vitro* TR-FRET assay. Reporter assays and ex-vivo co-culture assays were used to assess T-cell proliferation and function. Pharmacokinetics were performed in multiple pre-clinical species to derive at bioavailability and brain penetration. In vivo efficacy was assessed in partially humanized mice efficacy models.

Results JBI-2174 showed strong *in vitro* IC_{50} of 1.5 nM in TR-FRET assay that measures interaction between PD-1 and PD-L1 and let to stabilization of PD-L1 as measured by thermal shift assay. This molecule also augmented T-cell co-inhibitory signalling as observed by Jurkat cell/SHP-1 assay. Competition study between anti-PD-L1 blocking antibody and x-ray crystal structure studies clearly demonstrated that JBI-2174 leads to dimerization of PD-L1. More importantly, JBI-2174 showed excellent oral bioavailability across pre-clinical species and strong and sustained (up to 24 h) brain exposure (0.66 to 2.1 fold plasma vs. brain ratio). JBI-2174 showed comparable or better efficacy to the anti-PD-L1 antibody Atezolizumab in hPD-L1/MC38 syngeneic and brain orthotopic models by oral administration with a concomitant increase in tumor infiltrating lymphocytes. Toxicological studies conducted in non-human primates clearly show that the molecule is well tolerated at exposures much higher than efficacious exposure.

Conclusions Oral administration and brain exposure of these small molecule PD-L1 inhibitors provides an attractive option to be used in the treatment of glioblastoma and other solid tumors with brain metastasis. IND enabling studies are being initiated for this molecule to initiate clinical trials in humans.

1377 **PRECLINICAL CHARACTERIZATION OF D3L-001, A NOVEL BISPECIFIC ANTIBODY THAT ENHANCE PHAGOCYTOSIS AND ERADICATION OF HER2 POSITIVE SOLID TUMOR VIA HER2 AND CD47 DUAL BLOCKADE**

[1]Haopeng Rui*, [2]Siwei Nie, [2]Jiaxiang Shao, [1]Xiaofeng Yang, [1]Jiahao Chen, [1]Jia Wang, [1]Zhiqiang Zheng, [1]Jingtao Lu, [1]Allison Wang, [3]Jin Hong, [3]Xiaosong Chen, [3]Kunwei Shen, [1]George Chen. *[1]D3 Bio (Wuxi) Co. Ltd., Shanghai, China; [2]WuXi Biopharmaceuticals Shanghai Co. Ltd, Shanghai, China; [3]Ruijin Hospital, Shanghai, China*

Background HER2 is overexpressed in different solid tumors, including 15-20% of breast cancer. The advent of HER2-targeted drugs, including antibodies (Ab), TKI and ADC, have revolutionized HER2+ cancer treatment; however, the disease will eventually recur in most patients. Recent studies have suggested efficacy of HER2 target antibodies (Ab) therapy could be further enhanced by antibody-dependent cellular phagocytosis (ADCP) principally regulated by antiphagocytic "don't-eat-me" CD47 signals. CD47 is overexpressed in many HER2+ cancers, which suppresses phagocytosis through binding to SIRPα

In this study, an internally discovered anti-HER2×CD47 bispecific antibody (bsAb), D3L-001, demonstrated synergistic anti-tumor effect by HER2 guided CD47 co-blocking. It enhances macrophage mediated phagocytosis and significantly suppresses *in vivo* tumor growth while sparing hematological toxicities, which are typically induced by anti-CD47 antibodies.

Methods SK-BR-3, HCC1954 and Jurkat cells were used. Cellular binding and *in vitro* blocking of CD47 and SIRPα interaction by Abs were measured by FACS. Monocytes were isolated from PBMC and differentiated into macrophages, which were then used for ADCP assays. Abs *in vivo* efficacy were examined in HER2+ tumor models.

Results D3L-001 was designed to have higher HER2 affinity (K_D < 1 nM) than that of CD47 (K_D >10 nM). With this unique design, D3L-001 showed preferential binding to HER2/CD47 double positive tumor cells as compared to CD47 single positive cells (figure 1). This preferential binding prevents D3L-001 from inducing red blood cell hemagglutination *in vitro*. Moreover, its binding to HER2+ tumor cells wasn't affected by whole blood cell pre-culture treatment, indicating low systemic CD47 antigen sink effect. Intriguingly, we found that D3L-001 can block the interaction between SIRPα and CD47 on HER2+ tumor cells very effectively, probably due to the avidity effect induced by the addition of HER2 binding arm (figure 2). This potent blocking translated well into enhanced *in vitro* phagocytosis ability. D3L-001 showed stronger anti-tumor effect than trastuzumab in a panel of HER2+ tumor models. We observed significant tumor growth inhibition and regression in trastuzumab resistant xenograft models in a dose-dependent manner. D3L-001 demonstrated better efficacy than combination of trastuzumab and magrolimab, indicating synergistic effect of co-blocking HER2 and CD47 in bispecific form. In addition, the combination of D3L-001 with pertuzumab also showed synergistic *in vivo* efficacy.

Conclusions D3L-001 is a novel HER2×CD47 bsAb which demonstrated potent and synergistic anti-tumor effect via HER2 guided CD47 co-blocking in both *in vitro* and *in vivo* models. D3L-001 might provide a novel treatment approach for HER2+ cancers and overcome their resistance to current therapies.

1378 PRECLINICAL CHARACTERIZATION OF IMGS-001, A DUAL ANTAGONIST ANTI-PD-L1, ANTI-PD-L2 ANTIBODY WITH EFFECTOR FUNCTION, TO TREAT PATIENTS RESISTANT TO IMMUNE CHECKPOINT BLOCKADE

[1]Ahmad Salameh*, [1]Federica Pericle, [1]Christine Gagliardi, [1]Paul Blezinger, [2]Michael Curran.
[1]*ImmunoGenesis, Inc., Houston, TX, USA*; [2]*MD Anderson Cancer Center, Houston, TX, USA*

Background Antibody drugs which block engagement of the T cell co-inhibitory receptor programmed cell death-1 (PD-1) or its cognate ligand programmed death-1 ligand-1 (PD-L1) are a key pillar of modern oncology. While the impact of these drugs has been profound, their efficacy remains limited to cancers with pre-existing immune infiltration and/or higher numbers of mutational neoantigens. To expand the percentage of cancer patients that benefit from immunotherapy, drugs are needed which can diminish multi-modal immune suppression in immune excluded tumors to the extent that T cells can accumulate and expand sufficiently to benefit from PD-1 pathway blockade. Thus, we characterized IMGS-001, a human monoclonal antibody against PD-L1 and PD-L2 with effector functions, developed in collaboration with MD Anderson. IMGS-001 is being tested *in vitro* and *in vivo* to support clinical development in patients resistant or naïve to immuno-oncology (IO) treatment.

Methods *In vivo* dose-regimen anti-tumor activity was analyzed using syngeneic mouse models of colon cancer (CT26-expresing mouse PD-L2, MC38) and melanoma (B16F10 expressing mouse PD-L2). Tumor-bearing mice were treated with IMGS-001 at 5-10-20 mg/kg twice a week for 3 weeks. In addition, IMGS-001 mediated antibody dependent cellular cytotoxicity (ADCC) was assessed in immune-competent and immune-deficient mice (nu/nu) injected with CT26-PD-L2 and MDA-MB-231, respectively. In both studies, mice were treated with IMGS-001 twice a week for 3 weeks while a second group (only CT-26-PD-L2 model) was first depleted of natural killer (NK) cells.

Results IMGS-001 significantly inhibited CT26-PD-L2 tumor growth compared to PBS treatment ($p=0.0239$) and extended survival ($p=0.0007$) with an optimal dose of 10 mg/kg. Against MC38, 70% of animals treated with $\geq$10mg/kg IMGS-001 were alive with no evidence of tumor 70 days post-inoculation. IMGS-001 (10mg/kg) showed 90% inhibition of B16F10-PD-L2 tumor volume compared to the control ($p<0.0001$). In mice lacking T cells, IMGS-001 significantly inhibited MDA-MB-231 tumor growth at 10 mg/kg, indicating a mechanism of action driven by ADCC. Moreover, in NK-depleted immune-competent mice, IMGS-001 lost activity against CT26-PD-L2 ($p=0.0403$).

Conclusions These data suggest 10 mg/kg of IMGS-001 being the optimal dose to induce a strong anti-tumor activity *in vivo*. Moreover, IMGS-001 displayed a mechanism of action driven by the cytoreduction of immune suppressive stroma *in vivo* via ADCC. These results, with a favorable PK, the absence of off-target activity and a clean toxicology profile, support the clinical development of IMGS-001. IMG-S001 would increase the benefit of IO therapy for patients with immune-infiltrated tumors and could mediate significant clinical responses against immune-excluded cancers.

1379 ENGINEERED TOXIN BODY TARGETING TIGIT DEPLETES TREGS IN THE TUMOR MICROENVIRONMENT AND REDUCES TUMOR BURDEN IN MICE

Elizabeth Saputra, Amit Chaudhary, Desirae Martinez, Jennifer Mitchell, Rebecca Martin, John Majercak, Joseph Dekker, Chris Moore, Swati Khanna, Swati Khanna*. *Molecular Templates Inc., Austin, TX, USA*

Background TIGIT (T cell immunoreceptor with Ig and ITIM domains) is an immune inhibitory receptor, which is known to be over-expressed on Tregs in the tumor microenvironment (TME) of multiple solid tumors and functions as an immunological checkpoint. TIGIT is often co-expressed with PD-1 on Tregs and CD4+ and CD8+ T cells in the TME.[1-3] Monoclonal antibodies (mAb) blocking TIGIT have shown little efficacy as a monotherapy or in combination with αPD-L1 mAb in clinical studies.[4-5] We have shown previously that TIGIT targeting Engineered Toxin Bodies (ETBs) show cytotoxicity in vitro on TIGIT over-expressing cell lines and TIGIT expressing immune cells, including Tregs.[6] Here, we demonstrate the efficacy and pharmacodynamic (PD) effects of TIGIT ETB in a hTIGIT/PD-1 expressing humanized mouse model. Contrary to mAbs, which function by steric hinderance of the TIGIT-CD155 axis, TIGIT ETBs function by direct cell kill of TIGIT expressing cells and represent a novel approach to targeting TIGIT expressing cells in cancers.

Methods MC38 tumor bearing humanized mice (hTIGIT/PD-1) were treated with TIGIT ETB as a monotherapy and in combination with αPD-1 mAb. The effect of TIGIT ETB was compared with αPD-1 and αTIGIT mAbs used alone or in combination. Tumor volumes were measured during the study and all tumors were harvested at study conclusion on day 18 for evaluation of test article effects on tumor immunophenotype.

Results TIGIT ETB monotherapy resulted in the best overall reduction in tumor burden and was comparable with the αPD-1 mAb group. Strikingly, TIGIT ETB monotherapy worked better than the αTIGIT+ αPD-1 mAb combination. TIGIT ETB+ αPD-1 mAb showed similar effects on tumor growth as the αTIGIT+ αPD-1 mAb combination. These effects on tumor growth coincided with significant reduction in Tregs and increased CD8:CD4 ratio in the TME across all TIGIT ETB treatment groups. This TME Treg depletion was not observed with αTIGIT+αPD-1 mAb combination.

Conclusions These data demonstrate that targeting TIGIT using our Engineered Toxin Body platform promotes tumor regression through elimination of TIGIT/PD-1 co-expressing immune cells within the TME. Our data supports using ETB as a monotherapy to target TIGIT and represents a wholly novel approach for modulating TIGIT within the TME.

1380 SYNERGISTIC ANTI-TUMOR EFFECT OF ALLOCETRA-OTS, A CELLULAR IMMUNE-THERAPY, IN COMBINATION WITH IMMUNE CHECKPOINT INHIBITORS/ CHEMOTHERAPY/CAR T, THROUGH IN-VIVO REPROGRAMMING OF MACROPHAGES

[1]Dror Mevorach*, [2]Barak Reicher, [2]Oren Hershkovitz, [2]Yehudit Shabat. *[1]Hadassah-University Hospital, Jerusalem, Israel; [2]Enlivex Therapeutics, Jerusalem, Israel*

Background Immune checkpoint inhibitors (ICI) revolutionized solid tumor treatment, however, in many tumors only partial response is achieved. Allocetra-OTS has an immune modulating effect on macrophages[1] and showed an excellent safety profile in patients including patients with sepsis.[2] Here we investigated the anti-tumoral effect of Allocetra-OTS cellular therapy, in solid tumor animal models.

Methods Allocetra-OTS is manufactured from enriched mononuclear fractions and induced to undergo early apoptosis.

In an immunecompetent model, Balb/c mice were inoculated intraperitoneally (IP) with AB12 (mesothelioma) with pLenti-PGK-V5-Luc-Neo and treated with anti-CTLA4 with or without Allocetra-OTS. Mice were monitored daily for clinical score and weekly using IVIS. Kaplan-Meier log rank test was done for survival. For Allocetra-OTS preparation, enriched mononuclear fractions were collected by leukapheresis from healthy eligible human donors and induced to undergo early apoptosis.To follow tumor growth in vivo, HeLa-CD19 cells were stably transduced with pLenti-PGK-V5-Luc-Neo. For CAR preparation, fresh mononuclear cells (MNC) were transfected with CD19-CAR plasmids. SCID-Bg mice were injected IP with human HeLa-CD19 or HeLa-CD19-luciferase cells, 10×10 allocetraOTS or vehicle, and 10×10 CD19-CAR T cells or mock T cells.

Results In immune competent Balb/c mesothelioma model, anti-CTLA4 standalone therapy significantly improved survival from mean 34±9 to 44.9 ±20 days ($p<0.05$). Similarly, Allocetra OTS standalone therapy improved survival to 52.3 ±20 days ($p<0.02$). However, anti-CTLA4 + Allocetra-OTS combination therapy, ameliorated survival to 86.7±20 days ($p<0.0001$) with complete cancer remission in 60-100% of mice (figure 1 & 2). Similar anti-tumoral effects of Allocetra-OTS were seen in mesothelioma model in a combination therapy with either anti-PD1 or cisplatin.

In the CAR-T model, SCID-Bg mice were sacrificed or died from tumor progression in 30±5 days (range 27–37). CAR T cell therapy significantly improved survival to 55±11 days ($p < 0.05$ vs MOCK) but Alloctra-OTS further improved survival to 75±10 ($p < 0.001$) with 20-40% complete remission.

Conclusions During IP tumor progression, Allocetra-OTS as a standalone therapy or in combination with ICI, cisplatin or CAR-T therapy, significantly reduced tumor size and resulted in complete remission in up to100% treated mice.

Based on excellent safety profile in > 40 patients treated in prior clinical trials for sepsis and Covid-19, Phase I/II clinical trial of Allocetra-OTS plus chemotherapy has started and first patient already recruited. A second Phase I/II clinical trial of Allocetra-OTS plus anti-PD1, as a second- and third-line therapy in various cancers, is planned for Q4 2022.

1381 LACTATE MODULATION IN CANCER AND IMMUNE CELLS IS ASSOCIATED WITH ANTITUMOR EFFICACY OF DUAL MCT1/MCT4 INHIBITOR NGY-091

Nicole Bowman*, Sambad Sharma, Jennifer Duffy, Sanath Wijerathna, Nelly Kuklin, Jaime Escobedo, Vincent Sandanayaka. *Nirogy Therapeutics, Framingham, MA, USA*

Background Metabolic profiles of cells in the tumor microenvironment (TME) are known to be altered during the onset and progression of a tumor. Lactate is a key metabolic end-product of glycolysis that plays an important role in tumor progression and antitumor immunity. NGY-091, our first-in-class inhibitor of lactate transporters MCT1 and MCT4, has demonstrated a strong *in vitro* and *in vivo* antitumor efficacy.
Methods Cytotoxicity was evaluated in cancer cells by MTS assay. Lactate level was quantified to demonstrate on-target activity of NGY-091 in both cancer and immune cell types present in the TME by lactate glo assay (Promega). Human CD4+ T, CD8+ T and Treg cells were activated in the presence or absence of NGY-091, and expression of activation markers/cytokines and viability were assessed by flow cytometry. Human monocytes were differentiated to MDSCs followed by treatment with NGY-091. MDSC function and viability were examined by flow cytometry.
Results NGY-091 displayed a blockade of lactate import through MCT1 and lactate export through MCT4. The cytotoxic effect of NGY-091 was mediated by lactate import inhibition through MCT1 and the subsequent decrease in mitochondrial respiration. When studying the phenotypic effect of NGY-091 in immune cells under culture conditions mimicking the TME, we found that CD4+ and CD8+ T cells were strongly activated without affecting their proliferative ability. In contrast, viability and function of suppressive immune cells, Treg and MDSCs, were significantly reduced by NGY-091. In CD4+ and CD8+ T cells, NGY-091 treatment increased accumulation of intracellular lactate and subsequently decreased extracellular lactate that indicated blockade of glycolysis. We examined lactate import by MDSCs and Tregs, as these cells are known to utilize lactate as a source of energy, and found that NGY-091 strongly decreased lactate import in these cells.
Conclusions NGY-091 modulates lactate transport to induce direct cytotoxicity in cancer and activate robust antitumor immunity.

1382 DKK1 IS A BIOMARKER AND IMMUNOTHERAPEUTIC TARGET FOR BONE METASTASES IN MALIGNANT CANCERS

Tao Shi*, Kaijie Liang, Xiaoyu Zhou, Xueru Song, Hanbing Wang, Yipeng Zhang, Lixia Yu, Baorui Liu, Jia Wei. *The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China*

Background Malignant tumors with bone metastases seriously threaten the survival of cancer patients. However, the understanding of bone-tumor microenvironment remains poor, and currently, there is no effective therapeutic target for bone metastases.

Methods Serum Dickkopf-1 (DKK1) expression from healthy donors and gastric cancer (GC) patients were detected. Mouse GC and breast cancer bone metastasis model was established by intro-caudal artery (CA) GC cell injection, and *in vivo* efficacy of DKK1 blockade with murine DKK1 antibody (mDKN-01) was evaluated by micro-CT, MRI and IHC staining modalities. The bone-tumor immune microenvironment (bone-TIME) was analyzed via flow cytometry and immunofluorescence.

Results Serum DKK1 expressions were increased in GC patients (n=63) than in healthy donors (n=25), and stage IV GC patients (n=42) had higher serum DKK1 levels than stage II-III patients (n=21), with bone-metastatic patients (n=22) displaying the highest DKK1 level. Also, serum DKK1 levels are increased in patients with progressive disease (PD), while decreased in patients who had complete response (CR)/partial response (PR) to treatments. DKK1 blockade by mDKN-01 obviously reduced the tumor burden of bone metastases, and significantly inhibited osteoclast activation and alleviates bone destruction in different bone metastasis models. Moreover, the bone-TIME was improved after DKK1 blockade, with increased proportions of $CD8^+$ T cells, M1-like macrophages, and activated dendritic cells (DCs).

Conclusions Our study suggests DKK1 as a potential predictor to bone metastasis and progressive disease in cancer patients. Blockade of DKK1 brings an improved bone-TIME, therefore, DKK1 could be considered as a novel and promising immunotherapeutic target for bone metastases.

1383 REMODELING HOST IMMUNE RESPONSE IN HEAD AND NECK CANCER WITH PERSONALIZED THERAPEUTIC MRNA NANO-VACCINES

[1]Natalie Silver*, [2]Rekha Garg, [2]Hector Mendez-Gomez, [2]Paul Castillo, [2]Carlos Souza, [2]Lana Fagman, [2]John Ligon, [2]Sadeem Qdaisat, [2]Frances Weidert, [2]Jonathan Chardon-Robles, [1]Jin Dai, [3]Siming Ma, [3]Jessica Geiger, [3]Emrullah Yilmaz, [3]Shlomo Koyfman, [3]Jamie Ku, [1]Daniel McGrail, [3]Timothy Chan, [2]Duane Mitchell, [2]Elias Sayour. *[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, USA; [2]University of Florida, Gainesville, FL, USA; [3]Cleveland Clinic, Cleveland, OH, USA*

Background The translational pipeline for novel immunotherapeutics is often stymied due to the lack of relevant immune-competent pre-clinical animal models, which can facilitate the path to human clinical trials. Our group has developed a novel tumor-specific mRNA-vaccine and nano-liposome platform capable of delivering increased mRNA payload and inducing antigen-specific immunity.[1,2] In order to assist clinical translation, we investigated the feasibility, anti-tumor activity, and immunogenicity of therapeutic personalized RNA-nanovaccines in head and neck cancer pre-clinical murine models and client-owned felines with spontaneously occurring oral cancer.

Methods 1) C57B/6 mice were injected with syngeneic mouse oral cancer cell lines MOC1 or MOC2 orthotopically (tongue) or subcutaneously (flank). Mice were treated with tumor-derived mRNA nano-vaccines intravenously weekly, x3 weeks. Tumor volumes and survival was recorded. Immune cell infiltration of tumors and spleens were analyzed using flow cytometry. 2) A client-owned feline clinical trial was initiated (UF College of Veterinary Medicine, protocol #IACUC202200000077) to treat pet cats with spontaneously occurring oral squamous cell carcinoma. Tumor biopsies were obtained from enrolled felines (N=4), and tumor-specific mRNA-nano-vaccines were generated from the surgical specimen. The felines were administered three cycles of biweekly vaccines administered intravenously. The cats were monitored for adverse events and followed for clinical outcomes. Flow cytometry was performed to evaluate immune responses.

Results 1) Mice treated with tumor-derived mRNA-nanovaccines had significantly decreased tumor volumes when compared with controls in both MOC1 and the more aggressive MOC2 cell lines ($p<0.001$). Orthotopic models for MOC1 tumors were more responsive to RNA nano-vaccine administration than subcutaneous (flank) models. Treatment response was characterized by intra-tumoral and systemic activated CD4+ ($p=0.027$) and CD8+ (0.041) T-cell infiltration as well as decreased intra-tumoral immunosuppressive myeloid cell infiltration compared to controls. 2) Feline subjects (N=4) experienced no toxicities or adverse events. Profound CD8+ and CD4+ T cell activation was noted in blood following vaccine administration (4h). There was significant survival benefit with 0/6 untreated felines surviving, while 3/4 of the treated pets are living with either stable or undetectable disease.

Conclusions Personalized RNA-nanovaccines are effective and safe in preclinical murine and feline models of oral cancer demonstrating safety in a large animal study and immune activity. This agent is currently in clinical trials for human brain cancer (NCT04573140). Data from studies in both large and small preclinical models will inform our human clinical trial design for head and neck cancer patients with recurrent/metastatic disease.

1384 NOVEL, IMMUNE AGONISTIC CEACAM1/5 ANTIBODY (YB-200) DEMONSTRATES ANTI-TUMOR EFFICACY AND SIGNIFICANTLY INCREASES B-CELL RESPONSE IN SYNGENEIC LIVER HEPA1-6 TUMOR MICROENVIRONMENT

[2]Michel Janicot, [1]Katrin Rupalla*, [3]Alexej Schmidt, [4]Iris Helfrich, [5]Bernhard B Singer. *[1]Ymmunobio AG, Riehen, Switzerland; [2]JMI ONConsulting, Ukkel, Belgium; [3]University of Umea, Umea, Sweden; [4]Ludwig-Maximillians University, Munich, Germany; [5]University Hospital Essen, Essen, Germany*

Background Carcinoembryonic antigen-related cell adhesion molecule 1 (CEACAM1) and 5 (CEACAM5, CEA) are members of the carcinoembryonic antigen (CEA) family. CEACAM1 is expressed on a variety of immune cells and acts as a cell–cell communication molecule. The signal transduction process is associated with immune cell activation, apoptosis, proliferation and differentiation. In the pathophysiological stage, CEACAM1 and 5 are dysregulated in various malignancies including, for instance, breast, lung, and gastrointestinal cancer. This seems associated with poor prognosis linked to a novel checkpoint blockade mechanism mediated by homophilic CEACAM1□1 and heterophilic CEACAM1□5 interaction between immune and tumor cells, respectively. YB-200 is a novel IgG1 antibody targeting CEACAM 1/5, which has shown to preserve the immune agonistic function of CEACAM1 on leukocytes in addition to potentially inhibiting both the homophilic and heterophilic checkpoint blockade of CEACAM1 and 5 on tumor cells. The present study was designed to test the *in vivo* anti-tumor activity of YB-200 and its effect on immune cells.

Methods Anti-tumor activity of YB-200 was assessed using the validated ReactionBiology's SubQperior® experimental syngeneic liver Hepa-1-6 tumor model. The tumor cells were injected into the mammary fat pad of C57BL/6 mice. On Day 5 after tumor cell injection, animals were randomized (median tumor size ~50 mm^3) in two groups and treatment started. Mice were treated i.p. BIWx3 with either isotype control or YB-200 at 10 mg/kg/administration. Animals were euthanized on Day 20, and tumors harvested for flow cytometry analysis. Flow cytometry for immune-cell profiling was performed using the ReactionBiology All-in-one® staining panel.

Results Treatment with YB-200 induced statistically significant tumor growth inhibition by ~80% compared to isotype control, at well-tolerated dose. Flow cytometry analysis revealed that YB-200 led to a 10-fold increase in B-cells in the tumor micro-environment compared to the isotype control. In addition, a statistically significant increase in CD3+ and CD4+ T-cells was observed while granulocytes decreased.

Conclusions This study demonstrates that treatment with YB-200 induced statistically significant tumor growth inhibition compared to isotype control in a validated hepatocellular carcinoma model. Consistent with the role of CEACAM1 as cell-cell communication molecule the anti-tumor activity of YB-200 was correlated with a strong modulation of the immune cell compartment in the tumor micro environment.

Ethics Approval This animal study has been approved by the Ethics Committee for Animal Experimentation and is registered by the regional board Freiburg, Germany. Mice were handled according to the German animal welfare law and the GV-SOLAS guidelines.

1385 DIVERGENT THERAPEUTIC OUTCOMES OF STING AGONIST ADU-S100 IN INTRATUMORAL AND INTRAVESICAL TREATMENT REGIMENS IN SYNGENEIC MURINE MB49 AND IN THE N-METHYL-N-NITROSOUREA (MNU) RAT MODEL OF UROTHELIAL CARCINOMA

[1]Kara Lombardo, [1]Monali Praharaj, [1]Andres Matoso, [1]William Bishai, [2]Trinity Bivalacqua, [2]Alok Singh*. *[1]Johns Hopkins Medicine, Baltimore, MD, USA; [2]University of Pennsylvania, Philadelphia, PA, USA*

Background STING agonist ADU-S100 as an intratumoral (IT) therapeutic regimen shows excellent CD8+T cells-mediated antitumor immunity. Rapid absorption from IT sites, short terminal half-life and treatment related adverse outcomes caused withdrawal of ADU-S100 from clinical trials. We developed BCG-STING, a preclinical candidate for non-muscle invasive bladder cancer (NMIBC) that overexpresses a STING agonist (c-di-AMP) and confers superior antitumor immunity over BCG-WT by increasing tumor infiltrating CD4+ and CD8+ T cells and inflammatory macrophages.[1] Due to similarities in the mechanism of action, comparative antitumor efficacies of BCG-STING and ADU-S100 were examined in an IT and intravesical (IV) dosing regimen.

Methods Syngeneic MB49 flank tumors in C57BL/6 female mice were given IT treatment of BCG-WT, BCG-STING (5 x 10^6CFU) or ADU-S100 (100, 50 or 25 mg). End-point measurements included tumor volume and flow-cytometry based tumor immune infiltrate analyses (at 100 mg). MNU carcinogen rat model of NMIBC and the standard IV administration regimen was used for BCG-WT or BCG-STING (5 x 10^6 CFU, 6x weekly) or ADU-S100 (25 mg, 6x weekly). Histopathological analyses of MNU rat bladders were performed for tumor involvement index (TII) and pathological tumor staging.

Results IT administration of ADU-S100 in MB49 tumor showed greatest tumor regression over BCG-WT or BCG-STING even at lowest dose (25 mg). ADU-S100 caused strongest infiltration of TNF-a+MHCII+F4/80+CD11b+ macrophages and IFN-g+CD8+ T cells as compared to BCG-STING or BCG-WT. We did observe a significant increase in immunosuppressive IL-10+ and ARG-1+ $Ly6C^{(hi)}Ly6G^{(-)}$ monocytic myeloid-derived suppressor cells (M-MDSCs) in MB49 tumors treated with ADU-S100 and BCG-WT, but not BCG-STING. In contrast to MB49 model, lV induction course of BCG-STING in MNU rat model showed the greatest antitumor effects with only 5% residual TII compared to 30% in ADU-S100 or 42% in BCG-WT. Tumor staging revealed residual T1 (50%), CIS (25%) and Ta (25%) tumors in ADU-S100 group, BCG-WT treated group showed a lower degree of invasion to the lamina propria with CIS (50%), T1 (25%) and Ta (25%) residual tumors. BCG-STING IV therapy resulted in 60% of rat bladders showing complete tumor regression while 40% had minimal residual non-invasive tumors.

Conclusions Divergent therapeutic outcomes of IT vs IV treatment regimens of ADU-S100 over BCG-STING or BCG-WT in different urothelial carcinoma models indicate the critical role of tumor microenvironment and dosing regimens on relative efficacy. Induction of immunosuppressive M-MDSCs by ADU-S100 or BCG-WT suggests unique advantages of BCG-STING. The therapeutic targeting of M-MDSCs as combination may improve clinical efficacies of BCGs.

1386 NOVEL GUT-RESTRICTED SMALL MOLECULE INHIBITOR OF PD-L1 FOR TARGETING GI CANCERS

Dhanalakshmi Sivanandhan*, Sridharan Rajagopal, Chandru Gajendran, Naveen Sadhu M, Mohammed Zainuddin, Ramachandraiah Gosu, Luca Rastelli. *Jubilant Therapeutics Inc, Bedminister, NJ, USA*

Background The PD-1/PD-L1 molecular pathway is one of the primary mechanisms of immune evasion deployed by cancer cells and several anti-PD-L1 monoclonal antibodies (mAbs) have been approved for the treatment of multiple cancers, including cancers of the GI tract and liver. In such cancers, one of the issues observed is broad-spectrum autoimmune toxicities, including pneumonitis, and others. primarily owing to their long systemic half-life. Therefore, small molecule inhibitors of PD-L1 with gut restricted exposure should potentially be able overcome these toxicities. JBI-1527 is a small molecule PD-L1 inhibitor with similar binding and mechanism of action as anti-PD-L1 antibodies that shows much higher exposure in gastrointestinal tract and liver as compared to plasma. It shows comparable efficacy as approved mAbs in preclinical studies.

Methods Structure based drug design was used to design PD-L1 inhibitors; potency of these inhibitors was assessed in an in-vitro TR-FRET assay. Reporter assays and ex-vivo co-culture assays were used to assess T-cell proliferation and function. Pharmacokinetics studies were performed in multiple pre-clinical species to assess tissue distribution. In vivo efficacy was assessed in partially humanized mice efficacy models.

Results JBI-1527 showed strong in vitro IC_{50} of 2.9 nM in TR-FRET assay that measures interaction between PD-1 and PD-L1 and led to stabilization of PD-L1 protein as measured by thermal shift assay. This molecule also augmented T-cell co-inhibitory signalling as observed by Jurkat cell/SHP-1 assay. Competition study between anti-PD-L1 blocking antibody suggested that JBI-1527 finger-printing on PD-L1 is similar to mAbs. X-ray crystal structure studies clearly demonstrated that JBI-1527 caused dimerization of PD-L1. More importantly, JBI-1527 showed favourable gastrointestine localised pharmacokinetic profile with high exposure in colon, jejunum, duodenum, ileum (11 to >280 fold vs. plasma) as compared to plasma in preclinical species when dosed orally. JBI-1527 showed comparable efficacy to the anti-PD-L1 antibody Atezolizumab in hPD-L1/MC38 syngeneic and orthotopic models by oral administration and is well tolerated at efficacious doses.

Conclusions Gastrointestine localised pharmacokinetic profile of JBI-1527 provides an attractive option to be used in the treatment of colon cancer, HCC and other GI-related cancers with minimal systemic toxicity as compared to mAbs.

1387 INHIBITION OF THE CD47-SIRP□ AXIS FOR CANCER THERAPY A META-ANALYSIS OF EMERGING CLINICAL DATA

Ji Son*, Rodney Cheng-En Hsieh, Heather Lin, Kate Krause, Ying Yuan, Amadeo Biter, James Welsh, Michael Curran, David Hong. *MD Anderson Cancer Center, Houston, TX, USA*

Background CD47 interaction with SIRP□ acts as a "do not eat me" signal, which is exploited by cancer cells to downregulate immune surveillance. Given mounting evidence regarding the pivotal role of this axis in bridging the innate and adaptive immunity, there has been intense interest to develop a mechanism of blockade for therapeutic purposes. Preliminary data from clinical trials are now being reported, and we aimed to summarize and analyze these findings.

Methods We performed a comprehensive systematic review of relevant databases and conference abstracts. Eligible studies included clinical trials using CD47 and/or SIRP□ inhibitors in cancer treatment reporting oncologic outcome or toxicity data. Nonlinear mixed models were applied for comparison of response, with study as a random effect.

Results We retrieved 317 articles, 24 of which were eligible. These included a total of 771 response-evaluable patients with hematologic (47.1%) and solid tumors (52.9%). Of these, 6.4% experienced complete response, 10.4% partial response, and 26.1% stable disease for a 16.7% objective response rate (ORR), 42.8% disease control rate (DCR), and 4.8-month median duration of response (table 1). ORR was significantly higher for hematologic cancers (25.3%) than solid cancers (9.1%, p=0.042). Seven CD47 inhibitors and six SIRP□ inhibitors were given alone or combined with checkpoint inhibitors, targeted therapy, and/or chemotherapy. In solid cancers, SIRP□ inhibitors had a higher ORR (16.2%) than CD47 inhibitors (2.8%, p=0.079). This was particularly true for combination therapies using SIRP□ inhibitors (ORR 28.3% vs 3.0% in CD47 inhibitors, p=0.010). Response was seen in head and neck, colorectal, endometrial, ovarian, hepatocellular, non-small cell lung, and HER2+ gastroesophageal cancers. Dose-limiting toxicity (DLT) was seen in 3.3% of patients (5.4% CD47 inhibitors, 1.4% SIRP□ inhibitors; p=0.01). The frequency of treatment-related adverse events(TRAEs) ≥ grade 3 was 18.0% and was similar between the two groups (p=0.082) and mostly laboratory abnormalities. For CD47 inhibitors, the most common toxicities included grade 1-2 fatigue (27.2%), headache (21.0%), anemia (20.5%), and infusion-related reaction (IRR, 17.6%). For SIRP□ inhibitors, these included grade 1-2 IRR (23.1%), and fatigue (15.8%). CD47 inhibitors were significantly more likely than SIRP□ inhibitors to cause grade 1-2 fever, chills, nausea/vomiting, headache, and anemia.

Conclusions CD47-SIRP□ inhibition shows promise in cancer therapy. SIRP□ inhibitor combination therapies have higher response rates in solid tumors than CD47 inhibitor combination therapies. Hematologic changes were the main TRAEs, and SIRP□ inhibitors seemed to have a better grade 1-2 toxicity profile. Overall, treatment was well-tolerated with minimal DLTs.

Abstract 1387 Table 1 Patient-level data on the efficacy of CD47-SIRP□ inhibitors

	Total	CD47 inhibitor	SIRPα inhibitor	p value
Total (n)	771	341	430	
ORR (%)	16.7	12.6	20.0	0.11
DCR (%)	42.8	32.6	50.9	0.19

1388 UTILITY OF HUMANIZED ANIMAL MODELS FOR IN VIVO EVALUATION OF NK TICA™ NOVEL BICYCLE® TUMOR TARGETED IMMUNE CELL AGONISTS® BICYCLE TICA™ DESIGNED TO ENGAGE NK CELLS

Lukas Stanczuk*, Johanna Lahdenranta, Fay Dufort, Christopher Leitheiser, Punit Upadhyaya, Kevin McDonnell, Philip Brandish, Nicholas Keen. *Bicycle Therapeutics, London, UK*

Background The use of humanized animal models in preclinical evaluation of immunotherapeutics is often dictated by lack of homology between mouse and human target or divergence in the biology of studied immune cell subtypes. A target expressed on NK cells, NKp46 is a key activating receptor contributing to cytolytic function of NK cells. Bicycle® peptides are small (~1.5 kDa), chemically synthetic, structurally constrained bicyclic peptides discovered using phage display. NKp46-binding Bicycles conjugated to a tumor antigen-binding Bicycle® directed human NK cells to kill the tumor cells expressing the target antigen, and we term these molecules NK tumor-targeted immune cell agonists (NK-TICA™). Due to low homology of NKp46 ectodomain between mouse and human (~63% by NCBI BLAST), we evaluated different approaches to animal humanization to establish the most suitable model for in vivo evaluation of NK-TICA™. The main selection criteria included the number of circulating NKp46+ human NK cells as well as expression of activating and inhibitory receptors.

Methods Distinct approaches to animal humanization were employed: 1) reconstitution of human immune system (HIS) with CD34+ hematopoietic stem cells (HSCs) in NCG mice with hIL-15 hydrodynamic injection (HDI); 2) reconstitution of HIS with CD34+ HSCs in NCG.hIL-15 transgenic mice; 3) infusion of human PBMC-derived NK cells in NCG.hIL-15 transgenic mice. Characterization of NK populations in blood was conducted by multiplex flow cytometry.

Results Immunophenotyping analysis revealed striking differences in numbers of circulating NKp46+ NK cells between different humanized models. The lowest number was observed in mice engrafted with HSCs with transient expression of hIL-15 and the highest in mice infused with PBMC-derived NK cells in a transgenic model constitutively expressing hIL-15. We also observed expansion of NK cells over time in mice with transgenic expression of hIL-15 but not in mice treated with single hIL-15 HDI. Despite these differences, the proportion of NKp46+ NK cells expressing activation receptor NKG2D or activation marker CD69 was similar between all three study designs. In contrast, expression of NKp30 and NKG2A was different across tested models.

Conclusions Transgenic mice with constitutive expression of hIL-15 showed the highest numbers of NKp46+ NK cells in blood and a better expression profile of NK activating and inhibitory receptors making it a more suitable model for in vivo evaluation of NK-TICAs™.

Ethics Approval These studies were approved by the Institutional Animal Care and Use Committee (IACUC). The care and use of animals was conducted in accordance with regulations of the Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC).

1389 GIGA-564 A THIRD GENERATION ANTI CTLA 4 WITH MINIMAL ABILITY TO BLOCK CTLA 4 BINDING TO B7 LIGANDS HAS ENHANCED EFFICACY BUT REDUCED TOXICITY COMPARED TO IPILIMUMAB IN PRECLINICAL MODELS

[1]Erica Stone*, [1]Kyle Carter, [1]Ellen Wagner, [1]Michael Asensio, [1]Emily Benzie, [1]Yao Chiang, [1]Garry Coles, [1]Chelsea Edgar, [1]Bishal Gautam, [1]Ashley Gras, [1]Jackson Leong, [1]Renee Leong, [1]Vishal Manickam, [1]Rena Mizrahi, [1]Ariel Niedecken, [1]Jasmeen Saini, [1]Savreet Sandhu, [1]Jan Fredrick Simons, [1]Kacy Stadtmiller, [1]Brendan Tinsley, [2]LaRee Tracy, [1]Nicholas Wayham, [1]Yoong Wearn Lim, [1]David Johnson, [1]Adam Adler. *[1]GigaGen, San Diego, CA, USA; [2]Phastar, San Diego, CA, USA*

Background Anti-CTLA-4 antibodies such as ipilimumab were among the first immuno-oncology agents to show significantly improved outcomes for patients. However, existing anti-CTLA-4 therapies fail to induce a response in a majority of patients and can induce severe, immune-related adverse events. It has been assumed that checkpoint inhibition, i.e., blocking the interaction between CTLA-4 and its ligands, is the primary mechanism of action for current anti-CTLA-4 therapies.[1] Here we present evidence that anti-CTLA-4 therapies with minimal blocking activity can be efficacious in pre-clinical models.

Methods Mice expressing human CTLA-4 were used to investigate the mechanism of action of anti-CTLA-4 therapies including ipilimumab and GIGA-564. These and other humanized mice were also used to investigate the efficacy and toxicity of GIGA-564.

