Figure S1b. Neoantigen-specific T cell responses in early stage lung cancer patients treated with SABR. MANAFEST was performed on peripheral blood from patients ci1425 (A) and ci1424 (B) to identify neoantigen-specific T cell receptor clonotypes (left). Data are shown as the frequency of each antigen-specific TCR after 10 days of culture with the positive peptide (solid bar), and in every other condition that was tested (transparent bars). Empty bars indicate that the clone was not detected in that culture condition. TCR sequencing was also performed on uncultured peripheral blood T cells from ci1425. The frequency of each neoantigen-specific TCR clonotype is shown at each peripheral blood timepoint (A, right).