Results GIGA-564, a third generation anti-CTLA-4 with limitied ability to block CTLA-4 binding to its B7 ligands, has increased ability to induce in vitro FcR signaling and in vivo depletion of intratumoral Tregs and induces less proliferation of remaining Tregs. In agreement with this, GIGA-564 has superior anti-tumor activity compared to ipilimumab in a murine model. Further experiments showed that the enhanced FcR activity of GIGA-564 likely contributes to its enhanced anti-tumor activity. Importantly, we also showed that GIGA-564 was associated with lower toxicity in murine models.

Conclusions Our work shows that in pre-clinical models GIGA-564 has enhanced efficacy but reduced toxicity compared to ipilimumab.

1390 RNA NANOPARTICLE VACCINES OVERCOME THE IMMUNOSUPPRESSIVE TUMOR MICROENVIRONMENT OF METASTATIC OSTEOSARCOMA

[1]John Ligon*, [1]Brian Stover, [1]Hector Mendez-Gomez, [1]Adam Grippin, [1]Frances Weidert, [1]Lana Fagman, [1]Jonathan Chardon-Robles, [1]Paul Castillo, [2]Natalie Silver, [1]Joanne Lagmay, [3]Rowan Milner, [1]Duane Mitchell, [1]Elias Sayour. *[1]University of Florida, Gainesville, FL, USA; [2]Cleveland Clinic, Cleveland, USA; [3]UF College of Veterinary Medicine, Gainesville, FL, USA*

Background We previously developed a complex of tumor-derived mRNA (whole tumor transcriptome) with a liposomal nanoparticle to allow systemic delivery of tumor-specific antigens to antigen presenting cells for induction of antigen specific T cell immunity.[1-3] We tested this approach to circumvent the lack of specific targets, overcome antigenic heterogeneity, and reprogram the immunosuppressive tumor microenvironment (TME)[4] present in osteosarcoma, where immunotherapy has not yet been effective.

Methods Total-tumor mRNA was amplified from tumor cell lines or tumor biopsy tissue before complexation in lipid nanocarriers/cationic lipids, generating an RNA-nanoparticle (RNA-NP) for systemic administration. We also developed non-specific RNA-NPs to measure the anti-tumor effect of an "off-the-shelf" immunomodulator. Preclinical murine models were generated using K7M2, KHOS or 143B osteosarcoma cells in either C57Bl/6, BALB/c or BALB/c SCID mice inoculated by tail vein injection to mimic minimal residual metastatic disease from pulmonary osteosarcoma. We launched a comparative oncology clinical trial for client-owned canine patients (pet-dogs) with osteosarcoma through collaboration with the UF College of Veterinary Medicine (UF IACUC#202111376, PI: Milner).

Results In mice inoculated with pulmonary osteosarcoma, total-tumor RNA-NPs elicit significant anti-tumor efficacy in the K7M2 model with long term survivor benefits (7/8 treated mice). These total-tumor RNA-NPs reprogram the TME with significantly less tumor associated macrophages and myeloid-derived suppressor cells ($p<0.01$). RNA-NPs localize to the perivascular region of the TME, transfect CD45+ myeloid cells, and induce upregulation of genes such as BATF3 known to be related to myeloid reprogramming into activated dendritic cells. Furthermore, monotherapy with non-specific pp65 RNA-NPs generated significant anti-tumor effect in SCID mice ($p<0.05$). Long-term survivor outcomes from tumor loaded mRNA-NPs correlates with an increase in intratumoral central memory T cells (not observed in animals vaccinated with GFP RNA-NPs). In our first three canine subjects with osteosarcoma, total-tumor RNA-NPs were safe and immunologically active with changes in peripheral blood markers of dendritic cell and T cell activation within 6 hours of vaccine administration.

Conclusions RNA-NPs redirect immunosuppressive myeloid cells which are a hallmark of the osteosarcoma TME[4], resulting in an immune activated state and leading to increased intratumoral central memory T cells. These vaccines bypass MHC restriction and can be made readily available for all patients/canines providing a renewable antigen resource that can be used to continuously vaccinate patients. This agent, which is FDA-IND approved (BB-19304, Sayour) and in human clinical trials for patients with brain tumors (NCT04573140), may be a promising potential novel therapy for patients with recurrent pulmonary metastatic osteosarcoma.

1391 ZM008 A FIRST IN CLASS MONOCLONAL ANTI LLT1 ANTIBODY DEMONSTRATED CLINICAL POTENTIAL IN MULTIPLE SOLID CANCERS

Maloy Ghosh*, Anurag Tiwari, Ashvini Dubey, Sanghamitra Bhattacharjee, Yogendra Manjunath, Shalini Kashipathi, Subith Krishna. *Zumutor Biologics, Bangalore, India*

Background Lectin-like transcript 1 (LLT1/CLEC2D) interaction with CD161 on NK cells facilitates tumor immune escape.[1, 2, 3] Others and we have shown that anti LLT1 antibody disrupts LLT1-CD161 interaction to release the break on NK cells, activate NK cells, improve immune cell infiltration and enhance tumor cell cytotoxicity.[4, 5, 6] Present work describes a novel anti LLT1 antibody ZM008, it's mode of action, GLP safety and toxicity studies, in vivo and ex vivo anti-tumor effects.

Methods Cytokine release and immune cell activation were monitored using human PBMC. PC3 xenografted HuNOG-EXL mice were treated with ZM008 to monitor anti-tumor effects and tumor IHC was performed to study the TME. 4 weeks repeat dose GLP study in Cynomolgus monkey was conducted to determine safety and toxicity of ZM008 at 10-125mg/kg dosing. 3D ex vivo culture of patient biopsies from NSCLC and muscle invasive bladder cancer (MIBC) were used to determine efficacy of ZM008.

Results ZM008 induced CD69 activation and perforin/granzyme B expression on cytotoxic CD8+ T cells and CD16+ NK cells and promoted release of IFNγ and TNFα from immune cells. In HuNOG-EXL-PC3 xenograft mice, ZM008 treatment resulted in ~48% tumor growth reduction and significant tumor infiltration of CD8+ T cells, CD56+ NK cells and NKG2D+ cells was observed. Additionally, low Ki67 and high caspase 3 expression after ZM008 treatment indicates antitumor effects (figure 1). ZM008 exposure was maintained over the treatment period with no mortality or toxicity and was well tolerated in 4 weeks repeat intravenous dosing in Cynomolgus monkeys. No ZM008 related gross pathological findings, organ weight changes or histologic lesions were observed. 3D tumoroid culture from biopsies of NSCLC and MIBC patients were treated with ZM008 monotherapy and Pembrolizumab combination therapy revealed >50% reduction of tumoroids. High-content imaging of the tumoroid clearly shows disintegration of TME and infiltration of immune cells (figure 2).

Conclusions This is the first report describing anti LLT1 antibody efficacy in patient biopsy samples. Tumoroids derived from lung cancer and bladder cancer biopsies revealed significant growth reduction and immune cell infiltration with ZM008 treatment. ZM008 disrupts LLT1-CD161 pathway and transforms the TME to immune responsive "Hot" tumor by activation of immune cells, cytokine secretion, granzyme B/perforin release, and tumor cytotoxicity. GLP safety and toxicity studies in Cynomolgus monkey support future clinical application of ZM008. Overall, the data suggests ZM008 drug product is poised to initiate phase 1 trial (monotherapy and combination with Pembrolizumab) in multiple solid cancers.

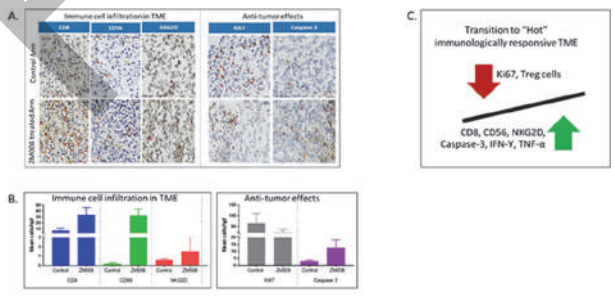

Figure 1

Abstract 1391 Figure 1
Transformation of tumor microenvironment (TME) in HuNOG-EXL mice bearing PC3 tumors upon ZM008 treatment
PC3 xenografted HuNOG-EXL mice were treated with 10 mg/kg ZM008 and vehicle control intraperitonealy. In vivo efficacy of ZM008 revealed nearly 48% tumor growth reduction in animals treated with ZM008. Animals were humanely sacrificed intermittently to observe effects of ZM008 on TME. Immunohistochemistry (IHC) of cryopreserved tumor sections were carried out to determine infiltration of human CD8+, CD56+ and NKG2D+ immune cells. In addition, the tumor sections were stained with antibodies against Ki67 and Caspase 3. Critical cytokines and chemokines were also evaluated from peripheral blood of these animals.
A. Tumor IHC images from ZM008 treated animals suggest significant infiltration of CD8+ T cells, CD56+ NK cells and NKG2D+ immune cells (red arrows) compared with control arm. In addition, low Ki67 and high caspase 3 staining (red arrows) were observed in these tumors indicating anti-tumor effects of ZM008 treatment.
B. Bar diagram showing increased infiltration of CD8+ T cells and CD56 + NK cells and NKG2D+ immune cells whereas significant reduction of Ki67 and caspase 3 on the tumor cells.
C. Cartoon showing overall changes observed in the TME of animals treated with ZM008. The representation indicates transition to "Hot" immunologically responsive TME as evidenced by increased infiltration of CD8+, CD56+, NKG2D+ immune cells and decreased Treg cells; low

Ki67 and high Caspase-3 levels in tumor cells; release of proinflammatory cytokines like IFNγ and TNFα after ZM008 treatment.

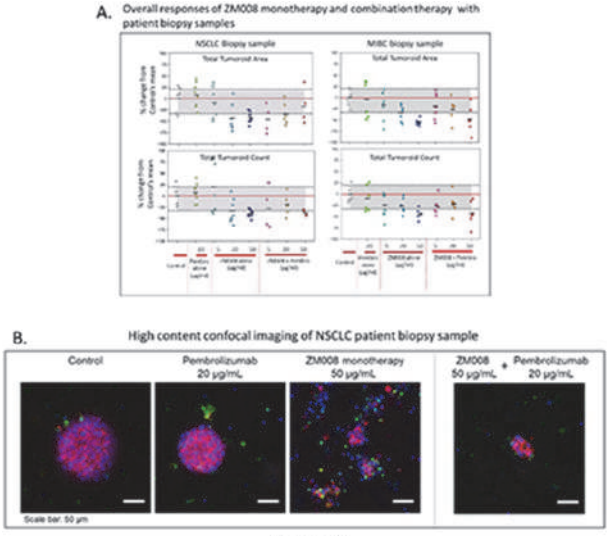

Figure 2

Abstract 1391 Figure 2

Efficacy of ZM008 was determined as monotherapy or in combination with Pembrolizumab using Ex Vivo Clinical Trial's (EVCT) Platform. Freshly isolated patient biopsy samples from Non-Small Cell Lung Cancer (NSCLC) and muscle invasive bladder cancer (MIBC) indications were co-cultured with labeled autologous PBMCs. 3D cell culture system was used to culture the tumoroid in presence or absence of ZM008 or Pembrolizumab. Pembrolizumab was used at 20 µg/mL and ZM008 was used at 5, 20 and 50 µg/mL concentrations. Separate wells were used to test the effects of ZM008 and Pembrolizumab combinations. Quantitative image analysis of tumoroid area and tumoroid count were performed to evaluate the effects of ZM008 treatment.

A. Overall responses of ZM008 monotherapy and combination therapy with Pembrolizumab in terms of tumoroid area and tumoroid count in NSCLC and MIBC biopsy samples. The data is represented as percentage change from mean value of the control set (red line). The upper dotted line represents 20% increase of tumoroid area and count, responses above this line indicates tumor progression. The lower dotted line represents 33% decrease in tumoroid area and count, below this line could be considered as partial response to ZM008. The grey shaded area represents no significant change in tumoroid area and count, could be considered similar to stable response. Analysis of the data suggests ZM008 monotherapy and combination therapy with Pembrolizumab revealed significant reduction of tumoroid area and count. This indicates anti-tumor effects of ZM008 on patient biopsies in solid cancers.

B. Few samples were chosen for high content image analysis using confocal microscopy. Tumor cells in the tumoroid structures were indicated by actin staining (red), autologous PBMCs were stained with Cell tracker (green) and nuclei were stained with DAPI (blue). Images represent maximum projection of confocal stacks taken with 20X water immersion (WI) objective and images were processed using ImageJ. Representative image analysis showing significant reduction in tumoroid area upon treatment with ZM008 monotherapy at 50 µg/mL as well as in combination with Pembrolizumab. Reduction in size of tumoroid was monitored by disintegration of actin signal. Immune cell infiltration was represented by presence of green cells within the tumoroid structures in samples treated with ZM008 monotherapy as well as ZM008 +Pembrolizumab combination therapy.

1392 AN ATYPICAL CENTRAL MEMORY LIKE PHENOTYPE CAN BE INDUCED IN HUMAN T CELLS BY INNATE TCRαβ ENGAGEMENT

[1]Khiyam Hussain*, [1]Pierre Vantourout, [1]Maria Poole, [1]Josephine Eum Eum, [1]Thomas Hayday, [1]Adam Laing, [2]Seb Battaglia, [3]Madan Katragadda, [3]Jessica Lowry, [3]Jonathan Hsu, [1]Adrian Hayday. *[1]King's College London, London,, UK; [2]Bridge Informatics, Salem, MA, USA; [3]Marengo Therapeutics, Cambridge, MA, USA*

Background The αβ T cell receptor (TCR) has immense diversity, primarily for peptide-MHC (pMHC) complexes that clonally interact with complementarity-determining region (CDR) 3 motifs assembled by quasi-random somatic gene rearrangement of TCRα and TCRβ gene segments. This adaptive biology is shown to an even greater extent by TCRγδ with its ligands being qualitatively more diverse than pMHC. However, TCRγδ can also function as an innate receptor whereby germline-encoded variable γ residues are sufficient to engage butyrophilin (BTN) or BTN-like (BTNL) that drive a variety of phenotypic outcomes distinct from clonal CDR3-mediated interactions. This broadened perspective on TCR biology has not hitherto been systematically extended to αβ T cells.

Methods A panel of human TCR variable β (TCRVβ) chain targeting antibodies was assembled, and their binding motifs determined. Using multi-colour flow cytometry and single-cell RNA sequencing, the impact of these antibodies on peripheral blood T cells was assessed by comparison with the impacts of anti-CD3ϵ reagents, including OKT3.

Results Antibodies engaging germline-encoded regions of human TCRVβ chains consistently activated primary human T cells towards an atypical central memory (TCM)-like phenotype distinct from those induced by anti-CD3ϵ stimulation. Although the cells show myriad surface markers associated with chronic stimulation, they are not exhausted but are highly proliferative with strong cytolytic/Tc1 effector profiles, including expression of T-bet and IRF4. Strikingly, this phenotype can be induced in cells previously driven toward effector memory (T_{EM}) and effector memory T cells re-expressing CD45RA (T_{EMRA}) states.

Conclusions In sum, the use of TCRαβ as an innate receptor offers new insight into T cell biology and an approach in which antibody mediated TCR agonism may be relevant to distinct clinical settings.

1393 BEYOND CCR8 KEY EPITOPES TARGETING DYNAMIC CCR8 CONFORMATIONAL STATES AND A DIVERSITY OF MONOCLONAL ANTIBODIES TO MODULATE THE TUMOR MICROENVIRONMENT FOR THE TREATMENT OF CANCERS

Claudine Vermot-Desroches, Iseulys Richert, Malaury Schappler, Alice Gentil Dit Maurin, Mégane Jeannelle, Solène Rose, Luc Baron, Quentin Ruet, Camille Dietsch, Pauline Urquia, Safia Ayachi, Orphée Blanchard, Christel Franchet, Stephan Schann, Xavier Leroy*. *Domain Therapeutics, Illkirch, France*

Background Chemokine (C-C motif) receptor 8 (CCR8) belongs to the G protein-coupled receptor (GPCR) family. Based on the transcriptional landscape of tumor infiltrating T regulatory cells, it has been found that CCR8 positive tumor infiltrating T regulatory cells (TITR) were highly immune suppressive and defined as a specific signature molecule. Generation of functional antibodies against integral membrane proteins such as the G-protein coupled receptor CCR8 is technically challenging for several reasons, including the coverage of epitope diversity related to transcriptional and post-transcriptional regulation CCR8 transmembrane protein and its dynamic conformational according to activation cellular state or immunosuppressive cell subsets.

Methods Domain Therapeutics has generated wide monoclonal antibodies (mAbs) libraries targeting a diversity of separate and non-overlapping CCR8 epitopes. Using different sources of native CCR8 positive cell subsets, distinct mAbs cellular reactivity profile has been also determined. Using different approaches (BRET, ELISA, FCM, …), mAb activities were characterized in binding and several functional assays, including the inhibition of different G-proteins and B-arrestin 2 recruitment. A deep molecular and pharmacological characterization of each mAb was also performed by taking account the kinetic exposure and the nature of targeted CCR8 ligand. Some experiments were also conducted mimicking the tumor microenvironment conditions.

Results A panel of antibodies targeting human CCR8 was successfully generated. A wide diversity related to targeted epitopes was obtained, combined with high affinity binding properties. The requirement to target, or not, selective post-translational modifications (PTM) was also documented to trigger the highest inhibition level of CCR8 signaling. In parallel, treatment of tumor-bearing mice with cell-depleting anti-CCR8 antibody indeed eradicated established tumors with induction of potent tumor-specific effector/memory T cells. Thus, specific depletion of clonally expanding tumor Tregs is clinically instrumental for evoking effective tumor immunity without autoimmune adverse effects.

Conclusions Due to the high and relatively specific expression of CCR8 on tumor infiltrating Tregs, CCR8 represents an attractive immunotherapeutic target. Up to date, targeting selective CCR8 epitopes mimicking dynamic conformational CCR8 stage according to CCR8 positive cell subset or activation cellular state will be a key issue and differentiate therapeutic approach for the TME modulation in the treatment of cancer. Moreover, the use of depleting anti-CCR8 mAb with enhanced cytotoxic activity (i.e., ADCC, CDC, ADCP) can also reduce the number of CCR8 immune suppressive cells in a tumor.

1394 PRECLINICAL CHARACTERIZATION OF BIODEGRADABLE INJECTABLE ANTIGEN PRESENTING NANOPARTICLES AIM INJ FOR IN VIVO TREATMENT OF SOLID TUMORS

Haiyun Liu*, Aniket Wadajkar, Sophia Zhang, Christian Wirick, Duong Nguyen, Daniel Dembrow, Sojung Kim, Mathias Oelke. *NeImmune Inc., Gaithersburg, MD, USA*

Background NexImmune's artificial immune modulation (AIM™) technology is designed to direct T cell function and drive a T cell-mediated response. AIM antigen-specific immunotherapies rely on a nanoparticle-based artificial antigen presenting cell (aAPC) platform. The off-the-shelf injectable nanoparticles (INJ) are developed using biodegradable PLGA-PEG or PLA-PEG core materials and designed to mimic the function of natural APCs. AIM INJ nanoparticles present (i) an antigen-specific recognition signal delivered by an MHC molecule loaded with an antigenic peptide (Signal 1), and (ii) a co-stimulatory signal (anti-CD28, Signal 2) to induce expansion of the T cells activated through Signal 1.

Methods AIM INJ nanoparticles were synthesized by nanoprecipitation method on the Ignite NanoAssemblr™ microfluidic system. Murine AIM INJ nanoparticles were formulated by conjugating murine protein Signal 1 and 2, and then loading with tumor-specific peptides. Physicochemical characterization, stability, and in vitro functional tests were performed to assess antigen-specific $CD8^+$ T cell proliferation, expansion, and cytokine production upon nanoparticle exposure. In vivo biodistribution and efficacy studies were performed in B16-F10 melanoma model by s.c. injection of AIM INJ nanoparticles. Biodistribution studies were conducted using ^{89}Zr radiolabeled nanoparticles. For the efficacy study, on day 7 after nanoparticle injection, tumor tissues were harvested and stimulated ex vivo to measure the expression of CD107a and cytokines IFN-γ, TNF-α, IL-2 by the tumor infiltrating lymphocytes (TILs).

Results PLGA-PEG based AIM INJ nanoparticles, with ~100nm diameter, PDI < 0.2, and close-to-neutral surface charge, have round morphology and were stable in liquid formulation over 6-months. The peptide-loaded murine AIM INJ nanoparticles activated $CD8^+$ T cells in antigen-specific manner by promoting cell proliferation, expansion, and poly-functionality. The biodistribution studies showed a significantly higher amount of AIM INJ nanoparticle accumulation in the tumor (24 hours) and draining lymph node (96 hours) compared to naked nanoparticles (no proteins/peptides). In an in vivo treatment study, we demonstrated that the peptide-loaded AIM INJ nanoparticles induced significant amounts of poly-functional $CD8^+$ TILs in a B16-F10 melanoma model. In addition, we will present data from ongoing studies using different sizes and formulations of AIM INJ nanoparticles.

Conclusions We demonstrated that biodegradable AIM INJ nanoparticles can activate and expand multiple antigen-specific $CD8^+$ T cells in vitro and in vivo to induce anti-tumor activity. These studies along with other in vivo pre-clinical characterization will be used to support multiple INDs and advance AIM INJ into Phase 1 studies for various solid tumors.

1395 CLN 619 A CLINICAL STAGE MICA B SPECIFIC IGG1 ANTIBODY WHICH RESTORES THE MICA B-NKG2D AXIS REQUIRES FC FUNCTION FOR POTENT ANTI-TUMOR ACTIVITY

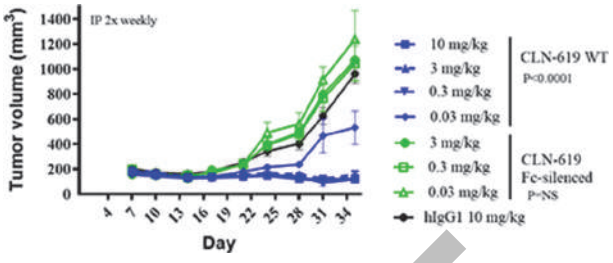
[1]Kerry Whalen*, [1]Mehta Naveen, [1]Kristan Meetze, [2]Neil Gibson, [1]Jennifer Michaelson, [1]Patrick Baeuerle. *[1]Cullinan Oncology, Inc., Cambridge, MA, USA; [2]COI Pharmaceuticals, Inc., San Diego, CA, USA*

Background MICA and MICB are stress-inducible, highly polymorphic, surface glycoproteins that are expressed on a wide variety of human tumors but restricted in normal tissues. Engagement of MICA/B by NKG2D on natural killer (NK) cells and certain T cell subsets stimulates immune cell activation and subsequent target cell lysis. In cancer patients, tumor cells can escape NKG2D-mediated lysis by shedding MICA/B from the cell surface via proteases in the tumor microenvironment. High concentrations of shed MICA have been observed in serum from patients across multiple tumor types, correlating with poor survival. CLN-619 is a humanized anti-MICA/MICB monoclonal IgG1 antibody being developed for the treatment of multiple cancer indications. It has broad reactivity across MICA/B alleles, prevents shedding of MICA/B from the tumor cell surface, enhances the interaction of MICA with NKG2D, and engages Fcg receptors on effector cells to collectively drive potent anti-tumor activity. We herein describe the significance of Fc functionality for the therapeutic activity of CLN-619.

Methods MICA/B levels were measured in supernatants by ELISA and on the cell surface by flow cytometry. The Promega ADCC Bioassay Complete Kit was used to evaluate ADCC. MICA binding to NKG2D was measured by flow cytometry. In vitro killing was assessed in a co-culture assay of donor PBMC and MICA-expressing tumor cells. In vivo studies were conducted in human xenograft tumor models.

Results CLN-619 inhibited the shedding of MICA/B shedding and enhanced the interaction of MICA with NKG2D. The latter was mediated by CLN-619 Fc effector function as well as by intrinsic enhancement of MICA-NKG2D binding by CLN-619. A functional Fc domain was also found necessary for CLN-619 induced immune-mediated cell killing of MICA/B expressing cells in vitro and for efficacy in mice bearing subcutaneous HCC1534 human xenograft tumors (figure 1). An Fc-silenced version of CLN-619 had no anti-tumor activity in HCC1534 at 3 mg/kg whereas CLN-619 showed significant tumor control even at 0.03 mg/kg.

Conclusions CLN-619 treatment resulted in robust anti-tumor activity in mice bearing MICA/B-expressing xenograft models. Activity of CLN-619 was dependent on a functional Fc domain. Simultaneous stimulation of the NKG2D-MICA/B axis and ADCC by CLN-619 may uniquely synergize in activating the lytic potential of NK cells. CLN-619 is currently in a Phase 1 clinical trial for the treatment of patients with advanced malignancies (ClinicalTrials.gov Identifier: NCT05117476).



Abstract 1395 Figure 1 Efficacy of CLN-619 depends on a functional Fc-domain
BALB/c SCID mice were inoculated subcutaneously with HCC1534 human lung cancer xenograft cells (N=10/group). Treatment was administered 2X weekly for four weeks intraperitoneal. Statistics were analyzed by one-way ANOVA adjusted for multiple comparisons.

1396 ANTIBODY BLOCKADE OF THE IMMUNOINHIBITORY RECEPTOR SIGLEC 10 POLARIZES TUMOR ASSOCIATED MYELOID CELLS AND PROMOTES ANTI-TUMOR IMMUNITY

[1]Julia Schanin*, [1]Thuy Luu, [1]Robert Sanchez, [1]Milene Peterson, [2]Lisa McEwan, [2]Evan Henneberry, [1]Katherine Chang, [1]Wouter Korver, [1]John Leung, [1]Bradford Youngblood.
[1]Allakos Inc, San Carlos, CA, USA; [2]LM Biostat Consulting Inc., British Columbia, Canada

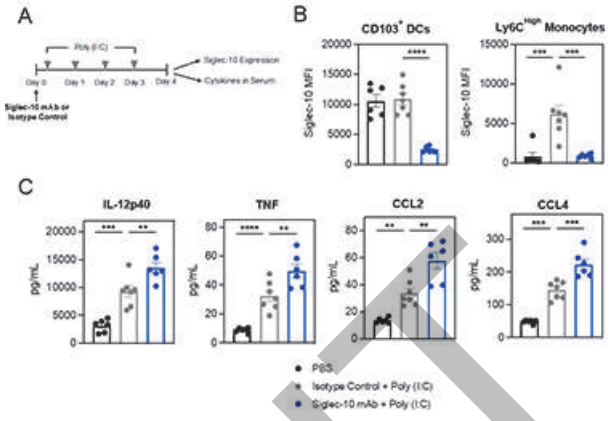
Background Myeloid cells are the most abundant immune cells within the tumor microenvironment (TME) where they play important roles regulating anti-tumor immunity. Targeting myeloid-specific inhibitory receptors to modulate the TME represents an attractive strategy to improve the therapeutic outcome of current cancer immune therapies. Siglec-10 is an inhibitory receptor expressed on tumor-associated macrophages (TAMs) and dendritic cells that regulates immune cell activation via immunoreceptor tyrosine-based inhibitory motifs. Recently, Siglec-10 was shown to induce immunosuppression and promote tumor immune escape through interaction with CD24. Similarly, CD52 and vascular adhesion protein-1 have been shown to drive immunosuppression via Siglec-10, indicating that Siglec-10 functions as an inhibitory receptor through multiple ligands. Here, we report that Siglec-10 expression is upregulated in human tumors and blockade of Siglec-10 with a monoclonal antibody (mAb) enhances proinflammatory responses and delays tumor growth in vivo by modulating myeloid cell function.

Methods Siglec-10 expression was evaluated in human tumors by flow cytometry and RNA-sequencing. Anti-human Siglec-10 mAbs were generated using hybridoma technology and recombinantly produced on mouse IgG1 backbones. Internalization and function of Siglec-10 mAbs were evaluated in vitro by flow cytometry and cytokine production using isolated human $CD16^+$ monocytes. To assess the in vivo activity of a Siglec-10 mAb, transgenic mice expressing Siglec-10 were generated and challenged with poly I:C. Anti-tumor activity of a Siglec-10 mAb was determined using the MC38 syngeneic mouse model.

Results RNA-sequencing data revealed high expression of Siglec-10 across multiple tumors compared to normal tissues, including glioblastoma, colorectal carcinoma, and kidney renal clear cell carcinoma. Specifically, Siglec-10 was found to be highly and selectively expressed on intratumor dendritic cells and macrophages. Siglec-10 mAb treatment blocked ligand binding, induced complete receptor internalization, and significantly enhanced TLR-mediated human monocyte activation in vitro. Similarly, in vivo administration of a Siglec-10 mAb induced receptor internalization and enhanced TLR-mediated inflammation as evidenced by increased levels of cytokines, such as TNF and IL-12p40 (figure 1). To assess the potential of a Siglec-10 mAb as an anti-cancer immunotherapy, we established a colon carcinoma model in Siglec-10 transgenic mice. Siglec-10 mAb blockade polarized myeloid cells towards an inflammatory phenotype, enhanced adaptive immune cell activation and promoted anti-tumor activity.

Conclusions Siglec-10 is highly expressed on tumor-associated myeloid cells and antibody blockade promotes anti-tumor immunity through activation of TAMs and dendritic cells. Our findings highlight Siglec-10 as a promising myeloid cell target for enhancing anti-tumor immunity in solid tumors.

Ethics Approval All legal and ethical requirements have been met with regards to the humane treatment of animals described in this study.



Abstract 1396 Figure 1 Anti-Siglec-10 treatment induces receptor internalization and enhances proinflammatory responses in a model of TLR-mediated lung inflammation in Siglec-10 transgenic mice. (A) Schematic of experimental TLR-mediated lung mouse model. (B) Siglec-10 expression levels on CD103+ DCs and Ly6Chigh MHC+ inflammatory monocytes in lung tissue from mice intranasally challenged with poly (I:C) and dosed with a Siglec-10 mAb (blue) or isotype control (gray) compared to PBS challenged mice (black). (C) Levels of cytokines and chemokines in serum of mice challenged intranasally with poly (I:C) or PBS control. Data are plotted as means +/- SEM for individual mice (n=6-7/group). ** p = <0.01; *** p = <0.001; **** p = <0.0001 as determined by one-way ANOVA with Tukey's multiple comparisons

1397 ATG 027 A FIRST IN CLASS B7 H3 PD L1 BISPECIFIC ANTIBODY SHOWS POTENT T CELL ACTIVATION CAPABILITY AND IN VIVO ANTI TUMOR EFFICACY

[1]Hui Yuwen, [1]Tengteng Li, [1]Yijing Ren, [2]Linjie Tian*, [3]Jay Mei, [4]Bo Shan, [3]Bing Hou. *[1]Shanghai Antengene Corporation Limited, Shanghai, China; [2]Antengene Biotech LLC, Doylestown, PA, USA; [3]Antengene Corporation Co., Ltd, Shaoxing, China; [4]Antengene Corporation Co., Ltd,, Shanghai, China*

Background Programmed death-ligand 1 (PD-L1) and programmed cell death protein 1(PD-1) blockade therapy has been approved for the treatment of many malignancies whereas the majority of patients with solid tumors do not respond well.[1] B7-H3, another newly identified immune checkpoint molecule, has limited expression in normal human tissues while highly expressed on cancer cells and tumor-infiltrating antigen-presenting cells (APCs), which is associated with T-cell exhaustion in cancer patients. In addition, B7-H3 is overexpressed by the tumor-associated vasculature and stromal fibroblasts, and contributes to the development of cancer through both immune-dependent and nonimmune routes.[2] However, clinical therapeutic antibodies targeting B7-H3, such as Enobituzumab, have not shown an immune checkpoint blockade effect. ATG-027, a novel B7-H3/PD-L1 bispecific antibody, was designed to exert the anti-tumor efficiency through reinforcing T cell activation by dual-blocking of B7-H3 and PD-L1, antibody-dependent cellular cytotoxicity (ADCC), complement dependent cytotoxicity (CDC), and antibody-dependent cellular phagocytosis (ADCP).

Methods ATG-027 was developed by introducing high-affinity PD-L1 scFv into a human IgG1 B7-H3 monoclonal antibody (mAb). The bispecific antibody employed wild type Fc domain which enables ADCC and ADCP effects. A series of in vitro studies were performed to evaluate the immune regulating function and anti-tumor efficacy of ATG-027. The in vivo efficacy of ATG-027 was evaluated in mice bearing syngeneic MC38 colorectal cancer cells overexpressing human B7-H3 (MC38-hB7-H3).

Results In the cell-based assay, ATG-027 binds with nanomolar affinity to both B7-H3 and PD-L1 expressing cells. ATG-027 demonstrated higher ADCC/CDC activity compared with anti-PD-L1 and anti-B7-H3 parental antibodies. ATG-027 also demonstrated greater ADCP potency than anti-PD-L1, anti-B7-H3, or the combination. Interestingly, in a Mixed Lymphocyte Reaction (MLR) experiment to assess the T cell activation, the B7-H3 parental antibody (30-C7) or the Fab region of 30-C7 (30-C7-Fab) induced robust IL-2 and IFNγ production, indicating T cell activating function, whereas Enobituzumab showed no effect in the experiment (figure 1). ATG-027 also demonstrated superior in vivo anti-tumor activity in mouse MC38-hB7-H3 models compared to parental antibodies. Biweekly dosing of 7.5mg/kg ATG-027 induced tumor shrinkage or complete tumor regression.

Conclusions By binding to a specific epitope of B7-H3, ATG-027 blocks the protein's inhibitory function, leading to strong T cell activation. ATG-027 can also inhibit the interaction between PD1/PD-L1 to rescue T cell activity suppression. ATG-027's dual T cell activation function and powerful ADCC, CDC, and ADCP properties contribute to its promising anti-tumor efficacy in preclinical models.

1398 PERSONALIZED IMMUNOTHERAPEUTIC PLATFORM WITH EVIDENCE OF CLINICAL ACTIVITY IN GLIOBLASTOMA PROTECTS MICE AGAINST OVARIAN LIVER AND BLADDER CANCER TUMOR CHALLENGES

[1]Amelia Zellander*, [1]Christopher Uhl, [1]Christopher Cultrara, [1]Kenneth Kirby, [1]Essam Elrazaq, [2]Charles Scott, [1]David Andrews, [1]Jenny Zilberberg, [1]Mark Exley. *[1]Imvax, Philadelphia, PA, USA; [2]CBS Squared, Philadelphia, PA, USA*

Background Imvax is developing a novel personalized immunotherapeutic platform combining irradiated, patient-derived tumor cells and Insulin-Like Growth Factor Type-1 Receptor antisense oligonucleotide (IMV-001) in biodiffusion chambers (BDC; 0.1-micron pores). The combination product IGV-001 was recently evaluated in a newly diagnosed glioblastoma (GBM) phase 1b clinical trial.[1] Median overall survival of highest exposure IGV-001-treated 'Stupp-eligible' patients[2] was 38.2 months compared with 16.2 months in recent standard-of-care-treated patients (P=0.044).[1] We have now found activity with the equivalent murine approach in multiple cancer models, highlighting the transformative potential of this immunotherapeutic platform beyond glioblastoma.

Methods We utilized the ID8-luciferase (-Luc) intraperitoneal ovarian cancer, the orthotopic Hepa1-6-Luc hepatocellular carcinoma model and orthotopic MBT-2 urothelial murine cancer models. BDCs containing saline or 1x106 IMV-001-treated tumor cells (hereon IOC-001, IHC-001, and IUC-001 respectively) were implanted in flanks of mice and explanted 48 h later, as per glioblastoma clinical protocol. Primary tumor challenge was conducted 28d after chamber implantation. Intra-mammary rechallenge in the Hepa1-6 model was conducted 102 days after orthotopic challenge alongside naive controls, since no primary controls were still alive. Mice were monitored for survival and tumor growth. Cytokine analysis and immunophenotyping were conducted.

Results 60% of IOC-001-treated mice survived to end of study at 58d post–tumor challenge, compared to only 19% of mice in the saline control group (MST=37d, P=0.004). Circulating IFN? was significantly higher in IOC-001-treated mice compared to controls on 1d post-tumor challenge (p<0.001) and trended higher in those receiving IHC-001 14d after tumor challenge. In the Hepa1-6 model, 50% of IHC-001-treated mice survived beyond 110d post-tumor (MST = 60.5d at end of study); Hepa1-6 intramammary rechallenge at 102d demonstrated durable systemic immunity in survivors. There were no survivors in the primary control group beyond 28d (MST = 18d; P=0.004). In the MBT-2 model, 42% of IUC-001-treated mice survived up to 90d post-tumor challenge (MST=33d at end of study); all control mice expired by 37d (MST=21d; P=0.0163). Low end of life bladder weights in surviving IUC-001-treated mice suggested minimal tumor burden. Further Immunological and Pathology data will be provided.

Conclusions These data support the durable antitumor activity of Imvax's immunotherapeutic platform in multiple cancers beyond glioblastoma. Results suggest that efficacy is associated with a systemic immunological response, resulting in generation of Th1 antitumor cytotoxic T cells. Future studies are seeking additional biomarkers of response using phenotypic evaluation of T cell activation/exhaustion markers and Th1/Th2 responses.

1399 ZL 1218 TARGETS THE MOST SUPPRESSIVE INTRATUMORAL TREG SUBPOPULATION TO AVOID PERIPHERAL TOXICITIES

[1]Jing Zhang*,[1]Linda Liu, [1]Grace Wang, [1]Joshua Zeng, [1]Tao Geng, [1]Chakrapani Tripathi, [2]Lei Wang. *[1]Zai Lab (US) LLC, Menlo Park, CA, USA; [2]Zai Lab (China) LLC, Shanghai, China*

Background Accumulating evidence demonstrates that the removal of Treg cells is able to evoke and enhance anti-tumor immune response. However, systemic depletion of Treg cells may concurrently elicit deleterious autoimmunity. CCR8, a chemokine receptor expressed by tumor infiltrating Treg cells, is associated with poor cancer prognosis. We have recently reported that ZL-1218, a humanized therapeutic antibody targeting CCR8, exerts its anti-tumor effect as a monotherapy and in combination with PD-1 blockade treatment. In the current study, we aimed to understand the underlying biology of $CCR8^+$ regulatory T cells and the mechanism of action of ZL-1218.

Methods Human and mouse dissociated tumor cells (DTCs) were immuno-profiled using multi-color flow cytometry. The CCR8 expression was quantified by both flow cytometry and immunohistochemistry (IHC)/ISH assay. The 10x Genomics single cell RNAseq (scRNAseq) was conducted, and the data was analyzed using unsupervised K-means clustering. nTreg cells were isolated from human buffy coat using EasySep™ Human $CD4^+CD127^{low}CD25^+$ Treg Isolation Kit.

Results We demonstrated that CCR8 is highly expressed on intratumoral $FoxP3^+$ Treg cells in multiple cancers and is absent on other major intratumoral immune cell populations or any immune cell population in the peripheral blood. The percentage of $CCR8^+$ Treg cells and CCR8 expression level indicated large donor-to-donor variations. In vitro anti-CD3/28 stimulation of nTregs suggested that Treg activation could be a trigger for CCR8 expression. Next, we assessed whether CCR8 is part of a larger Treg activation program using the scRNAseq analysis of selected DTC samples. $CCR8^+$ tumor infiltrating Tregs indeed showed a significantly higher surface expression level of Treg activation markers such as GITR, OX-40, 4-1BB, CTLA-4 and TIGIT, which are also the markers for a highly suppressive Treg subpopulation. This implies that $CCR8^+$ Treg cells represent a highly activated and suppressive Treg population. Importantly, we further demonstrated that ZL-1218 depleted about 50% Treg cells from selected DTC samples, which is consistent with the percentage of $CCR8^+$ Treg cells in these samples. Additionally, in human CCR8 knock-in mice, ZL-1218 treatment depleted comparable intratumoral Tregs leading to increased CD8T/Treg ratios without affecting peripheral Tregs. The toxicology study of ZL-1218 in non-human primates following 5 weekly intravenous infusion administrations demonstrated no safety concerns up to 100 mg/kg.

Conclusions These findings suggest that ZL-1218 antibody may deliver optimal tumor-targeted Treg depletion in the clinic while limiting peripheral toxicities to avoid autoimmune response.

Ethics Approval The study was approved by IACUC committee in Zai Lab (US) LLC (Protocol approval number 2020-11_1).

1400 DM919: A POTENT ANTI-MICA B ANTIBODY REINFORCES NKG2D MICA B AXIS AND PROMOTES ANTI TUMOR ACTIVITIES IN PRECLINICAL MODELS

Guangan Hu, Quanju Zhao, Lai Shi, Xiaochun Chen, Xiaodong Jiang, Sheng Yin, Nan Bing, Dong Zhang*. *D2M Biotherapeutics Inc, Natick, MA, USA*

Background Genome-wide association studies have identified MICA/B proteins as a causal factor for multiple cancers. Membrane MHC-I related MICA/MICB are stress-responding proteins and trigger the cytotoxic effector activity of NK cells and co-stimulatory activation of $CD8^+$ T cells through NKG2D receptor. Many human tumors develop immune escape mechanism via proteolytic cleavage of MICA/B from the cell surface. Shedding of MICA/B leads to lack of recognition by NKG2D. Soluble shed MICA/B not only are natural decor of NKG2D, but also downmodulate NKG2D receptor and inhibit NK cell function. DM919, a potent anti-MICA/B antibody, prevents MICA/B shedding and stabilizes surface MICA/B, and presents shed MICA/B to activate NKG2D on NK or T cells and mediates ADCC.

Methods Mice were immunized with recombinant proteins of a3-domain from mutiple alleles of MICA/B proteins to maximize allotype coverage in human population (~99.1%). Resulted IgG H&L chain variable regions were PCR amplified from plasma cells and built into yeast displayed scFv libraries. The libraries was screened for specifically binding to multiple alleles of MICA/B and evaluated for ability to prevent the shedding of MICA/B and activate NK and T cells via NKG2D. The selected anti-MICA/B hits were humanized, and affinity maturation was carried out using yeast display technology. Optimized hits were further screened and characterized in series of assays to evaluate functional activities and physicochemical properties. The lead candidate DM919 was identified based on its desirable characteristics and further evaluated in multiple syngeneic and xenograft mouse tumor models.

Results DM919 binds specifically to multiple alleles of MICA/B proteins with sub nanomolar affinities. DM919 inhibits the MICA/B shedding and stabilizes their surface expression. DM919 captures soluble MICA/B and activate NK cells and co-stimulate T cells through NKG2D. DM919 enhances the activation and degranulation of primary human NK cells and increases the cytotoxicity of human NK cells to lyse tumor cells. DM919 demonstrated excellent stability in vitro andin vivo. DM919 significantly inhibited xenograft tumor growth in vivo in SCID mice. DM919 inhibited in vivo growth of syngeneic mouse tumor cells transgenically expressing human MICA/B in a dose dependent manner. DM919 treatment reduced serum soluble MICA/B, which is a pharmacodynamic biomarker.

Conclusions DM919, a high affinity and potent the anti-MICA/B antibody has been developed. DM919 has demonstrated desirable functional and physicochemical characteristics in vitro. DM919 has shown significant antitumor activities in multiple syngeneic and xenograft tumor models. The data support further development of DM919 as an immunotherapeutic for solid tumor malignancies.

Ethics Approval All animal studies and procedures were approved by the Institutional Animal Care and Use Committee (IACUC) of Worcester polytechnic Institute. The protocol ID is #21-134.

1401 SIGLEC15 INDUCES MONOCYTE APOPTOSIS AND AN SIGLEC15 ANTIBODY ES012 REVERSES MYELOID CELLS DRIVEN IMMUNOSUPPRESSION

Maofa Zheng*, Dawei Sun, Yanan Geng, Rui Gao, Jinfeng Zhao, Zhihao Wu, Xiaoyan Zheng, Jingfeng Yu, Quan Qiu, Chunnian Wang, Yangsheng Qiu, Yingchao Liu, Yefeng Lu, Zheng Song, Mei Shi, Hongtao Lu. *Elpiscience Biopharma, Shanghai, China*

Background Siglec15 (S15) is a glycan-recognition proteins belongs to the Siglec family, preferentially recognizing the Neu5Aca2–6GalNAca– structure. Siglec15 is induced by MCSF and is highly expressed on TAM and many tumor cells, which inhibits T cell activity. The detailed mechanism of S15 function on T cells and myeloid cells, however, remains unclear. In this study, we seek to investigate Siglec15 biology and generate anti-Siglec15 antibodies for therapeutic use.

Methods The binding and function of Siglec15 on different cell subsets from healthy donor PBMC were evaluated. Siglec15 antibodies were screened and characterized by antigen binding, ligand blocking assay, rescue of monocyte apoptosis, reversion of monocyte inhibition and PBMC T cell activation assay. Selected leads underwent epitope binning by Bio-layer interferometry (BLI) and mapping by hydrogen deuterium exchange mass spectrometry (HDX-MS), they were then evaluated in MC38/hS15 bearing human S15 knock-in B6/C57 mice for PK profile and in vivo efficacy. Finally, the selected chimeric antibody (ES012) was humanized and undergone preclinical assessment, including potential acute toxicity study in cynomolgus monkeys and the pharmacokinetics (PK) study.

Results S15 expresses on human monocyte cells, M2 macrophage and DC cells but not on M1 macrophage. S15 also mainly binds to myeloid cells (including monocytes, M1 and M2 macrophage and THP-1 cell lines). S15-Fc dose-dependently inhibited OKT3-driven T cell proliferation in a PBMC culture, but not T cell proliferation driven by either PMA plus ionomycin, PHA or CD3/CD28 beads, all of which imply that S15-Fc probably does not directly suppress T cell activity; instead, this T cell inhibitory effect is proably through the inhibition on monocyte. We found that S15 dose-dependently induced the apoptosis of subsets of monocyte and down-regulated the surface expression of CD86, HLA-DR and CD14.

ES012 is a S15 humanized monoclonal antibody with strong blocking activity between S15 and multiple ligands including SiaTn and LRRC4C. ES012 dose-dependently rescued S15-mediated monocyte apoptosis, reversed S15-mediated monocyte inhibition, and rescued S15-mediated T cell inhibition. ES012 exhibited a good PK profile and showed excellent anti-tumor activity in a hS15 KI syngeneic mice model with 100% CR at dose of 5mg/kg.

Conclusions In summary, we found that siglec15 has a major effect on myeloid cells (inducing monocyte apoptosis and inhibiting monocyte activation) and an indirect inhibitory effect on T cell function. Based on this newly discovered S15 biology, we have developed a potent, functional anti-Siglec15 mAb ES012 that has great potential to reverse immune suppression in the TME to promote anti-tumor immunity.

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1401

1402 PH 894: AN INTASYL SELF-DELIVERING SIRNA TARGETING BRD4 HAS DUAL FUNCTIONS TO SENSITIZE TUMOR CELL KILLING AND ACTIVATE CD8 T CELLS

Shenghua Zhou*, Benjamin Cuiffo, Melissa Maxwell, Dingxue Yan, Brianna Rivest, Andrew Boone, James Cardia, Simon Fricker. *Phio Pharmaceuticals Corp., Marlborough, MA, USA*

Background Bromodomain containing proteins such as BRD4 play critical roles during cancer development and progression. BRD4 regulates oncogenes such as MYC and contributes to escape from immunosurveillance by decreasing tumor cell immunogenicity. Therefore, BRD4 is an attractive target for cancer therapy. Current clinical studies have focused on small molecule inhibitors of BRD4, however, these are not selective for BRD4 but inhibit other BRD proteins and are associated with toxicity and development of resistance. PH-894 is a self-delivering RNAi compound that specifically silences the BRD4 gene. We previously demonstrated potent antitumor activity of PH-894 in syngeneic mouse tumor models. Here we use B16ova melanoma cells which express ovalbumin peptide (OVA) and OT-1 T cells which recognize OVA to further explore the antitumor mechanism of PH-894.

Methods OT-1 T cells were stimulated with irradiated EG7 cells, followed by treatment with either PH-894 or a chemically matched non-targeting RNAi control (NTC). Seventy-two hours post-treatment, the levels of secreted IFN-γ were assayed by ELISA and BRD4 protein expression determined by flow cytometry. B16ova tumor cells were pre-treated with IFN-γ for 18 hours, followed by treatment with PH-894 or NTC for 3 days, and BRD4 protein expression assessed. To investigate whether PH-894 pretreatment could sensitize the killing of B16ova cells by OT-1 T cells, B16-OVA cells treated with IFN-γ were pre-treated with PH-894 or NTC-647 for 3 days. The treated B16ova cells were cocultured with anti-CD3-activated OT-1 $CD8^+$ T cells for 20 hours. OT-1 T cells were removed and B16ova cell viability was measured using CellTiter-Glo. Specific killing activity was calculated by normalizing luminescence in wells with cocultured B16ova/OT-1 T cells to those with B16ova cells only.

Results The expression of BRD4 was downregulated by PH-894 in both IFN-γ treated B16ova tumor cells and EG7 activated OT-1 T cells. Treatment with PH-894 resulted in a significant increase of IFN-γ production by the OT-1 cells. PH-894 pretreatment of the B16ova tumor cells significantly increased cell killing activity of the tumor cells by activated OT-1 T cells (90.8% killing activity with PH-894-treated B16ova cells compared to 68% in untreated cells).

Conclusions We demonstrate that PH-894 potently activates $CD8^+$ T cells, and PH-894 pretreatment of tumor cells can sensitize tumor cell killing by $CD8^+$ T cells. These data provide additional mechanistic insight and support further development and clinical investigation of PH-894 as a new class of antitumor therapeutic.

Other

1403 OUTCOMES FOLLOWING FIRST-LINE IMMUNOTHERAPY WITH OR WITHOUT CHEMOTHERAPY STRATIFIED BY KRAS MUTATIONAL STATUS – A REAL WORLD ANALYSIS IN PATIENTS WITH ADVANCED NSCLC

[1]Charu Aggarwal, [2]Halla Nimeiri, [2]James Chen, [3]Iker Huerga, [4]Leora Horn, [4]Nataliya Trunova, [5, 6]Jyoti Patel*. *[1]University of Pennsylvania, Philadelphia, PA, USA; [2]Tempus, Chicago, IL, USA; [3]Tempus and AstraZeneca, Chicago, IL, USA; [4]AstraZeneca, Chicago, IL, USA; [5]Northwestern University, Chicago, IL, USA; [6]Robert H Lurie Comprehensive Cancer Cent, Chicago, IL, USA*

Background Recent meta-analysis from 12 registrational studies[1] in patients with advanced non-small cell lung cancer (NSCLC) with KRAS mutations (mt), including G12C, evaluated efficacy outcomes of chemotherapy (CTx), immune checkpoint inhibitors (ICI), or ICI with CTx in the first line (1L) setting. Treatment with ICI + CTx provided superior efficacy, independent of KRAS and PD-L1 status and use of ICI + CTx was suggested as the preferred comparator arm in future 1L trials for patients with KRASmt. Herein, we report the largest, multimodal real world data (RWD) analysis for outcomes with 1L therapy in patients with advanced NSCLC stratified by KRASmt status.

Methods Deidentified multimodal RWD was accessed via the Tempus Lens database to retrospectively analyze 2,680 advanced 1L NSCLC patients. Patients were diagnosed between January 1, 2017 – December 31, 2021, had Tempus xT genomic sequencing and received CTx, ICI, or ICI + CTx. Patients were stratified by KRAS status: mutant (mt), G12C, or wildtype (wt). Median overall survival (mOS) was estimated using Kaplan-Meier methods. Subgroup analyses were performed using Cox model stratified by KRAS status, PD-L1 status [High (TPS $\geq$ 50), Low (TPS $\geq$ 1- 49), Negative (TPS < 1)] and pathogenic alterations in STK11, KEAP1 and TP53.

Results *KRAS*mt were identified in 31.4% (840/2680), 11.3% (303/2680) were G12C. Proportion of patients with PD-L1 TPS $\geq$ 50% was highest in *KRAS*mt and G12C groups compared to wt (30%, 31% vs 20% respectively). Demographics were balanced across all subgroups, except for a higher% of squamous histology (wt 25% vs 4% mt) and never-smokers (wt 14% vs. 5% mt). The prevalence of pathogenic variants between mt vs. wt groups were: *STK11* (16% vs 10%), *KEAP1* (9% vs 8%) and *TP53* (48% vs 37%). OS results are shown in (table 1). In the mt subgroup, the greatest benefit was seen in PDL-1 $\geq$ 50%; mOS (months): High: 27.56, Low: 15.26, Negative: 14.1. Notably, the G12C + PDL-1 high group displayed the longest mOS (47.4). Patients with co-mutations had the worst outcome: *KRAS*mt/*STK11* (OS 11.53m) or *KEAP1* (OS 11.33m) (table 2).

Conclusions Our analysis suggests that advanced NSCLC patients with KRASmt, including G12C with high PD-L1, had the best outcomes when treated with 1L ICI including ICI alone. Outcomes were significantly worse when STK11/KEAP1 co-mutations were present. This implies that patients with KRASmt NSCLC may represent a heterogeneous group requiring a tailored 1L trial design to account for variabilities in outcome.

1404 HPV33-DRIVEN OROPHARYNGEAL SQUAMOUS CELL CARCINOMAS ARE INCREASING IN PREVALENCE AND ARE CHARACTERIZED BY LOW CD8 INFILTRATION AND EPITOPE PRESENTATION DEFICIENCIES

[1]Shilpa Bhatia*, [1]Brinda Vijaykumar, [1]Qiaomu Tian, [1]Yanbo Sun, [2]Charles Quinn, [2]Sean Donnelly, [2]Ravindra Uppaluri, [2]Ann Marie Egloff, [1]Daniel Pregibon, [1]Lakshmi Srinivasan, [1]Anthony Coyle, [2]Glenn Hanna, [1]Christine McInnis. *[1]Repertoire Immune Medicines, Cambridge, MA, USA; [2]Dana Farber Cancer Institute, Boston, USA*

Background The evolving dynamics of human papillomavirus (HPV) genotypes has the potential to impact the prognosis of HPV-associated malignancies. HPV33+ oropharyngeal squamous cell carcinoma (OPSCC) patients in particular may have inferior survival rates compared to the other high-risk HPV subtypes. Despite heterogeneity in disease biology and varying clinical outcomes, ambiguity exists for the optimal clinical management of non-HPV16 high-risk subtypes. Here, we interrogated tumor from HPV33+ HNSCC patients to gain an in-depth understanding of cellular heterogeneity, identify high-risk MHC alleles, and explore disease-relevant targets that may inform strain-specific disease management.

Methods Treatment-naïve HPV+ OPSCC patients (n=19) were prospectively enrolled under an institutional review board (IRB)-approved tissue collection protocol (DF/HCC#09-472) for collection of surgical specimens. Subtype was assessed using TTMV-HPV DNA. Multiplexed, barcoded peptide-MHC-I tetramer libraries containing epitopes derived from the HPV33 genome were used to probe dissociated tumors followed by single cell RNA sequencing using the 10x Genomics platform. SingleR and published gene marker sets were used to phenotype and perform broad lineage assignment. Bulk RNA-sequencing data from additional HNSCC dataset was interrogated to validate select findings.

Results Our cohort (Total patients n=237; HPV33+ n=17, 7.2%) showed a ~2.4 fold higher rate of HPV33-driven OPSCC compared to published reports (3%). Single cell RNA-seq of tumor cells revealed that HPV33+ tumors exhibited a distinct HPV gene expression profile compared to HPV16+ tumors. HPV33+ tumors showed evidence of less infiltration of cytotoxic T-cells, exhausted T-cells and overall CD8+ T-cells. Interrogation of an independent HPV+ OPSCC cohort confirmed an overrepresentation of A*02:01 allele in HPV33 + OPSCC patients compared to HPV16+ OPSCC. Comparative epitope prediction analysis revealed that HPV33 lacks a key epitope found in HPV16 that is known to play a key role in immune recognition in A02:01+ patient samples.

Conclusions Targeted therapeutic trials have focused on HPV16+, rather than other high-risk HPV subtypes such as HPV33. Our data highlight reduced CD8+ T cell infiltrates as a potential correlate to poor outcomes in these patients. In addition, the observed A*02:01 ratios demonstrates potential immunoediting in HPV16+ patients. Increasing prevalence underscores an unmet need and presents a unique opportunity to design novel precision-based immunotherapeutic approaches for HPV33+ malignancies and potentially improve clinical outcome in this growing patient subpopulation.

1405 A CRISPR-CAS9 SCREEN IDENTIFIES NOVEL EPIGENETIC REGULATORS OF T CELL EXHAUSTION

[1]Gayathri Bommakanti, [1]Elizabeth Jaensch, [1]Aparna Gorthi, [2]Sin Lih Tan, [2]Verena Brucklacher-Waldert, [1]Steven Criscione, [1]Deanna Mele*. *[1]Astrazeneca PLC, Waltham, MA, USA; [2]Horizon Discovery, Waterbeach, UK*

Background Exhausted T cells (Tex) represent a distinct cell state, with a unique transcriptional and chromatin accessibility profile compared to their functional effector counterparts. Terminally exhausted T cells are epigenetically committed and non-responsive to checkpoint blockade therapies.[1,2] With the aim to identify epigenetic factors which contribute to T cell exhaustion, we carried out a CRISPR screen in an in vitro T cell exhaustion system.

Methods In vitro exhausted T cells were generated by repeated stimulation of human T cells (isolated from healthy donor leukopaks) with anti-CD3 and anti-CD28 antibodies over a period of 10 days. In vitro Tex were characterized by flow cytometry, cytokine secretion, RNA Seq and ATAC Seq. An arrayed CRISPR screen was carried out by Horizon Discovery in this Tex model targeting 829 genes (focused on the human epigenome) for KO in T cells from 3 donors (3 biological replicates). IFNγ, IL-2, TNFα and cell titer glo (viability readout) were used to assess functional ability of KO cells after the final stimulation.

Results We first established an in vitro T cell exhaustion system and showed that it recapitulated phenotypic, functional, transcriptomic and epigenetic features of exhausted T cells (figure 1). An epigenome focused CRISPR screen was then performed in the Tex model to evaluate the role of different epigenetic factors in T cell exhaustion (figure 2). Hits were identified as genes which when knocked out were able to increase cytokine secretion across at least 2 donors. From the screen, we identified previously established[3,4] and novel regulators of T cell exhaustion (figure 3). We validated the role of ikaros, a top hit from the screen, in T cell exhaustion using functional cytokine and T cell mediated tumor killing assays (figure 4).

Conclusions A positive control (CBLB) used in the screen and other previously reported factors were hits in the screen. Several novel regulators of T cell exhaustion were also identified. Hits from the screen could potentially be targeted to reinvigorate exhausted T cells and expand responses to check point therapies. We identified a novel role for ikaros in controlling T cell exhaustion, perhaps supporting a possibility in treating solid tumors. The therapeutic target of IMiDs are the Ikaros family of transcription factors which are approved drugs for the treatment of multiple myeloma and other hematological malignancies.

1406 ASSESSMENT OF ADDED ACTIVITY OF AN ANTITUMOR AGENT

Zhiping Sun, Eric Rubin, David Weinstock, Emmett Schmidt, Cong Chen*. *Merck and Co., Inc., Rahway, NJ, USA*

Background Growing clinical evidence shows that treatment effect of most approved combination therapies can be largely explained by the independent drug action model (IDA), i.e., the benefit a patient receives from a combination therapy is driven by the drug component his or her tumor is most sensitive to. IDA has been successfully used to predict objective response rate (ORR), progression-free-survival (PFS), and duration of response (DoR) for many combination therapies.[1-5] We built upon the model to develop a simple index to measure the added activity of a new drug when combined with any other drug to shed light on oncology drug development.

Methods When IDA is applied to ORR (aka Bliss model[6]), the ORR of the combination therapy is expected to be the sum of ORRs from Drug 1 and Drug 2 minus the product of the two (figure 1). When IDA model is applied to DoR, those who potentially respond to both drugs will have the best duration to a drug component. ORR or DoR alone is not adequate to capture the overall antitumor activity but jointly may.[7-8] Integrating results from the two, the added activity from Drug 2 to combination is:

ORRxDoR of Drug2x(1-ORRxDoR of Drug1/Sum of DoRs of Drug1 and Drug2)

Clearly, any new drug with single-agent ORR too low or DoRtoo short is unlikely to add much activity to the combination.

Results Further inspection of the index suggests that DoR of Drug 2 is more impactful than ORR. It also reveals that it is more impacted by ORR than by DoR of Drug 1, implying that there is more room for improvement over standard-of-care with lower ORR (but longer DoR) than with shorter DoR (but higher ORR). When Drug 2 has a superior DoR than Drug 1, the benefit of Drug 2 is largely retained after combination, which explains why some immune checkpoint inhibitors are successful after combining with chemotherapies. Conversely, when Drug 1 has a superior DoR than Drug 2, the benefit of Drug 2 is largely derived from those who do not respond to Drug 1, predicting the challenges in developing new drugs with short DoR for combining with established immune checkpoint inhibitors.

Conclusions We have derived a simple index to help researchers make early Go-No Go decisions on combination therapies. It is insightful, and, assisted with proper analysis method [9-10], it can potentially play a critical role in executing FDA's forthcoming Project FrontRunner.

1407 UNDERSTANDING THE DEFINITION OF HYPERPROGRESSIVE DISEASE (HPD) AND ITS INCIDENCE – A NEW PATH FORWARD

[1]Trie Arni Djunadi, [1]Youjin Oh, [1]Liam Il-Young Chung, [2]Timothy Hong, [3]Soowon Lee, [1]Zunairah Shah*, [1]Joo Hee Park, [1]Sung Mi Yoon, [1]Young Kwang Chae. *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, USA; [2]Northwestern University, Evanston, IL, USA; [3]Baylor University, Waco, TX, USA*

Background Hyperprogressive disease (HPD) is a phenomenon where tumors grow exponentially following immunotherapy. Multiple definitions have been proposed, and the incidence of HPD varies from 5.9% to 43.1% depending on the definition.[1] As HPD is associated with worse patient outcomes, it is important to have a clear definition of HPD to identify and prevent such cases.[2,3] There is much discussion about how to best define HPD as RECIST criteria only considers the target lesions.[4] iRECIST and irRECIST have been newly proposed to incorporate new lesions. This study proposes a new, modified definition for HPD using RECIST 1.1 and taking the sum of new lesions into consideration.

Methods This study retrospectively analyzed 128 lung cancer patients' data (N of patients = 128) and 144 total number of regimens (N of regimens = 144) at a large metropolitan academic medical center. This study compares the incidence of hyperprogression using different definitions including Champiat, Saada-Bouzid, and Ferrara et al.[5-7] As a modification to these definitions, the new lesions were included into the sum of lesions. The difference of incidence between original and modified definitions was evaluated with Chi-squared test.

Results The incidence rate of hyperprogression ranged from 5% to 15%, depending on the original definitions and modified definitions. Among the 144 treatment regimens, hyperprogression was detected in 5% (N=7), 10% (N=14), and 0% (N=0) using the original Champiat, Saada-Bouzid, and Ferrara et al. definitions respectively. The incidence of hyperprogression increased when new lesions were included in the definition. The incidence rate with modified Champiat, Saada-Bouzid and Ferrara et al. definitions were 11% (N=16), 15% (N=21) and 6% (N=9) respectively (table 1). Incorporating new lesions enabled the detection of more HPD cases, and the change in the sum of lesions are depicted in figure 1. The difference in incidence between original and modified definitions was statistically significant only for the Champiat et al. (X2= 3.0, p=0.05).

Conclusions Incorporation of new lesions in the definition of hyperprogression resulted in an increase in HPD incidence for all three definitions. However, statistically significant difference was observed only for the Champiat et al. definition. There are limitations of utilizing RECIST 1.1 in the identification of HPD as it does not take new lesions into consideration. This study highlights the importance of including new lesions when defining HPD to accurately capture HPD.

1408 RISK FACTORS FOR HYPERPROGRESSIVE DISEASE IN LUNG CANCER PATIENTS USING TWO DIFFERENT DEFINITIONS

[1]Trie Arni Djunadi, [1]Youjin Oh, [1]Liam Il-Young Chung, [2]Timothy Hong, [3]Soowon Lee, [1]Zunairah Shah*, [1]Joo Hee Park, [1]Sung Mi Yoon, [1]Young Kwang Chae. *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, USA; [2]Northwestern University, Evanston, IL, USA; [3]Baylor University, WACO, TX, USA*

Background Hyperprogressive disease (HPD) is the accelerated growth of tumor size after treatment with immunotherapy. As HPD is associated with poorer outcomes, it is important to understand the risk factors (RF) to prevent HPD.[1,2]. Some RF for HPD include age, primary lesion size, and presence of metastases in the contralateral lung, pleura, liver, and bone.[3] Others identified Eastern cooperative oncology group scale of performance status (ECOG PS) >1, having more than two metastasis sites, and liver metastasis as significant RF.[4] With existing findings showing varying results, this study aims to complement and identify potential RF for HPD in lung cancer patients.

Methods This study retrospectively analyzed 128 patients' data (N of patients = 128) and 144 total number of regimens (N of regimens = 144) at a large metropolitan academic medical center. Multiple variables were analyzed using chi-squared tests and t-tests to identify RF using two definitions of HPD by Champiat and Saada-Bouzid et al.[5,6] The variables that were analyzed are treatment line, regimen, immunotherapy type, histology, PD-L1 status, tumor mutational burden (TMB), diagnosis age, sex, smoking status, ECOG PS, neutrophil-to-lymphocyte ratio (NLR), TNM staging, platelets, number of metastases, and the presence of metastases in the brain, bone, and liver.

Results Among the 144 cases, immunotherapy was used as the first line in 27% (N=34), second line in 51% (N=65), and third or more line in 23% (N=29). Immunotherapy was used as a single agent in 77% of cases (N=111) and as a combination with other chemotherapy, targeted therapy in 23% of cases (N=33).

Using the Champiat et al. definition of HPD, immunotherapy only regimen, non-adenocarcinoma histology of tumor (histology was classified as adenocarcinoma, squamous cell carcinoma, small cell lung cancer and other), and bone metastasis were associated with HPD (table 1). Using the Saada-Bouzid et al. definition, histology and immunotherapy only regimen was shown to be marginally associated with HPD. However, no associations were identified between HPD and other clinicopathological variables, including, but not limited to, age, the number of sites of metastatic disease, genomic alterations, and peripheral blood biomarkers, including the NLR.

Conclusions Bone metastasis, non-adenocarcinoma histology, and immunotherapy only regimens were associated with HPD. Given the small sample size, further investigation is warranted to elucidate the correlation with hyperprogression and other clinicopathologic and genomic features.

1409 REGULATION AND ROLES OF THE POLYAMINE-HYPUSINE AXIS IN CD8$^+$ T-CELL FATE AND FUNCTIONS

Aya Elmarsafawi*, John Cleveland, Rebecca Hesterberg. *Moffitt Cancer Center, Tampa, FL, USA*

Background CD8$^+$ T cells play central roles in tumor immune surveillance and are major effectors in adoptive cell therapy. Thus, strategies that enhance their functions are an urgent clinical need. Metabolic reprogramming determines T cell fate and function.[1] The roles of amino acid catabolism in controlling CD8$^+$ T cell fate and function are less well understood.[2,3] Glutamine is essential for nucleotide biosynthesis and as an anaplerotic fuel source for the tricarboxylic acid (TCA) cycle.

Methods Isotope tracing experiments with ^{13}C glutamine or ^{13}C arginine

Pharmacologic inhibition of ODC and DHPS

Results Pharmacologic inhibition of Odc using difluoromethylornithine (DFMO), or inhibition of hypusination using the pharmacologic inhibitor of Dhps, GC7, augments cytokine production in activated CD8$^+$ T cells, including IFN-γ and TNF-α. Indeed, inhibition of Odc or Dhps augments other TRM phenotypes, including increases in CD69^{high};S1PR1^{low}; CD62L^{low} cells that define the tissue resident memory (TRM) CD8$^+$ T cells that play key roles in tissue and anti-tumor immunity anti-tumor reactivity. In addition, ACT of DFMO treated CD8$^+$ T cells augments their survival in vivo and augments the generation of CD69$^+$CD103$^+$CD69$^+$CXCR6$^+$ and Ly6C$^+$ TRMs in the bone marrow. Finally, DFMO or GC7 treatment enhances IFN-γ and TNF-α production in human CD8 T cells.

Conclusions We conclude that polyamine-hypusine axis is a metabolic check point in CD8$^+$ TRM generation and are an actionable target to improve the anti-tumor immunity of T-cell based immunotherapies.

1410 **ESSENTIAL ROLE OF INNATE EFFECTOR IMMUNE RESPONSES FOR THE THERAPEUTIC EFFICACY OF PEPTIDE VACCINE TO TREAT HPV+ TUMORS**

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1410

[1]Venkatesh Hegde, [1]Madison O'Hara, [1]Ananta Yanamandra, [2]Gloria Sierra, [1]Jagannadha Sastry*. *[1]MD Anderson Cancer Center, Houston, TX, USA; [2]CARsgene Therpaeutics Corporation, Bellaire, TX, USA*

Background High-risk type human papillomaviruses (HPV) are associated with genital and oral cancers, and the incidence of head and neck squamous cell cancers is fast increasing in the USA and worldwide. Survival rates for patients with locally advanced disease are poor after standard of care chemoradiation treatment, while immune therapeutic strategies including vaccines that target the virus-encoded E6 and E7 oncoproteins have mostly been ineffective in inducing regression of established HPV+ tumors despite promoting antigen-specific adaptive immunity. Therefore, vaccination strategies to significantly enhance antitumor immune responses with multiple effector functions to overcome the prevailing immunosuppressive tumor microenvironment are necessary to achieve curative efficacy against established HPV+ tumors. We present here preclinical evidence for the essential role of innate immune effector responses induced by a therapeutic HPV peptide vaccine incorporating two clinically relevant adjuvants QS-21 and CpG-ODN to induce sustained, complete regression of oral HPV tumors.

Methods We used mEER and TC-1, two mouse tumor cell lines expressing HPV-16 E6 and E7 along with h-Ras for tumor induction in the tongue and vaginal mucosa in syngeneic C57BL/6J mice. All animal studies were pre-approved and carried out in accordance with the University of Texas MD Anderson Cancer Center Institutional Animal Care and Use Committee (IACUC) guidelines. At days 5 and 11 following tumor implantation vaccine was administered via intranasal route and tumor growth monitored by MRI (for oral mEER) and IVIS (for vaginal TC-1). Around 15 or 16d post-tumor challenge, mice were euthanized and TIL analyses was performed to determine correlates of protection.

Results Vaccination resulted in robust induction of antigen-specific anti-tumor CD8 effector T cell responses along with expanded repertoire of innate cytotoxic effector responses that included unique natural killer cell subsets. The therapeutic efficacy of the vaccine was dependent on CD8 T cells and in addition required NK cells subsets as shown by in vivo antibody depletion and adoptive transfer to HPV peptide vaccine non-responsive oral tumor bearing mice. The combined polyfunctional populations of cytotoxic CD8 and NK cell subsets producing IFNg and granzyme B significantly outnumbered suppressive immune cell repertoire. Notably, the vaccine was effective in treating HPV tumors at both the vaginal and oral mucosal tissues

Conclusions Overall, these data provide strong support for therapeutic strategies promoting innate immune responses along with antigen-specific immunity, as evidenced by the therapeutic HPV peptide vaccine formulation in the present investigation, for potential clinical assessment in patients with HPV + cancers.

1411 BREAST CANCER IMMUNOPEPTIDOMES CONTAIN NUMEROUS SHARED TUMOR ANTIGENS

[1]Eralda Kina*, [1]Jean-Philippe Laverdure, [1]Chantal Durette, [1]Joël Lanoix, [1]Mathieu Courcelles, [1]Qingchuan Zhao, [1]Anca Apavaloaei, [1]Jean-David Larouche, [1]Marie-Pierre Hardy, [1]Krystel Vincent, [1]Patrick Gendron, [1]Leslie Hesnard, [1]Maria Virginia Ruiz Cuevas, [2]Gregory Ehx, [1]Pierre Thibault, [1]Claude Perreault. *[1]University of Montreal, Montreal, Canada*; *[2]University of Liege, Liege, Belgium*

Background Hormone-receptor-positive breast cancer (HR+) is an immunologically cold cancer that has not benefited from advances in immunotherapy. In contrast, triple-negative breast cancer (TNBC) displays high levels of leukocytic infiltration and responds to immune checkpoint inhibitors. CD8 T cells, the main effectors of anti-cancer responses, recognize MHC I-associated peptides (MAPs). Our work aimed to characterize the repertoire of MAPs presented by HR+ and TNBC tumors.

Methods Using a proteogenomic approach relying on mass spectrometry, we identified 57 094 unique MAPs in 26 primary breast cancer samples (14 HR+, 12 TNBC).

Results MAP source genes showed a high overlap between both subtypes (>70%). We identified 25 tumor-specific antigens (TSAs) derived from various genomic regions, of which 24 were unmutated. TSAs were mainly identified in TNBC samples (70%) and were more highly shared among TCGA TNBC than HR+ samples. In the TNBC TCGA cohort, the predicted number of TSAs positively correlated with leukocytic infiltration ($p<0.05$) and overall survival ($p<0.05$, figure 1), suggesting that these TSAs are immunogenic in vivo. We also identified 49 overexpressed tumor-associated antigens (TAAs), some of which derived from cancer-associated fibroblasts. FEST assays confirmed the in vitro immunogenicity of our TSAs and TAAs.

Conclusions Well-defined antigens were identified in both subtypes of breast cancer and represent attractive targets for cancer immunotherapy. The higher prevalence and immunogenicity of TSAs in TNBC tumors provide a molecular rationale for the responsiveness of TNBC to immune checkpoint inhibitors.

Ethics Approval Approved by the comity for clinical research of University of Montreal (CERC-20-012-D)

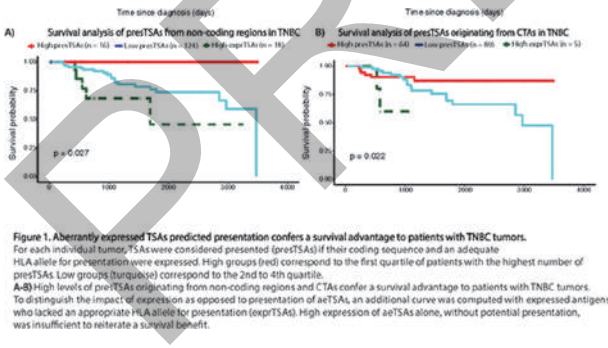

Figure 1. Aberrantly expressed TSAs predicted presentation confers a survival advantage to patients with TNBC tumors.
For each individual tumor, TSAs were considered presented (presTSAs) if their coding sequence and an adequate HLA allele for presentation were expressed. High groups (red) correspond to the first quartile of patients with the highest number of presTSAs. Low groups (turquoise) correspond to the 2nd to 4th quartile.
A-B) High levels of presTSAs originating from non-coding regions and CTAs confer a survival advantage to patients with TNBC tumors. To distinguish the impact of expression as opposed to presentation of aeTSAs, an additional curve was computed with expressed antigens who lacked an appropriate HLA allele for presentation (exprTSAs). High expression of aeTSAs alone, without potential presentation, was insufficient to reiterate a survival benefit.

1413 THE OVERALL SURVIVAL (OS) AND PROGRESSION-FREE SURVIVAL (PFS) OF HYPERPROGRESSIVE DISEASE (HDP) IN LUNG CANCER PATIENTS

[1]Youjin Oh, [1]Trie Arni Djunadi, [1]Liam Il-Young Chung, [2]Soowon Lee, [3]Timothy Hong, [1]Zunairah Shah*, [1]Joo Hee Park, [1]Sung Mi Yoon, [1]Richard Duan, [1]Young Kwang Chae. *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, USA; [2]Baylor University, WACO, TX, USA; [3]Northwestern University, Evanston, IL, USA*

Background Hyperprogressive disease (HPD) is the acceleration of tumor growth observed in patients treated with immunotherapy. HPD was seen to be negatively associated with the overall survival (OS) and progression-free survival (PFS) when compared to patients without HPD.[1–5] Various definitions of HPD have been used to evaluate the relationship between HPD and OS/PFS.[2,6–11] This study uses two HPD definitions from Champiat and Saada-Bouzid et al. to evaluate the association between HPD and OS/PFS in lung cancer patients.[8,11]

Methods This study retrospectively analyzed 128 patients (N=128) and 144 regimens (N=144) at a large metropolitan academic medical center. The overall survival (OS) and progression free survival (PFS) were analyzed using cox regression to produce a hazard ratio. Clinicopathologic variables were controlled for.

Results Among the 128 patients that were analyzed in this study, immunotherapy was used as the first line in 27% (N=34) and second line in 51% (N=65) of them. Immunotherapy was also used as a single agent in 77% (N=111) of all 144 regimens. In a survival analysis, the presence of hyperprogression was strongly negatively associated with PFS and OS in both definitions (figure 1.) Using the Champiat et al. definition, patients with HPD were about 20 times more likely to show future progression [Hazard ratio (HR) 22.30; 95% confidence interval (CI) 7.84-63.42, p<0.001]. Also, OS was greater in patients without hyperprogression [HR 2.69; 95% CI 1.11-6.5, p=0.029, table 1]. This trend was also seen with the Saada-Bouzid et al. definition, revealing a higher risk of future progression [HR 4.46; 95% CI 1.78-11.18, p<0.001] and death [HR 3.17, 95% CI 1.61-6.2, p<0.001] among patients with HPD (table 2). According to the Champiat et al. definition, patients who were female or had Eastern cooperative oncology group scale of performance status (ECOG PS) 3-4 were more likely to experience future disease progression. The Saada-Bouzid et al. definition showed that patients who were female, ECOG PS 3-4, or had immunotherapy as third line treatment or beyond resulted in a higher chance of future disease progression.

Conclusions Both definitions of HPD were associated with worse OS and PFS in lung cancer patients even after adjusting for confounding variables. Given its clinical importance associated with the poorer prognosis of patients, further attention and efforts are needed to identify hyperprogression and prevent its detrimental effects. Further studies with larger cohorts are warranted.

1414 RACIAL ETHNIC DIFFERENCES IN TREATMENT OF ADVANCED NON-SMALL CELL LUNG CANCER WITH IMMUNE CHECKPOINT INHIBITORS: ANALYSIS OF A LARGE REAL-WORLD DATASET

[1]Laura Oswald*, [1]L Robert Gore, [1]Melanie Buhlmann, [2]Naomi Brownstein, [1]Kea Turner, [1]Andreas Saltos, [1]Jhanelle Gray, [3]Shirish Gadgeel, [1]Clement Gwede, [1]Susan Vadaparampil, [1]Brian Gonzalez, [1]Heather Jim. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]Medical University of South Carolina, Charleston, SC, USA; [3]Henry Ford Cancer Center, Detroit, MI, USA*

Background Immunotherapy is a promising treatment for advanced non-small cell lung cancer (advNSCLC), with several immune checkpoint inhibitors (ICIs) FDA-approved since 2015. As ICI indications expand, disparities in treatment selection could result in disparate lung cancer mortality. This study examined differences in ICI treatment by race/ethnicity using a large cohort of real-world advNSCLC patients.

Methods This study used the nationwide Flatiron Health electronic health record-derived de-identified database.[1,2] Data included individuals diagnosed with advNSCLC between 2011-2021 with available treatment information. Logistic regression analyses assessed the likelihood of receiving an ICI (any line of therapy) by race/ethnicity before FDA-approval of the first ICI for advNSCLC (2011-2014) and after (2015-2021). Patients aged <65 years (younger) and 65+ (older) were assessed separately due to changes in Medicare eligibility at age 65. Significant racial/ethnic differences in ICI treatment accounting for covariates are reported as adjusted odds ratios (OR) with 95% confidence intervals. Covariates were: diagnosis year, geographic region, practice setting (academic/community), gender, age, insurance coverage within 90 days of treatment, smoking history, ECOG performance status within 60 days of diagnosis, documented biomarker testing (before ICI treatment/none), and PDL1 expressed (<1%/1%+).

Results Of 52,031 patients, most were non-Hispanic White (NHW) (68.7%) followed by unknown race/ethnicity (9.2%), Black/African American (AA) (8.6%), other race/ethnicity (8.1%), Hispanic/Latino (3.1%), and Asian (2.2%). Of patients treated before FDA-approval of ICIs for advNSCLC (N=16,219), 11.8% received ICI treatment. Relative to younger or older NHWs respectively, likelihood of ICI was higher among younger Asians (OR=1.94, 1.24-3.05) and lower among younger and older patients with unknown race/ethnicity (OR=0.50, 0.32-0.79; OR=0.45, 0.32-0.63, respectively). Of patients treated after FDA-approvals (N=35,812), 59.1% received ICI treatment. Relative to younger or older NHWs respectively, likelihood of ICI was lower among younger and older Asians (OR=0.48, 0.37-0.62; OR=0.64, 0.53-0.77, respectively), younger and older patients with unknown race/ethnicity (OR=0.83, 0.72-0.96; OR=0.77, 0.70-0.84, respectively), older Hispanic/Latinos (OR=0.85, 0.73-1.00), and older patients with other race/ethnicity (OR=0.90, 0.81-1.00).

Conclusions Most racial/ethnic disparities in ICI treatment were observed among older advNSCLC patients in the years after FDA-approval. Among younger patients, Asians were more likely than NHWs to receive an ICI before FDA-approvals, but this association reversed thereafter. Though not assessed, this was possibly due to differences in prevalence of EGFR mutations. There were no differences in likelihood of ICI treatment between Black/AAs and NHWs. These results suggest a need for concerted effort to offer all patients appropriate ICI treatment irrespective of race/ethnicity and/or age.

1415 A FLUORESCENT BIOSENSOR METHOD FOR QUANTIFYING ANTIBODY BINDING AND INTERNALIZATION INTO EFFECTOR CELLS AND TARGET CELLS IN A CO-CULTURE SYSTEM

Shu Mao, Yu-Lin Su, Frank Delfino, Craig Meagher, Jason Giurleo, Dangshe Ma, Travis Shaffer*. *Regeneron Pharmaceuticals, Tarrytown, NY, USA*

Background Antibody-mediated delivery of agonists into the tumor microenvironment to selectively activate intracellular targets in immune cells (effector cells) relative to tumor cells (target cells) is not well understood. Here we develop a method using a fluorescent biosensor to quantitatively assess the number of antibodies binding to a cell and frequency of internalized antibodies per cell in both tumor and immune cells in co-cultures by utilizing quantitative spectral flow cytometry.

Methods A hIgG1, anti-HER2 monoclonal antibody (HER2-mAb) or isotype-matched control antibody (Iso-mAb) were conjugated with a fluorescent biosensor consisting of Alexa Fluor 568 (AF568) and Alexa Fluor 647 (AF647) separated by a cathepsin B-cleavable peptide linker. AF568 fluorescence is quenched until the biosensor is cleaved inside cells, while AF647 is fluorescent pre- and post-cleavage. Quantitative flow cytometry calibration curves were prepared to calculate the number of fluorophore molecules per cell and antibody molecules per cell using the measured median fluorescent intensity (MFI).

Murine effector cells, RAW264.7 and RAW309 (macrophage) and MutuDC1940 (dendritic), were plated in 96-well plates 24 hours prior to the addition of target cells expressing variable levels of HER2: JIMT-1, N87, and SKBR3, preloaded with pHrodo green cell tracker. Target cells and biosensor-conjugated mAb were added simultaneously to effector cells at 37 °C for 0, 1, 4, or 24 hours. At each designated time point, cells were stained with CD11b-BV785, and flow cytometry was conducted with at least three independent runs.

Flow gates were placed on live single cells of either pHrodo green positive tumor cells, CD11b-BV785 positive immune cells, or double-positive cells. The AF568 and AF647 MFI values were converted to the number of fluorophore molecules or antibodies bound per cell allowing for the number of antibody molecules and% internalized antibody per cell to be determined.

Results Target cells expressing HER2 were required for appreciable HER2-mAb binding and internalization into effector cells. Antibody binding on effector cells correlated with increased HER2 expression across the three tumor cell lines. Importantly, the HER2-mAb-biosensor showed rapid and increased internalization into immune cells with 40-60% of antibody internalized by 1 hour in contrast to <10% internalization into tumor cells.

Conclusions This in vitro quantitative flow cytometry allowed determination of both the number of antibodies and the% internalized antibodies per cell, important parameters for modeling delinvery of antibody-mediated immunostimulatory agonists. The demonstrated methodology can be applied to in vivo models to optimize therapeutic agonist delivery.

Regulatory, Financial and Access Considerations

1416 METHODS FOR GATHERING PATIENT-RELEVANT CONCEPTS: THE USE OF THE PATIENT QUALITATIVE ASSESSMENT OF TREATMENT (PQATV2) IN EARLY ONCOLOGY DEVELOPMENT

Nneka Onwudiwe*Keri Brady, Jane Wells, Catherine Coulouvrat, Vicky DiBiaso, Christelle Lorenzato, Giovanni Abbadessa, Peter Adamson. *Sanofi, Washington, DC, USA*

Background The importance in measurement and analysis of patient-reported outcomes (PROs) in early oncology development as toxicity and efficacy endpoints— particularly with the emergence of targeted therapies and immunotherapies, has been recognized among researchers.[1-6] Recently, more attention has been directed towards considerations for applying PROs to early oncology development by the FDA in public workshops.[7,8] Despite their recognized value, methods for collecting, analyzing, and interpreting early phase PRO data are complex, leading to infrequent use in early oncology trials. The aim of this abstract is to conduct a scoping review of PRO usage in early oncology trials and highlight the novelty of a Sanofi-developed PRO measure, Patient Qualitative Assessment of Treatment version 2 (PQATv2).

Methods To validate our approach to PQATv2 implementation, we sought to identify early phase industry-sponsored oncology trials reporting PRO endpoints registered with ClinicalTrials.gov between January 1, 2009, to July 20, 2022—a start date to coincide with the publication of the 2009 FDA PRO Guidance for Industry. The PQATv2 is a 6-item, generic PRO measure. The PQATv2 includes: two 11-point numeric rating scales assessing participant-perceived treatment benefits and disadvantages (0 = not at all beneficial/disadvantageous to 10 = extremely beneficial/disadvantageous); an item assessing participants' willingness to continue treatment after the trial (yes/no); a 7-point Likert-type item assessing participants' overall benefit/risk ratio perceptions (-3 = 'disadvantages of the drug I received significantly outweighs the benefits' to 3 = 'the benefits of the drug I received significantly outweigh the disadvantages'); and three free-text items assessing participant-perceived treatment benefits, disadvantages, and reasons why the participant would be willing or unwilling to continue the treatment after the trial.

Results Of the 78 early phase studies reporting PRO endpoints and registered with ClinicalTrials.gov, Phase 1 oncology trials accounted for 33.3% (n=26) and Phase 1|2 at 66.7% (n=52). The PQATv2 is being included in several of our early oncology studies. Recognizing the need to enrich traditional efficacy and safety endpoints, Sanofi believes the PQATv2 is a novel and important approach to identifying salient and important concepts that guide the identification of future PRO measures in later phases.

Conclusions The PQATv2 is a novel exploratory measure aimed at generating additional hypotheses to guide selection of fit-for-purpose PROs in later phases. Further analysis of the utility of PROs in early phase oncology, and their impact in guiding preparation of PROs for later stage studies will be conducted as we gain more experience.

1417 UTILIZATION OF IMMUNE-BASED RESPONSE CRITERIA IN NCI-CTEP SPONSORED IMMUNOTHERAPY CLINICAL TRIALS

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1417

Sarah Shin*, Alice Chen, Martha Kruhm, David Loose, Geraldine O, Naoko Takebe, Elad Sharon. *NIH/NCI, Bethesda, MD, USA*

Background Immune modulation with immunotherapy in various tumor types has resulted in pattern of responses unique from chemotherapy or targeted therapy, suggesting the need to modify established response criteria to accurately assess and interpret responses to immunotherapy regimens. Multiple iterations of immune-based response criteria adapted from the RECIST criteria have been proposed to date, with the development of the irRC in 2009, followed by the irRECIST criteria in 2013, iRECIST in 2017,[1] and imRECIST in 2018. However, the extent of use of modified response criteria in clinical trials is unknown. We evaluated the trends in the inclusion of immune-based response criteria as an objective in immunotherapy-based CTEP-sponsored clinical trials.

Methods We conducted a retrospective analysis of all NCI-CTEP sponsored investigational clinical trials initiated by the data cut-off date of April 28, 2022. Trials for patients with solid tumors in which an immunotherapy agent was administered in at least one treatment arm were included in the analysis. Stated objectives for each trial were extracted and assessed for utilization of an immune-based response criteria.

Results A total of 160 solid-tumor trials were identified in the CTEP database to have immunotherapy as at least one of the treatment arms. Thirty (19%) of the trials incorporated immune-based criteria to assess response as an objective: 12 iRECIST (40%), 3 irRECIST (10%), 10 irRC (33%), 3 iRANO (10%), 2 "immune RECIST", unspecified (7%). Sixteen of 97 randomized trials (16%) and 14 of 63 non-randomized trials (22%) used an immune-based response criteria. Of the 16 randomized trials utilizing an immune-related response criteria, 4 trials had incongruous arms comparing an immunotherapy-based regimen with a non-immunotherapy regimen. The remaining 12 randomized trials utilizing an immune-based response criteria had immunotherapy agents in all treatment arms. Forty-nine (92%) of the 53 randomized trials with a non-immunotherapy comparator treatment arm and 32 (73%) of the 44 randomized trials with immunotherapy in all treatment arms did not use immune-based response criteria.

Conclusions Our analysis demonstrates that only a small percentage of immunotherapy-based clinical trials utilized immune-based response criteria. Randomized trials with non-immunotherapy comparator treatment arm(s) tended to avoid inclusion of immune-based response criteria in the objectives, likely in favor of maintaining consistent response criteria for all arms. However, both randomized and non-randomized trials had similar rates of usage of immune-based response criteria, indicative of a generally low level of uptake of these novel response endpoints on immunotherapy clinical trials.

1418 EXPLORING RWE RWD-BACKED REGULATORY DECISIONS IN IMMUNO-ONCOLOGY

Valerie Limasi, Amin Osmani, Sheila Galan*. *Cedience Inc, Toronto, Canada*

Background Real-world data (RWD) and real-world evidence (RWE) has long been used in drug development programs: to help generate hypotheses and assess the feasibility of clinical trials, or for post-marketing surveillance purposes. There is a wealth of RWD sources; data can be gathered from medical records, registries and wearables, among others. This data is then analysed to obtain RWE. Today, RWD/RWE is also increasingly being used to support regulatory decisions, especially during market authorisation approval for new drugs or new indications. A number of immuno-oncology drug products have owed their approval to the use of RWD/RWE.

Methods The objective of this experiment is to identify and trace the regulatory history of selected immuno-oncology products to understand how RWD/RWE has been applied in their drug development programs to market, and the perspective of the regulators at the time of review. Using Cedience, we identify the RWD/RWE-generating trials used in an immuno-oncology drug's submission. Cedience is a next-generation regulatory intelligence platform that allows a user to answer regulatory precedent questions, monitor topics of interest, and analyse past development strategies by using a database of documents compiled from various regulatory agencies. We have previously used Cedience to identify drug products associated with RWD/RWE and reconstruct a timeline of said drug products by collecting correspondence letters from the FDA.

Results Using Cedience, case studies were built that show the timeline of a drug's regulatory history; a picture of the drug's journey through development. This timeline focuses on RWD/RWE-generating trials used to examine the immuno-oncology drug, as well as the evidence available prior to said trials. In the context of these regulatory submissions, RWD/RWE functions to support randomised clinical trials by providing a second source of data that is more generaliseable to the wider population.

Conclusions From this data, an analysis of how RWD/RWE was used in the real world could be seen: what percentage of FDA approvals are RWD/RWE-backed, the clinical evidence that can be generated from RWD/RWE, and what type of study designs are appropriate for the generation of RWD/RWE. The regulator's perspective could be seen as well: how they evaluate RWD/RWE, and whether any issues or concerns are raised.

Tumor and Stromal Cell Biology

1419 HIGH PREVALENCE OF IMMUNE EXCLUSION IN EPITHELIAL TUMORS

[1]Antoine Italiano, [2]Jean-Philippe Guégan*, [3]Xinwei Sher, [3]Laura Dillon, [3]Tamas Oravecz, [3]Thomas Schürpf, [3]Guy Clifton. *[1]Institut Bergonie, Bordeaux, France; [2]Explicyte, Bordeaux, France; [3]Parthenon Therapeutics, Inc, Boston, MA, USA*

Background Immune infiltrated tumors have high levels of lymphocytes in contact with tumor cells and are more responsive to immune checkpoint inhibitors. Tumors with a paucity of lymphocytes contacting tumor cells can be divided into immune deserted and immune excluded phenotypes. Immune exclusion is characterized by lymphocytes restricted to the periphery of cancer nests, typically to the peritumoral stroma. Mechanisms that prevent lymphocyte infiltration in immune exclusion may be distinct. Understanding the immune phenotype landscape across tumors is necessary to ensure novel therapies targeting immune exclusion are directed at optimal indications.

Methods Samples from colorectal cancer (CRC), non-small cell lung cancer (NSCLC), ovarian cancer (OC), pancreatic cancer (PDAC), triple-negative breast cancer (TNBC), leiomyosarcoma (LMS), and undifferentiated pleomorphic sarcoma (UPS) were evaluated. Slides were stained with a multiplex IHC assay for CD8 and CK and evaluated by two pathologists who characterized the tumors as: deserted, characterized by a paucity/absence of CD8+ T cells (<1%); excluded, characterized by the presence of CD8+ T cells that do not penetrate the tumor parenchyma; and infiltrated, characterized by the presence within the tumor parenchyma of CD8+ T cells.

Results Overall, 143 samples were evaluated with 18.9% of tumors defined as deserted, 46.9% as excluded, and 34.3% as infiltrated (Table 1). In the 103 epithelial tumors, 19.4% (n=20) were defined as deserted, 63.1% (n=65) as excluded, and 17.4% (n=18) as infiltrated. Of the 40 sarcoma samples, 17.5% (n=7) were defined as deserted, 5% (n=2) as excluded, and 77.5% (n=31) as infiltrated. Immune exclusion was highest in CRC (70.0%), PDAC (71.4%), and TNBC (71.4%).

Conclusions Immune exclusion is the most prevalent immune phenotype in CRC, NSCLC, OC, PDAC, and TNBC. LMS and UPS have a low rate of immune exclusion and are predominantly infiltrated. Further research is warranted to understand and target the mechanisms underlying immune exclusion.

Ethics Approval Ethics approval obtained at Institut Bergonie

Abstract 1419 Table 1 Prevalence of immune phenotypes across evaluated cancer types

Tumor Type	n	Desert (%)	Excluded (%)	Infiltrated (%)
Colorectal	20	3 (15.0)	14 (70.0)	3 (15.0)
NSCLC	21	6 (28.6)	12 (57.1)	3 (14.3)
Ovarian	20	3 (15.0)	9 (45.0)	8 (40.0)
PDAC	21	5 (23.8)	15 (71.4)	1 (4.7)
TNBC	21	3 (14.3)	15 (71.4)	3 (14.3)
LMS	20	3 (15.0)	1 (5.0)	16 (80.0)
UPS	20	4 (20.0)	1 (5.0)	15 (75.0)

1420 TARGETING ENDOPLASMIC RETICULUM STRESS-RESPONSIVE PERK IN MELANOMA ELICITS PARAPTOSIS-MEDIATED IMMUNOGENIC CELL DEATH AND INDUCTION OF TYPE I INTERFERON-DEPENDENT ADAPTIVE ANTITUMOR IMMUNITY

[1]Jessica Mandula*, [2]Shiun Chang, [3]Eslam Mohamed, [2]Rachel Jiminez, [2]Rosa Sierra-Mondragon, [2]Darwin Chang, [2]Alyssa Obermayer, [2]Carlos Moran-Segura, [2]Das Satyajit, [2]Julio Vazquez-Martinez, [2]Karol Pierto, [2]Ann Chen, [2]Keiran Smalley, [2]Brian Czerniecki, [2]Peter Forsyth, [4]Richard Koya, [2]Brian Ruffell, [5]Juan Cubillos-Ruiz, [6]David Munn, [2]Timothy Shaw, [2]Jose Conejo-Garcia, [2]Paulo Rodriguez. *[1]Moffitt Cancer Center, Tampa, FL, USA; [2]H. Lee Moffitt Cancer Center and Research, Tampa, FL, USA; [3]California North State University, Elk Grove, CA, USA; [4]University of Chicago, Tampa, FL, USA; [5]Sandra and Edward Meyer Cancer Center, Weill Cornell Medicine, Ithica, NY, USA; [6]Georgia Cancer Center, Augusta University, Augusta, GA, USA*

Background In order to survive the hostile tumor microenvironment, cancer cells activate endoplasmic reticulum (ER) stress-associated response proteins, including the protein kinase R (PKR)-like endoplasmic reticulum kinase (PERK). Although intrinsic adaptation to chronic ER stress via PERK has been reported to limit the antitumor potential of immune cells, whether PERK activation in melanoma cancer cells contributes to immune evasion remains poorly understood and therapeutically untargeted.

Methods To establish the mechanistic role and therapeutic potential of targeting PERK in melanoma, we utilized both genetic and pharmacological approaches in both syngeneic transplantable and autochthonous inducible melanoma murine models. To substantiate these findings in a clinical context, we also leveraged bioinformatic interrogation of multiple independent human cohorts and tissue microarray analysis of human melanoma samples.

Results After the elimination or inhibition of PERK, melanoma cells undergoing ER stress activated a process characterized by the accumulation of misfolded proteins, ER enlargement, massive cytoplasmic vacuolation, and elevation of reactive oxygen species, which culminated in paraptosis and release of immunogenic cell death (ICD) mediators. Induction of paraptosis in PERK-ablated melanoma cells was dependent on factor SEC61b. Injection of PERK-null melanoma cells into mice or treatment of melanoma-bearing mice with PERK inhibitors resulted in the accumulation of ICD mediators, dramatic antitumor responses, robust protective T cell immunity, and activation of abscopal responses. Notably, we detected the expansion of monocyte-derived dendritic cells (MoDC) in PERK-null tumor beds, which produced Type I IFNs in response to the accumulated ICD mediators. Subsequently, MoDC-derived IFNB1 directed CCR2 driven recruitment of splenic common monocyte progenitors (cMoPs) which further developed into MoDCs and perpetuated the development of anti-tumor immunity. Blockade of Type I IFN receptor, elimination of IFNb, or deletion of STAT1, prevented the differentiation of cMoPs into MoDC. Additional studies in human settings substantiated the clinical impact of the activation of PERK signaling in melanoma. Higher expression of active PERK in cancer cells from human melanoma tumors correlated with limited intra-tumoral T cell frequency. In addition, elevated expression of a PERK-activation signature in different human melanoma cohorts corresponded to lower overall survival and impaired response to immunotherapy. Consistently, inhibition or ablation of PERK in murine melanoma tumors augmented response to checkpoint immunotherapy.

Conclusions Collectively, our findings underline the immunotherapeutic potential of targeting PERK in melanoma, support further development of ER-targeted treatment approaches in cancer and reinforce the benefit of combining ER-stress targeted therapies with checkpoint immunotherapy in cancer.

1421 ELK3 MODULATES THE IMMUNE LANDSCAPE AND IMMUNE RESPONSE TO NATURAL KILLER CELLS IN TRIPLE NEGATIVE BREAST CANCERS

[1]Joo Dong Park*, [2]Kwang-Soo Kim, [1]Dae-Keum Lee, [1]Seung Hee Choi, [1]Hae-Yun Jung, [1]Kyung-Soon Park. *[1]CHA University, Seongnam-Si, Korea, Republic of; [2]Northwestern university, Chicago, IL, USA*

Background Due to its aggressive behavior and frequent development of chemotherapy resistance, triple negative breast cancer (TNBC) is the most lethal subtype of breast cancer.[1] Although natural killer (NK) cell-based immunotherapy is a promising strategy for overcoming treatment barriers,[2] the therapeutic efficacy of NK cells against TNBC falls short of expectations. ELK3, an E26 transformation-specific transcription factor, is highly expressed in TNBCs and acts as a master regulator of the epithelial-mesenchymal transition.[3 4]

Methods Two representative human TNBC cell lines, MDA-MB231 and Hs578T, were engineered with ELK3-targeting shRNA or ELK3-expressing plasmid. A combination of gene expression profiling and molecular analysis was used to identify ELK3's downstream target genes. The role of ELK3 in determining TNBC immunosensitivity to NK cells was studied in vitro and in vivo in terms of mitochondrial fission-fusion transition and reactive oxygen species concentration. With syngeneic mouse model of Elk3 knockout 4T1 cells, tumor infiltrated immune cells were analyzed.

Results The status of ELK3-dependent mitochondrial fission-fusion in TNBCs was linked to the concentration of mitochondrial superoxide and was a major determinant of NK cell-mediated immune responses. In TNBCs, we discovered that mitochondrial dynamics proteins of 51 (Mid51), a major mediator of mitochondrial fission, is a direct downstream target of ELK3. In addition, we found that ELK3 expression correlated inversely with Mid51 expression, and that the ELK3-Mid51 axis is directly related to mitochondrial dynamics and immune response to NK cells. With a syngeneic mouse TNBC model, we found that ELK3 expression in TNBC is associated with a landscape of immune cells derived from both innate and adaptive immunity that infiltrate the tumor.

Conclusions Taken together, these findings suggest that ELK3 in TNBCs regulates mitochondrial dynamics, which is directly linked to tumor immunosensitivity. Targeting ELK3 in TNBCs is anticipated to shed new light on strategies for improving the efficacy of NK cell-based immunotherapy for TNBC (figure 1).

1422 CYTOKINES IMPACT FIBROBLAST ACTIVITY AND TUMOR FIBROSIS IN PANCREATIC DUCTAL ADENOCARCINOMA

Neel Nissen*, Morten Karsdal, Nicholas Willumsen. *Nordic Bioscience, Herlev, Denmark*

Background Pancreatic ductal adenocarcinoma (PDAC) is a devastating disease. The five-year survival is only 11%. One hallmark of PDAC is the excessive fibrotic reaction in the tumor microenvironment surrounding the tumor cells. Tumor fibrosis is characterized by an increased activity of fibroblasts and turnover of collagens. Unfortunately, this leads to reduced drug-uptake, impaired immune cell activity and as a result reduced survival in patients. Cytokines in clinical cancer immunotherapy, either as monotherapy or in combination with check-point inhibitors have gained much attention as anti-cancer drugs. Some cytokines have been shown to possess pro- and anti-fibrotic properties and could therefore provide additive value to the anti-cancer efficacy. TGF-β, PDGF-AB, IL-1α, IL-1β, IL-8 and IL-15, are six cytokines highly investigated in clinical trials as monotherapies or in combination with immunotherapies. In this study, we investigated the pro- and anti-fibrotic effects of these cytokines in molecular crowding pancreatic fibroblast culture assays in combination with collagen biomarkers measuring formation of type I, III and VI collagen (PRO-C1, PRO-C3 and PRO-C6, respectively).

Methods Humane pancreatic fibroblasts were cultured in Ficoll-media. Fibroblasts were treated w/wo TGF-β (1ng/mL), PDGF-AB (100 ng/mL), IL-1α (10 ng/mL), IL-1β (10 ng/mL), IL-8 (10 ng/mL) and IL-15 (10 ng/mL). The fibrotic activity of the fibroblasts was investigated by measuring PRO-C1, PRO-C3 and PRO-C6 in the supernatant at days 3, 6, 9 and 12. Cell-viability was evaluated by Alamar-blue.

Results The formation of type I collagen (PRO-C1) was significantly increased when fibroblasts were treated with TGF-β, IL-1α and IL-1β, but not PDGF, IL-8 and IL-15 at days 6, 9 and 12. The formation of type III collagen (PRO-C3) was significantly increased when fibroblasts were treated with TGF-β, IL-1α and IL-1β, but not PDGF, IL-8 and IL-15 at days 6, 9, compared to no treatment. At day 12 PRO-C3 was significantly increased in supernatant from fibroblasts treated with TGF-β, IL-1α, IL-1β and IL-8, but not IL-15, compared to no treatment. Interestingly, the formation of type VI collagen (PRO-C6) was only increased when fibroblasts were treated with PDGF-AB compared to no treatment at days 3, 6, 9 and 12. There were no differences in cell viability between treatments.

Conclusions TGF-β, PDGF-AB, IL-1α, IL-1β, IL-8 and IL-15 have differential effects on the pro-fibrotic activity of pancreatic fibroblasts. This is important knowledge when developing cytokine drugs for clinical cancer immunotherapy trials, suggesting that tumor fibrosis needs to be accounted for when designing and evaluating such studies.

1423 BREAST TUMOR CELL HEME METABOLISM ALTERS MACROPHAGE IMMUNE SUPPRESSION AND FUNCTION TO SUPPORT LUNG METASTASIS

Michelle Williams*, Sabrina Hafeez, Jessica Christenson, Nicole Spoelstra, Kathleen O'Neill, Li-Wei Kuo, Lyndsey Crump, Jill Slansky, Jennifer Richer. *University of Colorado Anschutz Medical Campus, Aurora, CO, USA*

Background Bilirubin, a metabolite of the heme degrading enzyme heme oxygenase-1 (HO-1/HMOX1), is commonly believed to be a waste product. Studies in other diseases revealed that bilirubin can alter normal immune cell function including macrophage antigen presentation and phagocytosis. However, the effects of bilirubin on the tumor microenvironment (TME) remain unknown. We **hypothesized** that tumor cell-HO-1 activity and subsequent bilirubin secretion enhance triple-negative breast cancer (TNBC) metastasis by supporting immune suppressive, pro-tumor macrophage function.

Methods We tested the impact of tumor cell-HO-1 and bilirubin on macrophage immune suppression and efferocytic capacity (engulfment of dead tumor cells) using qRT-PCR, flow cytometry and live cell imaging. Human and mouse macrophages were analyzed after treatment with exogenous bilirubin or bilirubin-depleted conditioned medium collected from tumor cells treated with tin mesoporphyrin (SnMP), an FDA approved HO-1 enzymatic inhibitor. Primary tumor growth, lung metastatic burden and macrophages were observed in immunocompetent mice harboring 66Cl-4 mammary tumors without and with HO-1 genetic depletion (shHO1). Human TNBC specimens were analyzed via CIBERSORT to predict immune cell abundance in patients with high versus low levels of HMOX1.

Results Macrophages cultured with conditioned medium from tumor cells treated with the HO-1 inhibitor SnMP demonstrated a 35-65% decrease in immune suppressive genes (Arg1, Cd274, Tgfb1) and a 25% increase in the efferocytosis gene Mertk compared to those treated with control conditioned medium. This effect was rescued by exogenous treatment with 2.5 μM bilirubin. Direct bilirubin treatment enhanced macrophage PD-L1 mRNA and protein expression by over 6-fold. In contrast, bilirubin decreased expression of Mertk by at least 50% and nearly ablated macrophage efferocytic capacity. To test whether bilirubin supports tumor progression via modulation of macrophages, we evaluated tumor growth and metastasis after tumor cell-HO-1 genetic depletion. While mice with shHO1 tumors had enhanced primary tumor growth compared to shCnt tumors, HO-1 depletion decreased lung metastatic capacity. Flow cytometry revealed that macrophages from shHO1 primary tumors had decreased expression of suppressive markers including PD-L1 and CD206 than control tumors. In human TNBC specimens, CIBERSORT analysis revealed that tumors with high levels of HMOX1 have a significant increase in the abundance of suppressive M2-like macrophages compared to those with low HMOX1.

Conclusions Tumor cell-HO-1 may support immune cell suppression and dysfunction during TNBC metastasis via bilirubin. Since HO-1 inhibitors including SnMP are FDA approved for treatment of other diseases, these findings could rapidly be translated to provide an alternative or companion immunotherapy for metastatic TNBC.

1424 M^{6}A REGULATORS RELATED TO MOLECULAR FEATURE, IMMUNE MICROENVIRONMENT AND PROGNOSIS IN LUNG ADENOCARCINOMA

Zhibo Tan, Min Chen, Yujie Zhao, Feng Peng, Ying Li, Mengqi Yang, Lei Zhang, Xin Li, Pengfei Yang, Zhe Zhang, Daming Li, Zhaoming Peng, Yajie Liu. *Peking University Shenzhen Hospital, Shenzhen, China*

Background The dynamic changes of N^6-methyladenosine controlled by m^{6}A regulators are vital for cancer biology.[1] However, the role of m^{6}A regulators in lung adenocarcinoma (LUAD) remains unclear. This study aimed to gain a deeper insight into the roles of m^{6}A regulators in LUAD by bioinformatics.

Methods 31 m^{6}A regulators were retrieved from previous literature. The expression levels of the 31 regulators were investigated by TIMER2.0. The association between the 31 regulators and overall survival (OS) were explored via K-M plotter and Cox regression. Next, mutations status and copy number alterations of the 31 regulators were probed through cBioPortal. Moreover, the interaction between the 31 regulators were revealed via principal component analysis (PCA), protein-protein interaction (PPI), and Metascape enrichment by R programming, STRING 11.5, Cytoscape, and Metascape. Then, the immune microenvironment including immune score, specific immune cells infiltration, and expressions of immune-related gene families were probed via ESTIMATE, TIMER2.0, TIMER, and R programming. Next, LUAD samples were divided into 3 clusters based on the expression patterns of the 31 regulators by k-means method. The differences of OS, gene enrichment, immune microenvironment of the 3 clusters were compared by Log-rank test, GSVA, ESTIMATE, and CIBERSORTx. Moreover, a m^{6}A Score Model was constructed using stepwise regression in this study. The predicting ability of the m^{6}A Score Model was verified by GEO LUAD dataset and TCGA Pan- adenocarcinoma dataset.

Results 22 out of 31 regulators showed differential expression levels between LUAD and normal lung (figure 1). 28 out of 31 regulators were linked with OS (figure 2). The frequency of mutation and copy number alterations were 26.6% and 29.1% respectively (figure 3). PCA revealed the 31 m^{6}A regulators displayed almost completely distinct distribution patterns between LUAD and normal lung (figure 4). PPI and Metascape enrichment indicated the 31 m^{6}A regulators displayed close interrelation (figure 5). Between high and low expression groups of 20, 20 and 29 regulators, tumor purity, immune score, immune cells infiltrations exhibited statistical difference (figure 6). Moreover, 3 clusters displayed distinct OS, gene enrichment, and immune microenvironment (figure 7). Notably, a m^{6}A Score Model was built up upon 15 m^{6}A regulators (figure 8). The model was associated with OS for LUAD and pan-adenocarcinoma (figure 9).

Conclusions m^{6}A regulators are associated with molecular features, immune microenvironment and prognosis in LUAD. m^{6}A Score could be used as a reference to immunotherapy and a prognostic index for LUAD.

1425 IN VIVO CRISPR SCREENS IDENTIFY HDAC1 AS AN IMMUNE SENSITIZER REVERSING IMMUNE RESISTANCE DRIVEN BY STK11 LOSS

[1]Chengyin Min*, [2]Wenrong Zhou, [1]Yi Yu, [1]Shangtao Liu, [1]Xuewen Pan, [1]Jennifer Tsoi, [1]Matthew Goldstein, [1]Alan Huang. *[1]Tango Therapeutics, Cambridge, MA, USA; [2]WuXi Apptec, Shanghai, China*

Background Immunotherapy with checkpoint blockade is effective in only a subset of cancer patients and additional treatment strategies are needed. Here we used a pooled in vivo CRISPR-based genetic screening approach to discover cancer cell intrinsic regulators of immune resistance and sensitization. A two-step approach was taken to uncover tumor suppressor gene loss driving immune evasion as step one, and immune sensitizers specifically reversing the immune evasion driven by certain tumor suppressor loss as step two. Through this approach, we are determined to identify genetic context specific immune sensitizers, also known as synthetic lethal immune targets.

Methods We first performed a pooled CRISPR-Cas9-based in vivo genetic screen targeted to a pre-defined set of tumor suppressor genes to mimic loss-of-function mutations in syngeneic tumor models. CRISPR edited tumor cells were implanted into immune-deficient or immune-competent C57BL/6 mice, a subset of which were treated with anti-PD1 to simulate increased immune pressure in vivo. Tumor samples at the endpoint were subjected to next generation sequencing and statistical analysis to identify tumor suppressor genes driving immune evasion. Furthermore, a second pooled CRISPR-Cas9-based in vivo genetic screen targeted to a set of potentially druggable genes was performed in MC38/STK11-/- model vs MC38 wild type model in the presence of increasing immune pressure in vivo. Next generation sequencing and statistical analysis were conducted to uncover STK11 loss specific immune sensitizers.

Results The screen confirmed previously identified immunotherapy targets such as CD47 as well as known drivers of immune resistance in the interferon signaling and antigen presentation pathways. Importantly, STK11 loss was identified as a driver of immune evasion in MC38 and 3LL models. STK11 knockout in MC38 or 3LL tumor cells significantly accelerated tumor growth in immune-competent mice and in these mice treated with anti-PD1. Tumor infiltrating lymphocyte profiling suggests that STK11 knockout induces an immune suppressive tumor microenvironment. Our second step target identification screen discovered HDAC1 as an immune sensitizer specific for STK11 loss context.

Conclusions CRISPR-based in vivo genetic screen is an effective approach to identify tumor cell-intrinsic drivers of immune resistance and sensitization. HDAC1 was identified as an immune sensitizer specifically reversing immune resistance driven by STK11 loss. STK11 mutations are found in ~15% of non-squamous non-small cell lung cancer and have been reported as a predictor of primary resistance to PD-1 blockade. Inhibitors selectively targeting HDAC1 & 2 in combination with anti-PD1 represent a promising therapeutic opportunity for non-small cell lung cancer patients with STK11 mutations.

1426 COMPREHENSIVE ANALYSIS OF A NOVEL ANTI-PDL1 RESISTANT SARCOMA MOUSE MODEL

[1]Alban Bessede*, [1]Jean Philippe Guegan, [1]Imane Nafia, [1]Assia Chaibi, [1]Christophe Rey, [1]Oren Ngouala, [2]Florent Peyraud, [2]Antoine Italiano. *[1]Explicyte, Bordeaux, France; [2]Institut Bergonié, Bordeaux, France*

Background Soft Tissue Sarcoma (STS) is known to be resistant to cancer immunotherapy including the prototypical immune checkpoint inhibitor (ICI) anti-PD1 (1). It's therefore crucial to develop innovative strategies aiming at improving current clinical benefit. To this end, a well-characterized sarcoma preclinical model that mimics resistance to immunotherapy is needed. Starting from the anti-PD(L)1-sensitive MCA205 sarcoma mouse model, we therefore aimed at developing and characterizing a novel model resistant to anti-PD1.

Methods Anti-PDL1 antibody was first administered to the ICI-sensitive MCA205 mouse sarcoma model (MCA205-S) and tumor growth was followed overtime. Tumor from a "non-responder" animal – tumor growth profile being similar as in the vehicle group – was then retrieved and processed for tissue dissociation and cell culture. Tumor cells were then amplified and inoculated into immunocompetent C57BL/6 mice that were exposed or not to anti-PD1 antibody, and tumor growth was monitored for a 8-week period. In addition, tumor samples from satellite animals were collected and processed for intratumoral immune landscape characterization by multiparametric flow cytometry as well as for gene expression analysis by RNA sequencing and spatial transcriptomics.

Results While anti-PD1 antibody demonstrated a strong anti-tumor effect in MCA205-S tumor-bearing mice, administration of anti-PD1 to the mice inoculated with the non-responder mouse-originating MCA205 cells did not yield to a significant anti-tumor effect thereby validating the resistant profile of this new MCA205-R cell line. Flow cytometry analysis of tumor-infiltrated immune cells revealed a higher abundance of macrophages (defined as CD11b+/F4:80+) in MCA205-R when compared to the MCA205-S model, which more likely harbor a M2 phenotype. Also, anti-PD1 treatment favored an important MCA205-R tumor infiltration by gMDSC which was more limited in the MCA205-S model. Data from gene expression analysis and spatial transcriptomics will be presented at the meeting.

Conclusions We developed and validated a novel preclinical mouse model of sarcoma (MCA205-R) characterized by its resistance to anti-PD1 and a high tumor infiltration by macrophages. This model – more reflecting the clinic in terms of immunotherapy sensitivity – can thus serve to evaluate novel immunotherapeutic regimens either alone or in combination with reference ICI, to ultimately translate into clinical benefit for STS patients treated with immunotherapy.

1427 COMPARATIVE ANALYSIS OF HUMAN IMMUNE SUBSETS AND RITUXIMAB ANTITUMOR RESPONSE ACROSS MULTIPLE NSG STRAINS ENGRAFTED WITH HUMAN HEMATOPOIETIC STEM CELLS

[1]Wonyoung Kang, [2]Sunitha Bachawal, [2]Anandaroop Mukhopadhyay, [1]Ilian Radichev, [1]Li-Chin Yao, [1]Mingshan Cheng*, [1]James Keck. *[1]The Jackson Laboratory, Sacramento, CA, USA; [2]Bristol-Myers Squibb, Redwood City, USA*

Background Although humanized NSG mice engrafted with hematopoietic stem cells (HSCs), constituting a human immune system, are a robust in vivo platform for analyzing effectiveness of novel immune modulators in cancer, inter and intra-experimental variability in immune subsets and anti-tumor response, resulting from utilization of diverse HSC donors, adds complexity to the data, making analysis challenging. To reduce variability, we acquired a significant amount of HSCs from the same donor and humanized six different NSG strains. Frequency and diversity of human immune subsets were characterized across non-tumor bearing humanized mice strains, and treatment effects of Rituximab on tumor burden and immune profiles in Raji-tumor bearing humanized mice were investigated.

Methods The six different NSG strains (NSG, NSG-IL15, SGM3, SGM3-IL15, NSG-TLR4, and NSG-FLT3) were engrafted with 0084 HSCs. Immune subsets in the periphery were assessed by high-dimensional cytometry. Furthermore, the humanized mice in NSG, NSG-IL15, SGM3 and SGM-IL15 strains were implanted with Raji cells subcutaneously and treated with Rituximab two or three times a week for 3 weeks, whole blood and tumors were collected, and the human immune subsets were profiled by flow cytometry.

Results Although the levels of hCD45 engraftment were comparable across the six different humanized strains, CD3+ T cells were more enriched in SGM3, SGM3-IL15 and NSG-FLT3, while higher frequency of CD56+ NK cell was observed in NSG-IL15, SGM3-IL15 and NSG-FLT3. Furthermore, the human FLT3 transgene expression improved myeloid development in the periphery (NSG-FLT3L ~11.7% vs. NSG ~1%). Interestingly, administration of Rituximab resulted in significant Raji tumor growth inhibition in NSG-IL15, SGM3 and SGM3-IL15 mice, but not in the NSG strain. While CD19+ B cells diminished in all humanized strains, trends in CD3 increases in tumor microenvironment were only observed in strains which demonstrated tumor growth inhibition.

Conclusions Humanization of NSG strains engrafted with HSCs from the same donor not only provided an effective platform to assess the influence of different human transgenes on degree and diversity of human immune subsets, but also allowed for investigating Rituximab response in multiple tumor bearing strains with no donor variability. Interestingly, robust anti-tumor effect upon rituximab treatment was observed in NK rich NSG-IL15 and SGM3-IL15 mice suggesting a possible NK driven antibody-dependent cell-mediated cytotoxicity mechanism contributing to tumor growth inhibition. Additionally, antitumor response also seemed to track with an increase in CD3+ T cell however the mechanism of action of Rituximab mediated by T cells requires further investigations.

1428 MELANOCYTE-INTRINSIC PDL1 PROMOTES TUMORIGENESIS AND PROGRESSION IN A NOVEL AUTOCHTHONOUS MELANOMA MODEL

[1]Carlos Ontiveros*, [1]Yilun Deng, [1]Anand Kornepati, [1]Clare Murray, [2]Mary Jo Turk, [1]Harshita Gupta, [1]Alvaro Padron, [2]Tyler Curiel. *[1]UT Health San Antonio, San Antonio, TX, USA; [2]Dartmouth College, Lebanon, NH, USA*

Background Tumor PDL1 signals extrinsically to immune cell PD1 to evade antitumor immunity and is highly expressed on distinct cancers.[1-7] Aside from tumor-extrinsic functions, we and others discovered various pathologic tumor-intrinsic PDL1 signals in distinct cancers, including melanoma.[2 7 8] We found that melanocytes (the melanoma cell-of-origin) do not express PDL1 but exhibit a gradual progression of PDL1 expression as cells transform from benign nevi to malignant melanomas, suggesting a role for PDL1 in melanomagenesis. We now investigate melanocyte-intrinsic PDL1 signaling, to distinguish bona-fide PDL1 signaling influence on melanomagenesis in the absence of potentially confounding compensatory mechanisms in prior genetic $PDL1^{KO}$ studies in established tumors. We hypothesized that melanocyte-intrinsic PDL1 signals drive melanomagenesis and progression through immune and non-immune mechanisms.

Methods To test melanocyte-intrinsic PDL1 signals during melanomagenesis, we developed an autochthonous, tamoxifen-inducible, UV accelerated, Nras-driven mouse model where mice develop melanomas that are $Nras^{Q61R}$ mutant and lack PDL1 specifically only in melanocytes versus littermates. Mice were induced with tamoxifen on post-natal days 2-3 ± distinct UV exposures and monitored for tumor growth. We established transplantable cell lines from derived tumors and SQ challenged into WT BL6 mice for in vivo treatment studies and studied PDL1 signaling in vitro.

Results Melanocyte PDL1 promotes melanomagenesis in a UV dose-dependent manner. Tumor latency was significantly increased in $PDL1^{KO}$ TN^{Q61R} mice versus littermates at 2 kJ/m^2 UV ($p<0.02$) suggesting an immune latency contribution. At 4.5 kJ/m^2 UV, $PDL1^{KO}$ TN^{Q61R}versus littermate melanoma latencies were indistinguishable, but faster than respective cohorts at 2 kJ/m^2 possibly from immunosuppression at higher UV doses. Genetic $PDL1^{KO}$ in B16 melanoma induces synthetic lethality to small molecule Chk1 inhibitors by destabilizing Chk2 protein through increased ubiquitination, an effect phenocopied in vitro and in vivo in tumors from $PDL1^{KO}$ TN^{Q61R}versus littermates. Tumors from $PDL1^{KO}$ TN^{Q61R}versus littermates transplanted into WT recipients were resistant to αPD1, αPDL1, αPDL2, and CD122-biased IL2 immunotherapies, differing from B16 melanomas that are sensitive to all these treatments. Notably, tumor PDL1 suppresses ERK signaling, a downstream target of Nras, in TN^{Q61R} cell lines, suggesting PDL1 control of Nras-mediated oncogenesis.

Conclusions Our novel model dissociates bona-fide cell-intrinsic PDL1 signals from potential genetic $PDL1^{KO}$ compensation confounding effects, allows studies of earliest PDL1 signals in melanomagenesis and progression, helps understand if PDL1 affects Nras-driven oncogenesis, and helps test immunotherapy and small molecule treatment effects. A parallel bladder cancer model was also developed, to be reported later.

1429 IMMUNE RECEPTOR PIRB DELETION IMPACTS PANCREATIC CANCER GROWTH AND ANTI-TUMOR IMMUNE RESPONSE

[1]Alessandro Scagliotti*, [1]Claudia Curcio, [1]Silvia Brugiapaglia, [1]Giorgia Tiberi, [1]Francesco Novelli, [2]Toshiyuki Takai, [1]Paola Cappello. [1]*University of Turin, Torino, Italy*; [2]*Tohoku University, Sendai, Japan*

Background Paired immunoglobulin-like receptor B (PIRB), the murine ortholog of human leukocyte immunoglobulin-like receptor B 2 and 3 (LILRB2/3), is an inhibitory receptor expressed on the surface of macrophages, granulocytes, dendritic cells and B lymphocytes, in which it down-regulates their principal functions.[1] The peculiarity of this protein is the presence of three intracellular Immunoreceptor Tyrosine-based Inhibitory Motives, able to recruit Src homology 2 domain-containing protein tyrosine phosphatases (SHP-1/2) when the receptor is activated by contacting its principal ligands, major histocompatibility complex class I molecules.[2] Previous studies have underlined how PIRB loss is associated with i) the presence of hypersensitive B cells, which display a higher production of antibodies,[3] ii) increased cytotoxic T cells[2] and iii) less suppressive myeloid cells polarized toward an M1-like anti-tumoral phenotype.[4] In the light of this, we wanted to better characterize extrinsic role of PIRB in modulating the anti-tumoral immune response in mouse models of pancreatic ductal adenocarcinoma (PDA), as well as the intrinsic role.

Methods To this, mice lacking PIRB gene ($Pirb^{-/-}$) were crossed with genetically engineered mice (GEM) that spontaneously develop pancreatic cancer. Histological and immunohistochemical analyses of pancreatic tissues were performed to measure tumor lesions and characterize the immune infiltrate. To investigate the ability to mount a memory response, OVA-expressing PDA cells were used as immunizer. ELISPOT experiment was performed to assess IFNg and IL17 secretion. ELISA assay was performed on sera to investigate anti-tumor humoral response. MTT and soft agar assay were performed to investigate proliferative and colony formation ability of wild-type and $Pirb^{-/-}$ PDA cell lines respectively.

Results PIRB ablation significantly improved survival rate of GEM compared to the Pirb proficient counterpart, and this correlated with a reduced percentage of transformed ducts. Immunohistochemical analyses of pancreatic tissues demonstrated increased frequency of effector immune cells inside the tumor microenvironment. The absence of PIRB significantly delayed OVA-expressing PDA cell engraftment after immunization with OVA and increased also both antigen specific T and B cell response. Concerning the intrinsic role, in vitro experiments showed a lower proliferation rate and a lower colony formation ability by $Pirb^{-/-}$ PDA cell line.

Conclusions Overall, PIRB represents a promising target to improve the anti-tumor immune response and deserves further characterization to design novel immunotherapy strategies for the treatment of PDA.

1430 THE IMMUNOLOGICAL AND GENOMIC PROFILING OF COLORECTAL AND BREAST CANCER CELL LINES CAN DISTINGUISH STEM LIKE FROM DIFFERENTIATED TUMOR CELLS: IMPLICATIONS FOR CANCER IMMUNOTHERAPY

[1]Neha Gopinath, [2]Tanwir Habib, [1]Mohammed Toufiq, [1]Alice Turdo, [1]Asma Al-Sulaiti, [1]Ishita Gupta, [1]Rebecca Mathew, [1]Harshitha Shobha Manjunath, [3]Matilde Todaro, [3]Giorgio Stassi, [1]Sara Tomei, [4]Soldano Ferrone, [5]Ira Skvortsova, [1]Cristina Maccalli*. *[1]Sidra Medicine, Doha, Qatar; [2]Weill Cornell Medicine, Doha, Qatar; [3]University of Palermo, Palermo, Italy; [4]MGH, Pittsburgh, PA, USA; [5]University of Innsbruck, Innsbruck, Austria*

Background Rare cells endowed with "stemness" and tumor initiating properties, cancer stem cells (CSCs), are considered responsible of metastatization and resistance to therapy, including immunotherapy. The aim of this study is to identify the molecular mechanisms regulating the immunological properties of CSCs isolated from solid tumors.

Methods CRC (N=15) and BC (N=21) cell lines), including differentiated tumor cells and CSCs, and, for BC cell lines, selected in vitro for radioresistance or invasiveness were used for this study. The expression of HLA molecules and the components involved in the antigen processing machinery (APM) was assessed through flow cytometry. DNA and RNA were isolated from these cell lines. The nCounter platform (Nanostring) was utilized to assess the hybridization with 800 probes for miRNAs and the RNA seq-based transcriptomic profile was also assessed. The methylation profiling of cancer cell lines was investigated through Infinium EPIC arrays (Illumina). In addition, the co-culture of tumor cells with HLA-matched lymphocytes, either with or without the treatment with immunomodulatory or epigenetic agents, was performed to assess the ability of the CRC and BC cells to elicit antigen-specific T cell responses.

Results A general impairment of the expression of HLA and APM (e.g., LMPs, TAP and tapasin) molecules was observed in CRC and BC lines. The down-modulation of the expression of HLA and APM was superior in "stem-like" cells as compared to the differentiated tumor cells. The treatment of these cells with immunomodulating or epigenetic agents could only partially restore the expression of these molecules. The induction in vitro of anti-tumor T cell responses through the co-culture of tumor cells with PBMCs, was suboptimal and with variability depending on the subtype of cells and the pre-treatment or not of tumor cells with either immunomodulating or epigenetic agents.

Differential miRNAs, transcriptomic and methylation profiles ($p<0.05$) were identified in either CRC or BC cells with stemness properties vs. differentiated cells, and in different subtypes of cells. These includes genes and their regulators involved in immunological functions.

The integration analyses among methylation, miRNAs and transcriptomic profiles is under investigations, although preliminary results are available showing the differential involvement in CSCs vs. differentiated tumor cells of immune related pathways.

Conclusions The immunological and genomic profiles of CRC and BC are associated with cell subtypes. These investigations will contribute to understand the mechanisms regulating the biological and immunological properties of tumor cell endowed with variable cell fate and their susceptibility to immunotherapy.

1431 INTRATUMORAL PH 109 INTASYL™ SELFDELIVERING RNAI TARGETING CONNECTIVE TISSUE GROWTH FACTOR PROVIDES EFFICACY IN VIVO IN A MOUSE MODEL OF METASTATIC BREAST CANCER

Benjamin Cuiffo*, Melissa Maxwell, Dingxue Yan, Andrew Boone, Brianna Rivest, Shenghua Zhou, James Cardia, Simon Fricker. *Phio Pharmaceuticals, Marlborough, MA, USA*

Background Breast cancer is the most diagnosed cancer and the second leading cause of cancer-related deaths globally among women, frequently due to metastatic disease. CTGF orchestrates diverse multicellular processes including embryonic development, wound healing, and tissue repair. CTGF promotes inflammatory diseases and contributes to cancer cell proliferation, migration, invasion, metastasis, and epithelial-mesenchymal transition. High CTGF is associated with poor prognosis in breast cancer. CTGF-inhibition has shown promise in decreasing metastatic dissemination and sensitizing to cancer cells to chemotherapy in preclinical models. PH-109 is a self-delivering RNAi compound built on proprietary INTASYL™ technology, designed to silence human CTGF with high specificity and without need for specialized formulations or drug delivery systems. PH-109 was originally developed and approved as an investigational new drug (IND) for treatment of dermal hypertrophic scarring (Phase 2; NCT02246465) and subretinal fibrosis (Phase 1/2; NCT02599064). Treatment resulted in a statistically significant reduction of CTGF mRNA and protein at the treatment site, with no significant toxicity or adverse effects. Here we present proof-of-concept (POC) in vivo data showing efficacy of intratumorally administered PH-109 in an orthotopic 4T1 model of metastatic mammary cancer.

Methods PH-109 mediated mRNA silencing of CTGF was validated in 4T1 cells in vitro by RT-qPCR. In vivo, 4T1 cells were implanted into the mammary fat pad of BALB/c mice. When tumors reached threshold volume (150 mm^3), animals were randomized into treatment groups; test treatments were administered intratumorally (IT) on Days 1, 4, 7, 10 and 13. Vehicle (PBS), a chemically-identical non-targeting control (NTC) INTASYL or PH-109 at two dose concentrations (0.5 mg; 2 mg) were administered IT; doxorubicin chemotherapy (5 mg/kg) was administered intraperitoneally on Days 1, 7, 13. Tumor volumes and body weights were recorded longitudinally. Primary tumors were resected from each animal at ~500 mm^3 in survival surgeries and stained with anti-α-SMA to assess stromal content by immunohistochemistry. Three weeks post-resection animals were euthanized and lungs insufflated with India ink and lung macrometastases enumerated.

Results PH-109 provided concentration-associated silencing of CTGF in vitro. In vivo, IT PH-109 elicited antitumor efficacy and improved outcome compared with vehicle- or NTC-treated tumors. In contrast to doxorubicin, PH-109 showed no evidence of toxicity as indicated by weight loss.

Conclusions PH-109 was previously evaluated in over 150 patients without significant toxicity. This, combined with these data in a clinically relevant orthotopic mouse model of metastatic breast cancer, could support accelerated clinical investigation of PH-109 as an anticancer therapeutic.

Ethics Approval Animal studies were performed at Pharma Models LLC, Marlborough, MA 01752, under standard protocol approved by their IACUC.

1432 DISCOVERY OF HIO 3 A TUMOR-PRODUCED PROTEIN THAT BINDS THE HUMAN IGG1 FC CH3 DOMAIN AND SUPPRESSES ANTIBODY DEPENDENT CELLULAR CYTOTOXICITY AND COMPLEMENT DEPENDENT CYTOTOXICITY

Nicolas Nicolaides, Luigi Grasso, Brad Kline*. *Navrogen Inc., Cheyney, PA, USA*

Background Human cancers employ a number of mechanisms to evade host immune responses against novel antigens generated from aberrant over-expression, mutations and/or epigenetic alterations. Humoral immunity utilizes antibodies and immune-effector cells as well as molecular immune complexes involving the complement system to mediate the killing of dysregulated cancer cells. We refer to these anti-cancer mechanisms as Humoral Immuno-Oncology (HIO). Suppression of HIO is mediated by tumor-produced proteins called HIO factors. One such factor is CA125, which was previously shown to bind IgG-type antibodies and inhibit their antibody dependent (ADCC) and complement dependent (CDC) cellular cytotoxic activities. Using a combination of experimental screening and literature searches, we screened a number of proteins that have been produced by tumors and associated with a variety of cancer indications to determine if they could impact HIO. Herein, we describe the initial characterization of soluble ICAM-1 (sICAM-1), a tumor antigen capable of binding IgG-type antibodies that inhibits their immune-effector activity.

Methods Deletion and site-directed mutatgenesis of the heavy constant domain of IgG1 was performed and constructs expressed as GST fusions in 293F cells. Recombinant proteins were then used in direct binding and competition ELISA formats to determine amino acid residues essential for binding of HIO-3. Constant region mutants that lost HIO-3 binding were then generated to whole IgG constructs for in vitro characterization of HIO-3 resistance.

Results Amino acid substitutions in this domain were able to abrogate sICAM-1 binding and overcome ADCC suppression.

Conclusions These findings highlight yet another mechanism by which tumors can suppress the host's immune system for survival and offers new concepts for developing antibody-based therapies that can aid in the treatment of various cancer indications. Moreover, the findings here offer clinical design opportunities to improve upon existing approved immune-mediated therapies for which this factor is present.

1433 CHARACTERIZATION OF THE SPATIAL AND TEMPORAL DISTRIBUTION OF TUMOR RESIDENT IMMUNE CELL POPULATIONS IN A 3DEXPLORE HUMAN TUMOROID MODEL AND ASSESSMENT OF RESPONSE TO IMMUNOTHERAPEUTICS EX VIVO

Seth Currlin*, Sharon Camacho, Angie Rivera, Jared Ehrhart, Soner Altiok. *Nilogen Oncosystems, Tampa, FL, USA*

Background Tumor cells cause significant chemical, cellular and physical alterations to surrounding tissue. The resulting tumor microenvironment (TME) includes a diverse population of immune and stromal cells contributing to tumor development and response to immunotherapeutic drugs. The 3D-EXplore ex vivo tumoroid platform enables high-throughput drug discovery within human tumor samples with intact TME for improved clinical translation. The work herein provides an in-depth assessment of the heterogenous TME for multiple cellular populations including immune, stromal and tumor cells, as well as non-cellular components of the extracellular matrix (ECM) in a tumor 3D tumoroid platform using fresh patient tumor tissue.

Methods Tumoroids from fresh RCC tumor samples measuring 150 μm in size were generated using a proprietary mechanical process without any enzymatic digestion or propagation. This study was approved by Vanderbilt University Ethics Board, approval number 031078. An array of multiplexed immunofluorescent panels including lymphoid and myeloid markers were applied at timed endpoints with drug treatments ex vivo to highlight dynamic changes among tumor, immune and stromal components of the TME. Samples were then imaged with confocal microscopy.

Results In this study we analyzed the interaction between the tumor cells (CA9), cancer-associated fibroblasts (FAP), and endothelial cells (CD31) in patient renal cell carcinoma tumoroids. Systematical mapping of the immune landscape in tumoroids treated ex vivo with a STING agonist alone or in combination with nivolumab with a cGAS-STING pathway activation allowed characterization of the spatial and temporal distribution of tumor resident T-cells (CD3, CD4 and CD8), B-cells (CD20), and macrophages (CD68, CD163, and CD11b) in the intact tumor microenvironment. These findings were correlated with treatment-mediated changes in tumor cell killing. To further document treatment mediated changes in the tumor immune microenvironment, we performed 17-plex cytokine release assays (GM-CSF, scd137, ifnγ, sfas, sfasl, Granzyme A, Granzyme B, IL-2, IL-4, IL-5, IL-6, IL-10, IL-13, MIP-1α, MIP-1β, TNF-α, Perforin) with supernatants collected from ex vivo treated tumoroid cultures.

Conclusions In this comprehensive multiplexed immunofluorescence 3D tumoroid study we demonstrated that the 3D-EXplore ex vivo platform supports an intact tumor microenvironment, ideal for monitoring treatment-induced changes in the tumor resident immune cell populations and their interaction with the epithelial and stromal components of the tumor.

Ethics Approval All tissues in this study were collected under proper patient consent and approved by the Institutional Ethics Board, approval number Pro00014313

1434 INTERPLAY BETWEEN THE TUMOUR AND GUT MICROBIOME AND THE TUMOUR IMMUNE MICROENVIRONMENT IN COMPLETE RESPONDER CANCER PATIENTS

[1]Nicola Annels*, [1]Tyler Wooldridge, [1]Kate Relph, [1]Anna Krukowsha, [2]Izhar Bagwan, [1]Hardev Pandha. *[1]University of Surrey, Guildford, UK; [2]Royal Surrey NHS Foundation Trust, Guildford, UK*

Background The most important insights into mechanisms of tumour rejection, and how these could be exploited therapeutically, is likely to come from patients displaying the best responses. Those individuals with complete and sustained anti-tumour responses, without maintenance therapy, will provide the best evidence of genuine disease modification. Despite much speculation as to how these exceptional responses are generated there is increasing evidence for an immune basis which may be influenced by the tumour microbiome underlying the mechanism for sustained tumour rejection.

Methods To focus on individuals with complete and sustained metastatic disease resolution, we designed a pilot study, the Continuum Long-Term Survivor study, to evaluate patients with the best outcomes, where disease modification may have occurred. The study targeted only those patients (n=50) with a sustained (>5 years) complete clearance of metastatic cancers, without requiring maintenance therapy. Matched controls comprised patients unable to generate an initial response, or those who relapsed within 12 months. DNA extracted from tumour samples was analyzed by 16S BENCHMARK™ microbial amplicon sequencing (Diversigen) to profile the tumour microbiome, whilst the microbial composition of stool samples was determined using BoosterShot Shotgun Sequencing. In parallel mRNA expression from the tumour tissue was evaluated using NanoString's PanCancer IO360 gene expression panel. From a homogeneous subgroup of bowel cancer long-term survivors and their matched controls, multiplex IHC using a panel of 8 immune markers to identify tertiary lymphoid structures (TLS) was performed on the tumour tissues and imaged using a PhenoImager (AkoyaBiosciences).

Results Results will be presented comparing tumour and gut-derived microbial species diversity between long-term vs. short-term survivor matched controls using alpha diversity estimates as well as differential abundance analysis. This will define the microbial species that are more likely to be associated with long-term survivorship. Characterization of the immune gene transcriptional patterns within the tumour microenvironment (TME) from long-term survivors vs controls will also be reported along with any observed differences from the multiplex IHC analysis of immune infiltrates in corresponding patient tissue. To explore any connections of the tumour-microbiome on the TME, an integrated analysis of the microbiome and tumour immune transcriptome will be presented.

Conclusions This study will reveal whether changes in TME influenced by the tumour microbiota may be important factors associated with long-term survivorship. Understanding the precise mechanisms of total tumour rejection in patients, and their evaluation may be game-changing in terms of design of new molecular, biological and immune therapies.

Ethics Approval This study was approved by the University of Surrey Ethics Board; approval number 266581.

1435 COMPARISON OF THE CYTOKINE AND CHEMOKINE SECRETOME OF BENIGN AND MALIGNANT PERITONEAL FLUID IDENTIFIES FGF AND IL 1R ALPHA AS POTENTIAL DRIVERS OF TUMOR GROWTH

[1]Patrick Wagner*, [2]Vera Donnenberg, [1]Christian Cruz Pico, [2]Albert Donnenberg, [1]David Bartlett. [1]*Allegheny Health Network Cancer Institute, Pittsburgh, PA, USA*; [2]*University of Pittsburgh School of Medicine, Pittsburgh, PA, USA*

Background Peritoneal fluid, in patients with carcinomatosis, constitutes a fluid phase tumor microenvironment that could contribute significantly to tumor progression in the peritoneal cavity. Little is known of the changes in cytokine or chemokine concentration (i.e., the secretome) along the spectrum from benign physiologic peritoneal fluid to fluid from patients with localized abdominal malignancy to those with frank carcinomatosis. In this study, we compare the peritoneal fluid secretome from participants in each of these categories to identify potential drivers of tumor growth and dissemination in the peritoneal fluid tumor microenvironment.

Methods In this pilot study, we compared the normal peritoneal secretome (n=5, derived from patients undergoing elective surgery for benign conditions) with that of abdominal cancer patients (colon, stomach, cholangial, liver, appendix, pancreas cancers), either with (n=29) or without (n=21) carcinomatosis. The peritoneal secretome of patients without carcinomatosis was also compared to that of their serum (n=22). The peritoneal fluid secretome was defined as quantitative assessment of cytokine and chemokine concentrations from fluid specimens, as determined using the Luminex 38plex panel plus IL-6Ralpha and TGF-beta.[1]

Results The secretomes of benign physiologic fluid and peritoneal fluid collected from patients with cancer but without carcinomatosis were indistinguishable, but differed from serum in having markedly upregulated FGF2 and IL1Ralpha concentrations. The secretome of peritoneal fluid from patients without carcinomatosis had higher FGF2(1983 pg/mL) than either serum (400-fold, p=0.000000) or malignant ascites (50-fold elevation, p=0.000002). However, the peritoneal fluid from patients with carcinomatosis had significantly elevated levels of GRO, EGF, EOTAXIN, TGFalpha, sCD40L, CCL22, CX3CL1, CXCL10, GM-CSF, TGFbeta, TNFalpha, VEGF, MCP3, MIP-1beta, IL-1beta, IL-6, IL-6Ralpha, IL-10 and IL-12.

Conclusions Physiologic peritoneal fluid contains markedly elevated levels of FGF2 and IL1Ralpha, which may contribute to tumor progression by driving the epithelial to mesenchymal transition or through down regulation of E-cadherin,[2] among other mechanisms. We identified characteristic secretome abnormalitites of peritoneal fluid derived from patients with carcinomatosis, compared with physiologic fluid or patients with localized cancers. The secretome profile described here could find utility both in developing biomarkers of advanced disease status and in identifying potential targets for directed immunotherapeutic interventions in patients with peritoneal malignancy.

1436 MODULATION OF CYTOKINE SECRETION AND MACROPHAGE DIFFERENTIATION IN A 3D HETEROTYPIC SPHEROID MODEL OF COLON CANCER

Jacqueline Bersano, Hiren Gosh, Eva Oswald, Kanstantsin Lashuk, Julia Schueler*. *Charles River Laboratories, Freiburg, Germany*

Background The tumor´s immunogenicity is modulated by the tumor microenvironment (TME), which mostly turns out to be immunosuppressive, thereby promoting disease progression. To better understand the crosstalk between tumor, immune and stromal cells we developed an in vitro system enabling the interaction of the different cell types in a 3D environment.

Methods We cultivated three different colorectal cancer cell lines HCT-116, HT-29 and CXF269, two fibroblast lines, human dermal fibroblasts (HDF) or cancer associated fibroblasts (CAFs) and macrophages from healthy donors as mono-, co- and triple cultures in a matrigel-collagen matrix in a 96-well format. Analysis of the secreted cytokines in the supernatant as well as the differentiation of the macrophages was performed after 10 days of culture. We analyzed 45 cytokines in duplicates by using a multiplex bead-based assay. The macrophage differentiation was determined by flow cytometry (FC) based on the expression of CD45, CD11b, CD86 and CD209.

Results The macrophages in monoculture displayed a M1/M2 ratio of 1.39 after 10 days of culture. The co-culture with HDF did not change the phenotype dramatically whereas the cell-cell contact will CAFs induced a marked increase in M1 leading to a ratio of 3.36. A similar diverse pattern was seen in co-culture with tumor lines. Whereas HT29 did not influence the ratio remarkably, HCT116 reduced the ratio to 1.14 and CXF269 increased the M2 fraction clearly, leading to a M1/M2 ratio of 0.85. The triple culture with CAFs presented an additive effect on the macrophage polarization: CAFs led to an increase in the M1 population which was most pronounced in HT29 and least distinct with CXF269. The triple culture with HDF supported the M2 population most prominent in the CXF269 (M1/M2 ratio: 0.77). The presence of fibroblasts induced an enhanced secretion of IL-6, CCL2 and CCL3 in all settings. All tumor lines secreted high levels of VEGF-A and SDF-1 in mono- and co-culture with fibroblasts. However, the secretion was down regulated in the presence of macrophages. Finally, the addition of macrophages to any co-culture induced an increase of IL-1Rα in the supernatant. A cluster analysis of the cytokine data defined two major clusters mainly separated by the presence or absence of macrophages.

Conclusions The modular nature of the 3D heterotypic spheroid model enables the deconvolution of the different players in the TME. This flexible mid throughput platform will hopefully help to shed more light into the complex role of tumor associated macrophages in cancer progression.

1437 SINGLE CELL PROFILING OF PANCREATIC DUCTAL ADENOCARCINOMA TUMOR MICROENVIRONMENT IN RESPONSE TO FLT3 LIGAND REVEALS MOLECULAR AND CELLULAR INTERACTION BETWEEN DENDRITIC CELL LINEAGE AND CANCER ASSOCIATED FIBROBLASTS

[1]Pratha Budhani*, [1]Brianna Flynn, [1]Robert Norgard, [1]Joshua Tagore, [1]Lucinda Thiede, [1]John Holt, [2]Shengyang Wu, [2]Chris Kang, [1]Xiaobin Wang, [1]Jessica Potts, [1]Charlie Cote, [1]Greg Peet, [1]Ruby Wasti, [1]Mohanapriya Kamalakannan, [1]Varenka Rodriguez DiBlasi, [1]Sarah O'Brien, [1]Abhishek Kashyap, [1]Kang Liu. [1]*Boehringer Ingelheim, Ridgefield, CT, USA*; [2]*Analytical Biosciences, Beijing, China*

Background Pancreatic ductal adenocarcinoma (PDAC) has an environment characterized by heterogeneity in cancer associated fibroblasts (CAF) as well as an immune desert phenotype. It is well-established that dendritic cells (DCs) which are often dysfunctional in the PDAC tumor microenvironment (TME), are crucial in priming and sustaining T cell immunity. It is speculated that this immune dysfunction is potentially caused by crosstalk between DCs or their progenitors with tumor or CAF, but this mechanism is not well characterized. Flt3L is known to drive expansion and mobilization of DCs, in particular, the cross-presenting DC1s into the tumor.

Methods We utilized a magnetic bead-based method to capture the tumor, immune and stromal components of the KPCY (Pdx-1-Cre, $KRAS^{G12D}$, $p53^{-/-}$, YFP^{+}) TME in response to Flt3L injection followed by scRNAseq profiling to examine overall changes.

Results As expected, Flt3L injection induced increased DC numbers in the TME. Interestingly we observed several genes downregulated in tumor cells and a change in the CAF subpopulation upon Flt3L treatment. Because tumor and CAF cells do not express Flt3, our observation suggests this change results from the cross-talk between Flt3-induced DC lineage with tumor and/or CAF subpopulations. Using differential expression of gene (DEG), pathway and ligand-receptor analysis, we characterized molecular interactions between Flt3L-responsive DC lineage with tumors and CAF cells in the TME.

Conclusions Our results highlight the impact of these DCs on tumors and TME stroma as an additional function to shape immune response, thereby providing a rationale to modify TME with Flt3 agonism.

1438 INTEGRATIVE ANALYSIS OF SINGLE CELL MULTIOMICS DATA USING DEEP LEARNING TO IDENTIFY IMMUNE RELATED BIOMARKERS IN A PATIENT DERIVED 3D EX VIVO TUMOROID PLATFORM

[1]Sarah Carl, [1]Juana Flores-Candia, [2]Jeremy Staub, [2]Jasmin D'Andrea, [2]Brittney Ruedlinger, [2]Kate Shapland, [2]Jared Ehrhart*, [2]Soner Altiok. [1]*Scailyte AG, Basel, Switzerland*; [2]*Nilogen Oncosystems, Tampa, FL, USA*

Background Our previous studies demonstrated that multiple types of omics data obtained from Nilogen's comprehensive 3D-EXplore ex vivo drug testing platform using tumoroids with intact tumor microenvironment prepared from unpropagated fresh patient tumor samples can reveal cellular mechanisms that are active in individual tumors. This approach allows classification of tumors into subtypes for response to immunotherapeutic drug treatments. Here we aimed to utilize Scailyte's cluster-free, unbiased, and highly sensitive AI platform ScaiVision to better understand the cellular and molecular mechanisms of cGAS-STING activation alone or in combination with an anti-PD-1 treatment to discover clinically relevant biomarker signatures.

Methods For the 3D-EXplore ex vivo platform, tumoroids measuring 150 µm in size were prepared from procured fresh tumor tissue of renal cell carcinoma (RCC) and colorectal carcinoma (CRC) patients. The study was approved by the Institutional Ethics Board, approval number Pro00014313. Tumoroids were generated using a proprietary mechanical process without any enzymatic digestion or propagation and were treated ex vivo with STING agonists ADU-S100 and 2'3'cGAMP alone or in combination with nivolumab. Treatment-mediated changes in the tumor immune microenvironment were analyzed using Cellular Indexing of Transcriptomes and Epitopes by sequencing (CITE-seq), multicolor flow cytometric analysis, and multiplex cytokine release assays.

Results Here we present the results from the integrative analyses of multiomic data generated from the treatment of fresh patient tumor samples in the ex vivo assays. To identify cellular and molecular mechanisms associated with ex vivo responses to the cGAS-STING pathway activation and PD-1/PD-L1 checkpoint blockade therapy we used a supervised machine learning algorithm (ScaiVision) that trains a convolutional neural network with a single layer to predict sample-level labels using single-cell data as inputs. This approach allowed an in-depth characterization of the tumor resident immune cell subsets in the patient tumoroids before and after ex vivo drug treatment to reconstruct cell-type-specific signaling responses to identify cell populations associated with response to immunotherapeutics ex vivo.

Conclusions Our results revealed that the ScaiVision platform allows the integration of high-parameter single-cell data together with multiple types of omics data derived from Nilogen's 3D-EXplore platform to better understand molecular and cellular mechanisms of drug mode of action that may allow the discovery of new clinically-relevant immune-related biomarkers to predict clinical outcome of immunotherapy.

Ethics Approval All tissues were collected under proper patient consent and the study approved by the Institutional Ethics Board, approval number Pro00014313

1439 TERMINALLY EXHAUSTED CD8$^+$TILS PROMOTE AGGRESSIVE CANCER STEM CELLS WHILE CONCURRENTLY EVADING ANTI PD1 THERAPY

[1]Sukanya Dhar, [1]Saurav Bera, [2]Kamalika Roy, [3]Abhipsa Sinha, [1]Anirban Sarkar, [1]Shayani Dasgupta, [1]Avishek Bhuniya, [1]Akata Saha, [1]Saptak Banerjee, [1]Neyaz Alam, [1]Manisha Vernekar, [2]Chiranjib Pal, [3]Dipak Dutta, [1]Rathindranath Baral, [1]Anamika Bose, [1]Mohona Chakravarti*. *[1]Chittaranjan National Cancer Institute, Kolkata, India; [2]West Bengal State University, Barasat, India; [3]CSIR Central Drug Research Institute, Lucknow, India*

Background Tumor-infiltrated CD8$^+$T cell (TIL) heterogeneity is serving as one of the major hurdles in successful PD1 therapy. According to recent reports, among two subpopulations of exhausted CD8$^+$TILs, (progenitor-exhausted, CD8$^+$T$_{PEX}$; terminally-exhausted, CD8$^+$T$_{TEX}$), CD8$^+$T$_{TEX}$ do not respond to anti-PD1 therapy.[1–3] However, functional status of intra-tumoral-CD8$^+$T$_{TEX}$ remains elusive. Whether and how they participate in tumor advancement holds immense clinical importance. Given the prominence of Cancer Stem Cells (CSCs) in establishing metastatic cancer progression by evading therapies, we became interested to study CD8$^+$T$_{TEX}$ behaviour in terms of CSC regulation.

Methods CD8$^+$T$_{TEX}$ (Lin$^-$PD1$^+$TCF1$^-$) and CSC (Lin$^-$CD44$^+$CD24$^-$CSCs) frequency and their co-relation in regards to tumor advancement were analysed in human carcinomas (n=33; from 22 breast and 11 ovarian carcinoma patients). Furthermore, MACS-isolated CD8$^+$T-cells from human-PBMC or murine-spleenocytes were repeatedly exposed to tumor-lysate and tumor-supernatant in presence of antigen-loaded DCs for 120h to obtain CD8$^+$T$_{TEX}$ (PD1$^+$TIM3$^+$TCF1$^-$CXCR5$^-$IFNγ^{low}) in-vitro. These CD8$^+$T$_{TEX}$ were co-cultured with MCF7, MDAMB-231 and 4T1 cells respectively to study the influence of CD8$^+$T$_{TEX}$ on CSCs. RT-PCR, colony-formation assay, matrigel-invasion-assay, tumor-sphere assay and in-vivo tumorigenicity assay with Crl:NU-Foxn1nu athymic nude mice were utilized to characterise CD8$^+$T$_{TEX}$ influenced CSCs. ELISA, Western-blot, flow-cytometry, immune-staining, pharmacological inhibition or genetic knockdown by in-vitro and in-vivo si-RNA silencing were used to study mechanism behind CD8$^+$T$_{TEX}$- CSC cell-interaction.

Results Screening of human primary tumors disclosed that CD8$^+$T$_{TEX}$ cells remain strongly enriched across cold (low-TIL frequency) advanced-carcinomas, compared to hot (high-TIL frequency) advanced-carcinomas ($p<0.001$). Additionally, CD8$^+$T$_{TEX}$ cells positively correlated with CSC frequency ($r = 0.8809$) throughout cold-advanced carcinomas; suggesting their interdependency on tumor advancement. Furthermore, in-vitro co-culture assay as well as in-vivo adoptive transfer of CD8$^+$T$_{TEX}$ resulted in increment of intra-tumoral CSC frequency. However, this upregulation was not brought down by anti-PD1 therapy ($p<0.001$). Additionally, CD8$^+$T$_{TEX}$-influenced-CSCs exhibited increased tumorigenic and metastatic potential in athymic-nude mice. They showcased invasive and migratory phenotype with long invadopodias by overexpressing CXCR4, MMP7 and Cofilin (figure 1). These CSCs remained sustained by overexpressing OCT4, SOX2, KLF4 and NANOG. Involvement of LAMP3/NRP1-VEGFR2 axis in CD8$^+$T$_{TEX}$-CSC crosstalk was also observed (figure 2).

Conclusions Cumulative results counsel against indiscriminate use of anti-PD1 therapy. Rather a prior screening of CD8$^+$TIL and CD8$^+$T$_{TEX}$ frequency in carcinoma patients would be beneficial. Additionally, LAMP3, NRP1 and VEGFR2 could be utilized as prospective therapeutic targets against CD8$^+$T$_{TEX}$-influenced aggressive CSCs at advanced carcinoma patients with cold-tumor stroma.

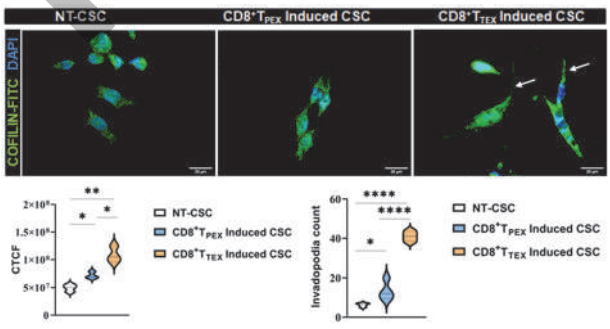
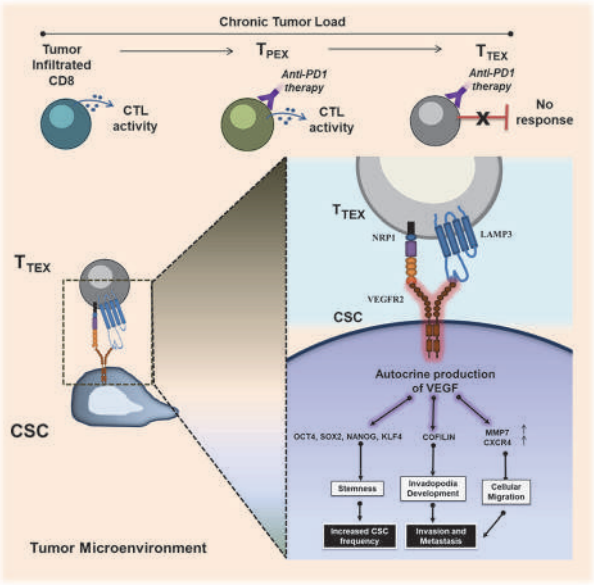
Approval numbers are CNCI-IEC-RB-2019-6, IAEC-1774/RB-15/2017/2 and IAEC-1774/RB-19/2017/15. All patients included gave informed consent before taking part in the study.



Abstract 1439 Figure 1 CD8+TTEX induce invasive CSC generation Representative immune-fluorescence micrographs at 100x magnification for CSCs stained with Cofilin-FITC. Invadiopodias are demarked by white arrows. Corrected total cell fluorescence intensity (CTCF) and number of invadopodias were quantified and displayed as violin graphs (mean± SD). Statistical alpha value was calculated from unpaired t-test (n=4).



Abstract 1439 Figure 2 Model proposing CD8+TTEX mediated aggressive CSC generation
Due to chronic tumor load, CD8TILs undergo terminal exhaustion and generate CD8+TTEX cells which does not respond to anti-PD1 therapy. These CD8+TTEX cells however take part in tumor advancement by generating an invasive and aggressive CSC variant through LAMP3/NRP1-VEGFR2 axis.

1440 ARGINASE-1 PEPTIDE-BASED VACCINE IS AN EXCITING APPROACH TO MODULATE THE TUMOR MICROENVIRONMENT AND DRIVE EFFICACY IN PRECLINICAL TUMOR MODELS

Marion Chapellier*, Marco Carretta, Ines Lecoq, Evelina Martinenaite, Tine Hannibal, Preeyam Patel, Brian Weinert, Alireza Alavi, Muhammad Al-Hajj, Ayako Pedersen. *IO Biotech, Copenhagen, Denmark*

Background Arginase-1 (ARG1) regulates tumor cells immune escape through various mechanisms in the tumor microenvironment (TME) and is being targeted experimentally in the clinic. However, selective and efficacious inhibitors of ARG1 remain elusive. Vaccination against TME targets have shown to be an exciting therapeutic approach where an IDO1/PD-L1 dual vaccine has shown substantial activity in early trials in melanoma[1] (and confirmatory Ph3 trial underway NCT05155254). We previously showed that vaccination against ARG1 increases anti-tumor activity preclinically.[2] Here we set out to develop a biological rationale for an ARG1 vaccine as a monotherapy or in combination with other immune therapies and understand the underlying mode of action of the treatment.

Methods ARG1 expression was examined by multiplex immunofluorescence in a tumor microarray (TMA) panel of cancer indications with a hyperplexed visualization of multiple markers on a single section. Vaccination was evaluated in mouse models expressing ARG1. Mice were inoculated with tumor cells and treated with ARG1 peptides. Tumor growth was monitored, organs and tumor samples were collected. Histopathological examination was performed on multiple tissues. Vaccine activity was determined per IFNgamma Elispot assay on splenocytes. Tumor samples were processed, RNA sequencing and flow cytometry analysis of the immune infiltrate were conducted.

Results The TMA analysis confirmed ARG1 expression in the TME and revealed that a distinct immune suppressive population of cells in the TME expresses it independently of IDO1/PD-L1 providing a rationale for combining the vaccines. ARG1 surrogate peptides of 20 amino acids ($ARG1_{261-280}$, $ARG1_{191-210}$) were identified and selected based on the induction of ARG1-specific IFNgamma recall responses in BALB/c or C57BL/6 animals. Both peptides demonstrated anti-tumor activity in vivo. This was associated with increased infiltration of CD45+cells, CD3+ and CD4+ T-cells at tumor site. The anti-tumor effect was enhanced when ARG1 treatment was combined with anti-PD-1 mAb, and/or in combination with a the dual IDO1/PD-L1 vaccine. Detailed efficacy results in the models will be discussed in addition to the cellular and molecular analysis of the tumors in the various cohorts and treatments elucidating the mode of action of the treatment.

Conclusions ARG1 is an attractive TME target and vaccination against it drove efficacy in vivo by increasing the recruitment of immune cells at tumor site thus changing from an immunosuppressive to a pro-inflammatory microenvironment. These data support the preclinical development of an ARG1 vaccine for the treatment of multiple solid tumors.

1441 A POTENT AND SELECTIVE SMALL MOLECULE ANTAGONIST OF CD73 ABSK051 REVERSES IMMUNOSUPPRESSION THROUGH REDUCTION OF ADENOSINE PRODUCTION

Haibing Deng, Wenqun Xin, Weiling Pan, Zhixuan Zhu, Mei Ning, Hongping Yu, Zhui Chen, Haiyan Ying*. *Abbisko Therapeutics, Shanghai, China*

Background CD73, an ecto-5-nucleotidase involved in ATP metabolism, converts AMP into adenosine, thereby plays a critical role in immunosuppression in tumor microenvironment. Overexpression of CD73 has been observed across cancer types and correlated with poor prognosis. Therefore, targeting CD73 enzymatic activity can potentially rescue the immunosuppression induced by adenosine and bring clinical benefits to cancer patients. Unlike antibodies, small molecule modulators may offer potential advantages in dosing regimen, tumor penetration, and others. In this study, we investigated the in vitro and in vivo function of ABSK051, a novel small molecule antagonist of CD73 discovered by Abbisko, and also its anti-tumor efficacy as a potent immune modulator.

Methods The effects of ABSK051 on adenosine production were evaluated using cell based luciferase assay. Its function in rescuing AMP induced immunosuppression was investigated by monitoring activation levels of CD8+ T cells. For in vivo studies, tumor-bearing syngeneic mice were treated with ABSK051 and its inhibition on plasma CD73 activity and tumor growth were measured. In addition, humanized tumor models were also developed using several human cancer cell lines and utilized to evaluate the efficacy of ABSK051

Results ABSK051 demonstrated strong in vitro inhibition of CD73 enzymatic activity, thereby effectively rescued the immune inhibition induced by adenosine. It also demonstrated in vivo anti-tumor efficacy as a single agent in various preclinical tumor models and in combination with other immune-oncology agents.

Conclusions Taken together, these data demonstrated desirable preclinical biological profile of ABSK051 against CD73 and in regulating tumor growth, paving the road for further development of it as a preclinical drug candidate and potential clinical evaluation as an immune agent for cancer patients.

1442 INVESTIGATING THE TUMOUR IMMUNE MICROENVIRONMENT OF BREAST IMPLANT ASSOCIATED ANAPLASTIC LARGE CELL LYMPHOMA USING SINGLE CELL RNA SEQUENCING

[1]Harini de Silva, [1]Niko Thio, [1]Piers Blombery, [1]Ella Thompson, [2]Anand Deva, [1]Miles Prince, [1]Paul Neeson, [1]Criselle DSouza*. [1]*Peter MacCallum Cancer Centre, Melbourne, Australia*; [2]*Macquarie University, Melbourne, Australia*

Background Breast implant-associated anaplastic large cell lymphoma (BIA-ALCL) is a newly recognised T cell lymphoma that occurs in women with textured implants and is mostly limited to the periprosthetic seroma space. However, it is not clear how this ALCL forms and whether the tumour microenvironment (TME) plays a key role in ALCL survival and proliferation in breast tissue. To address these issues, we investigated the immunobiology of both the ALCL and endogenous immune cells within the breast seroma from a cohort of patients.

Methods We established a multi-centre national cohort study, and received breast implant seroma samples [benign (n=10) and BIA-ALCL (n=23)] via cosmetic and reconstructive surgeons. We performed single cell CITEseq, RNAseq to characterise the endogenous immune cells and ALCL cells; and abTCRseq and TCRVb deep sequencing to explore their clonal relationship. Finally, we analysed the microenvironment by investigating the seroma cytokine and chemokine levels, and performed an interactome analysis to provide putative cell-cell interactions **(figure 1).** We also performed targeted sequencing of BIA-ALCL samples to define mutations present.

Results scRNAseq data showed ALCL cells clustered together for individual patients, however their gene expression profile was distinct between patients. ALCL cells expressed common gene signature genes such as BATF3, SERPIN family genes, TNFSFR8, and IL2RA; along with genes unique to each patient. Endogenous T cells from the BIA-ALCL seroma displayed an activated/exhausted phenotype, immune checkpoints and endogenous T cell clonal expansion. In contrast, benign seroma endogenous T cells had a Th1/Th17 profile and limited T cell clonal expansion. Myeloid clusters were abundant in the BIA-ALCL seroma, but not the benign seroma. TME studies showed a significant increase in BIA-ALCL seroma for cytokines IL13, TNF, IL10 and secretory-PDL1. The single cell interactome analysis described potential unique cell-cell interactions in the BIA-ALCL TME including tumour-tumour, tumour-myeloid DC and tumour-CD8$^+$ T effector memory cells. Mutational analysis revealed novel JAK1 mutations and STAT3 mutations along with chromosome 20 loss consistent with previous studies.

Conclusions BIA-ALCL cells are different between patients and from the endogenous immune cells. Furthermore, BIA-ALCL seroma is characterised by endogenous T cells with an exhausted profile and clonal expansion, increased IFN-g and TNF levels suggesting these T cells are responding to TME antigens. In addition, the BIA-ALCL TME has high levels of IL-13 and IL-10 which are generated via tumour-tumour and tumour-myeloid cell interactions.

Ethics Approval This study was approved by Peter MacCallum Cancer Centre human research ethics committee (Reference no. 44068) or by Macquarie University human research ethics committee (Reference No. 5201600427). Informed consent was obtained from all participating patients.

1443 SUPPRESSION OF HUMAN GAMMA DELTA T CELL ACTIVATION BY SOLUBLE FACTORS PRODUCED BY PANCREATIC DUCTAL CANCER ORGANOTYPIC CULTURE

Johnathan Ebben*, Nicholas Hess, Zachary Mayhew, Jeremy Kratz, Christian Capitini, Melissa Kinney. *University of Wisconsin-Madison, Madison, WI, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) is highly resistant to immunotherapies. Gamma delta (gdT) cells play a key role in driving immunosuppression within the tumor microenvironment.[1] In PDAC, the tumor microenvironment is heavily infiltrated with immunosuppressive gdT cells.[2] However, the mechanism by which circulating gd T cells acquire an immunosuppressive phenotype within the tumor microenvironment specific to PDAC remains unknown. We hypothesized that secretory cues produced by PDAC act on infiltrating gd T cells to drive immunosuppressive phenotypes.

Methods PDAC organoids were generated from surgical specimens obtained with IRB approval (UW-Madison B00000976). Organoids were cultured in defined media in serum-free conditions. Conditioned media was collected at passaging. Whole blood was collected, and samples were enriched for T cells (RosetteSep, Stem Cell Technologies), followed by magnetic gdT cell isolation. gdT cells were cultured in conditioned media from two separate patient-derived organoid lines, versus control base media for 72 hours. Cells were then activated with anti-CD3/CD28/CD2 beads in the presence of GolgiStop cocktail. These cells were subjected to intracellular cytokine phenotyping by flow cytometry.

Results After 72 hours of incubation in PDAC conditioned media, production of IFN-gamma and TNF-alpha, indicative of a Th1 antitumor phenotype, are significantly diminished (71% IFN-g+ in control vs 48% in PDAC1 media, 56% in PDAC2 media; $p<0.002$) in conditioned media cultured gdT cells versus control (figure 1B-C). In a separate series of experiments, we evaluated the specificity of this suppression. Interestingly, there is increased suppression of gdT activation relative to either CD4+ or CD8+ ab T cells, with 40% reduction in IFNg producing gdT cells versus 10% reduction in IFNg producing cells amongst CD4 and CD8+ abT cells (preliminary data).

Conclusions Our work demonstrates for the first time a specific effect of a secreted mediator produced by PDAC that preferentially drives gdT cell immunosuppression. We demonstrate that circulating gdT cells from healthy donors produce significantly less Th1 cytokines after TCR stimulation, following incubation in conditioned media derived from multiple, independent human PDAC organoids. Our next steps include scRNAseq of conditioned gdT cells as well as bulk RNAseq of PDAC organoids to identify ligand-receptor interactions between tumor and gdT cells, aiming to use proteomics approaches to validate and modulate these candidates in the tumor microenvironment. In the broader clinical context, this may suggest a new axis that drives immunosuppression in PDAC, with our work identifying new targets for therapeutic modulation.

Acknowledgements We are unspeakably grateful to the patients who agreed to donate tissue to establish pancreas ductal adenocarcinoma organoids that made this work possible.

1444 TARGETING SIALIC ACID ON STROMAL CELLS REVERSES T CELL SUPPRESSION IN THE COLORECTAL TUMOUR MICROENVIRONMENT A NEW TUMOUR STROMAL CELL IMMUNE CHECKPOINT

[1]Aideen Ryan*, [1]Oliver Treacy, [1]Kevin Lynch, [2]Kim De Veirman, [2]Karin Vanderkerken, [1]Laurence Egan, [1]Thomas Ritter, [1]Aisling Hogan, [3]Keara Redmond, [1]Sean Hynes, [3]Emma Kerr, [1]Michael O'Dwyer, [1]Philip Dunne, [1]Niamh Leonard, [1]Hannah Egan. *[1]NUI Galway, Human Biology Building, NUI Galway, Ireland; [2]Vrije Universiteit Brussel, Brussels, Belgium; [3]Queens University Belfast, Belfast, UK*

Background Hypersialylation of cancer cells induces an immunosuppressive microenvironment. The binding of sialic acid by siglec receptors expressed on immune cells initiates a downstream response via immunoreceptor tyrosine-based inhibitory motif (ITIM) signalling. Cancer associated fibroblasts (CAFs) in the colorectal cancer (CRC) microenvironment are highly immunosuppressive and associated with poor survival. The role of sialyation in stromal cell-mediated immunosuppression, however, is unknown. Here, we investigated if sialylation of CAFs contributed to their potent immunosuppressive properties.

Methods Tumour cell secretome (TCS) from multiple CRC cell lines was used to condition primary human and mouse bone marrow-derived stromal cells, as CAF precursors. Normal and CAFs were isolated from colon tumour resections. Stromal cells were cultured with stimulated splenocytes (mouse) or PBMCs (human) and their immunosuppressive properties were assessed by flow cytometry. An in vivo mouse model of CT26 CRC was used to assess the role of highly sialylated stromal cells in tumour development. Mice were injected subcutaneously with CT26 cells alone, or co-injected with TCS-conditioned stromal cells, either control or de-sialylated. 14 days post induction, tumous, draining lymph nodes and spleen were assessed for frequency and expression of T cell activation markers.

Results Tumour conditioning resulted in significantly higher expression of both α2,6-linked sialic acid and specific Siglec ligands on stromal cells. CAFs were significantly more sialylated than stromal cells isolated from adjacent normal associated tissue (NAFs) (figure 1). Following co-culture, CAFs induced significantly higher levels of CD8+ T cells with an exhausted phenotype as determined by TIM-3 and PD-1 expression. Siglec-7 and -9 receptors were induced by CAFs on CD8 T cells. Furthermore, de-sialylation of CAFs, specifically, prior to co-culture resulted in a significant reduction in exhausted CD8+ T cells and attenuation of their immunosuppressive ability (figure 2).

14d post tumour induction in vivo, mice with TCS-conditioned, stromal-dense tumours had significantly fewer activated CD4+ and CD8+ CD25-expressing T cells, both intratumourally and distally in the draining lymph nodes and spleen. They also had low levels of cytotoxic granzyme B-expressing CD8+ T cells. Interestingly, this suppression was sialylation-dependent. De-sialylation of TCS-conditioned stromal cells led to restoration of activated T cell levels in tumours and peripheral lymphoid tissues, as well as a marked increase in cytotoxic T cells (figure 3).

Conclusions These results demonstrate, for the first time, that tumour stromal cells suppress activated T cells through sialic acid dependent interactions. We show that targeting stromal cell sialylation may represent a novel immune checkpoint to reactivate anti-tumour immunity.

Ethics Approval The animal study was approved by the Animals Care Research Ethics Committee of the National University of Ireland, Galway (NUIG) and conducted under individual and project authorisation licenses from the Health Products Regulatory Authority (HPRA) of Ireland (AE19125/P077). The study using human samples was approved by University Hospital Galway Ethics committee under an ethically approved protocol (Clinical Research Ethics Committee, Ref: C.A. 2074).

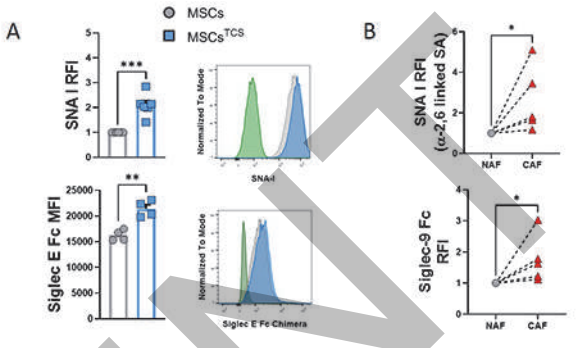

Figure 1. Exposure of stromal cells to tumour cell secretome or microenvironment increases sialic acid and specific Siglec ligand expression. (A) Mouse bone marrow-derived mesenchymal stromal cells (MSCs) have elevated SNA I (α2,6 sialic acid) and Siglec E ligand expression following exposure to tumour cell secretome from CT26 murine colon cancer cells (MSC^{TCS}). Isotype control is shown as green histogram. (B) Cancer-associated fibroblasts (CAFs) isolated from colorectal cancer patient biopsies express higher levels of SNA I and Siglec 9 ligand compared to fibroblasts isolated from non-cancerous (NAF), adjacent intestinal tissue. Data are mean ± SD; *p < 0.05, **p < 0.01, and ***p < 0.001 using (A) unpaired t-test and (B) ratio paired t-test. n = 4 biological replicates.

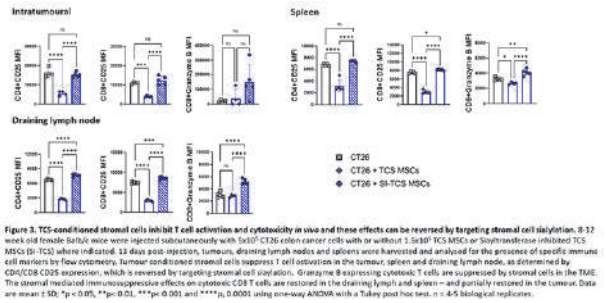
Abstract 1444 Figure 2 CAFs induce an exhausted phenotype in CD8 + T cells which is reversible by de-sialylation. (A) Schematic overview depicting the process of NAFs and CAFs isolation. (B) Frequency (%) of CD8+PD-1+ and CD8+PD-1+Tim-3+ T cells after co-culture with NAFs or CAFs. (Ci) Frequency (%) of CD8+Siglec-7+ T cells after co-culture with NAFs or CAFs. Frequency (%) of CD8+Siglec-7+ T cells after co-culture with NAFs (Cii) or CAFs (Ciii) pre-treated or not with a sialyltransferase inhibitor (SI). (Di) Frequency (%) of CD8+Siglec-9+ T cells after co-culture with NAFs or CAFs. Frequency (%) of CD8+Siglec-9+ T cells after co-culture with NAFs (Dii) or CAFs (Diii) pre-treated or not with SI. Data are mean ± SD; *p < 0.05 and **p< 0.01 using (B, Ci and Di) one-way ANOVA with a Tukey post hoc test and (Cii, Ciii, Dii and Diii) a ratio-paired t-test. n = 3-4 biological replicates.

Ci and Di) one-way ANOVA with a Tukey post hoc test and (Cii, Ciii, Dii and Diii) a ratio paired t test. n = 3-4 biological replicates



Abstract 1444 Figure 3 TCS-conditioned stromal cells inhibit T cell activation and cytotoxicity in vivo and these effects can be reversed by targeting stromal cell sialylation. 8-12 week old female Balb/c mice were injected subcutaneously with 5x105 CT26 colon cancer cells with or without 1.5x105 TCS MSCs or Siayltransferase inhibited TCS MSCs (SI-TCS) where indicated. 13 days post-injection, tumours, draining lymph nodes and spleens were harvested and analysed for the presence of specific immune cell markers by flow cytometry. Tumour conditioned stromal cells suppress T cell activation in the tumour, spleen and draining lymph node, as determined by CD4/CD8 CD25 expression, which is reversed by targeting stromal cell siaylation. Granzyme B expressing cytotoxic T cells are suppressed by stromal cells in the TME. The stromal mediated immunosuppressive effects on cytotoxic CD8 T cells are restored in the draining lymph and spleen – and partially restored in the tumour. Data are mean ± SD; *p < 0.05, **p< 0.01, ***p< 0.001 and ****p, 0.0001 using one-way ANOVA with a Tukey post hoc test. n = 4-5 biological replicates.

[1]Ohio State University Comprehensive Cancer Center, Columbus, OH, USA
[2]*The Ohio State University College of Medicine, Columbus, OH, USA***Background** Immune checkpoint inhibition (ICI) has been established as an essential treatment for lung and other cancers. Preclinical studies revealed that DNA-demethylating agents induced type I interferon (IFN-I) response and primed the tumor microenvironment (TME) to enhance antitumor immunity.[1] [2] However, this promising effect has not been successfully demonstrated in clinical trials of combined treatments of ICI and DNA hypomethylation agents in lung cancer.[3] We hypothesize that azacytidine (AZA), a DNA hypomethylation agent and a broad-spectrum epigenetic programmer, might inevitably also activate key immune suppression mediator(s). We demonstrated that absent melanoma 2 (AIM2), a DNA sensing component of inflammasome, negatively impacts AZA-induced antitumor immunity in non-small cell lung cancer (NSCLC) by modulating IFN-I response and T effector cell tumor infiltration.

Methods We tested gene expression upregulated by AZA in lung cancer cell lines and used genetic modeling to identify the mechanism mediating AZA-induced AIM2 expression. Aim2-deficient ($Aim2^{-/-}$) tumor cells (CMT167 and LLC) were established with the CRISPR/Cas9 system. We adopted an immune-competent syngeneic mouse tumor model to investigate the impacts of AIM2 on TME and tumor growth. We measured tumor growth and analyzed tumor samples with flowcytometry (FCM) and immunohistochemistry staining (IHC).

Results AIM2 expression was highly synergistically induced by AZA and IFN-γ in multiple human and mouse lung cancer cell lines. We demonstrated that AZA upregulated AIM2 expression through a RNA sensing mechanism. Analysis of AIM2 expression in 1925 NSCLC patients with KM-Plotter (https://kmplot.com/analysis/)[4] showed that high AIM2 expression was associated with significantly shorter overall survival in NSCLC. We showed that AZA and IFN-γ induced IFN-I response was enhanced in $Aim2^{-/-}$ CMT167 cells comparing to $Aim2^{+/+}$ cells. Using $Aim2^{-/-}$ and $Aim2^{+/+}$ CMT167, and the immune-competent syngeneic mouse model, AZA treatment induced significant growth suppression of $Aim2^{-/-}$ tumors, but not $Aim2^{+/+}$ tumors. FCM of the tumor tissue demonstrated that the number of CD8+ T cells was significantly increased after AZA treatment in both $Aim2^{-/-}$ and $Aim2^{+/+}$ tumors, whereas IHC revealed AZA promoted significantly more CD8 + T cell infiltration into the TME in $Aim2^{-/-}$ tumors than in $Aim2^{+/+}$ tumors. We demonstrated that CD8 depletion negated AIM2's effect on AZA-treated tumor growth in vivo and indicated that the impact of AIM2 on tumor growth would depend on CD8+ T cells.

Conclusions AIM2 is a key negative regulator for AZA-induced antitumor immunity and a potential novel therapeutic target in optimizing epigenetic and immune therapy in NSCLC.

1446 MULTIPLEXED ION BEAM IMAGING IDENTIFIES B-CELL ENRICHMENT IN THE RHAMM-HIGH INVASIVE NICHE OF BREAST CANCER

[1]Yuyu He*, [1]Grant Barthel, [2]Raghav Padmanabhan, [1]Colleen Forster, [1]Hanna Root, [2]Mate Nagy, [2]Stanislaw Nowak, [1]James McCarthy, [1]Kathryn Schwertfeger, [1]Andrew Nelson.
[1]University of Minnesota, Minneapolis, MN, USA; *[2]Ionpath Inc, Menlo Park, CA, USA*

Background Receptor for hyaluronan (HA) mediated motility (RHAMM) has been shown to work cooperatively with CD44 to mediate tumor progression,[1] but its specific roles in breast cancer are still unclear. In our previous studies, we have shown tumor cell RHAMM deletion significantly inhibits cancer progression in xenograft models and that RHAMM is heterogeneously expressed within human breast tumors.[2] We propose that focal RHAMM upregulation creates an invasive niche and have identified an RHAMM-dependent signature in this niche that is associated with poor prognosis of breast cancer patients.[2] Importantly, we found that Type II Interferon signaling and MHC Class I & Class II Antigen Presentation pathways are co-enriched in the RHAMM high invasive niche. This indicates that RHAMM might be involved in regulating immune responses. Herein we characterize the immune infiltrates associated with the RHAMM high invasive niche using a mass spectrometry-based proteomic imaging technique.

Methods FFPE tissues from 5 breast cancers were analyzed by multiple ion beam imaging (MIBI). Sections were stained with 20 antibodies simultaneously, including biomarkers to define immune cell phenotypes. Fields of views (FOVs) were selected from RHAMM high regions and RHAMM low regions. Novel machine-learning-based algorithms were applied to segment the images into spatially resolved single-cell data and to classify immune cell populations in RHAMM-high and RHAMM-low regions.

Results In triple-negative breast cancer (TNBC), the RHAMM-high tumor invasive margin (TI-high) shows a high level of intra-tumoral immune cells compared to the RHAMM-low tumor core (TC-low), wherein immune cells are largely restricted to the peri-tumoral stroma (figure 1). The RHAMM-low invasive margin (TI-low) is fibrotic and only sparsely populated by macrophages. Segmented single-cell data from our novel machine learning-based algorithms show high levels of infiltrating B cells in the TI-high region (figure 2A-B). The invasive margin overall is characterized by higher levels of cytotoxic T-cells, T-helper cells, and macrophages vs. the core (figure 2C-F). Notably, the B-cell-rich TI-high region has fewer cytotoxic T cells than the TI-low region.

Conclusions Our data highlights potentially novel interactions between RHAMM expression/function and B-cell infiltrates in TNBC. Given the dynamic roles of B-cells in cancer immunology,[3] this suggests new possible avenues for immune modulation to inhibit RHAMM-supported breast cancer progression. On-going work is confirming this linkage in additional TNBC and expanding the analysis to other molecular subtypes of breast cancer.

1447 A 30 PDX PANEL OF 3D IN VITRO TUMOR MODELS IDENTIFIES RESPONDERS TO PEMBROLIZUMAB AND SOLITOMAB

http://dx.doi.org/10.1136/jitc-2022-SITC2022.1447

[1]Kolin Hribar*, [1]Bin Xue, [1]Christopher Harrod, [2]Julia Schuler. [1]*Cypre Inc, South San Francisco, CA, USA*; [2]*Charles River Laboratories, Freiburg, Germany*

Background Immunotherapies are emerging as a novel approach to combat cancer. Among them, checkpoint inhibitor treatment has found success in a subset of cancer patients by reversing T cell dysfunction and unleashing their cytolytic potential in the immunosuppressive tumor microenvironment (TME).[1] Nevertheless, many tumors which constitutively express these targets fail to respond to checkpoint inhibitors due to a range of issues – lack of T cell infiltrate, alternative dysfunction pathways, exhaustion and others.[2] Thus, there is a critical need to assay antitumor effects of novel immunotherapies or combinations across a range of target expression status and tumor indications. Here, we describe a 3D Tumor Panel of 30 patient-derived xenograft (PDX) in vitro models for rapid and scalable screening of immunotherapy. The models incorporate tumors cells, fibroblasts, and peripheral blood monocytes (PBMCs) in a hydrogel matrix to recreate the complex TME and are screened for antitumor effects using high content image analysis.

Methods Thirty PDX-derived tumor cell lines and human dermal fibroblasts (HDF) were grown in a hydrogel matrix[3] in 96-well plates. The PDX histotypes included lung, renal, colon, gastric, breast, head and neck, liver, uterus, pancreatic, pleura-mesothelioma, sarcoma, melanoma, and ovary. PBMCs along with test compounds – Pembrolizumab (anti-PD-1) and Solitomab (EpCAM/CD3 bispecific antibody) – were later added to wells in a six-dose, serially diluted fashion. Response was detected at day four endpoint using high content image analysis of tumor size (Hoechst nuclear stain) and killing (DRAQ7 cell death and Caspase 3/7 apoptosis markers).

Results A subset of tumors responded to Pembrolizumab after four days of treatment, where the strongest responders resided in colon, lung and renal cancer. Interestingly, Solitomab responded in pancreatic tumors where Pembrolizumab failed to respond, however, oppositely, Solitomab did not respond in 75% of renal tumors on the Panel. In both compounds, antitumor effect was principally observed by tumor size and total tumor area reduction.

Conclusions A robust and diverse 3D PDX tumor panel comprising various solid tumor indications was developed in a hydrogel matrix platform. The PDX cells were grown along with fibroblasts and PBMCs to mimic the tumor, stromal and immune compartments of the TME. Endpoints including tumor size and killing highlighted PDX responders to both Pembrolizumab and Solitomab. These data highlight the ability to screen various immunotherapy compounds in a standardized 3D PDX in vitro panel for determining antitumor effect in drug discovery and translational research to enhance patient outcomes.

1448 ALTERED MYELOID MEMORY FUNCTION BY BMP SIGNALING IN BREAST CANCER BONE METASTASES

[1]Claire Ihle*, [1]Desiree Straign, [2]Johana Canari, [1]Kathleen Torkko, [1]Kathryn Zolman, [1]Erin Smith, [1]Philip Owens. [1]*University of Colorado Anschutz Medical Campus, Aurora, CO, USA*; [2]*Case Western Reserve University, Cleveland, OH, USA*

Background Metastatic breast cancer (mBC) patients exhibit a 5-year survival rate of only 29% and metastasis most commonly occurs in the bone.[1 2] Myeloid progenitors in the bone marrow can undergo trained innate immune responses, resulting in long-lasting inflammatory myeloid memory.[3 4] Myeloid memory has been shown to promote anti-tumorigenic myeloid functions in the tumor microenvironment (TME).[5 6]. The TME in bone includes unique myeloid cells which are dynamically regulated by bone morphogenetic proteins (BMPs).[7 8] We investigated myeloid memory in the context of BMP signaling in the mBC bone TME. Identifying the driver of myeloid functions distinct to mBC bone metastases will advance the understanding of potential immunotherapies to overcome incurable mBC bone lesions.

Methods A cohort of human mBC bone metastases and matched patient primary tumors and bone metastases were assembled and profiled. Gene expression analysis was performed on patient bone metastases and matched primary tumors using nCounter immune-oncology gene expression probes. Clinical bone metastasis regional protein expression was analyzed with GeoMx Digital Spatial Profiling (DSP). Single cell protein expression and spatial analysis was measured in matched patient primary tumors and bone metastases with Akoya Polaris panels. Syngeneic mouse models of MMTV-PyMT orthotopic tumors and intratibial bone metastases were treated with beta-glucan to induce trained innate immunity and/or LDN-193189-2HCl to inhibit BMP signaling. Mouse model readouts included tumor measurements, mBC progression by histology and circulating blood analysis, and myeloid memory function by circulating blood and Akoya Polaris analysis.

Results Differential nCounter gene expression analysis of clinical mBC bone metastases revealed a subset of patient samples with a high myeloid gene signature. High myeloid gene signature patients exhibited enhanced inflammatory gene pathways and BMP signaling. Regional DSP and single cell Polaris protein expression analysis of this patient cohort showed elevated myeloid cell infiltration and heterogeneity as well as myeloid memory phenotypes in the high myeloid gene signature samples. Analysis of matched patient primary tumor and bone metastases with nCounter gene expression panels exhibited enhanced BMP signaling and myeloid cell infiltration in bone samples compared to primary tumors. Syngeneic mouse models of mBC showed beta-glucan induced myeloid memory restricted primary tumor growth. mBC mouse models of bone metastases treated with beta-glucan and LDN-193189-2HCl revealed BMP signaling is required for myeloid memory anti-tumor functions in bone metastases.

Conclusions Distinct bone metastasis patients exhibited myeloid memory and BMP signaling which could allow for precision immunotherapy treatments to prevent myeloid suppression in mBC.

1449 LEVERAGING CRISPR CAS9 SCREENING PLATFORM FOR DISCOVERY OF NOVEL TUMOR INTRINSIC PHAGOCYTOSIS MODULATORS

Grace Trombley*, Chengyin Min, Lei Ji. *Tango Therapeutics, Cambridge, MA, USA*

Background Targeting "don't eat me" signaling has achieved profound responses in clinal trials for hematologic malignancies, highlighting the potential therapeutic value of macrophage-mediated phagocytosis for cancer treatment. In recent years, CRISPR-Cas9 based in vitro co-culture screens have significantly expanded our knowledge of the key tumor-intrinsic mechanisms mediating cytotoxic lymphocyte killing. However, the interactions between tumor cells and macrophages remain elusive. To illuminate the tumor-intrinsic biology governing the interactions between tumor cells and macrophages, we developed both positive and negative screening strategies, and deployed multiple primary bone marrow-derived macrophages (BMDM) or macrophage cell line-based co-culture screens.

Methods DLD1 and MDA-MB-231 cancer lines were infected with a whole-genome CRISPR-Cas9 library and co-cultured with Raw264.7 or J774A.1 in the presence or absence of the therapeutic antibodies magrolimab or cetuximab. MC38 syngeneic cancer cells were infected with a library of 3000 immune-related genes and co-cultured with primary BMDM. For negative selection, the macrophages were selectively killed off post co-culture and the tumor cells were collected for next generation sequencing (NGS) and statistical analysis. For positive selection, macrophages and tumor cells were fully dissociated from the plate post co-culture, and the mixture of cells was subjected to a CD11b positive selection column. Macrophages and tumor cells were enriched separately for downstream analysis.

Results Bioinformatic analysis revealed that CD47 knockout in tumor cells strongly sensitized macrophage-mediated clearance of target cells both from naïve and cetuximab-treated conditions. Furthermore, CD47 or EGFR knockout conveyed growth advantage in co-culture upon treatment with magrolimab or cetuximab, respectively. For the positive screen, we developed a method to sequence bar-coded DNA from tumor cells engulfed by macrophages. Consistently, CD47 sgRNAs were significantly enriched inside macrophages in the naïve condition and were depleted upon treatment with magrolimab. Together, these findings demonstrated the robustness of our phagocytosis-based CRISPR screening platform. In additional to validating the role of CD47 in this system, discovered and validated a group of novel tumor intrinsic regulators of macrophage-mediated phagocytosis.

Conclusions We successfully established and implemented multiple macrophage and tumor cell co-culture screening platforms, and systematically revealed tumor intrinsic regulators of phagocytosis, uncovering multiple known and novel therapeutic targets regulating vulnerability of tumor cells to macrophage-mediated phagocytosis. Our proprietary high-throughput phagocytosis CRISPR screening platform provides an unbiased and rapid solution to study macrophage and tumor cell interactions and discover novel targets for cancer therapy.

1450 TGFβ DEPENDENT LRRC15$^+$ MYOFIBROBLASTS DICTATE THE TUMOR FIBROBLAST SETPOINT TO PROMOTE CANCER IMMUNOTHERAPY RESISTANCE

Justin Shyer, Akshay Krishnamurty*, Minh Thai, Vineela Gandham, Matthew Buechler, Rachana Pradhan, Soren Muller, Shannon Turley. *Genentech, South San Francisco, CA, USA*

Background Single cell transcriptomics has led to the generation of large-scale atlases to understand cellular heterogeneity across both healthy and diseased tissues at the highest resolution. Such atlases have allowed for in silico inferences of fibroblast ontogeny and function, but without in vivo substantiation are limited in their utility to inspire novel fibroblast-directed therapies to improve disease outcome. In cancer, single cell studies identified the emergence of a myofibroblast population, in both mice and humans, uniquely marked by a highly restricted leucine rich repeat containing protein, LRRC15. This cancer-associated myofibroblast population expresses a multitude of extracellular matrix (ECM) associated and immunosuppressive genes. Clinically, high expression of an LRRC15$^+$ CAF gene signature in bulk RNAseq data from cancer patients correlated with lack of response to anti-programmed death ligand-1 (aPDL1) checkpoint blockade therapy. It remains unclear if LRRC15$^+$ CAFs are the cause of this lack of response, or if they represent a read-out of tumor-intrinsic features driving the association. Also missing are in vivo substantiation of the cellular and molecular signals driving LRRC15$^+$ myofibroblast development and the direct impact LRRC15$^+$ CAFs have on anti-tumor immunity.

Methods To address these gaps, we paired newly developed preclinical genetic tools in murine tumor models of pancreatic cancer with a large clinical dataset of human stromal cell-sorted expression data from 159 cancer patients across 13 tumor types to understand LRRC15$^+$ CAF development and function.

Results In mouse models of pancreatic cancer, we provide in vivo genetic evidence that TGFβR2 signaling in healthy Dermatopontin (DPT)$^+$ universal fibroblasts is essential for development of tumor-associated LRRC15$^+$ myofibroblasts. Analysis of tumors from 159 patients across 13 indications revealed a conserved axis from universal fibroblasts to LRRC15$^+$ myofibroblasts. This axis is the predominant driver of fibroblast lineage diversity in human cancers. Using newly developed Lrrc15-Diphtheria toxin receptor knock-in mice to selectively deplete LRRC15$^+$ CAFs, we show loss of this population markedly reduced total tumor fibroblast content and recalibrated the CAF composition towards universal fibroblasts. This, in turn, relieved direct suppression of tumor-infiltrating CD8$^+$ T cells to enhance their effector function and significantly augmented tumor regression in response to anti-PDL1 immune checkpoint blockade.

Conclusions Collectively, these findings demonstrate that TGFβ-dependent LRRC15$^+$ CAFs dictate the tumor-fibroblast setpoint to promote tumor growth, directly suppress CD8$^+$ T cell functionality, and limit responsiveness to checkpoint blockade. Development of treatments that restore the homeostatic fibroblast setpoint by diminishing pro-disease LRRC15$^+$ myofibroblasts may improve patient survival and response to immunotherapy.

1451 THE IMPACT OF THE TUMOR MICROENVIRONMENT ON B CELL INFILTRATE AND TERTIARY LYMPHOID STRUCTURES IN HIGH GRADE SEROUS OVARIAN CANCER PATIENTS

[1]Ian MacFawn*, [1]Ayana Ruffin, [2]Sheryl Kunning, [1]Grant Magnon, [2]Rinda Soong, [3]Caleb Lampenfeld, [1]Huda Atiya, [2]Taylor Orellana, [1]Lan Coffman, [1]Tullia Bruno. *[1]University of Pittsburgh, Pittsburgh, PA, USA; [2]UPMC, Pittsburgh, PA, USA; [3]Other, Pittsburgh, USA*

Background B cell infiltrate is a common feature of High Grade Serous Ovarian Cancer (HGSOC) and ~15% of patients contain B and T cell-rich tertiary lymphoid structures (TLS) which organize adaptive immunity and correlate with immunotherapy response in other cancer types. Increased B cells, plasma cells, and TLS correlate with improved prognosis in HGSOC. Sadly, current immunotherapies have exhibited poor response in ovarian cancer (~10%), highlighting the need for synergistic or complementary strategies. This research aims to identify underlying stromal and tumor-intrinsic factors promoting TLS formation and maturation in the ovarian tumor microenvironment. We hypothesize that pro-tumorigenic cancer associated mesenchymal stem cells (CA-MSC) hinder TLS, while BRCA mutant tumors promote TLS via DNA damage response. Increasing number and maturity of TLS could boost the poor response of HGSOC patients to immunotherapy.

Methods HGSOC clinical samples were obtained with patient consent through the Pitt Biospecimen Core and clinician collaboration. Original Vectra MoTIF multiplex immunofluorescence panels were designed to capture immune phenotypes and consensus markers of TLS maturity. Digital image analysis was used to analyze TLS presence and maturity and CA-MSC to MSC ratios. These features are correlated with clinical annotations. Digital Spatial Profiling (DSP) using whole transcriptome libraries was conducted on n=16 HGSOC samples to provide a spatially resolved transcriptional signature of TLS, B cells, other immune cells and stroma. Analysis was performed in collaboration with the HCC Cancer Bioinformatics Services.

Results We report the development of a new TLS scoring strategy which relies on multiplex immunofluorescence and spatial transcriptomics. This approach was applied to a large cohort of HGSOC patient samples. Using multiplex immunofluorescence panels, we report the frequency, composition and maturity of TLS across HGSOC anatomical sites (fallopian tube, ovary, omentum), noting an unexpected enrichment of mature structures in tumors residing in the fallopian tubes. Additionally, this analysis reveals a role for BRCA mutations in TLS dynamics. We also quantified CA-MSC burden within tumors using a novel multiplex panel, allowing correlation of CA-MSC to MSC ratio with TLS presence. Complementing this imaging data, we used spatial transcriptomics (DSP) to produce highly precise transcriptional signatures of TLS, TLS-resident versus non-resident B lymphocytes, and TLS-adjacent versus TLS-distal stromal signatures.

Conclusions This work contributes a comprehensive and widely applicable TLS scoring strategy. Its application reveals stromal and tumor-intrinsic factors involved with TLS maturation, revealing plausible strategies for promoting the development of these anti-tumor structures, with the ultimate goal of increasing immunotherapy efficacy, and extending patient survival.

1452 IMAGING MASS CYTOMETRY IDENTIFIES NOVEL NATURAL KILLER CELL INTERACTIONS IN THE PANCREATIC DUCTAL ADENOCARCINOMA TUMOR MICROENVIRONMENT

[1]Zoe Malchiodi*, [1]Ivana Peran, [2]Elana Fertig, [2]Won Jin Ho, [1]Robert Suter, [2]Ludmila Danilova, [2]Atul Deshpande, [1]Sandra Jablonski, [1]Louis Weiner. *[1]Georgetown University, Washington, DC, USA; [2]Johns Hopkins University, Baltimore, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) has a 5-year survival rate of less than 10%,[1-3] which is due in part to its dense desmoplastic and immunosuppressive stroma, caused by cancer-associated fibroblasts (CAFs).[4-6] T cell function has been extensively explored in many cancers; however, natural killer (NK) cells of the innate immune system are relatively understudied in PDAC. Interestingly, we have previously shown that fibroblasts express known NK cell ligands and hypothesized that CAFs interact with NK cells as a potential immunosuppressive mechanism in PDAC.[7] To further examine immune-stromal cell interactions in the PDAC tumor microenvironment (TME), we utilized Imaging Mass Cytometry (IMC), a novel multiplex imaging system that uses up to 40 metal-conjugated antibody markers to gain information of both tissue structure and single-cell data to conduct higher order proteomic single cell analysis.[8] This novel technology will provide a deeper understanding of the immune architecture in PDAC.

Methods We designed a 34 metal-conjugated antibody panel for known immune, epithelial, and stromal cells, and various immune synapses, cytokines/chemokines, and activation markers. IMC was performed on a human PDAC tissue microarray generated at the Lombardi Comprehensive Cancer Center. IMC image data was pre-processed, segmented, and feature extracted to generate single-cell data,[9] and downstream analysis was performed using R. Single cells were clustered using Seurat-based clustering approaches to identify known cell populations based on the immune, epithelial, and stromal cell antibody markers. Identified cell clusters were spatially annotated on IMC images using the cytomapper R package.[9]

Results IMC images and single-cell analysis preliminarily identified that NK cells are: 1) present within the PDAC TME and 2) surprisingly, co-localize with malignant PDAC cells. This has not been previously reported.

Conclusions Using IMC, we have identified potentially novel interactions between NK cells and malignant epithelial cells in PDAC. Downstream cell neighborhood analysis will reveal further details on immune-stromal interactions in the PDAC TME and identify potential cell populations in further exploit in PDAC.

1454 MULTIOMICS AND MULTIMODAL ANALYSIS APPROACH TO CONSTRUCT A DIFFUSE LARGE B CELL LYMPHOMA ATLAS OF TUMOR MICROENVIRONMENT FOR PREDICTIVE MODELING

[1]Mike Mattie, [2]Regis Perbost, [2]Sarah Turcan, [2]Corinne Danan, [3]Frederick Locke, [4]Sattva Neelapu, [5]David Miklos, [6]Caron Jacobson, [7]Lazaros Lekakis, [8]Yi Lin, [9]Armin Ghobadi, [1]Jenny Kim, [1]Zixing Wang, [1]Allen Xue, [1]Simone Filosto, [1]Nathalie Scholler, [10]Jérôme Galon*. *[1]Kite, a Gilead Company, Santa Monica, CA, USA; [2]Veracyte, Marseille, France; [3]Moffitt Cancer Center, Tampa, FL, USA; [4]MD Anderson Cancer Center, Houston, TX, USA; [5]Stanford University School of Medicine, Stanford, CA, USA; [6]Dana-Farber Cancer Institute, Boston, MA, USA; [7]University of Miami Health System, Sylvester Comprehensive Cancer Center, Miami, FL, USA; [8]Mayo Clinic, Rochester, MN, USA; [9]Washington University School of Medicine, St. Louis, MO, USA; [10]Veracyte, INSERM, Sorbonne Université, Université de Paris, Centre de Recherche des Cordeliers, Equipe Labellisée Ligue Contre le Cancer, Laboratory of Integrative Cancer Immunology, Marseille, Paris, France*

Background Expansion of therapeutic strategies against diffuse large B-cell lymphoma (DLBCL) offers new opportunities to fight aggressive non-Hodgkin's lymphoma. To unveil mechanisms driving cancer evolution and tumor immune contexture from a personalized medicine and diagnostic assay perspective, we sought to build a first-in-class reference database. Using a high-quality testing and innovative multimodal and integrative approach, the first Veracyte Biopharma Atlas for DLBCL evaluated thousands of parameters across more than 150 pre-treatment DLBCL lesions and enabled us to precisely map the spectrum of tumor microenvironments across samples and to establish a robust unsupervised descriptive model. By projecting new specimens associated to relevant clinical information and sample data onto the referential map, Atlas analysis provides a detailed description of the tumor microenvironment and facilitates the development of predictive and prognostic tools.

Methods Veracyte Biopharma Atlas characterizes the tumor microenvironment by analyzing information from 3 different modalities: (i) proteomics (Brightplex® panels), (ii) transcriptomics (RNA sequencing and hybridization using Nanostring technology), (iii) genomics (somatic mutations by exome sequencing and/or the rearrangement of the V(D)J regions of the CDR3 receptor of T cells). The specificity, complexity and volume of the information generated required the development of mathematical and bioinformatics processing to extract relevant biological information. The Veracyte Biopharma Atlas innovative approach combines linear (multimodal factor analysis) and non-linear (self-organizing map) approaches with graphical representation of the data. Finally, the incorporation of clinical annotation, either from samples used to generate the map or from clinical specimens projected onto the Atlas, made it possible to identify specific patterns predictive of a clinical parameter of interest (eg, response or toxicity).

Results Gene expression profiling, genomic analysis and proteomics by multiplex spatial technology were performed on more than 150 DLBCL samples collected at diagnosis. Using a centralized multi-omics integrative approach, data were analyzed to capture DLBCL immune contexture. Multimodal analysis allowing multifactor integration was used to derive a unique Atlas map and identify key features. Baseline and screening samples from axicabtagene ciloleucel (axi-cel) anti-CD19 chimeric antigen receptor (CAR) T-cell treated patients from the pivotal ZUMA-1 trial were analyzed with the same multi-omics integrative approach. Projection of ZUMA-1 immune contexture data onto the Atlas map revealed actionable information related to patients receiving CAR-T-cell treatment.

Conclusions Projection of CAR-T clinical trial data highlighted the Veracyte Biopharma Atlas as a powerful tool to stratify patients and identify key immune biomarkers linked to response to CAR T-cell therapy.

Ethics Approval The study protocol for the single-arm, multicenter, registrational ZUMA-1 study of axi-cel in patients with relapsed LBCL was previously described.[1] [2] Each study site's institutional review board reviewed and approved the study protocol and amendments, and all patients provided written informed consent. The study was done according to the International Conference on Harmonisation Good Clinical Practice guidelines. Patients in the ZUMA-1 study did not receive compensation for their participation in the study.

1455 EFFECTIVE CO-TARGETING OF FIBROTIC AND IMMUNE MICROENVIRONMENTS TO IMPROVE THE OVERALL ANTI-TUMOUR RESPONSE IN MODELS OF ADVANCED PANCREATIC CANCER

Benjamin McLean, Diego Chacon Fajardo, Aji Istadi, Sean Porazinski, Marina Pajic, Marina Pajic*. *Garvan Institute of Medical Research, Sydney, Australia*

Background Pancreatic ductal adenocarcinoma (PDA) has a 5-year survival of only 10% and persists as the 3rd most common cause of cancer-related death in Western societies. New treatment options are urgently needed. We have previously defined specific molecular subgroups of PDA associated with pre-clinical and clinical response to select tailored treatment strategies.[1-2] One such molecular-guided therapy, RXC004, a potent and selective inhibitor of the Wnt/β-Catenin pathway regulator porcupine, is being investigated in a Ph2 study in patients with pancreatic cancer (NCT04907851). We have previously demonstrated interesting effects of tumour-cell targeted therapies on the environment of PDA.[2-4]

Methods We determined the preclinical efficacy and detailed antistromal effects of RXC004 and selective ROCK2 inhibitors in a range of patient derived and genetically-defined PDA models, including clinically relevant combinations with standard of care (SoC) chemotherapy and immunotherapy. Mechanistic assessment of alterations in tumour cell-stromal cell cross-talk was performed using comprehensive transcriptomics and immunofluorescence approaches.

Results In addition to reducing tumour growth and improving overall survival in patient-derived models of aggressive PDA, RXC004 demonstrated striking antifibrotic effects in vivo, with changes in cancer-associated fibroblast phenotype, accompanied by decreased levels of extracellular matrix components (fibronectin, periostin) and their organisation (collagen). Moreover, treatment with RXC004 as part of 'priming' combination therapy or 'maintenance' regimen significantly improved in vivo chemosensitivity. We also demonstrate that titrated modulation of fibrotic elements in vivo via ROCK2 targeting and as part of clinically-applicable therapeutic regimens, can lead to improved outcomes in diverse highly fibrotic and chemoresistant in vivo settings. Importantly, selective modulation of ROCK2 or Wnt signalling within the microenvironment of the immunocompetent LSL-KrasG12D/+; LSL-Trp53R172H/+; Pdx1-Cre (KPC) model of metastatic PDA revealed significant positive modulation of distinct immune components. These alterations include decreased level of immunosuppressive regulatory T cells, improved CD8+ and CD4+ T cell infiltration and increased presence of M1 pro-inflammatory macrophages in KPC tumours post-treatment, evident both within the tumour body and the invasive edge.

Conclusions These data demonstrate that therapeutic efficacy of RXC004 and select anti-fibrotics in preclinical development may be the result of targeting both tumour cells and key aspects of the fibrotic and immune PDA microenvironment and in addition provide scientific rationale for the design of future SoC chemotherapy as well as immunotherapy-based combinations in pancreatic cancer.

1456 CHARACTERIZATION OF INTER AND INTRA TUMOR HETEROGENEITY IN PRIMARY MELANOMA AND MELANOMA BRAIN METASTASES

[1]Alberto Mendoza Valderrey, [1]Daria Kessler, [1]Sierra Thompson, [2]Xinmin Li, [1]Kai Rau, [1]Stacey Stern, [3]Nicole Rudkin, [4]Kim Margolin, [3]Steven Kolker, [1]Maria Ascierto*. *[1]Saint John's Cancer Institute, Santa Monica, CA, USA; [2]UCLA, Los Angeles, CA, USA; [3]Saint John's Health Center, Santa Monica, CA, USA; [4]Saint John's Cancer Institute, Santa Monica, CA, USA*

Background Melanoma often metastasizes to the brain,[1] usually with a lethal outcome. Recent studies have reported that systemic immunotherapies (IOT) are effective in patients (pts) with melanoma brain metastases (MBM).[2 3] Nevertheless, the failure of IOT in nearly half of patients with MBM leads to the urgency to deeper investigate mechanisms of intrinsic and acquired resistance. The aim of this study is to deeply characterize the tumor microenvironment (TME) of primary melanoma (PM) and MBM and to assess inter- and intra-tumor heterogeneity in order to identify potential strategies able to increase the success of IOT in pts with MBM.

Methods Formalin-fixed, paraffin-embedded (FFPE) tumor biopsies were derived from 7 PM and 14 MBM biopsies from different pts. RNA was isolated from tumor regions and subjected to whole gene expression profiling (GEP). Ingenuity Pathway Analysis (IPA) was performed for enrichment assessment, and Microenvironment Cell Populations-counter (MCP-counter) method was used to estimate the abundance of immune and stromal infiltrated cell subpopulations. Selected transcripts including mRNA for CD163, CD45 and CD20 were evaluated by immunohistochemistry (IHC). Inter- and intra-tumor immune heterogeneity of n=59 selected immune protein was also determined in PM and MBM by digital spatial profiling (DSP) using Nanostring GeoMx technology.

Results Whole GEP revealed 888 transcripts differentially expressed between PM and MBM ($p \leq 0.01$). We observed an increased expression of genes involved in glycolysis (i.e. ALDOA, ENO2, PKM), immune checkpoint signaling (i.e. TIM3), macrophage activity (i.e MARCO, CD14), complement signaling (i.e C1QA/B/C) and chemotaxis (i.e CCL3) in PM vs. MBM. Conversely, overexpression of genes involved in epithelial signaling (i.e. KRT1), wound healing (i.e. WNT3), stem cell proliferation (i.e. YAP, TP63) and immunosuppressive cytokines and chemokines (i.e. CXCL21, CXCL19) was found in MBM vs. PM. Interestingly, by evaluating the protein expression of immunotherapy drug targets, pan-tumor targets, myeloid targets and immune activation targets using IHC and DSP, we found important inter- and intra-tumor immune heterogeneity in PM and MBM tumors.

Conclusions If confirmed in a larger cohort and correlated with therapy outcomes, our results might lead to the development of novel therapeutic strategies able to increase the success of systemic IOT therapy in patients with advanced melanoma who develop metastases at sites including, but not limited to, the brain.

1457 THE ROLE OF CD26 IN PANCREATIC DUCTAL ADENOCARCINOMA

[1]Brandon Ware, [1]Jacklyn Hammons, [1]Isaac Karpovsky, [1]Megan Wyatt, [2]Thomas Mace, [1]Shishir Maithel, [3]Bassel El-Rayes, [1]Chrystal Paulos, [1]Gregory Lesinski, [1]Maggie Phillips*. *[1]Emory University, Atlanta, GA, USA; [2]OSUMC, Columbus, OH, USA; [3]UAB, Atlanta, GA, USA*

Background Pancreatic ductal adenocarcinoma (PDAC) features a dense, fibrotic stroma that obstructs infiltration of immune cells. Our group investigates methods to improve immunotherapy efficacy in PDAC by targeting and manipulating the PDAC stroma. We hypothesize that dysregulated CD26/DPP4 enzymatic activity in PDAC contributes to constrained efficacy of immunotherapy. In addition, we postulate that in vivo pharmacological targeting of CD26 enzyme activity in PDAC, via inhibitors that are FDA-approved for adult patients with Type 2 Diabetes Mellitus, can influence immune cell infiltration and enhance responses to immune checkpoint blockade in murine models of PDAC.

Methods CD26 protein expression was evaluated in immortalized CAFs and PDAC cells by immunoblot and flow cytometry, while soluble CD26 was measured in supernatants by ELISA. In vivo studies used immune-competent C57BL/6 mice orthotopically implanted with syngeneic luciferase-expressing KPC-tumor cells into the pancreas. Tumor establishment was verified by bioluminescence imaging (BLI). Mice were randomized to the following treatment groups: sitagliptin (75mg/kg in drinking water, CD26/DPP4 inhibitor), anti-PD-L1 Ab (200 ug 3x/week), or both combined for 9 days. Controls received vehicle and/or isotype control Ab. BLI monitored tumor growth throughout the study. Tumors were harvested and weighed at study endpoint (day 9 of treatment) and immune cell infiltration was evaluated by flow cytometry. An additional in vivo study was performed to assess differences in efficacy of concurrent versus consecutive administration (2 weeks) of sitagliptin (75mg/kg) and anti-PD-L1 Ab by measuring BLI and pancreas weight at study endpoint.

Results CD26 protein expression was observed in both immortalized human CAFs (HT137 and h-iPSC-PDAC-1) and PDAC cells (HPAC and PANC1) through immunoblot and flow cytometry, however soluble CD26 was only detected in CAF supernatants. Concurrent administration of sitagliptin and anti-PD-L1 Ab limited tumor progression and increased tumor infiltrating CD4+ T cells ($p=.0302$, $p=.0208$ vs isotype control and anti-PD-L1, respectively), CD8+ T cells ($p=.0336$ vs anti-PD-L1), and macrophages compared to vehicle, sitagliptin, and anti-PD-L1 Ab alone. Further studies showed no significant difference in efficacy between concurrent and consecutive administration of sitagliptin together with anti-PD-L1 Ab.

Conclusions Our results reveal that CD26 enzyme inhibition (sitagliptin), augments anti-tumor activity of anti-PD-L1 Ab in PDAC tumor-bearing mice. This work identifies immune cell populations, including T cells and macrophages, that provide insight into mechanisms of efficacy in orthotopic murine models of PDAC. Continued investigations will evaluate the versatility of CD26 inhibition and its capacity to modulate immune checkpoint molecules, thus, broadening efficacy studies across other targets with relevance to PDAC.

1458 REGULATION OF NEOANTIGEN SPECIFIC T CELL INFILTRATION AND SPATIAL TUMOR IMMUNE ARCHITECTURE OF MYELOMA AND ITS PREMALIGNANT PRECURSORS

[1]Nancy Villa*, [1]Hope Robinson, [1]David Jaye, [1]Ajay Nooka, [1]Alyssa Duffy, [1]Samuel McCachren, [1]Julia Manalo, [1]Jeffrey Switchenko, [1]Ava Horvat, [1]Vaunita Parihar, [2]Jingjng Gong, [2]Yan Liang, [1]Geoffrey Smith, [1]Gupta Vikas, [1]Lawrence Boise, [1]Jonathan Kaufman, [1]Craig Hofmeister, [1]Joseph Nisha, Sagar Lonial, [1], [1]Kavita Dhodapkar, [1]Madhav Dhodapkar. *[1]Emory University, Atlanta, GA, USA; [2]Nanostring Technologies, Seattle, USA*

Background Entry of neoantigen-specific T cells into tumors is critical for immunotherapy but underlying mechanisms are poorly understood. Spatial aspects of immune infiltration impact outcome in solid tumors, but the impact of spatial immune patterns in hematologic malignancies such as multiple myeloma is unknown.

Methods We combined several high dimensional spatial analysis platforms with in-vitro/in-vivo modeling in humanized mice of human MM and its precursor monoclonal gammopathy of undetermined significance to gain mechanistic insights into entry of neoantigen-specific T cells into MM tumors.

Results Multiplex immune fluorescence immunohistochemistry (mIF-IHC) analysis of bone marrow biopsies from 95 patients with plasma cell malignancy or its precursor states (MGUS n=13, SMM n=12 and MM n=70) revealed a decline in TCF1+ stem memory like cells and increase in granzymeB+ effector T cells in transition from MGUS to MM. Spatial analyses of tumor/immune infiltration identified formation of microclusters with areas of T cell exclusion in MM but not MGUS. Multifocal growth of MM but not MGUS was reproduced in humanized MISTRG6 mice, indicating this as an intrinsic property associated with malignancy. Consistent with IHC data, MM tumors were resistant to entry of T cells in vitro. In these systems, T cells entry required T cell activation and was enhanced upon CD28-mediated costimulation. T cell entry also required CD2/CD58 interaction and was abrogated upon disruption of these interactions. Importantly, entry of neoantigen-specific T cells into antigen-expressing tumors required in situ stimulation with antigen-presenting dendritic cells (DCs). Upon adoptive transfer into humanized mice, while neoantigen-specific T cells selectively enrich at tumor site, entry of these T cells into tumor masses in vivo again depends on tumor-associated DCs. Spatial analysis of IHCs from MM biopsies revealed that T cell infiltration follows a gradient from CLEC9A+ DCs. Nanostring analyses revealed that CLCC9^{high} regions are enriched for immune activation genes. Patterns of T and myeloid infiltration also correlated with both overall and progression free survival in multivariable analyses.

Conclusions These data identify several distinct aspects of spatial immune alterations that correlate with evolution of malignancy and outcome in MM. They also demonstrate that entry of neoantigen-specific T cells into MM tumors depends on target recognition, costimulation, CD2/58 axis and in situ antigen presentation by tumor-associated DCs. These data therefore identify a novel role for specific antigen presentation by tumor-associated DCs in the effector phase of cancer immunity cycle, with broad implications for immunotherapy and T cell redirection.

1459 CHARACTERIZATION OF TUMOR BUDDING AND THE TUMOR MICROENVIRONMENT IN COLORECTAL CANCER USING HYPERPLEX IMMUNOFLUORESCENCE

[1]Cansaran Saygili Demir*, [1]Mauro Gwerder, [2]Deniz Eroglu, [2]Marco Cassano, [2]Maria Giuseppina Procopio, [2]Joanna Kowal, [2]Diego Dupouy, [1]Inti Zlobec. [1]*University of Bern, Bern, Switzerland*; [2]*Lunaphore, Tolochenaz, Switzerland*

Background Current colon cancer classification, prognostication, and therapy decisions are based mainly on cancer staging.[1 2] However, additional biomarkers are needed to improve patient stratification and complement treatment decision-making strategies. Tumor budding is recognized as an independent prognostic factor in a variety of solid cancers.[3] [4]Tumor buds (TBs) are isolated single tumor cells or groups of up to four tumor cells, located both peri- and intra-tumorally. A higher tumor bud count correlates with poor prognosis in colorectal cancer (CRC), and it is hypothesized that a subset of TBs represents, at least in part, an Epithelial-Mesenchymal Transition (EMT) state.[5] To explore this hypothesis further, we developed a sequential immunofluorescence (seqIF™)-based panel for a more spatial approach to characterizing TBs and the tumor microenvironment.

Methods Human CRC sections from different cohorts underwent initial pre-processing on PT Module™ (Thermo Fisher) followed by automated cycles of seqIF and imaging performed on COMET™ (Lunaphore Technologies). Hyperplex panels consisting of >20 protein biomarkers were generated using off-the-shelf antibodies and served to characterize the tumor-stroma interactions in a preliminary cohort of samples. In a second stage, the spatial screening was performed on larger cohorts of neoadjuvantly treated vs. untreated CRC patient samples. The final characterization of TBs and their interaction with the surrounding milieu was performed by downstream image analysis of the stained tissues.

Results With COMET™ we built an optimized panel including >20 biomarkers for characterization of the tumor and the surrounding stroma. The panel robustness was tested in 15 different CRC cases and resulted in outstanding staining quality with high signal-to-background ratio and elution efficiency (> 98%) for all biomarkers. The developed panel allowed the visualization of inter- and intra-tumoral heterogeneity of stained cases and the identification of cell populations including immune cells, cancer-associated fibroblasts, and tumor cells. In line with previously described EMT phenotype of TBs,[6 7] our observations showed loss of EpCAM and E-Cadherin in a group of TBs verifying decreased epithelial phenotype (figure 1).

Conclusions The >20-plex panels generated on COMET allowed (i) to discriminate TBs signatures within the depth of tumor-stroma interactions and (ii) to extract valuable TBs features in terms of marker expression. Next, crucial info about TBs phenotypes and their cellular neighborhood will be obtained through an unsupervised analysis approach. This will finally serve to better identify novel immunograms of these cellular entities, thus better defining their therapeutic potential for a personalized medicine approach.

1460 TREATMENT WITH SMALL MOLECULE NSC243928 IN MOUSE MAMMARY TUMOR MODEL INDUCES CHANGE IN TUMOR MICROENVIRONMENT ASSOCIATED WITH ANTI-TUMOR IMMUNE RESPONSES

[1]Benson Selvanesan, [2]Alvaro De Mingo Pulido, [1]Sheelu Varghese, [1]Daniel Hupalo, [3]Yuriy Gusev, [4]Sara Contente, [5]Matthew Wilkerson, [6]Clifton Dalgard, [5]Geeta Upadhyay, [7]Geeta Upadhyay*. *[1]Henry Jackson Foundation, Bethesda, MD, USA; [2]Moffit Cancer Center, Tampa, FL, USA; [3]Innovation Center for Biomedical Inform, Washington DC, DC, USA; [4]Pathology, Uniformed Services University, Bethesda, USA; [5]Uniformed Services University of Health, Bethesda, MD, USA; [6]Center for Military Precision Health, Bethesda, MD, USA; [7]Uniformed Services University of Health Sciences, Bethesda, MD, USA*

Background Previously, we identified that NSC243928 induces cell death in triple negative breast cancer cells in a LY6K dependent manner. NSC243928 has been reported as an anti-cancer agent in NCI small molecule library. The molecular mechanism of NSC243928 as an anti-cancer agent in the treatment on tumor growth in the syngeneic mice model is not established. With the success of immunotherapies, novel drugs which may elicit an anti-tumor immune response in addition to effecting cancer cell death are of high interest for developing novel drugs to treat solid cancer.

Methods We focused on studying if NSC243928 may elicit an anti-tumor immune response in the in vivo mammary tumor models of 4T1 and E0771.

Results We observed that treatment with NSC243928 induced in vivo tumor mass reductions. The bulk RNA seq analysis of tumor isograft samples showed that NSC243928 generates anti-tumor immune responses in both models. NSC243928 induced cell surface calreticulin expression, indicative of immunogenic cell death in both tumor cell lines at the micromolar concentrations. NSC243928 treatment led to reduced MDSCs in the peripheral blood and increased levels of intratumoral immune cells namely- patrolling monocytes and MHC II positive tumor associated macrophages in both mouse models. We observed that NSC243928 showed intra-tumoral immune response such as increased NKT cells, decreased PMN-MDSCs and increased B1 cells in the E0771 mouse model.

Conclusions Taken together we conclude that NSC243928 induces a superior immune response in the E0771 mouse mammary tumor model. Further studies are required to understand the link of NSC243928 associated anti-tumor immune response to determine the adequate molecular signature associated NSC243928 efficacy could be identified, which will be beneficial to future drug development.

1461 DISCOIDIN DOMAIN RECEPTOR 1 EXPRESSION IS ASSOCIATED WITH STROMAL TGF BETA SIGNALING IN SELECTED CANCERS

Xinwei Sher, Ziyin Wang, Thomas Schürpf, Laura Dillon, Tamas Oravecz, Laurent Audoly, Guy Clifton*. *Parthenon Therapeutics, Inc, Boston, MA, USA*

Background Discoidin Domain Receptor 1 (DDR1) has been implicated in cancer prognosis, invasion, and metastases in multiple tumor types.[1] More recently, DDR1 has also been implicated in immune exclusion.[2] However, the relationship between DDR1 and TGF beta-mediated immunomodulatory pathways is less clear and may vary by tumor type.

Methods The Cancer Genome Atlas (TCGA) was queried for the association between an 80-gene TFG beta pathway activation signature[3] and DDR1 gene expression in all tumors and by individual histologic types. To further understand role of the DDR1/TGF beta interaction, TGF beta isoforms (TGFB1, TGFB2, TGFB3) and binding proteins (LTBP1, LTBP3, LRRC32, NRROS) were compared to DDR1 expression by indications with a strong/moderate relationship between TGF beta signature and DDR1 compared to those with a weak or no relationship between the two.

Results DDR1 gene expression and TGF beta signaling expression are not correlated in a pan-tumor analysis (r=0.12). In individual indications, there is a strong relationship (r>0.75) in thymoma (r=0.79); moderate relationship (0.75>r>0.5) in papillary renal cell carcinoma (r=0.57), and thyroid cancer (0.52); a weak relationship (0.5>r>0.25) in testicular (r=0.49), prostate (r=0.49), hepatocellular carcinoma (r=0.47), endometrial (r=0.44), ovarian, lung squamous cell carcinoma (r=0.27), lung adenocarcinoma (r=0.29), rectal (r=0.32), cholangiocarcinoma (r=0.36), cervical (r=0.36), head and neck (r=0.30), esophageal cancers (r=0.30), glioblastoma (r=0.27); No relationship (<0.25) in all others. There was a strong, direct relationship (r=0.76, figure 1) between LTBP3 expression and DDR1 expression in indications with a strong/moderate correlation between TGF beta signaling signature and DDR1 and no relationship (r=0.17) in those with a weak or no relationship. All other correlations between DDR1 and TGF beta isoforms or binding proteins were weak or nonexistent (r<0.5).

Conclusions DDR1 expression is correlated with TGF beta signaling expression in multiple cancer types, but with varying strength of correlation. In indications with a strong or moderate relationship, DDR1 is also strongly correlated with latent-transforming growth factor beta-binding protein 3 (LTBP3) gene expression, suggesting a common stromal-mediated interaction.

1462 ADRENERGIC SIGNALING AUGMENTS CYTOTOXIC T CELL ANTI TUMOR ACTIVITY IN P53 DEFICIENT CANCERS BY CXCL10 RELEASE

[1]Deborah Silverman*, [2]DSara Leahey, [1]Shamima Akhter, [1]Tong Xie, [1]Simone Anfossi, [1]Jennifer Covello, [1]Frederico Netto, [1]Elien Doorduijn, [2]Yunfei Wang, [3]Emily Ashkin, [1]Jeffrey Myers, [1]George Calin, [2]Patrick Hwu, [1]Moran Amit. *[1]MD Anderson Cancer Center, Houston, TX, USA; [2]Moffitt Cancer Center, Tampa, FL, USA; [3]Stanford University, Palo Alto, CA, USA*

Background Harnessing the immune system through the attenuation of immune checkpoints has led to durable tumor rejection in a subset of tumors. However, the majority of epithelial cancers remain resistant to existing immunotherapies. It is imperative to understand how these resistant tumors escape the immune system in order to design more efficacious therapies. Often, nonresponsive tumor types, such as pancreatic cancer and head and neck cancers (HNCC), possess a complex tumor microenvironment (TME) infiltrated by immune and stromal cells, as well as nerve fibers arising from the peripheral nervous system. In comparison with other members of the TME, the role of tumor-infiltrating nerve fibers in oncogenesis and treatment resistance is understudied. Studies across murine models of prostate and pancreatic cancer have shown that ablation of portions of the peripheral nervous system prevents cancer progression.[1 2] We recently showed that existing nerves sprout and undergo reprogramming to an adrenergic-like phenotype as a result of orchestrated microRNA shuttling from cancer cells to neurons, resulting in activation of transcriptional programs that establish new neuronal identity.[3] Given that activated T-cell subsets express high levels of adrenergic receptors, we hypothesized that adrenergic signaling may also influence tumor-infiltrating T-cell function.

Methods We used murine models of HNCC to discern the effect of adrenergic signals on overall immune infiltration, tumor growth, and efficacy in combination with immune checkpoint inhibitors. We correlated our findings with patient cohorts using immunohistochemistry. We studied intratumoral and intra-T-cell pathway changes by RNA sequencing.

Results In T-cell cytotoxicity studies, a variety of adrenergic agonists, particularly β2 agonists, enhanced T-cell activity against tumor cells. Adrenergic agonists exerted this effect on T-cells not directly on adrenergic receptors on the T-cells themselves, but indirectly on adrenergic receptors on the cancer cells, forcing an increased release of cytokines and chemokines, most notably CXCL10. This dysregulation in immune signaling promoted not only recruitment but also activation/exhaustion pathways within CD8+ T-cells. Intriguingly, this signaling axis was dependent on p53 loss within the cancer cell.

Conclusions These results describe a new mechanism for p53's regulation of cancer, and contrast with the known role of adrenergic signaling in cancer. Although nerve-cancer crosstalk drives cancer progression, tumor innervation may also play a positive role in regulating the host's adaptive immune response. Therapeutic approaches targeting this critical component of tumor biology may lead to new efficacious, personalized treatments, expanding the use of immunotherapy and/or combination therapies in new cancer types and ultimately improving patient survival.

1463 ADDITION OF LOSARTAN TO FOLFORINOX AND CHEMORADIATION DOWNREGULATES PRO-INVASION AND IMMUNOSUPPRESSION ASSOCIATED GENES IN LOCALLY ADVANCED PANCREATIC CANCER

[1]Rakesh Jain, [1]Yves Boucher, [1]Jessica Posada, [2]Spencer Rosario, [1]Liqun Gu, [1]Ashwin Kumar, [1]Heena Kumra, [1]Mari Mino-Kenudson, [1]Nilesh Talele, [1]Dan Duda, [1]Dai Fukumura, [1]Jennifer Wo, [1]Jeffrey Clark, [1]David Ryan, [1]Carlos Fernandez-del Castillo, [1]Theodore Hong, [3]Mikael Pittet, [1]Sonu Subudhi*. *[1]Massachusetts General Hospital, Boston, MA, USA; [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [3]University of Geneva, Geneva, Switzerland*

Background Adding losartan to FOLFIRINOX (FFX) chemotherapy followed by chemoradiation (CRT) resulted in 61% R0 surgical resection in our phase II trial in patients with locally advanced pancreatic cancer (LAPC). Here we identify potential mechanisms of benefit by assessing the effects of neoadjuvant losartan+FFX+CRT versus FFX+CRT on the stromal tumor microenvironment.

Methods We performed a gene expression analysis of RNA extracted from pancreatic cancer tissue sections and immunohistochemistry (IHC) for cancer cells and immune cells using archived surgical samples from patients treated with losartan +FFX+CRT (**NCT01591733**), FFX+CRT (**NCT01591733**) or surgery upfront, without any neoadjuvant therapy. We then assessed whether certain gene sets could stratify the overall survival (OS) of patients.

Results Neoadjuvant losartan+FFX+CRT and FFX+CRT increased the expression of genes linked to vascular normalization, transendothelial migration of leukocytes, T cell activation and cytolytic activity, and dendritic cell (DC) related genes versus no neoadjuvant treatment. In comparison to FFX +CRT, losartan+FFX+CRT downregulated pro-invasion, immunosuppression, and M2 macrophages-related genes, and upregulated genes associated with tumor suppression, including the p53 pathway. Furthermore, immunostaining revealed significantly less residual disease in lesions treated with losartan +FFX+CRT versus FFX+CRT. Losartan+FFX+CRT also reduced $CD4^{+}FOXP3^{+}$ regulatory T cells in PDAC lesions with a complete/near-complete response. OS was associated with DC and antigen presentation genes for patients treated with FFX+CRT, and with immunosuppression and invasion genes or DC– and blood vessel-related genes for those treated with losartan+FFX+CRT.

Conclusions Adding losartan to FFX+CRT reduced pro-invasion and immunosuppression-related genes, which were associated with improved treatment outcomes in patients with LAPC. We have shown in murine models of pancreatic ductal adenocarcinoma that the angiotensin receptor 1 blocker losartan improves the delivery and efficacy of cytotoxic agents. Our phase II trial – stemming from our preclinical findings – in patients with LAPC showed that losartan plus FFX chemotherapy followed by CRT led to high rates of complete surgical resection. Here, we identified the potential mechanisms of benefit of neoadjuvant losartan+FFX+CRT. We show that both losartan+FFX+CRT and FFX+CRT improved the expression of genes linked to vascular normalization, transendothelial migration of leukocytes, T cell activation, cytolytic activity and dendritic cell maturation, effects mediated by chemotherapy. In addition, losartan+FFX+CRT downregulated immunosuppression and pro-invasion-related genes, likely mediated by losartan. These findings suggest that losartan potentiates the benefit of FFX+CRT by reducing immunosuppression and invasion, and thus, may help overcome resistance to immunotherapy.

Ethics Approval The study was approved by institutional review board (IRB) of Mass General Brigham (IRB protocol number: 2022P001372).

1464 KNOCKOUT OF COLLAGEN TYPE I IMPEDES TUMOR GROWTH AND SUPPORTS IMMUNE CELL INFILTRATION IN A MURINE MODEL OF PANCREATIC CANCER

[2]Marco Carretta, [2]Anne Mette Rømer, [3]Christina Jensen, [2]Dorota Kuczek, [2]Astrid Johansen, [2]Klaire Fjaestad, [3]Nicholas Willumsen, [2]Mads Andersen, [2]Daniel Hargboel Madsen, [1]Marie-Louise Thorseth*. *[1]Herlev Hospital, Herlev, Denmark; [2]Center for Cancer Immune Therapy, Copenhagen, Denmark; [3]Nordic Bioscience, Herlev, Denmark*

Background A key characteristic of cancer progression is remodeling of the extracellular matrix (ECM). This remodeling results in a tumor-specific ECM which is often of high density and rich in collagen. The high collagen density of the tumor ECM correlates with a poor prognosis in many types of cancer and with low infiltration of immune cells. The direct effects of increased intratumoral collagen on tumor progression are not yet fully understood. In this study, the role of collagen on tumor growth and immune cell infiltration were directly investigated in vivo using transgenic murine models allowing for manipulation of collagen levels.

Methods Two transgenic murine models were used to study the effects of the level of intratumoral collagen type I; a conditional knockout mouse model with decreased collagen deposition and a collagenase-resistant mouse model with increased collagen deposition. Changes in the level of collagen type I synthesis and content were demonstrated using qRT-PCR, ELISA, and histological staining. Collagen-mediated effects on immune cell infiltration were investigated using flow cytometry analyses, qRT-PCR, and immunohistochemistry. All animal studies were following institutional guidelines and were approved by the Danish Animal Experiments Inspectorate.

Results Collagen type I expression and deposition was significantly decreased in the conditional knockout mouse model. Knockout of collagen led to impeded growth of Pan02 pancreatic carcinomas. This was accompanied by increased infiltration of immune effector cells, including an increase in the amount of NK cells and an increased CD8/CD4 ratio. These results were backed up by employing the collagenase-resistant mouse model with increased collagen deposition. In these mice, tumor growth was increased and there was a higher CD4/CD8 ratio and an increased amount of immunosuppressive myeloid cells.

Conclusions The results of this study demonstrate pronounced effects of collagen on tumor progression and on the tumor immune microenvironment. The potential immunosuppressive role of collagen type I provides a rationale for extending future research in cancer immunotherapy to include focus on the ECM and in particular collagen type I.

1465 SOX2 EXPRESSION IN NSCLC MEDIATES CHANGES IN THE TUMOR MICROENVIRONMENT IMPAIRING T CELL INFILTRATION AND PROMOTING RESISTANCE TO CHECKPOINT BLOCKADE THERAPY

Stefani Spranger, Arjun Bhutkar, Kim Nguyen, Sally Weng, Ellen Duong, Sarah Blatt, Elen Torres-Mejia*. *Koch Institute at MIT, Cambridge, MA, USA*

Background Immunotherapies such as checkpoint blockade therapy (CBT) can be an effective approach to treat patients with metastatic tumors. In non-small cell lung cancer (NSCLC), four major immune subsets have been described, (a) the CBT-sensitive with T cell infiltration and PD-L1 expression, (b) the immune cell desert that lacks CD8+ T cell infiltration, (c) the non-functional T cell phenotype comprising T cells yet no PD-L1 expression, and (d) the T cell excluded phenotype, characterized by effector T cells surrounding the tumor.[1]Patients with a non-T cell-infiltrated tumor microenvironment (TME) correlate with a poor response to CBT.[2] Data from our lab showed that NSCLC patients can be classified into T cell-infiltrated and non-T cell-infiltrated using a T cell gene signature. Interestingly, we observed that Sox2 upregulation correlates with a lack of T cell infiltration. Using a syngeneic mouse model, we aim to investigate how tumor cell-intrinsic expression of Sox2 mediated immune evasion in NSCLC.

Methods We used a lung adenocarcinoma cell line (KPCt) derived from a $KrasG12^{D/+}$ and $Tp53^{-/-}$ mouse to overexpress Sox2 (KPS2). Subcutaneous or lung tumors were treated with anti-PD-L1 and anti-CTLA-4 blocking antibodies and analyzed for tumor burden. Tumor infiltration of T cells was evaluated by fluorescence microscopy. To characterize tumor-specific T cell responses, we engineered the KPCt and KPS2 cell lines to express the model antigen SIY. Finally, we performed a bulk RNA-seq analysis of KPCt.SIY and KPS2.SIY cell lines and subcutaneous tumors to determine candidate genes downstream Sox2 that could negatively affect T cell infiltration into the tumor.

Results We found that Sox2 overexpression induces resistance to CBT mediated by T cell exclusion from the tumor core. Analyses of tumor-reactive T cells indicated that T cell priming and differentiation into cytotoxic effector T cells were not affected, yet, cytotoxic T cells failed to infiltrate KPS2 tumors while enriched in the peritumoral regions. Bulk RNA-seq data showed that Sox2 overexpression changed the composition of the extracellular matrix. Furthermore, we observed in KPS2.SIY tumors an increase in endothelial vessel density; however, the size of the vessels was significantly reduced compared to KPCt.SIY tumors.

Conclusions Our results show that tumor cell-intrinsic activation of Sox2 in NSCLC promotes immune evasion and contributes to immunotherapy resistance by inducing changes in the TME. Understanding the molecular and immunological mechanisms mediating T cell exclusion from the lung TME will facilitate the development of novel combination treatment strategies for NSCLC patients.

1466 NOVEL CELL PHENOTYPES CORRELATED WITH CHECKPOINT IMMUNOTHERAPY RESPONSES IDENTIFIED IN THE TUMOR AND IMMUNE MICROENVIRONMENT OF PATIENTS WITH METASTATIC MELANOMA

Brian Thompson, Ann Strange, Jonathan Hester-McCullough, David Woods, Carol Amato*.
University of Colorado Denver AMC, Aurora, CO, USA

Background Visualizing and profiling cells within the tumor microenvironment (TME) is an important component of translational studies, particularly with the advent of immunotherapies. Successful optimization and utilization of multiplex immunofluorescence (mIF) allows researchers to identify cell populations and interactions involved in cancer biology. In separate publications, we describe novel immunophenotypes in the peripheral blood or tumors of patients with metastatic melanoma receiving immunotherapy.[1] [2] These populations include ectoenzyme expressing Tcells (CD38 and CD39), and melanoma cells that express CD83, a marker for dendritic cells. The aim of this current study is to create an mIF panel capable of interrogating the TME of melanoma samples for these phenotypes.

Methods Using the Vectra Polaris platform, a nine-parameter immunofluorescence panel was designed and optimized to detect distinct cell phenotypes in paraffin tissues (CD3, CD4, CD8, SOX10S100, KI67, CD38, CD39, and CD83). We implemented this panel to identify unique population(s) of cells within FFPE specimens from patients with melanoma undergoing anti-PD1 immunotherapy. Thirty-four samples from 23 patients were analyzed (including 11 responders and 12 non-responders). Based on specimen availability, we assessed a variety of tissue types collected across anatomic location and/or time points (ie primary or metastatic lesion; before or on-treatment). inForm and phenoptr software was used to discern tumor versus stroma compartments and distinguish phenotypes.

Results We detected the previously described immunophenotypes (CD3+/CD4+/CD38+/CD39+ , CD3+/CD8+/CD38+/CD39+, and SOX10S100+/CD83+) in all 34 specimens. After cell segmentation, the frequency of CD3+/CD4+/CD38+/CD39+ cells were higher in the tumor compartment compared to stroma (p= 0.0045). The frequency of CD3+/CD4+/CD38+/CD39+ cells was positively correlated with the frequency of Tregs in the tumor compartment of patients that were non-responsive to immunotherapy (no statistical significance; R^2=0.16, p=0.2). We also identified CD83-expressing Tcells (CD3+/CD8+/CD83+ and CD3+/CD4+/CD83+) and their frequencies were positively correlated in the stroma compartment of patients that responded favorably to immunotherapy (R^2=0.98, p<0.000001). Within the stroma compartment of the same patient cohort, similar increases in frequencies are seen with SOX10S100+/CD83+ cells and the two CD83-expressing Tcells phenotypes.

Conclusions We designed an mIF panel that identifies novel immunophenotypes and validated these populations in the TME of patients with metastatic melanoma. Notably, we detected populations that express CD83, a molecule often overlooked in solid tumors. Here we show CD83 expression on melanoma cells and Tcells, and their presence are associated with response to anti-PD1 therapy.

1467 AN HOLISTIC AND INTERGRATED APPROACH FOR INVESTIGATING THE BACTERIAL MICROBIOME, GENE EXPRESSION PROFILE AND IMMUNE CELL PROFILE IN THE NON-MUSCLE INVASIVE BLADDER CANCER TUMOUR MICROENVIRONMENT

[1]Tyler Wooldridge*, [1]Charles Rayner, [1]Sunny Sunshine, [2]Matthew Perry, [2]Izhar Bagwan, [1]Nicola Annels, [1]Hardev Pandha. *[1]University of Surrey, Guildford, UK; [2]Royal Surrey NHS Foundation Trust, Guildford, UK*

Background Bladder cancer (BC) is the 10th most common cancer world-wide with an estimated 570,000+ people being diagnosed in 2020.[1] It has been shown that communities of bacteria (bacterial microbiome) exist in both normal and cancerous tissues and can impact treatment efficacy (e.g. metabolising chemotherapeutics).[2 3] We investigated the microbiome in formalin fixed paraffin embedded (FFPE) tumour tissue across different stages of BC compared to adjacent normal tissue to investigate differentially expressed (DE) bacteria. We also investigated DE bacteria between Bacillus Calmette Guerin (BCG) treatment responders vs non responders. These findings were then correlated to differential host immune gene expression and infiltrating immune cell profiles and spatial relationships within the tumour microenvironment (TME).

Methods Bacterial signatures within urine (n=56) and FFPE tissues (n=66), (matching patients n=44), derived from the Royal Surrey Country Hospital, Guildford, UK, were determined using 16s rRNA sequencing (V3-V4). Sequencing data were processed through QIIME2 and clustered into operational taxonomic units (OTUs). Alpha (Shannon and observed) and Beta (Bray-Curtis, weighted and unweighted uniFrac) diversity analysis was performed, with non-parametric statistics for determining significance. RNA extracted from FFPE BC tissues generated gene expression data using the Nanostring IO360 panel (a 770 gene CodeSet) and was correlated to tumour microbiome profiles using SparCC analysis. 9 colour multiplex immunohistochemistry (mIHC) using Phenoimager HT (Akoya Biosciences) was also performed to investigate and spatially define immune cell types (CD4, CD8, CD68, CD57, FOXP3, GRZB, PD-L1, PANCK, DAPI), within tumour tissues (n=71).

Results BC bacterial microbiome showed decreased diversity and composition with disease progression ($P<0.01$). The bacterial profiles between urine and FFPE cancer tissues revealed independent groups ($P<0.01$), showing urine is not an accurate proxy. The bacterial microbiome of cancerous and normal tissue, and between responders vs non responders shared mostly similar bacteria, though differentially expressed bacteria were found. Immune cell profiles and spatial relationships determined via mIHC, showed differences between stromal and tumour regions, and low grade (LG) and high grade (HG) disease. Analysis has also shown links between bacteria, immune gene expression and immune cells populations.

Conclusions The analysis of the microbiome in BC has clearly shown differentially expressed bacteria going from low grade to high grade disease. Further investigation of bacteria influencing immune cell phenotype is currently being performed. The potential influence these bacteria have on the tumour immune microenvironment and thus disease and treatment outcomes will provide the rationale for pursuing approaches to modulate the tumour microbiome for improved therapeutic outcomes.

Late-Breaking Abstracts

Biomarkers, Immune Monitoring and Novel Technologies

1468 FIRST DATA READOUT OF STANDARDIZED TRANSCRIPTIONAL PROFILING FOR OPTIMIZING CELLULAR THERAPIES: A MULTI-CENTER PICI-NANOSTRING COLLABORATION

[1]Sarah Church*, [1]Christina Bailey, [1]Phi Phan, [1]Andrew White, [2]Lisa Butterfield, [2]Samantha Liang, [2]Tim Howes. *[1]NanoString Technologies, Seattle, WA, USA; [2]Parker Institute, San Francisco, CA, USA*

Background The field of cellular therapy remains one of the most promising areas for the development of new cancer treatments. To make improvements, it is imperative to broadly understand cell therapy products at the molecular level and to identify factors that contribute to their safety and efficacy. NanoString and the Parker Institute for Cancer Immunotherapy (PICI) have established a ground-breaking collaboration to characterize up to 1,000 apheresis and cellular therapy infusion products with the primary goal of identifying molecular pathways and features that correlate with optimal cellular therapies.

Methods Using a large and diverse sample cohort collected from four (and eventually 8 in Phase II) PICI network Cell Therapy Centers, we are studying Gene Expression Profiles (GEPs) that correlate with optimal apheresis and downstream cellular products, identifying biomarkers and signatures for clinical response and toxicity. We are exploring both cancer-specific and general characteristics associated with effective chimeric antigen receptor (CAR) T cells. Samples are being characterized using the standardized set of genes included in the nCounter CAR-T Characterization Panel, which measures essential features of CAR-T products, including metabolic fitness, TCR diversity, toxicity, activation, persistence, exhaustion and cell type abundances, along with individual transgene expression.

Results We are presenting the initial phase of gene expression analysis for multiple CAR-T cell products across both primary and metastatic hematological and solid tumors. Meta-analysis will be performed using the aggregated set of data alongside individual site-specific analyses. We will explore associations between manufacturing conditions, gene expression and outcomes, and we will examine differences across cancer types and target types.

Conclusions This is the first data output for this one-of-a-kind study characterizing GEPs in CAR-T cells. We anticipate that this information will prove useful across many aspects of the development, manufacturing and clinical application of cellular therapies, and we hope that the findings will lead to improvements in the safety and efficacy of cell therapy products. Data from this project will be made publicly available to the scientific community.

Clinical Trials Complete

1469 A PHASE II BASKET TRIAL OF DUAL ANTI–CTLA-4 AND ANTI–PD-1 BLOCKADE IN RARE TUMORS (DART SWOG 1609 COHORT 47) IN PATIENTS WITH GESTATIONAL TROPHOBLASTIC DISEASE

[1]Sandip Patel*, [2]Megan Othus, [3]Young Kwang Chae, [1]Michael Dennis, [4]Sarah Gordon, [5]David Mutch, [6]Wolfram Samlowski, [7]Elad Sharon, [8]Christopher Ryan, [9]Melissa Plets, [10]Charles Blanke, [11]Razelle Kurzrock. *[1]University of California San Diego, Moores Cancer Center, La Jolla, CA, USA; [2]SWOG Statistics and Data Management Center, Fred Hutchinson Cancer Center, Seattle, WA, USA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL, USA; [4]Thomas Jefferson University/Sidney Kimmel Cancer Center, Richmond, VA, USA; [5]Washington University School of Medicine, St. Louis, MO, USA; [6]Comprehensive Cancer Centers of Nevada, Las Vegas, NV, USA; [7]National Cancer Institute, Cancer Therapy Evaluation Program, Bethesda, MD, USA; [8]Oregon Health and Science University Knight Cancer Institute, Portland, OR, USA; [9]Fred Hutchinson Cancer Center, Seattle, WA, USA; [10]SWOG Group Chair's Office, Knight Cancer Institute, Oregon Health and Science University, Portland, OR, USA; [11]Medical College of Wisconsin Froedtert Cancer Center, Milwaukee, WI, USA*

Background Immune checkpoint blockade has improved outcomes across tumor types; little is known about the efficacy of these agents in rare tumors. We report the results of the gestational trophoblastic disease (GTD) cohort of SWOG S1609 dual anti–CTLA-4 and anti–PD-1 blockade in rare tumors (DART).

Methods We performed a prospective, open-label, multicenter phase II clinical trial of ipilimumab plus nivolumab across multiple rare tumor cohorts, with the GTD cohort reported here. Eligible patients had progressed following at least one line of standard systemic therapy. All participants received nivolumab 240 mg i.v. every 2 weeks and ipilimumab 1 mg/kg i.v. every 6 weeks on a continuous schedule. The primary endpoint was overall response rate [ORR; complete response (CR) and partial response (PR)] by quantitative serum β-hCG; secondary endpoints included progression-free survival (PFS), overall survival (OS), stable disease >6 months, and toxicity.

Results Four eligible patients were enrolled and received therapy. The median number of prior lines of therapy was 2.5 (range 2-4). The median follow-up duration was 11 months. Three of the four patients had a response to therapy [ORR = 75% (CR, 25%, n=1; PR, 50%, n=2) (table 1)], including patients with: malignant gestational trophoblastic neoplasm (n=1, CR, PFS 11+ months), gestational choriocarcinoma (n=1, PR, PFS 10+ months), and choriocarcinoma (n=1, PR, PFS 6+ months). One patient with epithelioid trophoblastic tumor had progression as the best response to therapy. The 6-month PFS was 75% (95% CI 43-100%); all 4 patients were alive at the last follow-up. There were two treatment-related adverse events (TRAEs) of grade 3-4 toxicity: arthralgia and colitis (each observed once), both were immune-related; there were no grade 5 events. No patients discontinued treatment due to TRAEs.

Conclusions Ipilimumab plus nivolumab is well tolerated and demonstrated a 75% ORR in patients with GTD

Background Eftilagimod alpha (E) is a soluble LAG-3 protein binding to a subset of MHC class II molecules to mediate antigen-presenting cell (APC) activation & T-cell (CD4/CD8) recruitment/activation. By stimulating APCs with E, T cells are recruited, possibly leading to stronger anti-tumor responses than with pembrolizumab (P) alone, especially in tumors not overexpressing PD-L1. Herein we report results of the 1st line non-small cell lung carcinoma (NSCLC) cohort in the TACTI-002 ("Two ACTive Immunotherapies") trial.

Methods Pts with measurable, 1st line metastatic NSCLC unselected for PD-L1 were recruited. The objective response rate (ORR) by iRECIST was the primary endpoint (EP). Secondary EPs include ORR by RECIST 1.1, ORR by blinded independent central read (BICR), duration of response (DoR), progression-free survival (PFS), overall survival (OS), PD-L1 and IFN-gamma, safety & tolerability. Pts received 30mg E SC q2w for 8 cycles (1 cycle= 3 weeks) & then q3w for up to 1 year with P (200 mg IV q3w for up to 2 years). Imaging was done every 8 weeks & assessed by investigator. PD-L1 was assessed centrally (22C3 antibody). The study was powered to detect a 52% increase in ORR compared to historical results for P 80% power & 1-sided alpha of 2.5%. Planned recruitment=110 pts.

Results From Mar 2019-Nov 2021, 114 pts were enrolled. Median follow-up was 13 mo (data cut-off Jul 1st 2022). Median age was 67 yrs (44-85) & 74% were male. ECOG PS was 0 & 1 in 37% & 63% of pts. Pts presented with squamous (35%) or non-squamous (63%) carcinoma and 93% had metastatic disease. All PD-L1 subgroups were represented (table 1). Pts received median 9.0 (range 1–18) P & 13.0 (1-22) E. 11 (9.6%) pts discontinued due to related adverse events (AEs). Common (≥15%) AEs were dyspnea (35%), asthenia (33%), decreased appetite (25%), cough (25%), anemia (23%), fatigue (21%), pruritus (21%), constipation (18%), nausea (17%), hemoptysis (16%) & diarrhea (16%).

ORR by iRECIST (primary EP) was 39.5% (95% CI 30.5-49.1) & median PFS was 6.9 mo (95% CI 4.9-9.3). Responses were observed in all PD-L1 subgroups (table 1). ORR (iRECIST) for squamous & non-squamous were 37.5% & 38.9%. Median duration of response was 21.6 mo. Results acc. to RECIST 1.1 were comparable. Early & sustained increases of circulating CXCL-10 & IFN-gamma levels were observed.

Abstract 1470 Table 1

Table 1.

Efficacy (iRECIST)	ORR, % [95% CI]	Median PFS, mo [95% CI]
ITT (N=114), investigator read	39.5 [30.5-49.1]	6.9 [4.9-9.3]
By PD-L1 (centrally tested; 22C3)		
<1% (N=32)	31.1 [16.1-50.0]	4.2 [3.6-6.1]
1-49% (N=38)	44.7 [28.6-61.7]	8.3 [4.4-15.7]
≥50% (N=20)	55.0 [31.5-76.9]	11.4 [4.0-16.8]
≥1% (N=58)	48.3 [35.0-61.8]	9.3 [6.3-15.7]

Conclusions E + P is safe & shows encouraging antitumor activity in 1st line metastatic NSCLC patients unselected for PD-L1, warranting late-stage clinical investigation.

Acknowledgements We thank all the participating patients & their families.

1471 PHARMACODYNAMIC AND PREDICTIVE BIOMARKERS ASSOCIATED WITH RESPONSE IN CANCER PATIENTS TREATED WITH TPST-1120: A FIRST-IN-CLASS, SMALL MOLECULE ANTAGONIST OF PEROXISOME-PROLIFERATOR ACTIVATED RECEPTOR-ALPHA

Nathan Standifer*, Yonchu Jenkins, Sam Whiting, Thomas Dubensky. *Tempest Therapeutics, South San Francisco, CA, USA*

Background TPST-1120 is a first-in-class, small molecule antagonist of peroxisome-proliferator activated receptor-alpha (PPAR-α), a transcriptional regulator of fatty acid oxidation and mediator of immune suppression. TPST-1120 was well tolerated and showed signs of activity in a phase I trial as monotherapy (53% disease control rate) and in combination with nivolumab (NCT03829436). In combination cohorts the objective response rate (ORR) was 23%, including 30% (3/10, all partial responses) in subjects treated at the two highest TPST-1120 doses. Responses included two subjects with renal cell carcinoma previously refractory to anti-PD-1 and one subject with late line cholangiocarcinoma.[1] We assessed gene expression changes in post-treatment whole blood and performed baseline mutational analysis on ctDNA to identify potential biomarkers.

Methods Differential expression of 780 genes in 30 subjects receiving 100 mg to 600 mg TPST-1120 BID was assessed using the nCounter® PanCancer Immune Profiling panel (NanoString Inc.) supplemented with 30 PPAR-α target genes. Associations between expression change magnitudes and TPST-1120 exposure levels on study day 8 were calculated, and genes exhibiting a False Discovery Rate p-value < 0.05 and effect size > 0.5 were categorized as potential pharmacodynamic biomarkers. Putative clinical response biomarkers were identified using linear discriminant analysis (LDA) with best objective response as categorical discriminants to identify genes differentially expressed by partial response (PR) patients ($p<0.05$ by Mann-Whitney U Test). Mutational analysis of ctDNA was performed using the PredicineCARE™ assay (Predicine Inc.).

Results Seven of 780 genes assessed were modulated by TPST-1120 exposure ($p<0.05$), including genes associated with enhanced immune responsiveness (*CXCL16*, *TNFRSF1A*), monocytes or macrophages (*ITGAX*, *FCGR2A*) and PPAR-α blockade (*NCF4*). Similar TPST-1120 exposure-biomarker associations were observed among monotherapy and combination therapy patients. LDA performed on combination therapy patients revealed that those with PR demonstrated significant elevations ($p<0.05$) in multiple genes including those associated with Th17 development (*RORC*), lipid transport (*APOE*) and down-regulation of CD155, a TIGIT ligand. Mutational analysis revealed that patients with PR or stable disease were more likely to bear mutations in isocitrate dehydrogenase (*IDH*) and phosphatase and tensin homolog (*PTEN*) compared to patients with progressive disease.

Conclusions TPST-1120 induces pharmacodynamic changes in circulating blood consistent with PPAR-α blockade and reversal of PPAR-α immune suppressive activities. Patients with PR demonstrated gene expression changes that implicate immune activation and alleviation of immune suppression as potential biomarkers of clinical benefit. Increased frequencies of responding patients bearing PI3K pathway or *IDH* mutations may reveal populations likely to benefit from treatment with TPST-1120.

Trial Registration TPST-1120 as Monotherapy and in Combination With Nivolumab in Subjects With Advanced Cancers (NCT03829436)

Background CD8 T-cells (CD8s) mediate the effects of most cancer immunotherapies. CD8s are typically assessed by biopsy which is inherently limited by sample availability, intratumoral and intrapatient heterogeneity, and difficulty with repeated, longitudinal assessment. Non-invasive CD8 PET imaging with 89-Zr-Crefmirlimab Berdoxam (crefmirlimab) could circumvent these barriers and has previously demonstrated feasibility and safety.

Methods We conducted a Phase II, prospective multicenter study to test the correlation between crefmirlimab PET signal and CD8 cell quantity by immunohistochemistry (IHC) in patients with solid tumors receiving standard of care immunotherapy. Patients underwent a baseline CD8 PET scan within 1 week prior to starting immunotherapy. A second crefmirlimab PET scan was performed 4-6 weeks after starting immunotherapy. Pre-treatment tissue and a biopsy 4-6 weeks on-treatment were used for CD8 IHC assessment by SP-57 antibody stain. Bone biopsies and those with <5% tumor were excluded. The primary endpoint was the correlation between PET uptake in the biopsied tumors [SUVmax, SUVmean, SUVpeak; normalized to reference tissue] and CD8 IHC results [CD8 cells/mm^2] using the Spearman's correlation coefficient.

Results Among 52 enrolled patients with ≥1 crefmirlimab scan and corresponding biopsy, 48 patients had 35 baseline biopsies and 34 on-treatment biopsies evaluable for the primary endpoint. Eight solid tumor types were represented with renal cell carcinoma (RCC, n=21 samples), melanoma (n=23), and non-small cell lung cancer (NSCLC, n=17) being the most common. Among the examined imaging parameters, SUVmean of the biopsied tumor, normalized to Aorta (SUVmean/SUVaorta) provided the best correlation. For all 69 biopsied lesions, the SUVmean/SUVmean aorta correlated with CD8 cell density [cells per mm^2] by IHC with a Spearman's correlation coefficient of 0.58 (95% CI: 0.385 - 0.697). For the 35 baseline biopsies the correlation was 0.66 (95%CI: 0.387 - 0.825), and for the 34 on-treatment biopsies the correlation was 0.48 (95% CI: 0.148 - 0.713). The correlation for RCC, melanoma, and NSCLC was 0.77 (95% CI: 0.552 - 0.913), 0.55 (95% CI: 0.084 - 0.727), and 0.54 (95% CI: -0.121 - 0.774), respectively. The mean SUVmean lesion/SUVmean aorta and mean CD8 cell density were 1.71 (IQR: 0.93-1.55) and 509 (IQR:114-461) at baseline and 2.43 (IQR: 0.80-3.60) and 759 (IQR:158-963) post-treatment respectively.

Conclusions Non-invasive CD8 PET scanning with crefmirlimab correlates with CD8 assessment by IHC and permits whole patient, longitudinal CD8s assessment. Crefmirlimab imaging is under investigation as a biomarker for immunotherapy responsiveness in ongoing trials (NCT05013099) and could ultimately provide a useful tool for immunotherapy drug development and clinical management.

Trial Registration NCT03802123

Ethics Approval The study was conducted in accordance with the Declaration of Helsinki and the International Conference on Harmonization Guidelines for Good Clinical

Practice (ICH-GCP) All patients provided written informed consent.

1473 MECHANISM OF ACTION OF BEMPEGALDESLEUKIN (BEMPEG) PLUS NIVOLUMAB (NIVO) IN PATIENTS WITH UNRESECTABLE OR METASTATIC MELANOMA FROM THE PHASE 3 RANDOMIZED OPEN-LABEL PIVOT IO-001 CLINICAL TRIAL

[1]Celeste Lebbe*, [2]Shruthi Ravimohan, [2]Antara Datta, [2]Aparna Chhibber, [3]Eva Muñoz Couselo, [4]Caio Pereira, [5]Shahneen Sandhu, [2]Ming Zhou, [6]Brendan Curti, [7]Nikhil Khushalani, [6]Matthew Taylor, [8]Alfonsus Van Den Eertwegh, [9]Ute Hoch, [10]Georgina Long AO, [2]Yull Arriaga, [11]Adi Diab, [12]Helen Gogas. *[1]Greater Paris University Hospitals, Paris, France; [2]Bristol Myers Squibb, Princeton, NJ, USA; [3]Vall d'Hebron Barcelona Hospital and Vall d'Hebron Institute of Oncology, Barcelona, Spain; [4]Fundação Pio XII – Hospital de Câncer de Barretos, Barretos, Brazil; [5]Peter MacCallum Cancer Centre, Melbourne, Australia; [6]Providence Cancer Institute of Oregon, Portland, OR, USA; [7]Moffitt Cancer Center, Tampa, FL, USA; [8]Amsterdam UMC, Amsterdam, Netherlands; [9]Nektar Therapeutics, San Francisco, CA, USA; [10]The Melanoma Institute Australia; The University of Sydney; Royal North Shore and Mater Hospitals, Wollstonecraft, Australia; [11]MD Anderson Cancer Center, Houston, TX, USA; [12]National and Kapodistrian University of Athens, Medical School, Athens, Greece*

Background BEMPEG is a pegylated interleukin-2 (IL-2) cytokine prodrug engineered to deliver a controlled and sustained IL-2 pathway stimulation, with the goal of preferentially expanding CD8+ T and natural killer (NK) cells over immunosuppressive regulatory T cells (Tregs) in the tumor microenvironment. In the phase 3 PIVOT IO-001 clinical trial (NCT03635983), BEMPEG+NIVO demonstrated no added clinical benefit over NIVO. This first disclosure of comprehensive biomarker analysis from a randomized controlled trial comparing a next-generation IL-2 agonist+NIVO with NIVO aims to gain mechanistic insights underlying the efficacy results.

Methods Patients with previously untreated, unresectable, or metastatic melanoma were randomized 1:1 to receive BEMPEG 0.006 mg/kg+NIVO 360 mg IV Q3W or NIVO 360 mg IV Q3W. Longitudinal changes within Cycle 1 (C1) and 5 (C5) in CD4+ and CD8+ T, NK, and Treg (CD4+CD25+FOXP3+) cell counts, and proliferating (Ki67+) populations, were characterized in blood by flow cytometry. Changes in systemic cytokines, including interferon gamma (IFNγ), were also evaluated. Changes in% tumor cell PD-L1 expression,% CD8+ tumor-infiltrating lymphocytes (TILs), and% FOXP3+ cells from baseline to C1 Day 21 (C1D21) were assessed in tumor biopsies by immunohistochemistry.

Results In peripheral blood, BEMPEG+NIVO mediated statistically significant increases in CD8+ and CD4+ T, NK, and Treg cell counts, as well as IFNγ levels, from baseline to day 8 of C1 and C5, with limited changes observed with NIVO. Compared with NIVO, BEMPEG+NIVO led to significant increases in proliferating Tregs and NK cells from baseline to D8 of C1 and C5. While significant increases in proliferating CD8+ and CD4+ T cells were observed in C1 and C5 following BEMPEG+NIVO, these effects were attenuated in C5. Systemic IFNγ increases, although significant, were attenuated in C5 with BEMPEG+NIVO. Changes in biomarkers measured in the tumor, including increases in CD8+ TILs, from baseline to C1D21 were similar between treatment arms.

Conclusions Observations in peripheral blood demonstrated that, in comparison with limited changes with NIVO, BEMPEG+NIVO increased all immune cell subsets interrogated. Despite greater expansion of peripheral CD8+ T cells within C1 following BEMPEG+NIVO vs NIVO, there was no substantive difference in CD8+ TIL increase between the two arms, suggesting no synergistic/additive tumor activity for BEMPEG+NIVO over NIVO. These observations, together with attenuation of peripheral T-cell proliferation over time, potentially explain the lack of added clinical benefit for BEMPEG+NIVO vs NIVO in PIVOT IO-001. Results from this study should be taken into consideration and interrogated further as next-generation IL-2 agonists are developed.

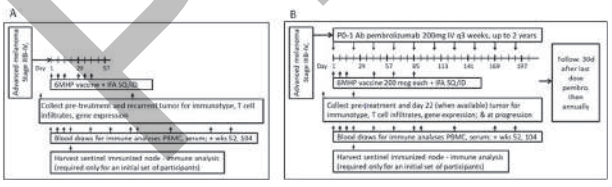
1474 CANCER VACCINE PLUS PD-1 BLOCKADE PROMOTES INFILTRATION OF MELANOMA METASTASES BY VACCINE-INDUCED T LYMPHOCYTES

Christine Tran*, Gabrielle Schwartzman, Walter Olson, Kelly Smith, Jennifer Bryant, Craig Slingluff. *University of Virginia, Charlottesville, VA, USA*

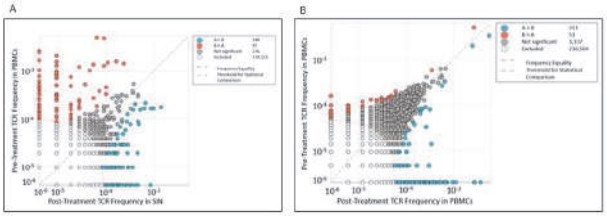
Background T lymphocytes reactive to melanoma antigens can cause regression of advanced melanoma and mediate long-term immunologic memory. However, immune control of melanoma depends on the ability of T cells to infiltrate sites of melanoma deposits. The objective of this study was to determine whether 6 synthetic melanoma helper peptides (6MHP) vaccine plus pembrolizumab increased infiltration of vaccine-induced T cells into tumor metastases compared to 6MHP vaccine alone.

Methods Patients in Mel64 (NCT02515227) received 6MHP vaccines on days 1/8/15/43/64/85. Pembrolizumab was administered intravenously every three weeks, beginning on day 1. Patients also provided blood samples, and sentinel immunized node (SINs) biopsies if available, at specific time points for immune analyses. Tumor biopsies were collected on days 1 (pre-treatment) and 22. Patients in a prior trial, Mel41 (NCT00089219), served as controls, who received 6MHP vaccines on days 1/8/15/29/36/43. Tumor biopsies were collected pre-vaccination and post-vaccination at time of tumor recurrence (figure 1). Across both trials, DNA was extracted from peripheral blood mononuclear cells (PBMCs) pre-treatment, and PBMCs/SINs at time of peak T cell response to 6MHP. These were submitted for high throughput T cell receptor (TCR) sequencing to assess for T cell clonotypes that were significantly increased in number post-treatment or novel clonotypes evident de novo post-treatment. Tumor biopsies were sampled, from which DNA was extracted and submitted for TCR sequencing. These sequences were cross referenced against those in PBMCs/SINs for those that overlapped and were present in tumor post-treatment, but not pre-treatment.

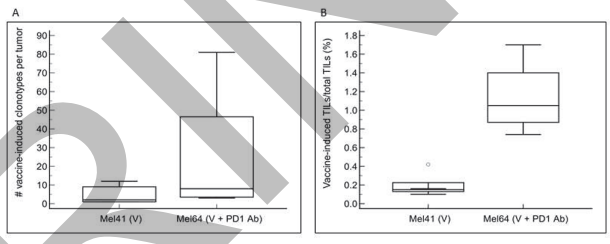
Results Patients across both trials (Mel41 n = 5; Mel64 n = 4) had expanded circulating vaccine-induced T lymphocytes in PBMCs/SINs post-treatment compared to pre-treatment (figure 2). All patients had novel T cell clonotypes in tumor post-treatment compared to pre-treatment, with Mel64 patients having upward trends of the number of vaccine-induced tumor infiltrating T cell clonotypes compared to Mel41 patients (figure 3A). The fraction of vaccine-induced tumor infiltrating lymphocytes (VITILs) of total tumor infiltrating lymphocytes (TILs) was significantly increased in Mel64 patients compared to that in Mel41 patients ($p = 0.0159$) (figure 3B).



Abstract 1474 Figure 1 Clinical Trial Designs for A) Mel41; B) Mel64



Abstract 1474 Figure 2 Single patient comparisons of TCR clonotypes in PBMCs pre-treatment vs. PBMCs/SINs post-treatment. Sequences in blue appear in higher frequency post-treatment vs. pre-treatment. Sequences present on the x-axis are present post-treatment but not pre-treatment. A) Patient 1 of Mel41: the high number of clonotypes present and increased in pre-treatment PBMC vs. post-treatment SIN is explained by circulating memory cells that are under represented in SIN, while clonotypes appearing in SIN post-treatment are related to vaccination. B) Patient 6 of Mel64.



Abstract 1474 Figure 3 A) Number of Vaccine-Induced Clonotypes per Tumor in Mel41 vs. Mel64; B) Fraction of Vaccine-Induced TILs/Total TILs in Mel41 vs. Mel64.
V = Vaccine; PD1 Ab = pembrolizumab

Conclusions These findings suggest that adding pembrolizumab may enhance infiltration of melanoma metastases by vaccine-induced T lymphocytes compared to 6MHP vaccine alone. This treatment combination holds promise in the management of advanced melanoma, and additional interventions may further enhance tumor infiltration of vaccine-induced T cells.

Trial Registration These clinical trials were conducted at the University of Virginia and registered with Clinicaltrials.gov (Mel41 NCT00089219, Mel64 NCT02515227).

Ethics Approval These clinical trials were performed with the University of Virginia Institutional Review Board (IRB), previously known as the Human Investigations Committee (HIC), approval (Mel41 HIC #10464, Mel64 IRB #18174). All participants provided their informed consent before taking part in these clinical trials.

Clinical Trials In Progress

1475 A PHASE 1 STUDY TO CHARACTERIZE THE SAFETY AND TOLERABILITY OF MP0317, A TUMOR TARGETING FAP DEPENDENT CD40 AGONIST DARPIN, IN PATIENTS WITH RELAPSED/REFRACTORY SOLID TUMORS

[1]Hilde De Winter*, [1]Elena Fernandez, [1]Vaia Stavropoulou, [1]Nina Stojcheva, [1]Paul Baverel, [2]Carlos Gomez-Roca, [3]Eelke Gort, [4]Neeltje Steeghs, [1]Kyriaki Ioannou, [1]Ana Maria Florescu, [1]Jennifer Krieg, [1]Patrick Mossi, [1]Vladimir Kirkin, [1]Philippe Legenne, [5]Philippe Cassier. *[1]Molecular Partners AG, Schlieren, Switzerland; [2]IUCT-Oncopole, Marseille, France; [3]UMC Utrecht, Utrecht, Netherlands; [4]Netherlands Cancer Institute, Amsterdam, Netherlands; [5]Centre Léon Bérard, Lyon, Rhone, France*

Background The development of CD40 agonists in immune-oncology has been hampered by dose-limiting toxicity (DLT) mainly caused by systemic CD40 activation and peripheral target-mediated drug disposition. By targeting fibroblast activating protein (FAP), our FAP/CD40 directed DARPin, MP0317, selectively activates CD40 within the tumor microenvironment, while precluding CD40 activation in the periphery. Here we present emerging data from the first-in-human trial (NCT05098405).

Methods This is a Phase 1, first-in-human, multicenter, open label, dose escalation study followed by a safety expansion part, evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary antitumor activity of MP0317 in adult patients with advanced solid tumors. The dose escalation scheme uses an adaptive Bayesian logistic regression model guided by the escalation with overdose control principle to determine the recommended dose. Up to 6 cohorts receive intravenous MP0317 3-weekly until disease progression, unacceptable toxicity, or other discontinuation criteria are met. Dose selection was guided by a translational PK/PD model that accounted for baseline FAP and CD40 expression levels and turnover rates.

Primary endpoints are incidence of DLTs and adverse events. Secondary and exploratory endpoints include PK/PD parameters, response rate (per RECIST and iRECIST), progression free and overall survival.

Results At time of submission, cohort 4 was enrolled, and cohorts 1-3 had completed the study, with no DLT observed. The most frequent AE were grade 2 infusion related reactions in 3/12 dosed patients.

The 7 patients in cohorts 1-3 received $\geq$2 (range 2-8) doses (range 0.03–0.3 mg/kg) of MP0317 and completed the 28-day DLT period. Preliminary PK data show sustained MP0317 serum levels across the dosing interval with evidence of target-mediated drug disposition.

Exposure in the tumor was confirmed with MP0317 co-localizing with FAP and CD40 in 3 out of 5 evaluable paired biopsies. No systemic toxicities were observed and there were no signs of systemic CD40 activation based on circulating PD markers and immunophenotyping data. A PD signal consistent with a tumor-localized myeloid cell activation was observed in cohort 3. Although limited clinical efficacy is expected in monotherapy setting, one heavily pre-treated patient maintained stable disease for 8 cycles.

Conclusions The preliminary clinical and biomarker data provide early evidence of the tumor-targeted CD40 activation mechanism of action of MP0317. As of submission, no DLTs had been observed. Enrollment in dose cohorts covering the projected therapeutic dose range is ongoing to further characterize MP0317 mechanisms of action and safety profile.

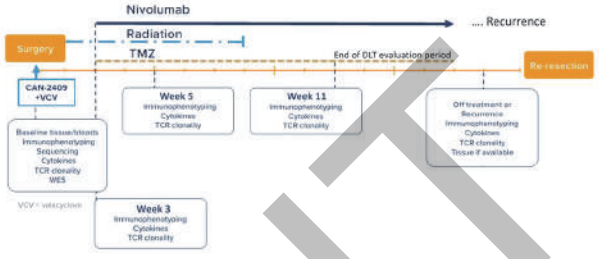
1477 FIRST EFFICACY AND MULTI-OMIC ANALYSIS DATA FROM PHASE 1 CLINICAL TRIAL OF ONCOLYTIC VIRAL IMMUNOTHERAPY WITH CAN-2409 + VALACYCLOVIR IN COMBINATION WITH NIVOLUMAB AND STANDARD OF CARE IN NEWLY DIAGNOSED HIGH-GRADE GLIOMA

[1]Patrick Wen*, [2]Caroline Duault, [2]Edgar Gonzalez-Kozlova, [2]Kevin Brennan, [2]Tyson Holmes, [2]Seunghee Kim-Schulze, [2]Kai Nie, [2]Kimberly Argueta, [2]Jacques Fehr, [2]Mina Pichavant, [2]Diane Del Valle, [2]Andrew Gentles, [2]Sacha Gnjatic, [2]Holden Maecker, [3]Xiaobu Ye, [1]David Reardon, [1]Wenya Linda Bi, [1]Pierpaolo Peruzzi, [1]Nirav Patel, [4]Roy Strowd, [4]Stephen Tatter, [5]Ian Lee, [5]Tobias Walbert, [5]James Snyder, [6]Steven Brem, [6]Arati Desai, [6]Stephen Bagley, [7]Nduka Amankulor, [7]Frank Lieberman, [7]Megan Mantica, [8]Lenika Lopez, [8]Susan Bell, [8]Andrea Manzanera, [1]Sean Lawler, [9]Lixian Jin, [3]Neeraja Danda, [10]Serena Desideri, [11]L Burt Nabors, [10]Stuart Grossman, [1]E Chiocca, [8]Paul Tak, [8]Francesca Barone. *[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]CIMAC Consortium, Stanford, CA, USA; [3]Adult Brain Tumor Consortium, Baltimore, MD, USA; [4]Wake Forest Baptist Health, Winston-Salem, NC, USA; [5]Henry Ford Health, Detroit, MI, USA; [6]University of Pennsylvania Hospital, Philadelphia, PA, USA; [7]University of Pittsburgh Medicine, Pittsburgh, PA, USA; [8]Candel Therapeutics, Nedeham, MA, USA; [9]Bristol-Meyers Squibb, Lawrenceville, NY, USA; [10]Adult Tumor Brain Consortium, Baltimore, MD, USA; [11]University of Alabama, Birmingham, AL, USA*

Background High-grade glioma (HGG) is characterized by a highly immunosuppressive tumor microenvironment and poor prognosis. Limited advances have been made in HGG standard of care (SoC) treatment, with immunotherapy failures reported in this indication. CAN-2409 is a replication-defective adenovirus that delivers HSV thymidine kinase to cancer cells, resulting in local conversion of oral valacyclovir into a toxic metabolite inducing immunogenic cell death. Preclinical data in a mouse model of HGG suggest CAN-2409 potential synergy with anti-PD1 agents.[1] An ongoing phase 1 clinical trial is evaluating safety, initial efficacy and immunological biomarkers associated with the combination of CAN-2409/valacyclovir with nivolumab plus SoC in patients with newly diagnosed HGG.

Methods Forty-one patients with HGG were recruited from February 2019 to March 2021. CAN-2409 was injected into the resection bed during neurosurgery, followed by valacyclovir and SoC chemoradiation. Nivolumab was initiated on day 15 and administered every 2 weeks for up to 52 weeks. Tumor and peripheral blood samples were longitudinally collected (figure 1) from 35 patients (evaluable population). Immune profiling was performed by the CIMAC network including plasma proteomics, multidimensional flow cytometry by CyTOF, whole exome sequencing (WES), TCR analysis and RNA sequencing.

Results Median OS (mOS) for patients with methylated MGMT promoter was 30.6mo for patients undergoing gross total resection (GTR) and 12.6mo for patients undergoing sub-total resection (STR). mOS for patients with unmethylated MGMT was 13.2mo (GTR) and 15.9mo (STR). Propensity score matching analysis is ongoing to evaluate mOS, controlling for known prognostic factors. Plasma proteomics at 3-week post-treatment identified increases in CXCL9, CCL11, GZMA, IFNG, CCL19, MCP1, and MCP3 concentrations (LogFC>1, FDR<0.05). Nivolumab treatment associated with significant increases in CXCL9, IL10, and PDCD1 concentrations (LogFC>1, FDR<0.05) and a trend towards elevated LAMP3, CXCL13, CXCL1, and TNFRSF9 concentrations (logFC>0.5, FDR<0.05 at week 5). Patients with methylated MGMT promoter displayed (at weeks 5 and 11) a significant increase in IL-5, IL-7, IL-10, CD4, CD27, CD40, CD38, CFS-1 and ICOSLG concentrations (FDR<0.05). Baseline concentrations of TIE2 correlated with survival (FDR<0.05). CyTOF analysis unveiled significant post-treatment changes, including increase in activated CD4 (p 0.0011; week 5), CD8 (p 0.0189; week 5), CD69+ gamma delta T cells (p0.0324; week 5), and plasmacytoid dendritic cells (p=0.0327, p=0.0020 at week 5 and 11). Additional biomarker analysis and canonical correlation analysis with clinical responses are ongoing.



Abstract 1477 Figure 1 Schema of treatment and biomarker timepoints

Conclusions Combination treatment of CAN-2409/valacyclovir plus nivolumab and SoC induces profound immunological changes and appears to associate with encouraging survival data.

Acknowledgements We would like to thank the Adult Brain Tumor Consortium for oversight on the study and the participating patients and their families, as well as site research and clinical staff.

Background NeoTCR-P1 is a personalized autologous T cell therapy for treatment of patients with solid tumors. Neoantigen-specific T cell receptors (neoTCRs) were isolated from the patients' own circulating CD8 T cells using the imPACT Isolation Technology®, followed by non-viral precision genome engineering into an autologous apheresis product for infusion back into the patient.

Methods This phase 1 trial is a first-in-human, multi-center, dose-escalation study to evaluate the safety, tolerability, and manufacturing feasibility of NeoTCR-P1 alone or in combination with IL-2 in solid tumors.

Patients with TCRs identified at screening and meeting eligibility criteria underwent apheresis to manufacture personalized NeoTCR-P1 cell product. Lymphodepleted patients received a single dose of up-to-three distinct NeoTCR cell products at dose levels of 0.4, 1.2, or 4×10^9 NeoTCR-edited T cells.

Pre- and post-treatment blood and biopsy samples were collected to evaluate NeoTCR-P1 pharmacokinetics, tumor trafficking, signs of T cell engagement or potential mechanisms of resistance.

Results Sixteen patients were infused with NeoTCR-P1 T cells including patients with MSS-colorectal cancer (11), breast cancer (2), ovarian cancer (1), melanoma (1), or non-small cell lung cancer (1). Four of the sixteen patients were treated with NeoTCR-P1 + IL-2.

Two patients experienced toxicities associated with NeoTCR-P1 cell infusions: a grade 1 CRS and a grade 2 ICANS. Five patients had stable disease as their best response at their first tumor assessment (day 28).

NeoTCR+ T cells detected in the peripheral blood had an average peak of 3.6% (range 0.9-7.3%) for DL1, 11.7% (7.7-20.8%) for DL2, and 19.8% (12.0-37.3%) for DL3. Increases in NeoTCR T cells were observed at higher dose levels, stronger lymphodepletion, or higher gene editing rates of the infused product.

Eight post-infusion biopsies were available for sequencing and imaging analysis; 17 of 22 neoTCR-T cells were detected in post-infusion biopsies with 12 neoTCRs among the top 4% of CDR3 sequences detected. The targeted neoantigens were detected in 7 of 8 post-treatment biopsies (15 of 22 targets), and personalized ctDNA confirmed targeting of a predicted sub-clonal mutation. An APOBEC signature and HLA-LOH were identified as potential mechanisms of resistance. By single-cell, spatial molecular imaging, neoTCR-T cells were visualized in post-treatment biopsies and found to differentially express potential markers of engagement.

Conclusions This study demonstrates the feasibility of isolating and manufacturing NeoTCR-T cells using non-viral precision genome engineering, the safety of infusing up-to-three gene edited NeoTCR-T cell products, and T cell persistence and trafficking to a variety of solid tumors.

Trial Registration NCT03970382
